Abstract

The studying of the soil biological activity is one of the most important criteria for evaluating the direction of soil processes. Biological activity of the soil allows about a condition of fertility of the soil. Microbiological activity depends on the type of soils, properties and many other factors. Anthropogenic loading in bigger or smaller intensity can cause suppression of the functions which are carried out microorganisms that leads to violation of their activity. In Perm Krai sod-podzolic soils of heavy granulometric composition occupy 69.6 % of the area of an arable land. Features of these soils – sour reaction of the environment, the relative poverty in elements and organic substance, is poorly expressed by structure, the availability of the inert podzolic horizon, and also flushing type of the water mode. All it determines the low level of biological activity of this type of soils. We have investigated the change in the biological activity of sod-podzolic soils with different content of available phosphorus and potassium. Mathematical processing of experimental results testifies the direct dependencies of content of mineral nitrogen in the soil on the content of available phosphorus and potassium (r = -0.415-0.952). Studies have shown that the content of mineral nitrogen in the soil depends on the content of labile phosphorus and potassium, which suggests an ability to predict the future availability of nitrogen for crop seeds. The best conditions for nitrification are marked on variants A_2B_1 (80.1 mg NO_3^-/kg/14 days) and A_3B_2 (77.0 mg NO_3^-/kg/14 days), worst on A_1B_1 (54.4 mg NO_3^-/kg/14 days) and A_3B_1 (51.3 mg NO_3^-/kg/14 days). Sod-podzolic soils of heavy granulometric composition have low biological activity, but when creating the optimal conditions for microbial, their activity increases.

Keywords: *Sod-podzolic soil, biological activity, phosphorus, potassium*

Introduction

The studying of the soil biological activity is one of the most important criteria for evaluating the direction of soil processes and allows to judge about change of the nitric mode of soils. Anthropogenic impact on soil not only can cause suppression of microorganisms functions, which leads to violation of activities of the latter, but can also improve the conditions for the occurrence of positive microbiological processes in the soil (Mudrykh et al., 2013, 2014; Kizilkaya et al., 2012, 2013).

Long-term studies established that the majority of arable crops most vigorously consume nitrate nitrogen from the soil. Scientists attribute this to the fact that the intake of nutrients (in the form of cations) into the plant is greater at the nitrate assimilation and to change in the ratio of ammonium and nitrate at the cultivation of the soil. Improving the physical and chemical properties tends to raise the proportion of nitrate in mineral nitrogen reserves: from 20 % in soils with low fertility to 60 % in well-cultivated soil. Nitrogen fertilization increases this number to 90 %, which is due to the intensification of nitrification in soils. Creating optimal conditions for the cultivation of arable crops improves conditions for the nitrification process, as these conditions are similar. So that is not a coincidence that the high nitrifying

activity has long been used as an indicator of good soil fertility (Koren'kov, 1990, Kidin, 2008).
The purpose of the study is to determine the effect of labile phosphorus and potassium on the soil nitrification process.

Materials and methods

Perm Krai is situated in Western Predural'e region and defined by 56°06′-61°39′ of northern latitude and 51°47′-59°03′ eastern longitude (Fig. 1). From north to south the territory of the Krai stretches for 600 km, from west to east in the southern part of the Krai – for 200 km, in the northern part – for 500 km (Ashkin et al., 2012, 2013: Mudrykh et al., 2014).

Figure 1. Location of the experimental field in Perm, Russia

The soil samples (56) was taken from experimental field at the Experimental Station of Perm State Agricultural Academy, Perm, Russia (57°56′00″N, 56°14′59″E) in 2011.
A composite surface soil sample from 0-20 cm depth was collected from the experimental site before initiating the experiment and analysis of soil samples on agrochemical indicators was carried out by standard techniques (Peterburgskii, 1981). Soil samples were air dried at room temperature; sieved with < 1 mm screen. An experiment was conducted to determine the effects of available phosphorus and potassium on soil enzyme activities under laboratory conditions. The laboratory experiment was carried out according to the procedure described by Kravkov.

Table 1. Scheme of laboratory experiment carried out to Petrburgskii (1981)

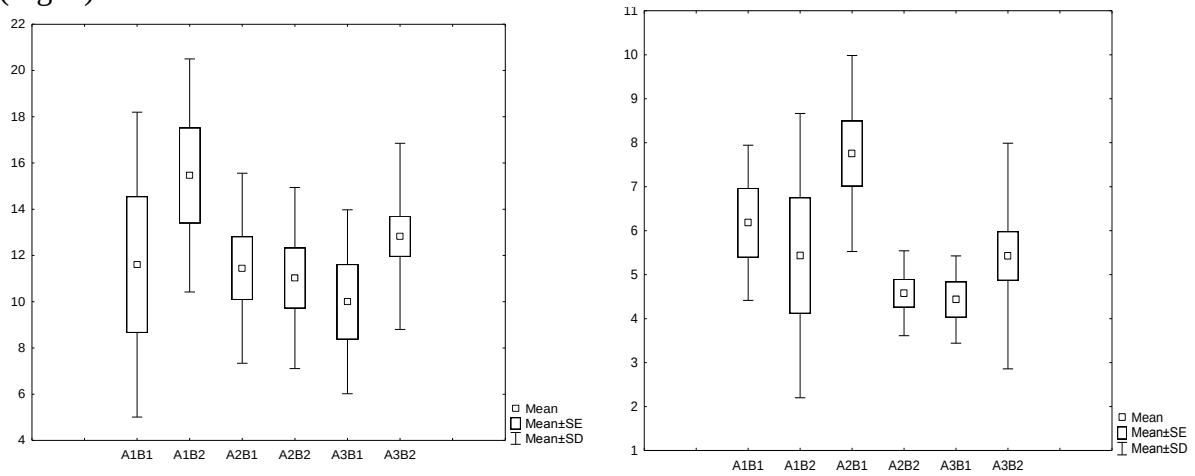
Factor B: Soil potassium range	Factor A: Soil phosphorus ranges (mg kg^{-1})		
	A_1 (101-105)	A_2 (151-200)	A_3 (over 200)
B_1 (41-80)	A_1B_1	A_2B_1	A_3B_1
B_2 (81-120)	A_1B_2	A_2B_2	A_3B_2

There was a double replication of the experiment variants. The experiment lasted for 14 days. Levels of labile phosphorus and potassium in the soil were formed artificially in experiments performed by the staff of the Department of Agricultural Chemistry with the use of organic and organic-mineral fertilizers. Analysis of soil samples for agrochemical parameters was carried out according to the standard procedures (Arinushkina, 1961; GOST, 1991, 1994; Mineev, 2001). The intensity of the nitrification was measured by the difference between the content of nitrate in the soil before and after incubation.
Soil samples have subacid pH close to neutral (5.3-5.6). Total exchangeable bases are within 18.2-20.2 mg-eq./100 g of soil. The soil is base-saturated (88-89 %), content of phosphorus 112.3-328.3 mg/kg, potassium 57.3-116.0 mg/kg of soil. Deviation of physic-chemical parameters values for variants of the experiment are within analytical error. Analysis of soil

samples taken before experiment beginning has shown that in major agrochemical parameters the soil in the experiment variants differ only in the content of phosphorus and potassium.
All data were analyzed using statistical software STATISTICA 7.0 and MINITAB 14.

Results and discussion

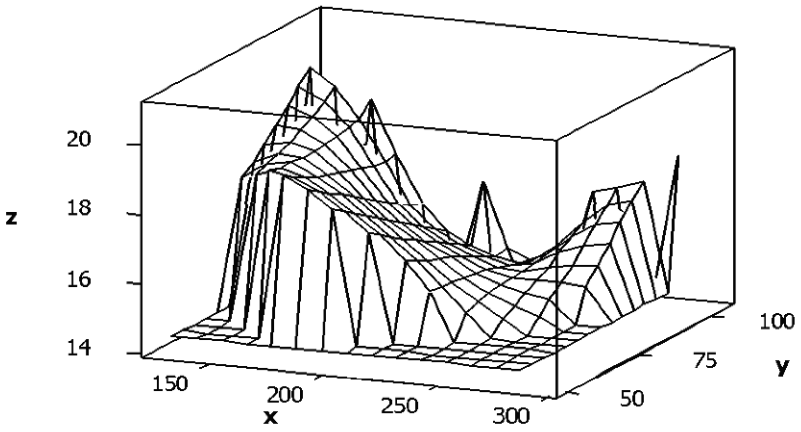
Petersburgsky (1991) has established that, in the non-chernozemic zone, 50 % in obtaining arable crops yield is due to nitrogen. Such a high increase in yield is due to the fact that the flushing regime of sod-podzolic soils, acid medium reaction, and the relatively low amount of organic matter determine low levels of nutrients in the soils of this type and, in particular, nitrogen. The content of mineral nitrogen in the soil depends on many factors. To improve the plants nitrogen supply, it is necessary to determine the mineral nitrogen content in the soil at certain stages of plant development to allow fertilizing, if necessary. Optimal conditions of nitrogenous nutrition of plants can be accomplished in two ways: soil cultivation (increasing reserves of nitrogen, controlling its transformation in soil) and application of mineral nitrogen fertilizers. The first one is the cheapest way to provide plants with nitrogen, as it requires no additional expenses and the method is environmentally safe (Koren'kov, 1990).
Soil samples were taken to determine the amount of mineral nitrogen in the soil in the tillering stage of winter rye before fertilization. Analysis of soil samples showed that the content of mineral nitrogen in the soil is very low (Fig. 2, 3). The maximum content of $N\text{-}NH_4$ (13.5 mg/kg of soil) was observed in variants with an average content of labile phosphorus (Fig. 2).



Figures 2. Impact of mobile phosphorus and potassium on the content of amount nitrogen (left) and nitrate nitrogen (right) in the soil, mg/kg

The increasing of labile phosphorus is followed by decreasing of amount of $N\text{-}NH_4$ up to 11.2-11.4 mg/kg of soil. Elevation of labile potassium level from low to average has led to a 2.1 mg/kg of soil increase of studied index. Detailed analysis and mathematical treatment of the results showed that the greatest range of variability of ammonium nitrogen was observed in the A_1B_1 variant, the lowest in A_3B_2. On variants A_1B_2 and A_2B_1 a close correlation between the content of labile phosphorus and ammonium nitrogen was established: r = -0.555 and -0.710. It should be noted that the amount of ammonium nitrogen in the soil is less dependent on the content of labile phosphorus, and more on potassium. The increase of potassium in the soil is followed by some increase in ammonium amount.
The content of nitrate nitrogen in the soil, as well as ammonia, is very low (Fig. 2).
On a variant with average content of labile phosphorus the amount of nitrate nitrogen was 5.8 mg/kg soil. An increase of labile phosphorus to high level was followed by slight increase of nitrate nitrogen content up to 6.2 mg/kg of soil. A further increase in the level of phosphorus in the soil led to some reduction in nitrate concentrations up to 4.9 mg/kg of soil.

In contrast to ammonium nitrogen, increase of the amount of potassium in the soil was followed by decrease in nitrate nitrogen amount. Thus, on variants with low potassium level the content of $N\text{-}NO_3$ was equal to 6.1 mg/kg of soil, and with the average level to 5.1 mg/kg of soil. Closer examination of the data indicated that the maximum content of nitrate (7.8 mg/kg of soil) is on the variant with a high labile phosphorus and low potassium content.
Mathematical analysis showed that the greatest range of variability of the ammonium nitrogen is on variant A_1B_2, the lowest on A_2B_2. With the increase of labile phosphorus in soils, in contrast to ammonium nitrogen, nitrate concentration decreases slightly. It is worth noting that the close correlation was noted on variant A_1B_1 between the content of labile phosphorus and nitrate nitrogen: r = -0.952. A similar dependence was observed in variants A_2B_2 and A_3B_1, the correlation coefficients were -0.517 and -0.415, respectively.
Evaluation of plants nitrogen nutrition was carried out on the basis of the content of mineral nitrogen in the soil ($N\text{-}NH_4$+$N\text{-}NO_3$). Comparison of mineral nitrogen accumulation in the soil in the tillering stage at different levels of labile phosphorus and exchangeable potassium shows that the Impact of the studied factors is not clear (Fig. 3).



Figures 3. Impact of mobile phosphorus (x) and potassium (y) on the content of mineral nitrogen (z) in the soil, mg/kg

Thus, at an average labile phosphorus level the maximum accumulation of mineral nitrogen up to 19.3 mg/kg of soil was observed. Increased labile soil phosphorus causes a reduction of the content of mineral nitrogen to 16.3-17.4 mg/kg of soil. Changing of labile potassium level in the soil from low to medium provides some increase in studied index from 17.1 to 18.2 mg/kg of soil. According to the providing group by the soil mineral nitrogen in the spring the amount of nitrogen in the experiment relates to class III, i.e. average. This indicates that mineral nitrogen level is sufficient for the initial development and growth. But for subsequent periods it is necessary to fertilize with additional nitrogen.
So, field data indicate a low biological activity in the soil, as the accumulated amount of nitrogen is not enough for the entire growing season, and additional expenses for feeding with nitrogen fertilizers are required for normal growth and development of winter rye.
Let's see if optimal conditions for biological activity will allow to achieve a sufficient, for winter rye, level of mineral nitrogen in the sod-podzolic soil.
To determine the intensity of the nitrification process under optimum conditions, was determined a content of nitrogen before and after incubation in samples for options of laboratory experiment. Analysis of the intensity of nitrification in sod-podzolic heavy loamy soil showed that the maximum microbial activity is observed in variants with a high content of labile phosphorus and medium content of potassium. On the variant with a high content of

labile phosphorus in the soil, nitrifying activity was 70.4 mg NO_3^-/kg of soil for 14 days. Decrease in labile phosphorus to an average and increase to high level led to a decrease in activity, respectively, to 59.7 and 64.2 mg NO_3^-/kg/14 days. Increasing potassium level from low to medium provided some increase in nitrifying activity from 61.9 to 67.6 mg NO_3^-/kg/14 days. The best conditions for nitrification are marked on variants A_2B_1 and A_3B_2, worst on A_1B_1 and A_3B_1.

Creation of optimal conditions for nitrification causes some accumulation of mineral nitrogen (Figure. 4).

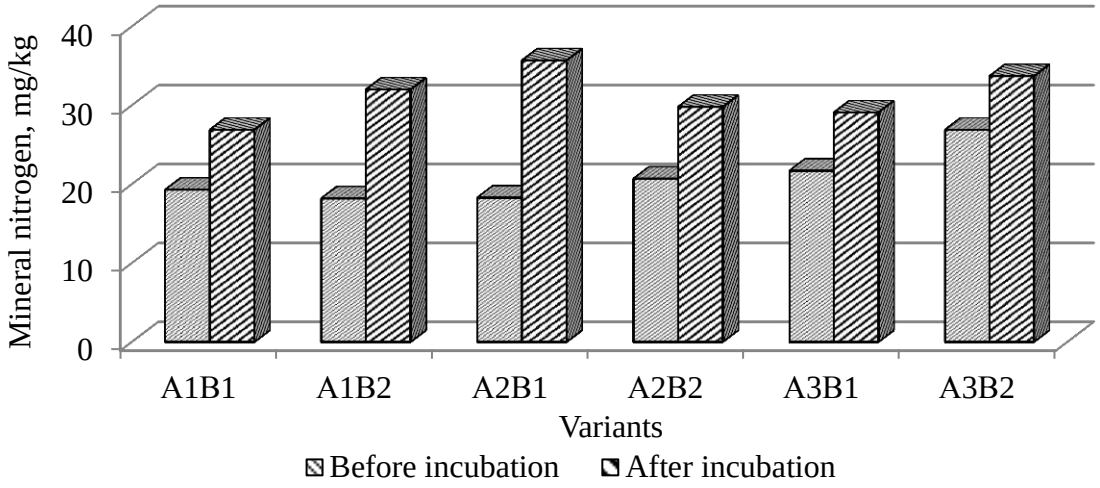


Figure 4. Impact of mobile phosphorus (A) and potassium (B) on the content of mineral nitrogen in the soil, mg/kg

Thus, prior to incubation mineral nitrogen content was 19.3 mg/kg of soil in variant A_1B_1, and after incubation 26.9 mg/kg of soil. A similar trend was also noted in other variants of the experiment. The most significant difference in the content of mineral nitrogen is marked in the variant A_2B_1 17.4 mg/kg of soil. The data indicate that under conditions favorable for the soil nitrification process a significant amount of mineral nitrogen can be accumulated. However, even those created favorable conditions for the accumulation of mineral nitrogen in the soil do not provide a sufficient amount of nitrogen for winter rye.

Conclusion

Activity of microorganisms in sod-podsolic the heavy loam soils the very low. The content of mineral nitrogen in the soil depends on the content of labile phosphorus and potassium, which suggests an ability to predict the future availability of nitrogen for winter rye.

On soils with average, elevated and high phosphorus content and low and medium potassium under optimal conditions an amount of mineral nitrogen sufficient for the growth and initial development is accumulated. The best conditions for nitrification are marked on variants A_2B_1 and A_3B_2, worst on A_1B_1 and A_3B_1.

For cultivation of winter rye on sod-podzolic soils of heavy texture with phosphorus level above average and potassium level low to medium, growing technology should provide nitrogen fertilizer that will provide the plant with necessary nitrogen.

Abstract

Soil erosion involves detachment and transport of soil particles from the upper parts of a slope and their deposition at its lower parts. Erosion causes soil degradation and reduces soil productivity. Soil eroded from the upland catchment causes depletion of fertile agricultural soil and the resulting sediment deposited at the river networks creates river morphological change and reservoir sedimentation problems. As regards the initiation of the wearing away of soil particles from the catchment slope, standard methods were used to quantify soil erosion. The aim of this study was to evaluate erosion factors in the catchment area of the Čančar brook, classified as a ravine. The annual erosion intensity is 113.23 m^3 km^{-2} of soil. Based on natural and anthropogenic factors, the Čančar brook catchment area belongs to erosion category IV, weak intensity, deep type, with the erosion coefficient of 0.40.

Keywords: *soil erosion, erosion intensity, sediment yield, soil, catchment, ravine*

Introduction

Land degradation and soil loss are global events. Human induced pressures on natural ecosystems are still in progress, along with conservation efforts (Hacisalihoğly et al., 2010). The main factor causing soil degradation worldwide is water erosion, which threatens 56% of the world's arable land (Oldeman et al., 1990).

Over 90% of the total land area in the Republic of Serbia suffers from different types and intensities of erosion (Djorović and Kadović, 1997). The erosion process can have both direct and indirect impacts, inducing permanent soil disappearance. The calculated value of the total annual sediment yield suggests that some 16.0 cm of soil are annually eroded off the 21,000 ha of land in Serbia (Spalević, 1997). In the Republic of Serbia (Central Serbia), there are 1.221 million ha of eroded soil, and 36,000 ha are in a steady state, now (Statistical Yearbook, 2008).

Erosion has mostly affected strongly sloping, deforested or cultivated shallow soils on slopes, formed on impermeable geological substrates, due to the effects of intense rainfall and fluctuating air temperatures (Spalević, 1997).

The tendency of air temperature to increase and of rainfall to decrease is quite evident in the region of Čačak (Šekularac, 2002). Climate change leads to degraded soil physical properties, increases soil erodibility and reduces the protective role of vegetation.

The above factors cause intensification of both surface and deep-cutting processes of erosion.

Given the above, the objectives of this study are quantitative assessment of soil erosion induced by a range of factors and estimation of sediment yield in one part of the catchment area of the Kamenica River (part of the Zapadna Morava catchment) i.e. its subbasin the Tinja, including its second order left-hand tributary the Čančar brook.

Materials and methods

The Čančar brook is located near Čačak (43^0 53' N; 20^0 21' E), Western Serbia, and belongs to the catchment of the Zapadna Morava river.

Figure 1. The Čančar brook catchment

Natural characteristics of the Čančar brook basin were studied using map data (hydrography, relief, geological substrate and soil), literature data (elements of climate: rainfall and air temperature) and data obtained through an immediate reconnaissance survey of the area (vegetation).

Maps of the studied area have the following scale: topographic map (1:25,000, Fig. 1; 1:50,000) by the Military Geographical Institute (1971), geological map (1:500,000) by the Institute of Soil Science (1966) and pedological map (1:50,000) by the Institute of Soil Science (1964).

Meteorological parameters for the catchment area were calculated using the method of interpolation of rainfall data (Republic Hydrometeorological Bureau, 1930-1961) by the rainfall gradient (Bonacci, 1984), and air temperature (Centre for Research in Agriculture, 1949-1995) calculations for any altitude (Dukić, 1984).

Erosion-induced soil losses can be predicted by various analytical models.

However, according to the experience of a number of researchers, the Erosion Potential Method – EPM (Gavrilović, 1972) is the most suitable on catchment level for watershed management purposes in this Region and is used in: Bosnia & Herzegovina, Bulgaria, Croatia, the Czech Republic, Italy, Iran, Montenegro, Macedonia, Serbia and Slovenia (Behzadfar et al., 2014; Spalevic et al., 2014; Kostadinov et al., 2014). This is why quantitative indicators of soil erosion in this research were calculated using the Erosion Potential Method - EPM.

The basic analytical equation for the calculation of erosion-induced soil losses, as developed by Gavrilović (1972), is as follows:

$$G_{yr\times sp^{/1}} = T \times H_{yr} \times \pi\sqrt{Z^3} \times R_u \qquad (1)$$

where:
$G_{yr\ sp}^{-1}$ – specific annual total erosion-induced sediment yield reaching the confluence, $m^3\ yr^{-1}\ km^{-2}$
T – temperature coefficient of the catchment
H_{yr} – amount of rainfall, mm
π – 3.14
Z – coefficient of erosion
R_u – coefficient of retention of soil in the catchment.

Results and discussion

The size, length, circumference and shape (perimeter) of a catchment area are among major catchment elements of importance for soil erosion. The Čančar brook catchment is 0.54 km^2 in area (F), 1.36 km in length (L), and 3.70 km in circumference (C).
The major physical and geographical elements of the Čančar brook catchment, relief characteristics, geological substrate features, soil type and soil utilisation method, are quantitative parameters or soil erosion in the catchment.

Table 1. The basic parameters of the Čančar brook catchment relief

Catchment Name: The Čančar brook	
The lowest point of the main watercourse and catchment (B), m	619
The highest point of the main watercourse (C), m	745
The highest point of the catchment (E), m	762
Average slope of the main watercourse in the catchment (I_a), %	8.3
Mean catchment altitude (A_m), m	700.74
Mean catchment altitudinal difference (D), m	81.74
Mean catchment slope (I_m), %	20.1
Coefficient of catchment relief erosion energy (E_r), $m/km^{1/2}$	53.16

Table 1 presents the Čančar brook relief which plays a primary role in the occurrence of soil erosion. The mean altitude (A_m) of the Čančar brook is 700.74 m and the mean altitudinal difference (D) is 81.74 m. The mean slope (I_m) is 20.1%. Relief of a region can also be determined by the coefficient of relief erosion energy (E_r), the value thereof for the Čančar brook catchment being 53.16 m $km^{-1/2}$. An increase in relief parameter values results in increasing intensity of soil erosion in the catchment.
Geological substrates contribute significantly to the erosion process within the Čančar brook catchment area (Table 2). Erosion resistance of geological substrates is directly related to water permeability. The geological substrate of the Čančar brook catchment is serpentine (100.00% of the total catchment area) and is with poor permeability. The water permeability coefficient of the serpentine geological substrate (S_1) is 1.00, suggesting non-resistance of the geological substrate to the erosion process (Table 2).

Table 2. Geological substrate of the Čančar brook catchment, coefficient of water permeability (S_1) and erosion resistance

Catchment name: The Čančar brook			
F_{ppr}-Poorly permeable rocks			
Serpentine		km^2	0.54
		%	100.00
Coefficient of geological substrate water permeability (S_1)		1.00	
Resistance of geological substrate to erosion		Non-resistant	

As an erosion agent, soil and its properties contribute, to a lesser or greater degree, to the erosion process. Due to the effect of pedogenetic factors, the soil type covering the Čančar brook catchment area is humus-siliceous soil on serpentine rock. It is classified as shallow soil. The profile of the humus-siliceous soil on serpentine is of A_h–C type. A strong degree of erodibility is found in the humus-siliceous soil on serpentine (Šekularac, 2000).

Table 3. The structure of the Čančar brook catchment according to type of land use and vegetative cover coefficient (S_2)

Catchment Name: Čančar brook			
F_f	Forests and coppice of good spacing	km^2	0.02
		%	3.70
F_g	Orchards	km^2	0.00
		%	0.00
	Meadows	km^2	0.07
		%	12.96
	Pastures and devastated forests and coppices	km^2	0.30
		%	55.56
$\sum f_g$		km^2	0.30
		%	68.52
F_b	Arable land	km^2	0.03
		%	5.56
	Infertile soil	km^2	0.12
		%	22.22
$\sum f_b$		km^2	0.15
		%	27.78
Vegetation cover coefficient (S_2)		0.84	

The most aggressive climate elements inducing and contributing to soil erosion include rainfall, air temperature, and soil temperature (indirectly, through air temperatures). This region has a temperate continental climate. The mean annual rainfall total (R) for the Čančar brook catchment is 799.1 mm, and the mean annual air temperature (T) is 8.1^0C. The data on rainfall reaching the catchment surface indicate an important role of rainfall as a climate element in soil erosion in the catchment area observed.

The contribution of the other soil erosion agents i.e. vegetation, both autochthonous and anthropogenic, and vegetative cover coefficient (S_2) is given in Table 3. The total area of land under forests and coppice of good spacing (F_f) in the Čančar brook catchment is 0.02 km^2 (3.70%), most of the land – 0.30 km^2 (55.56%) is under grass vegetation ($\sum F_g$), and 0.15 km^2 (27.78%) of land are under bare soil ($\sum f_b$). These forms of land-use facilitate the protection of the studied area against erosion (vegetative cover coefficient, $S_2 = 0.84$).

The devastating potential of the watercourse can be determined from the hydrographic and hydrologic traits of the region analysed. The traits pertaining to the family of the Čančar brook torrent (F_c) are as follows: F_c: F; IV; Z=0.40, meaning that the Čančar brook is a ravine

(F) classified as class IV of erosion category (a deep type of erosion) and having an erosion coefficient (Z) of 0.40 (weak erosion intensity).
The above traits of the erosion factors in the Čančar brook catchment result in sediment production and soil erosion of particular intensity.
The scale of erosion of the Čančar brook catchment is manifested through the mean annual erosion-induced sediment yield, W_{yr} of 321.80 m^3 yr^{-1}.
The mean annual volume of the total sediment yield (G_{yr}) reaching the Čančar brook confluence is 61.14 m^3 yr^{-1}, whereas the specific annual total erosion-induced sediment yield reaching the confluence with the Kamenica River ($G_{yr\ sp}^{-1}$) is 113.23 m^3 km^{-2} yr^{-1}. This finding regarding the weak erosion intensity is comparable to that on the low-intensity erosion of the Grliška River region (Eastern Serbia) of ($G_{yr\ sp}^{-1}$) 209.12 m^3 km^{-2} yr^{-1} (Stefanović et al., 2007). Using the method of EPM, in research of the Djuricka river basin (North of Montenegro), predicted that the soil losses were 645 m^3 km^{-2} per year (Spalevic et al., 2013). The said erosion intensity on the Čančar brook catchment is manifested through the relief erosion energy coefficient of 53.16 m $km^{-1/2}$, the erosion coefficient (Z) of 0.40, mean annual rainfall of 799.1 mm and average annual air temperature of 8.1^0C, with about 68.52% of land area under grass vegetation ($\sum F_g$), and the dominating humus-siliceous soil on serpentine rock.
The above data show that, in view of the annual sediment yield, about 0.03 ha of soil up to 20 cm depth are eroded off the Čančar brook catchment area i.e. about 0.05 t ha^{-1} of soil are lost annually. The amount of the eroded soil material can be categorised as class I (0-1 t ha^{-1} yr^{-1}) of permissible or tolerable erosion (Hacisalihoğly et al., 2010).

Conclusion

The Čančar brook is classified as a ravine. The value of Z coefficient of 0.40 indicates that the river basin belongs to destruction category IV. The strength of the erosion process is weak, and deep erosion dominates in the studied area.
These and the other soil erosion agents analysed in the catchment area have resulted in the mean annual erosion-induced sediment yield of 321.80 m^3 yr^{-1}, and erosion intensity of 113.23 m^3 km^{-2} yr^{-1}. The erosion observed in this region is of weak intensity, and the anthropogenic factor is the key agent in the process governing soil utilisation, soil conservation and protection from further erosion-induced degradation.

Abstract

Urbisols are considered as all soils in urban areas on which formation men had immediate impact. They are formed by mixing natural soil layers with laid down material. Heavy metals in natural soils originate from parent material, while the origin of these elements in urbisols also depends of the laid down material. In addition to these main factors, air pollutants also have influence on the dynamics of heavy metals in urbisols. Probably the biggest influence of air pollutants can be seen in the soils along roads, where the origin of heavy metals can be attributed to car exhaust fumes. Metals which most often occur as contaminants of these soil are cadmium (Cd), lead (Pb), mercury (Hg), cobalt (Co), chromium (Cr) and others. In this paper the results of the total content of heavy metals (Pb, Ni, Cd, Co and Cr) in urbisols along the Boulevard of Car Lazar, one of the most frequented roads in Novi Sad, are presented. In topsoil the highest values were found for Pb, Ni and Cr, while the values of Cd and Co are not too different from the control sample. As a control sample it is used soil from the park. The total content of Pb, Ni and Cr in the soil along the Boulevard is on average three to four, in some places five times higher than in the control sample. Compared with the maximum permissible concentrations (MPC), the values in the tested samples were enlarged, but do not exceed MPC. Compared to the deeper layers, surface layers of the soil had a higher content of heavy metals.

Keywords:*urbisols, the total content ofheavy metals*

Introduction

Soil is a mixture of a number of components, including organic matter, mineral constituents, all kinds of soil-borne organisms, water, air and man-made elements (Faiz et al., 2009). Depending on the location, soil can also contain pollutants originating from industrial emissions, waste disposal sites, agriculture, urban centers, or from emissions generated by motor vehicles (Modrzewskaet al., 2014). In urban areas, soils are formed by mixing natural soil layers with laid down material various origin. Urbisols usually have one or more layers and thickness of at least 50 cm, and the layers are composed of different materials that are formed by mixing, compaction, addition of substrate, synthetic materials etc. (Zemlyanitsky, 1963; Craul, 1985). Because of that characteristics urbisols are very various. Soil profiles show abrupt changes from one layer to another depending upon the constructional history of the soil properties while in most natural profiles gradually grade from one layer to the next, lower one (Craul, 1985). Nešić et al. (2014) said that the most vulnerable urban soils are soils next to road and they are almost totally changing by constant human activities. During the year that includes the various works on infrastructure networks, water supply, sewerage and electricity lines, and also to the roads and paths. Except this, roadside topsoil is affected by traffic pollutant which reduces their quality even more. In the past decades the number of motor vehicles has increased dramatically which means constantly rising contamination of the soil environment with heavy metals (Modrzewska et al. 2014). Most of the heavy metals

originate from exhaust fumes, oil leaks from cars, the wearing out of tires and brake disks and from corrosion of metal parts of vehicles, claim Faiz et al. (2009), Duong and Lee (2011), and Liu et al. (2012). Heavy metals found in soil are also derived from the lithosphere, being released during soil formation processes and therefore constituting the natural background of their total concentration (Ubavić, Bogdanović, 1995; Manojlović and Singh, 2012). The solubility and therefore the bioavailability of heavy-metal ions are very widely, because many factors influence their concentration in soil solution. The most important factors affecting metal availability are soil pH, clay content and organic matter content (Takáč et al. 2009). The most common heavy metals released from vehicles on road are cadmium (Cd), copper (Cu), lead (Pb), nickel (Ni), zinc (Zn), cobalt (Co) and Chromium (Cr) (Faiz et al. 2009).
The aim of this research was to determine concentrations of some heavy metals (Cd, Pb, Ni, Co and Cr) in roadside soil along Car Lazar Boulevard in Novi Sad, one of the busiest roads in town.

Materials and methods

The study was conducted in Novi Sad which is the second largest city in Serbia and the administrative seat of both, the province of Vojvodina and the South Bačka District. Since its founding, the population of the city has been constantly increasing. In the 1990s and 2000s, the city experienced significant population growth and today city has 341,625 inhabitants (Statistical Office of Republic of Serbia). Novi Sad is located in the southern part of the Pannonian Plain, on the border of the Bačka and Srem regions, on the banks of the Danube river, facing the northern slopes of Fruška Gora mountain. Area in which the trial is conducted is in geomorphologic point of view of the alluvial terrace of the Danube. Urbisols, in this area of the city, are formed in natural soil type fluvisol, which is hydromorphic soil and belong to class of under developed fluvial soils with soil profile (A) or G (A)-C. These soils are recent, river, sea and lake deposits with layers. Pedogenetic processes are poorly expressed due to youth of deposit or because of sedimentation prevails pedogenesis. Physical and chemical properties depend on the number of layers and their thickness, texture, origin and sequence. Some typical characteristics are rarely discussed and they are different from profile to profile (Živanov and Ivanisević, 1986, Nešić et al., 2014). By the construction of defensive levees leakage of the river is prevented and consequently the natural process of genesis of fluvisol is stopped.
Field studies were conducted in three representative locations, next to the busiest intersections. Sampling was performed at two depths of 0-30 cm and 30-60 cm, as this is the part of the bulk of the solum developing roots. At each location it was taken six samples, three in shallow and three in deeper layer, in a triangle around the tree. Soil from a nearby park was taken as a control site. Soil samples, 24 in total, were air-dried and manually sieved through a 2 mm sieve for chemical and texture analysis. The collected samples were analyzed at the Laboratory of Soil and Irrigation and the Laboratory for Agrochemistry at Faculty of Agriculture, University of Novi Sad, with contemporary, recognized methods used for this type of research.
Laboratory studies include the determination of texture according to International B-pipette method with preparation in sodium pyrophosphate; pH value in the suspension of soil with H_2O and KCl, and the measurement is carried out using a pH meter "inoLab"; content of humus, the method of Tjurin and concentration of heavy metals extraction from soil using nitric acid by AAS (Atomic Adsorption Spectrophotometer).
For verifying existence of statistically significant differences it is used LSD test. Statistical analysis was performed with Dunnet test at the significance level of 95%. In this way entered data allowed to compare locality - a layer – conc. of metal. All the localities were compared with a control site, and because of that this test was used. The null hypothesis was that there

was no significant statistical differences in the content of heavy metals in all localities, while the alternative hypothesis was that content of heavy metals in localities is larger than control site, M> Contr.

Results and discussion

The results are shown in the Tables 1, 2 and 3. Based on results of soil texture it can be said that the soil of examined localities belong to textural classes of loam, with small variations, texture and composition which ranges from coarse sand to clay loam. In all samples the largest share of the grain-size composition has a sand fraction. The content of the clay fraction of the studied sites in the surface layer ranges from 13.53 to 17.50%, while the deeper layers of soil values range is from 9.83 to 16.18%. At control site clay content is lower, and ranges are from 6.36 to 4.23%. Urbisols of examined localities have a higher clay content than natural fluvisols in a protected part of the Danube at Novi Sad, while the content of this fraction in the control site is not different than natural fluvisols. (Nesić et al. 2014)

Humus content is higher in the shallow layer of the tested sites and it ranges from 2.31 to 2.60%. This is understandable, because the soil surface is covered by grass, which enriched surface layer in organic matter. The values in the deeper layers are less, an average of 1%, and the lowest value were in the control site, 1.11%. According to Dugalić and Gajić (2012), surface layers can be classified into medium humus soil, while the deeper layers are light humus soil.

Of the soil parameters soil pH is one of the parameters that affect significantly the share of bioavailable forms of metals (Takáč et al. 2009). The pH of tested sites measured in H_2O ranges from 7.70 to 8.62 as according Dugalić and Gajić (2012), meaning that these soils belonging to poorly or very alkaline soils. This confirmed the results of measurements of pH and in the suspension with KCl, according to which these soils belong to the alkaline (Ubavić, Bogdanović, 1995). Compared to natural soils in this area, or fluvisol being examined by Pekeč (2010), it can be said that the values of pH are almost identical.

Tab. 1: Clay content, humus, pH values and Pb, Ni, Cd, Co and Cr total content in topsoil

	Depth	Clay content	Humus (%)	pH		Heavy metals content mg kg^{-1}				
				H_2O	KCl	Pb	Ni	Cd	Co	Cr
Locality 1	0-30	17.50	2.46	7.70	7.55	93.54	25.69	0.74	10.56	19.68
	30-60	16.17	1.41	7.94	7.77	51.75	24.87	0.73	10.02	16.79
Locality 2	0-30	13.88	2.44	8.62	7.65	35.71	19.17	0.67	8.46	14.02
	30-60	9.60	1.33	8.30	7.79	18.36	22.72	0.63	8.58	15.02
Locality 3	0-30	13.53	2.31	8.12	7.83	53.19	21.76	0.75	8.36	14.61
	30-60	9.73	1.86	8.15	7.92	39.59	18.60	0.68	7.90	12.77
Control site	0-30	4.23	2.60	7.91	7.23	14.42	20.86	0.41	9.31	17.90
	30-60	6.36	1.11	8.01	7.66	6.13	8.51	0.32	4.35	5.53
			Limited value			100	50	3	30	100

In the analyzed samples values of lead were within the range of 16.39 to 104.63 mg kg^{-1}, while the control soils have much lower Pb concentrations, from 2.96 to 14.53 mg kg^{-1}. The average values do not exceed the MPC of 100 mg kg^{-1}, but it is evident that the values in the Locality 1 are higher compared to other sites, particularly with shallow layer. The shallow layers have higher levels of lead than deeper. When we compare the results of lead along the Boulevard with average values for southern Bačka (24.4 mg kg^{-1}), which give Manojlović and Singh (2012) we can conclude that they are generally increased by two to three times.

Average values of concentrations of nickel in the research areas ranges from 18.60 to 25.69 mg kg^{-1} in localities along the boulevard, while the values on the control site are less. In the surface layer of the control site pollution value is 20.86 mg kg^{-1}, and in a layer of 30-60 cm is 8.51 mg kg^{-1}. The MPC of nickel in the soil is 50 mg kg^{-1}. The higher value in the shallow layer is probably caused by air pollution. According to Johansson et al. (2009) or Khan et al. (2011), both lead and nickel come from exhaust fumes. Helmreich et al. (2010) added that another source of nickel contamination of soils near roads is the wearing out of the road surface and use of paints containing lead.

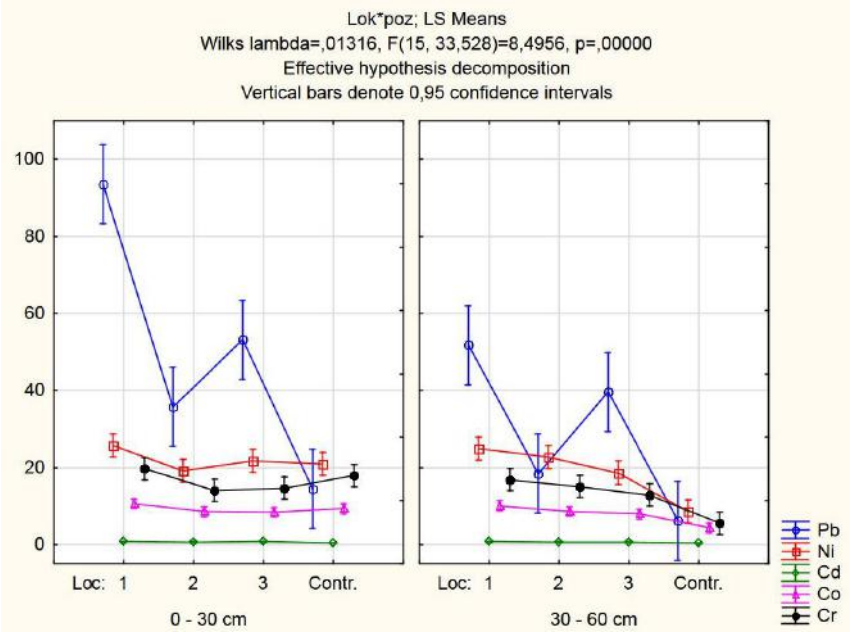

Fig. 1: Total content of Pb, Ni, Cd, Co and Cr in topsoil

Because of the very high toxicity of Cd for plants and to wild life, its MPC compared to other heavy metals are low (3 mg kg^{-1} of soil). On the tested sites content of cadmium is very low and does not exceed 1 mg kg^{-1} and so there is no danger of a negative effect of this element on the plant.

The values of cobalt content in the tested soil are below the MPC is 30 mg kg^{-1}. The highest content of this element has Locality 1 and it was 10.56 mg kg^{-1}. When we are comparing sites on the Boulevard in with the control site, it can be seen that there are no major differences.

The maximum level of chromium in the soil is the same like for lead is 100 mg kg^{-1}. In analyzed samples chromium values ranged from 5.53 to 19.68 mg kg^{-1}. When comparing the concentration of the surface and deeper layers it cannot be seen significant differences.

Contents of Co at all sites was at a low level because the coefficient of variation was 23.67%. The situation is similar with Cd where the average deviation from the mean value is 26.32%. The coefficient of variation for Ni amounts to 27.24%, and 31,15% for Co, which also indicates a lower average deviation from the mean value. These changes do not indicate greater variation in the amount of these heavy metals in the tested sites and control. Higher deviation of measured values of lead was observed at all sites. Even 70.58% is average standard deviation from the mean measured values. Minimum lead content was measured in a control sample and it was 2.96 mg kg^{-1} while maximum is measured in Locality 1 and it is showed in Table 2.

Tab. 2: Descriptive Statistics of measured samples

Variable	Descriptive Statistics						
	Valid N	Mean	Median	Minimum	Maximum	Std.Dev.	Coef.Var.
Pb	24	39.09	35.91	2.96	104.63	27.59	70.58
Ni	24	20.28	21.62	5.99	26.76	5.523	27.24
Cd	24	0.62	0.68	0.21	0.81	0.16	26.32
Co	24	8.44	8.85	2.74	10.86	1.99	23.67
Cr	24	14.54	15.69	4.06	21.56	4.53	31.15

Considering that the values of Ni, Cr, Co, Cd are far below the MPC, statistical analysis was not performed for these elements. Statistical analysis was performed with Dunnet test at the significance level of 95% for Pb. Some obtained data content of Pb in soil, adjacented to the maximum MPC. At the control site, between the deeper and shallow layers there are not statistical significance. Comparing pairs of site-layer there was a significant difference between contol and other localities, excluding locality 2 in a deeper layer. It can be said 95 % that the alternative hypothesis M> control it is comfimed.

Tab. 3: Dunnet test, M>Control

Dunnet test; variable Pb Probabilities for Post Hoc Tests (M>Control) Error: Between MS=70.266, df=16.000			
Locality 1	0-30 cm	0.000020	0.000020
	30-60 cm	0.000177	0.000036
Locality 2	0-30 cm	0.017382	0.001519
	30-60 cm	0.676677	0.183114
Locality 3	0-30 cm	0.000125	0.000031
	30-60 cm	0.005593	0.000498
Control site	0-30 cm	**14.425**	0.388614
	30-60 cm	0.995850	**6.1301**

Conclusion

Based on the research of texture, pH and humus content it can be said that urbisols on examined localities along Car Lazar Boulevard in Novi Sad belong to textural classes of loam, with small variations, texture and composition which ranges from coarse sand to clay loam. In all samples the largest share of the grain-size composition has sand fraction. As the consequence of the high content of sand fraction urbisols of this area does not have high capacity for cation adsorption. Humus content is at medium level of availability in the shallow layers, and at the low availability in the deeper layers. The pH value of tested samples is classified in the low to very alkaline. The total content of heavy metals is below ranges of MPC, but it can be seen increased content of lead and nickel compared to the control site. Because of that it can be said that the traffic flow had an effect on the content of heavy metals in roadside soils, which indicates increased risk of contamination of the soil with heavy metals in future.

PRECIPITATION IN VOJVODINA PROVINCE AND THEIR EFFECTS ON CROP PRODUCTION

Livija MAKSIMOVIĆ*, Vladimir SIKORA, Milka BRDAR-JOKANOVIĆ, Dušan ADAMOVIĆ, Janoš BERENJI

Institute of Field and Vegetable Crops, Maksima Gorkog 30, 21000 Novi Sad, Serbia

Abstract

Serbian crop production is concentrated in the northern plains of Vojvodina region, inter alia due to the favorable agro climatic conditions. The climate is continental with Danube precipitation regime, with the most rainfall occurring in early summer and the least in the beginning of spring and in the mid-autumn. The precipitation recorded for the past thirty years (1985-2014) at the Bački Petrovac meteorological station had the average annual value of 616 mm (248-973), with 363 mm (103-636) falling in the crop vegetation period. On the thirty-year average, sum of precipitation increased 4.5 mm per hydrological year; respectively 3.4 mm in crop vegetation, 1.0 mm in winter and 0.4 mm in July-August period. However, the eight years with the most extremely high or low precipitation were within the 2000-2014 period, causing frequent fluctuations in crop yields. Average yields were in the intervals of 2.9-8.8 t ha^{-1} for maize, 1.2-3.6 soybean, 1.5-3.0 sunflower and 24.7-55.6 t ha^{-1} for sugar beet. The yield variation may be due to the precipitation variation in July-August, when the crops have the highest water demands. Their average monthly water requirement is about 100 mm; however, 83 and 90% (July and August, respectively) of the analyzed thirty years were characterized by the lower sum of the precipitation. Only five and two years were with precipitation in July and August higher than 125 mm. The number of tropical days (maximum daily temperature > 30^{o}C) also increased during the analyzed thirty-year period (0.4 per year, on average) affecting crop production.

Key words: *weather conditions, precipitation, drought, crop production*

Introduction

The agricultural plant production is influenced by numerous factors; soil and climatic conditions, the grown cultivar or hybrid, agro technical procedures, irrigation, pests etc. Out of the listed factors, the climatic conditions are under the least influence of the producers. The precipitation and the distribution of the precipitation during the hydrological year affect soil water balance and plant nutrition processes (Dragović et al., 2004). The lack of precipitation is related to droughts of the various intensity and duration which can cause yield losses (Dragović et al., 2005). Therefore, the monitoring and the analysis of the precipitation are of particular importance for crop production. Frequent variations in rainfall amounts are recorded in Vojvodina province known as our most important agricultural region. Rainfall values in certain smaller geographic areas of Vojvodina province can represent average annual rainfall of its extended area.

Therefore, the aim of this study was to analyze the influence of rainfall on the yield of the four most common crops in 30-year period.

Materials and methods

The meteorological data used for this analysis are collected from the archive of Bački Petrovac climatological station and include a thirty year period (1985-2014). The measuring point is placed in the central part of the Vojvodina region (N 45º 20´E 19º 40´, 82 m elevation). The sum, distribution and trends of precipitation were analyzed, with special reference to summer period when the droughts occur more often. Official data of the Statistical Office of the Republic of Serbia were used for the analysis of maize, soybean, sunflower and sugar beet yields.

Results and discussion

The analysis of the sum of precipitation noted at the Bački Petrovac measuring point in the thirty year period (1985-2014) showed the average value of 615.5 mm (Tab. 1). However, the interval of variation for the parameter was considerably high (385.8 – 1045.5 mm). Winter precipitation (X-III months) were on average 253.3, and those recorded for crop vegetation period (IV-IX) 362.2 mm. Both parameters were characterized by high intervals of variation.

Table 1. Mean annual, seasonal and monthly sum of precipitation (mm); Bački Petrovac, 1984/1985-2013/2014 period

Month	Winter precipitation		Month	Vegetation precipitation	
	Average	Variation		Average	Variation
X	52.4	3.0 – 2005 154.9 – 1992	IV	47.2	0.0 – 2007 111.0 – 2004
XI	48.1	1.5 – 2011 136.4 – 2004	V	66.6	10.2 – 1993 178.5 – 2014
XII	44.3	1.5 – 2013 121.6 – 1999	VI	80.1	18.7 – 2000 191.1 – 2010
I	37.4	2.8 – 1989 96.8 – 1987	VII	67.1	12.6 – 1988 173.6 – 1987
II	34.6	0.8 – 1998 72.6 – 1999	VIII	49.5	0.0 – 1992 142.1 – 2006
III	36.5	1.8 – 1992 93.5 – 2001	IX	51.7	3.1 – 1986 159.0 – 2001
Sum	253.3	73.4 – 1988/89 409.4 – 2009/10	Sum	362.2	103.0 – 2000 636.1 – 2010
Mean annual sum: 615.5 mm, minimum 385.8 (2011/2012), maximum 1045.5 (2009/2010)					

Maximum and minimum sum of precipitation for the thirty year period were noted for two consecutive hydrological years (2009/10, 2011/12), implying the unpredictability and inconstancy of the sum of precipitation. Considerably high deviations from the long-term averages are a characteristic of the precipitation in Vojvodina region (Spasova et al., 1999; Maksimović et al., 2013).

Table 2. Five hydrological years with the lowest annual sum of precipitation (mm); Bački Petrovac, 1984/1985-2013/2014 period

Hydrological year	Month												Annual	Veg. season	Winter period
	X	XI	XII	I	II	III	IV	V	VI	VII	VIII	IX			
2008/2009	45	7	29	37	39	33	5	67	90	22	18	4	396	206	190
2011/2012	30	2	49	41	58	3	68	40	62	44	4	13	414	231	183
1999/2000	29	108	122	13	9	36	25	25	19	20	7	8	421	104	317
1989/1990	36	40	11	6	35	29	39	25	129	28	9	46	433	276	157

Max	85	108	122	47	58	36	68	67	129	53	36	46			

Out of five the driest years, four are noted after the year of 2000 (Tab. 2). Since winter and early spring droughts are becoming more common, even the deeper roots cannot provide plants with water (Kresović, 2003).

Table 3. Five hydrological years with the highest annual sum of precipitation (mm); Bački Petrovac, 1984/1985-2013/2014 period

Hydrological year	Month												Annual	Veg. season	Winter period
	X	XI	XII	I	II	III	IV	V	VI	VII	VIII	IX			
2009/2010	72	65	89	74	72	38	47	82	191	98	114	104	1046	636	410

2000/2001	8	28	52	42	25	94	110	81	174	30	16	159	819	570	249
1997/1998	92	42	79	67	1	23	41	98	111	75	84	78	791	487	304
2003/2004	121	26	15	53	46	19	112	136	106	45	51	38	768	488	280
Average	75	59	55	53	37	43	68	87	140	82	80	89	868	547	321
Min	8	26	15	27	1	19	30	39	106	30	16	38			
Max	121	136	89	74	72	94	112	136	191	161	137	159			

In addition, four of the five hydrological years with the highest sums of precipitation were within the 2001-14 period (Tab. 3), implying a high oscillation in the sum of precipitation (Fig. 1). Extreme years are becoming more often, either dry or rainy. Slight increasing trend was noted for sum of precipitation in hydrological years (4.5 mm per year), vegetation and winter period (3.4 and 1.0 mm per year, respectively). For July-August period this increase is not significant (0.4 mm per year). The results are not in accordance to the reports of Lalić et al. (2011), who used climatic models and scenarios to predict the decrease of annual sum of precipitation in the region of Vojvodina. Spasov and Spasova (2001) analyzed annual and seasonal rainfall time series in Serbia, in the period 1971-2000, and reported a decreasing trend for central Serbia, not only in annual, but, also in average rainfall during the growing season whereas a decreasing trend in rainfall in Vojvodina province over a growing season was less pronounced and no decrease in rainfall on an annual basis was observed.

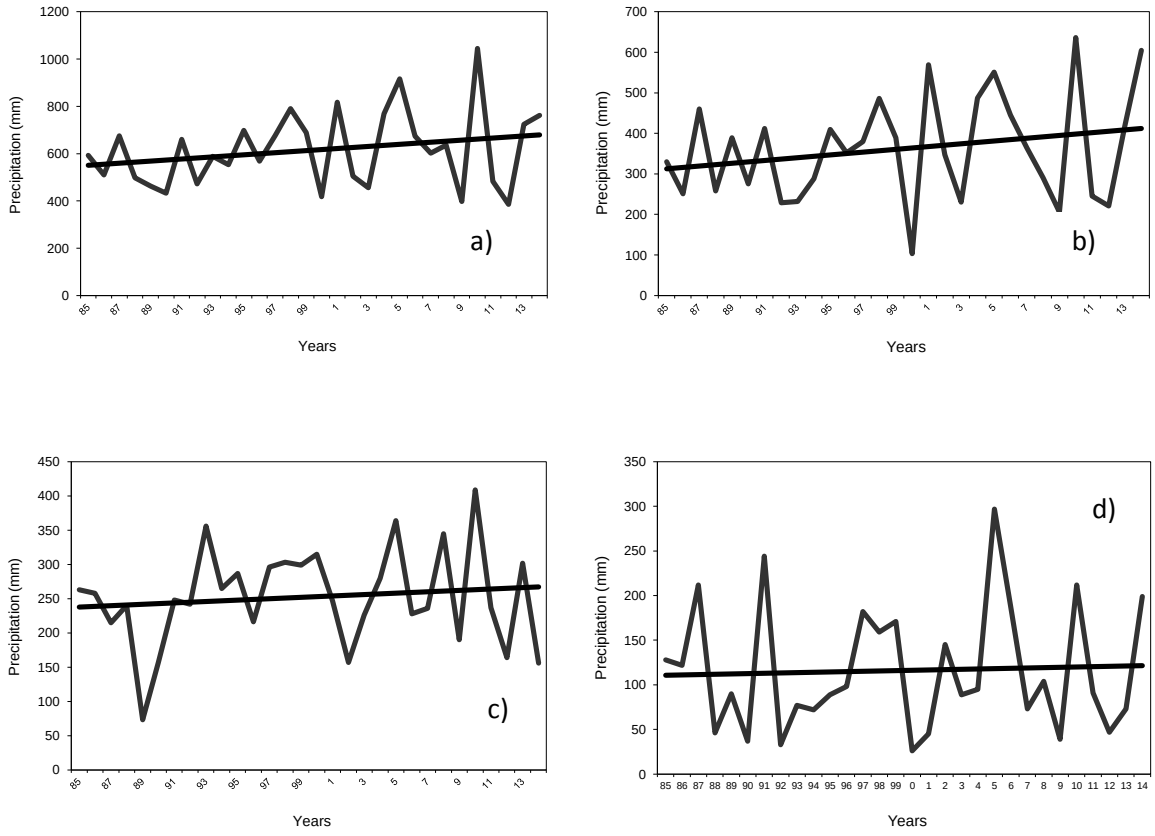

Fig. 1 Distribution of precipitation in Vojvodina (Bački Petrovac) – a) hydrological years; b) vegetation (IV-IX); c) winter period; d) July-August

Precipitation during vegetation is of particular importance for crop production, especially in July and August when most crops reach the phase of yield formation. Most crops require about 100 mm of woter in this period; therefore the value was used as a borderline between dry and rainy years. For the observed thirty year period, 90% of years were with dry August and 83% with dry July. Only five were rainy (>125 mm) in July and two years and August (Tab. 4).

Table 4. Dry and rainy years (%), based on sum of precipitation in July-August period; Bački Petrovac, 1985-2014

Rank	July		August		
(mm)	Number of years	%	Number of years	%	Category
0-25	5	17	8	27	Extremely dry
26-50	10	33	9	30	Very dry
51-75	7	23	6	20	Dry
75-100	3	10	4	13	Moderately dry
	25	83	27	90	Total dry
101-125	0	0	1	3	Moderately rainy
>126	5	17	2	7	Rainy
	5	17	3	10	Total rainy
Total	30	100	30	100	

Crop yields varied with the variation in sum and distribution of precipitation. The yields of four crops that are among the major in Vojvodina (maize, soybean, sunflower, sugar beet) and that are officially reported (Statistical Office of the Republic of Serbia) are given in Table 5; for five the driest and five the wettest years.

Table 5. Crop yields in Vojvodina region (t ha^{-1}) for five the driest and five the wettest years of the 1985-2014 period (Stat. Yearb. Serb. 1986-2014)

Precipitation (mm)-The driest years	Maize	Soybean	Sunflower	Sugar beet
247.7-2000	2.94	1.22	1.52	24.71
391.1-2011	6.01	2.71	2.52	50.96
425.0-1988	4.56	1.61	2.28	36.82
455.4-2012	3.04	1.74	2.24	36.48
455.6-1986	6.99	2.33	2.56	41.72
Precipitation (mm)-The wettest years	Maize	Soybean	Sunflower	Sugar beet
972.8-2010	6.71	3.21	2.25	50.15
863.4-2004	5.88	2.72	2.34	46.76
834.6-2001	5.59	2.39	1.98	42.69
807.2-2014	8.79	3.58	2.97	55.60
788.9-1999	5.35	2.75	1.48	42.32

The distribution of the precipitation is important for crop production. Satisfactory soil moisture in important plant developmental stages provides good yields, at the level of the years with generally good rainfall. The importance of the distribution of the precipitation can be illustrated with maize example: 1986 was dry year (455.6 mm); however, maize yield was higher (6.99 t ha^{-1}) than in four of the five the wettest years. Similar was for soybean and sugar beet, while sunflower yields were better in dry years (in most cases), related to fewer pest occurrence.

In addition, the increase in the number of tropical days (maximum daily temperature > 30°C) was noted for the analyzed thirty years (Lalić et al., 2011; Maksimović et al., 2014).

Conclusion

The analysis of the precipitation in the last thirty years (1985-2014, Bački Petrovac, central Vojvodina) showed the increase in the years with water regime which is unfavorable for spring crops. This is due to insufficient or excess rainfall and unfavorable precipitation distribution during the vegetation. Therefore crop yields vary, with significant losses in particular cases, such as the case of insufficient rain in July and August.

Abstract

Erosion caused by water is a natural process and in the studied river basin is generated primarily by rainfall and surface runoff. In defining potential measures to alleviate the environmental effects in certain areas it is important to understand this process and to detect the erosion prone areas. We used analytical model IntErO for the assessment of the soil erosion process, soil loss potential and runoff. Peak discharge from the studied Orahovacka Rijeka Watershed, Q_{max}, was calculated on 174 m^3s^{-1} (for the incidence of 100 years); 155 m^3s^{-1} (incidence: 50 years); 141 m^3s^{-1} (incidence: 25 years); 101 m^3s^{-1} (incidence: 10 years). The value of Z coefficient of 0.478 indicates that the river basin belongs to III destruction category (of five). The strength of the erosion process is medium, and according to the erosion type, it is surface erosion. The calculated real soil losses, G_{year}, were 2923 m³ per year, 256 m³ per square kilometer. This study, being a part of the long-term research in this Region, repeatedly has shown that IntErO model is a useful tool for calculation of sediment yield at the level of the river basin for this part of Southeast Europe. Further studies, in the wider Region where the studied watershed belongs, should be focused on the detailed analysis of the impact of the climate change on the soil erosion intensity and runoff, as well as on the trends of land use changes, closely following responses of soil erosion to the changed land use structure on soil erosion and sediment dynamics.

Keywords*: soil erosion, erosion potential, IntErO model, sediment yield, peak discharge*

Introduction

Soil degradation and desertification risk is a globally acknowledged issue with ecological, socioeconomic, cultural and political implications at both the regional and local scales. Those processes occur in both developed and emerging countries and affect arid, dry and even sub-humid areas (Helming *et al.,* 2011).

Soil degradation caused by erosion, together with rapid population increase, are ranked as the most important environmental problems in the world (Stoffel and Huggel, 2012; Ristic *et al.,* 2001) where the erosion is a key driver of land degradation heavily affecting sustainable land management in various environments worldwide (Ballesteros-Cánovas *et al.,* 2015; Stoffel *et al.,* 2013; Verheijen *et al.,* 2009). Every year, soil erosion leads to the loss of about ten million hectares of cropland, which reduces the limited amount of arable land available for food production, thereby contributing to malnourishment in millions of people (Pimentel, 2006). In addition, the accumulation of large volumes of sediment can cause severe sedimentation in reservoirs and channel beds, resulting in the loss of various functions in these hydraulic projects. Thus, it is important to determine the sediment yield rates in watersheds, which can provide a good basis to facilitate soil erosion control and river basin management (Zhao *et al.,* 2015).

Soil erosion is serious problem globally, but also in Europe (Yassoglou *et al.,* 1998). Structured information on soil erosion for the Western Balkan countries are missing in the reports for the European continent, but various research results have been recorded by the scientists Kostadinov and Ristic for Serbia (Lukic *et al.,* 2016; Kostadinov *et al.,* 2014, 2007; Ristic *et al.,* 2013), Spalevic for Montenegro (Spalevic *et al.,* 2015a; Spalevic *et al.,* 2015b; Spalevic *et al.,* 2015c; Spalevic *et al.,* 2015d; Spalevic *et al.,* 2015e; Spalevic *et al.,* 2015f; Spalevic *et al.,* 2015g; Spalevic *et al.,* 2015h; Spalevic *et al.,* 2015i; Spalevic *et al.,* 2015k), Blinkov for Macedonia and Albania (Blinkov, 2012; Blinkov and Kostadinov, 2010). Quantitative information on soil loss is needed for erosion risk assessment. The modelling of the erosion process has progressed rapidly, and a variety of models have been developed to predict both runoff and soil loss. The authors of this study used the computer - graphic models (Spalevic, 2011; Spalevic *et al.,* 1999a) for prediction of soil erosion intensity from the catchment area – IntErO model (Spalevic, 2011).

The objectives of the study were to compute the sediment yield for the studied Orahovacka Rijeka Watershed of the Polimlje River Basin on the north-eastern part of Montenegro; testing the possibility of application of the IntErO model in the conditions of the Western Balkans Watersheds.

Material and methods

The study was conducted in the area of the Orahovacka Rijeka Watershed in Montenegro (Figure 1).

Figure 1. Study area of the Orahovacka Rijeka Watershed, Montenegro

In terms of geomorphology and climate, it is part of the natural entity of the Polimlje Region (2188 km^2 in Montenegro), with the Lim River (the total length of 234 km, 123 km in Montenegro) as a main watercourse. The surface area of the Orahovacka Rijeka Watershed is 11.4 km^2 and the shortest distance between the fountainhead and the mouth, Lv, is 5.2 km. The average slope gradient in the river basin, Isr, is calculated on 32% what indicates that in the river basin prevailing very steep slopes. The average river basin altitude Hsr, is calculated on 857 m.

Fieldwork was undertaken to collect detailed information on the intensity and the forms of the soil erosion, the status of the plant cover, the type of land use, and the measures in place contributing to the reduction or alleviation of the erosion processes. Morphometric methods were used to determine the slope, the specific lengths, the exposition and form of the slopes, the depth of the erosion base, the density of the erosion rills, the degree of the rills, and other relevant parameters. Different forms: the shape of the slope, the depth of the erosion base and the density of erosion rills were determined (Draganic *et al.,* 2015).

Climatological data were received from the Meteorological Institute of Montenegro. Pedological survey was based on the research of the Agricultural institute from Podgorica led by Fustic and Djuretic (from 1964 to 1988), who analysed the physical and chemical properties of all soils in this Region, including those in the study area of the Orahovacka Rijeka Watershed, but also on the basis of Soil survey conducted by Spalevic (2011).
Various methods for erosion risk assessment are used in Europe. Development of erosion risk assessment methods, soil loss calculation and erosion intensity estimation has a long tradition (Blinkov, 2010) applying the three types of approaches: qualitative approach, quantitative approach, and model approach varying in their characteristics and applicability.
For the obtaining data on forecasts of peak discharge from the basin and the intensity of the soil erosion we used the program package Intensity of Erosion and Outflow - IntErO (Spalevic, 2011) that is an integrated, second-generation version of the program "Surface and Distance Measuring" (Spalevic, 1999a) and the program "River basins" (Spalevic, 2000). The Erosion Potential Method – EPM (Gavrilovic, 1972) is embedded in the algorithm of this computer-graphic method. The EPM and the IntErO model are currently in use in all the countries of Western Balkans (Barovic *et al.*, 2015; Barovic and Spalevic, 2015; Curovic *et al.*, 1999; Kostadinov *et al.*, 2014; Vujacic and Spalevic, 2015; Spalevic *et al.*, 2014a; Spalevic *et al.*, 2014b; Spalevic *et al.*, 2014c; Spalevic *et al.*, 2014d; Spalevic *et al.*, 2013a; Spalevic *et al.*, 2013b; Spalevic *et al.*, 2013c; Spalevic *et al.*, 2013d; Spalevic *et al.*, 2013e; Spalevic *et al.*, 1999b), but also used by some scientist teams from Brazil led by Pedro Veloso Gomes Batista (2015), Italy led by Alberto Tazioli (2009), Sadeghi, Behzadfar and the others from Iran (Sadeghi, 1993; Amiri, 2010; Behzadfar *et al.*, 2015; Behzadfar *et al.*, 2014a; Behzadfar *et al.*, 2014b, Barovic *et al.*, 2015), Saudi Arabia led by Ali M. Al-Turki (Al-Turki *et al.*,. 2015).

Results and discussion

The geological structure and soil characteristics of the area. Our analysis, extracting the geological data from the Geological map of Montenegro, shown that the poor water permeability rocks prevail (92%); and a part of the basin with medium permeable rocks is 8%. The coefficient of the region's permeability, S1, is calculated on 0.98. Based on the research of Fustic and Djuretic (2000); Spalevic (2011) and our own research, the most common soil types in the studied watershed are: Dystric Cambisols (96%) and Eutric Cambisols (4%).
There is a highly variable *climate* and human pressure on the land in the Orahovacka Rijeka Watershed. The climate is continental, with cold winters and warm, dry summers. The average annual precipitation, Hyear, is 873.7 mm; the temperature coefficient of the region, T, is calculated on 0.99; the amount of torrential rain, hb, on 157.6 mm.
Vegetation and land use. Good vegetation cover reduces overland flow velocity and increases infiltration by protecting the soil against rain drop impact and reducing the erosive capacity of the rain (Asfaha *et al.*, 2015) whereas deforestation leads to increased peak discharge. According to the available literature, using Google maps, including the records from the field half of the studied area is covered with forests (51%). The rest is under grass (41%), and minor part of the area is plough-land and ground without grass vegetation (9%). The coefficient of the river basin planning, Xa, is calculated on 0.48. The coefficient of the vegetation cover, S2, is calculated on 0.71.
Soil erosion and runoff characteristics. The dominant erosion form in this area is surface erosion. Problems with overgrazing are recorded also all over the studied area.
The input data for calculation of soil erosion intensity are presented at the (Table 1).

Table 1. Part of the IntErO report for Orahovacka Rijeka Watershed, Montenegro

Input data			
River basin area	F	11.4	km²
The length of the watershed	O	14.59	km
Natural length of the main watercourse	Lv	5.21	km
The distance between the fountainhead and mouth	Lm	4.07	km
The length of main watercourse with tributaries	ΣL	5.21	km
Basin length measured by a series of parallel lines	Lb	6.52	km
The area of the bigger river basin part	Fv	5.73	km²
The area of the smaller river basin part	Fm	5.67	km²
Altitude of the first contour line	h0	600	m
The lowest river basin elevation	Hmin	537	m
The highest river basin elevation	Hmax	1212	m
The volume of the torrent rain	hb	157.6	mm
Average annual air temperature	t0	8.9	°C
Average annual precipitation	Hyr	873.7	mm
Types of soil products and related types	Y	1.1	
Basin planning coefficient	Xa	0.48	
Equivalents of clearly exposed erosion process	φ	0.3	

The coefficient of the river basin form, A, is calculated on 0.55. Coefficient of the watershed development, m, is 0.44 and the average river basin width, B, is 1.75 km. (A)symmetry of the river basin, a, is calculated on 0.01 (the river basin is completely asymmetric). The value of G coefficient of 0.46 indicates there is very low density of the hydrographic network.
The height of the local erosion base of the river basin, Hleb, is 675 m. Coefficient of the erosion energy of the river basin's relief, Er, is calculated on 116.93. The value of Z coefficient of 0.478 indicates that the river basin belongs to III destruction category. The strength of the erosion process is medium, and according to the erosion type, it is surface erosion. We calculated the soil losses from the Orahovacka Rijeka catchment on 2923 m^3yr^{-1}, specific (per km^2) 256 m^3yr^{-1}. Peak discharge from the studied, Q_{max}, was calculated on 174 m^3s^{-1} (for the incidence of 100 years); 155 m^3s^{-1} (incidence: 50 years); 141 m^3s^{-1} (incidence: 25 years); 101 m^3s^{-1} (incidence: 10 years).

Conclusions

The study was conducted in the area of the Orahovacka Rijeka Basin, the left-hand tributary of the river Lim in Montenegro. We calculated the soil erosion intensity and runoff using the IntErO model. The value of Z coefficient of 0.478 indicates that the river basin belongs to III destruction category. The strength of the erosion process is medium, and according to the erosion type, it is surface erosion. We calculated the soil losses from the Orahovacka Rijeka catchment on 2923 m^3yr^{-1}, specific (per km^2) 256 m^3yr^{-1} and the peak discharge on 175 m^3s^{-1} (incidence of 100 years). This study further repeatedly confirmed the findings of Spalevic (2011) in possibility of implementing the EPM and the IntErO model in Montenegro and in all the Balkans (Blinkov, 2012; Kostadinov, 2007), but also wider, such as in Italy (Tazioli, 2009), Brazil (Batista, 2015, 2016), Iran (Draganic *et al.*, 2015a; Draganic *et al.*, 2015b; Barovic *et al.*, 2015; Behzadfar *et al.*, 2015; Amiri, 2010; Sadeghi 1993). That leads to the conclusion that the IntErO model may be a useful tool for researchers in calculation of sediment yield for the catchments which don’t have sediment sampling stations.

Abstract

Three maize growing systems are nowadays most present in Serbia: continuous maize cropping (15%), two crop rotation (maize -winter wheat - 60% and maize - soybean - 15%) and three crop rotation (maize - winter wheat - soybean - 5%). Despite to economic reasons, extended rotations are more sustainable than short-terms rotations, especially those one with legume crops that support reduction of N inputs and increase maize grain yield. Crop rotations facilitate the rotation of herbicides with different mode of action and are more effective in terms of planed weed control.

The aim of the research was to test effectiveness of combined application of crop rotation - maize continuous cropping, maize-winter wheat rotation and maize-soybean-winter wheat rotation and herbicides that are applied in recommended and reduced rates on maize weed control. Number of weed species and weed individuals per species and fresh biomass of manually uprooting weeds, were estimated in maize. Weed estimation was done four and six to seven weeks after the application of herbicides.

Weed association was composed of eleven most distributed species in all cropping systems: *Datura stramonium*, *Solanum nigrum* and two species from genera *Chenopodium* and *Amaranthus* and perennials *Convolvulus arvensis* and *Sorghum halepense*. Number of weed individuals and weed biomass were significantly lowered with herbicide application in all cropping systems and half of the full dose appears to perform nearly as well as the full dose.

Key words: *weeds, maize, rotation, herbicides*

Introduction

System or program of measures for Integrated Weed Management is usually define by the specific situation and level of weed infestation in the production area. In this regard, the preventive measures are used to prevent the spread of weeds and the introduction of new species while direct measures suppressing weeds directly. Among cropping measures it is important to properly complete the crop rotation (Spasojević et al., 2012; Simić et al., 2015). Crop rotation is effective and basic measure within Integrated Weed Management System (IWMS), (Bastiaans, 2010). By rotation of row and narrow crops and systems of measures for their production, including application of herbicides with different mode of action, weed community has no opportunity to become adapted and stabile.

In Serbia, there are three major maize growing systems: continuous maize cropping (15%), two crop rotation (maize -winter wheat - 60% and maize - soybean - 15%) and three crop rotation (maize - winter wheat - soybean - 5%) (Videnovic et al., 2013). Extended rotations involving legume crops reduce N inputs, increase maize grain yield and are more sustainable than current short-terms rotations (Stranger and Lauer, 2008). On the other hand, herbicides in recent time have to fulfil many tests during registration process in order to become approved as more environmentally friendly. They need to be effective and selective and do not make serious changes in weed community balance and encourage some troublesome weed species such as alien or perennial weeds, or emphasize resistant biotypes. For preservation of their

efficacy on the long term, IWM is also necessary (Claerhout et al., 2015). Studies showed that *Echinochloa cruss-gally* plants are more susceptible to some post-em herbicides than plants from long-term monocropping. Previous studies also showed that IWM tools such as crop rotation, provided sufficient weed control without any significant differences in yield and greatly reduced maize reliance on herbicides (Simić et al., 2012; Vasileiadis et al., 2015). Crop rotation determinates weed community composition, influences abundance of individuals and even seed bank richness (Simić et al., 2014b). Even, in crop rotations, competition pressure of weeds is weaker than in maize continuous cropping and highly dependent on herbicide application (Simić et al., 2015).

The aim of the research was to test effectiveness of combined application of crop rotations and herbicides that are applied in recommended and reduced rates on maize weed suppression.

Material and Methods

A field experiment was conducted during six years, 2009-2014, as a split-plot trial on slightly calcareous chernozem on the experimental field of the Maize Research Institute Zemun Polje, Belgrade, Serbia. The basic treatment was a plant production system: maize continuous cropping (MC), maize-winter wheat rotation (MW) and maize-soybean-winter wheat rotation (MSW). The hybrid ZP606, wheat variety Takovčanka and soybean variety Lana were conventionally sown within optimal periods in all production systems. Conventional tillage was used in the trial. A total of 30 t ha^{-1} of manure was incorporated in autumn of 2008 and then every third year in maize monoculture and MSW. In autumn of 2008 and 2010, 20 t ha^{-1} of manure was incorporated in two-crop rotation variant and every second year after. Different herbicide rates represented treatments in sub-plots. After sowing and prior to maize emergence the combination of isoxaflutole and acetochlor (Merlin 750-WG+Trophy 768-EC) was applied in two rates: HR- recommended (105 g a.i. + 1536 g a.i.) and ½ HR - half of the recommended rate (52.5 g a.i. + 768 g a.i.), while herbicides were not applied in the control. Each treatment had four replications. In wheat and soybean usual combination of herbicides for broadleaf and grass weed control was applied in whole variant.

Weed estimation was done four and six to seven weeks after the application of herbicides (I and II estimation). Samples were drawn randomly by the one square meter. Number of weed species and weed individuals per species and fresh biomass of manually uprooting weeds were estimated in maize.

Meteorological conditions were similar for maize production in 2009, 2011 and 2013. In 2013, in the middle of growing season (Jun and July), there were a lower amount of precipitation than in same period in 2009 and 2011 year. 2012 was extremely dry and hot, with absolutely unfavourable conditions for maize production.

Results and Discussion

Weed association was composed of eleven most distributed species in all cropping systems. Between them, annual broadleaf species *Solanum nigrum, Datura stramonium* and two species from genera *Chenopodium* and *Amaranthus* were dominant (Tables 1, 2 and 3). Number of individuals of perennial species *S. halepense* was even higher after some years in maize continuous cropping and in untreated control variants while *Convolvulus arvensis* was present as almost uncontrolled species even in a three crop rotation. In MSW crop rotation species *Hibiscus trionum* and *Cirsium arvense* were not detected after one rotation cycle.

Results shows that, in avreage for all herbicide treatments and years, the number of weed individuals decreased from MC (53.8 plants per m^2), trough MW (28.7 plants per m^2) to the MSW production system (16.9 plants per m^2), whic makes three crop rotation very effective measure for maize weed control (Simić et al., 2015).

Weed individuals of perennial species participated in total weed individuals' number with 28.44% in maize continuous cropping, 24.04% in MW rotation and 18.93% in three crop MSW rotation, which illustrate the weed control efficacy on each cropping system. Weed species richness decreased from untreated control to the HR treatments in all cropping systems and years, especially in MW and MSW production systems. After two cycles of double MW crop rotation, number of weed individuals was almost two times smaller comparing to maize continuous cropping, in the same years.

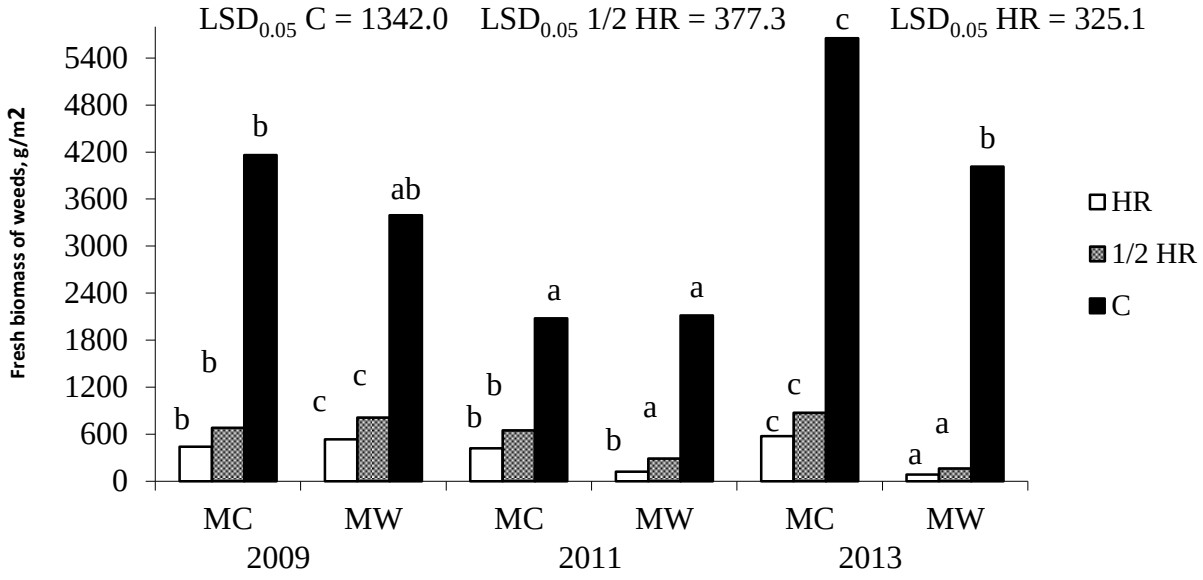

Figure 1. Biomass of weeds in maize continuous cropping (MC) and maize-winter wheat rotation (MW) independence of herbicide rates (II evaluation)

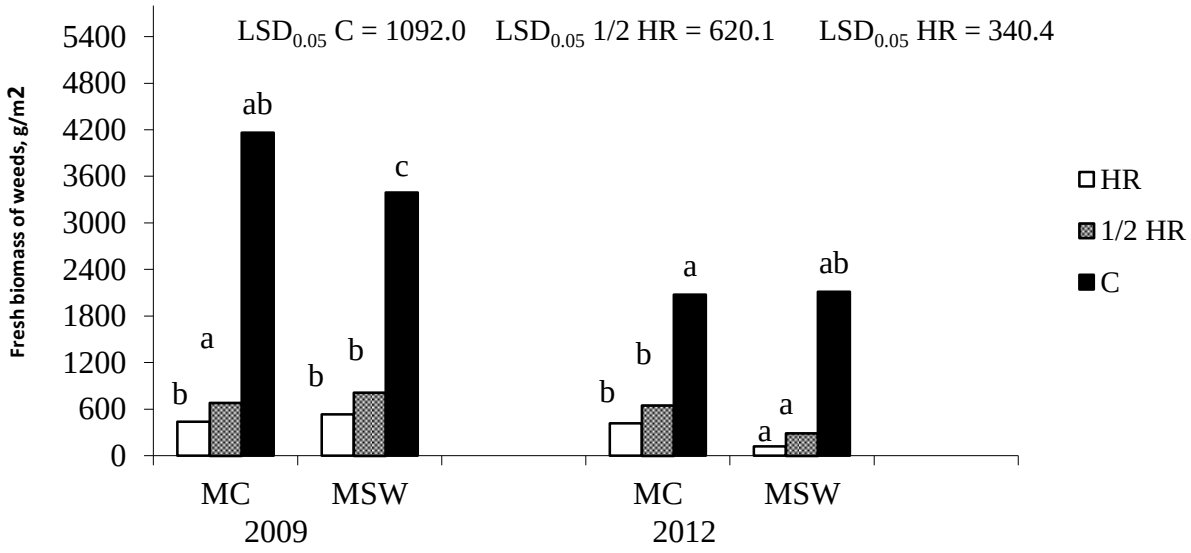

Figure 2. Biomass of weeds in maize continuous cropping (MC) and maize- soybean- winter wheat rotation (MSW) independence of herbicide rates (II evaluation)

Weed biomass was analysed in II evaluation, when present species and their individuals were fully developed and maize crop stand was almost completed (Figure 1 and 2). Weed individuals abundance and weed biomass were significantly lowered with herbicide application in cropping systems.

According to statistical analysis, differences in weed biomass between MC and MW, were higher after some rotation cycles (2013) than in the beginning of the experiment (2009). Similarly, the same regularity was observed between MC and MSW. Extremely dry and hot 2012 is exception and all measured values in this year were low. In most of the years, half of the full dose appears to perform nearly as well as the full dose.

Crop rotation and, due to it, the application of different herbicides, significantly contributes to control of annual, and especially of perennial weeds (Simic et al., 2014a). Weed species richness averaged over the rotation tended to decrease with herbicide application rate (Meziere et al., 20015). Wheat as a preceding crop, alongside with herbicides applied during the growing season as well as glyphosate-based herbicides applied to stubble fields after wheat harvest, greatly contribute to the reduction of weed infestation of maize as the following crop (Spasojevic et al., 2014). Even in especially dry 2012, when weeds tended to compete for water more than crops, the wheat x herbicide rate showed a great efficacy. Soybean as a component of three crop rotation system and herbicides applied during it’s growing, did not show significant effect on weed biomass decreasing probably because of completion of only one cycle of rotation.

Conclusion

The weed infestation level of maize crop can be successfully reduced by combined application of herbicides and crop rotation, even the simplest one such is maize-winter wheat rotation. Winter wheat as a cereal crop, together with an herbicide used for its production, was very effective for weed control. According to presented results, reduced herbicide rates together with rotations that include cereals or legume crops can facilitate suppression of weeds. The crop rotation should be implemented in a longer period of time in order to achieve reductions in weed abundance and higher maize yields.

INTERNET COMMUNICATIONS IN THE STATE ENTERPRISE FOR FOREST MANAGEMENT „SRBIJAŠUME“

Gordana JANČIĆ, Milka ZELIĆ

State Enterprise for Forest Management "Srbijašume", Belgrade, Serbia
*Corresponding author: milkablans@gmail.com

Abstract

The State Enterprise (SE) for Forest Management “Srbijašume“ Belgrade manages forests sustainably, i.e. in a manner and to an extent that permanently maintains and improves their productivity, biodiversity, regeneration capacity and vitality, which in the present and future ensures fulfillment of economic, ecological and social functions of forests.

The forest is the most complex ecosystem and plays a particularly important role in preserving the environment. Serbia is considered a medium-forested country. Total forest area in Serbia is 2,252,000 ha, out of which 1,194,000 ha (53%) are state-owned, and 1,058,387 ha (47%) are privately owned. SE “Srbijašume“ manages state forests and forestland on the surface of 893,417 ha and carries out professional activities in forests of private forest owners on the surface of 1,058,387.00 ha (condition as of 31st December, 2014).

Internet communications (in the form of a website and Facebook profile) have been introduced into everyday forestry practice in order to raise people's consciousness about the importance of nature, especially forests, for further development of society,

Social networks are interactive social media that provide means for users to create their own web pages, themes, groups, photo galleries and to make online friends. They were initiated in the first decade of the 21st century. The phenomenon of socialization on social networks is copied from real life, it is just that cyber socialization happens faster and easier than in real society.

SE “Srbijašume“ uses its Facebook profile with the aim of raising people's awareness of the need for sustainable use, restoration, care and protection of forests as an invaluable natural resource and a key element of the environment.

Keywords: *SE "Srbijašume", Internet communication, environmental protection*

Introduction

The global environmental situation is alarming; we are faced with warming, pollution of soil, air and water, as well as ozone layer depletion, so the imperative need is that everyone gets involved in solving environmental problems (Meffe, 2013). Man's ruthless relation to nature has led human civilization into danger of irreversible destruction of the natural environment and consequently to deterioration of people's health and threatening their existence (Katelyn, 2013). Mankind has come into this dangerous situation due to the tendency of limitless pursuit of material wealth (Republic of Serbia, 2007).

Forests greatly affect the reduction of environmental problems. They mitigate the effects of global warming. More precisely, forests contribute to mitigating climate change by storing carbon in forest trees, branches, leaves, roots and soil.

Forests as the most complex ecosystems have a particularly important role in the preservation of the environment (Aleksić and Jančić, 2013). SE "Srbijašume's" strategic-environmental vision is obligatory for foresters to be responsible to the Serbian population. The Enterprise manages forests sustainably, i.e. in a manner and to an extent that permanently maintains and improves their productivity, biodiversity, regeneration capacity and vitality, which in the

present and future ensures fulfillment of economic, ecological and social functions of forests (http://www. srbijasume.rs/growingstock.htm, 2015).
New surface areas are regularly afforested and the existing ones are enriched. SE "Srbijašume" has its own 25 nurseries with a production of 14 - 16 million seedlings. Each year during the spring and autumn planting, it carries out the planting of 4 - 5 million new seedlings. New plantations are raised for the purposes of burned area rehabilitation and total forest cover increase in Serbia.
Serbia is considered a medium-forested country. Its forest coverage, when compared on the global scale, is close to the average of 30%, and it is significantly lower than the 46% (2000) in Europe.
Forest cover increase compared to the reference year of 1979 is 5.2%, which has certainly had a positive impact on the environmental conditions and quality in general. In relation to population, there is a forested area of 0.3 ha per capita (in Russia - 11.11 ha per capita, Norway 6.93 ha, Finland 5.91 ha, Bosnia and Herzegovina - 1.38 ha of and Croatia - 1.38 ha).
Total forest area in Serbia is 2,252,000 ha, out of which 1,194,000 ha (53%) are state-owned, and 1,058,387 ha (47%) are privately owned. SE “Srbijašume“ manages state forests and forestland on the surface of 893,417 ha and carries out professional activities in forests of private forest owners on the surface of 1,058,387.00 ha (condition as of 31st December, 2014).

Objective

The objective is to find the best ways for SE "Srbijašume" to communicate with businesses, potential polluters, NGOs and citizens, regardless of age, gender or education, since each person can affect forest conservation and environmental preservation by either doing or non-doing.

Materials and Methods

The paper is based on: European and American research on social networks; the study of the German NGO Magicspeed on electronic forms of information presentation on social networks; statistical data on the representation of social networks in Serbia; European experiences of citizen interest in Internet communication and citizen knowledge of the environment (Barry, 2012; Cavanagh, 2013; Magicspeed, 2014; Media Center Belgrade, 2013; World Journalism Observatory for EU, 2013).
Social networking service is an online service, platform or website that focuses on building and imaging of the social relations among people who share interests and/or activities. Although online social services are considered services of social networks in a broader sense, social network services usually refer to services focused on the individual, while the online community services are focused on social groups (Saxenian, 2012).
Social networks are interactive social media that provide means for users to create their own web pages, themes, groups, photo galleries and to make online friends (who do not necessarily have to be friends in real life), with a high degree of interconnectedness of all elements of the social network and care to independent determining of privacy settings by every individual. 'Social networks' is a term that came to life on the web in the first decade of this century and that had been preceded by forums and chat rooms (Cavanagh, 2013).
Early social networks on the web (the World Wide Web) were developed in the form of generalized online communities, such as: theGlobe.com 1994, GeoCities.com 1994 and Tripod.com 1995. Many of these early communities focused on bringing people together for the sake of mutual influence through chat rooms and encouraged users to share information and ideas through personal web pages. The characteristics of today's social networks are more advanced forms of social media, compared to forums or chat rooms. The new generation of

social networking sites flourished with the emergence of Friendster.com in 2002, soon becoming part of the prevailing direction of the Internet.
Facebook was launched with the renowned American university Harvard as a local student network, which, however, within short time experienced an expansion into all possible categories and social groups, from students to working people (Blank, 2009).
It is estimated that, today, there are over 400 active sites using a wide range of models of social networks. Most of the online communities can be divided into categories: Information, Professional, Educational and Entertainment. The phenomenon of socialization of this type is copied from the real society, it is just that cyber socialization happens faster and easier than in real society, but these cyber communication in the developed world represent the backbone for the establishment of international professional contacts both in business and at private level (Katelyn, 2013).
An important feature for programmers is the ability to independently develop their own applications for Facebook that promote their own services and facilities, thus redirecting part of the traffic to their own sites and building a reputation for themselves, but also for Facebook by making it more popular and useful.
Modern man is exposed to a large amount of information and data, of which only the most interesting and most important attract his attention. This was the basis for the study carried out by Magicspeed, the German NGO, on the types and content of information on social networks (Magicspeed, 2014). Part of the study was a survey asking the question “Which is the format of your favourite information on the social network: sound, text, multimedia?” The survey was conducted on a sample of 1,500 citizens of capital cities in three European countries: Germany, Austria and Poland in 2012 and 2013. Its results are presented in Figure 1, showing the greatest interest in the multimedia format in all three countries. These results are consistent with other studies that prove that people find visual learning of data to be most memorable (Cavanagh, 2013). The above survey shows the need of application of multimedia information to serve environmental protection. Facebook in Serbia is synonymous with social networking on the web (Media Center Belgrade, 2013). Statistical data for 2013 in Figure 2 clearly show that Facebook is the most popular in Serbia and that it is used by 37% of the population. SE “Srbijašume“ uses its Facebook profile with the aim of raising people's awareness of the need for sustainable use, restoration, care and protection of forests as an invaluable natural resource and a key element of the environment. (https://sr-rs.facebook.com/pages/srbijasume, 2015).

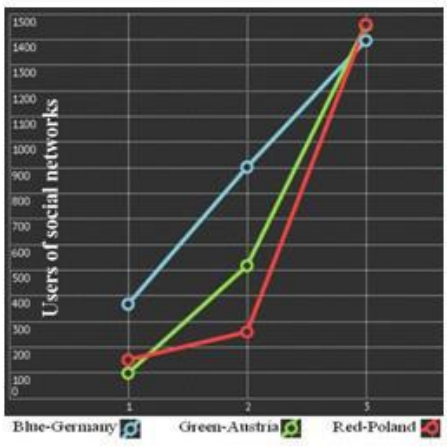

Figure 1. Overview of favourite information formats on social networks

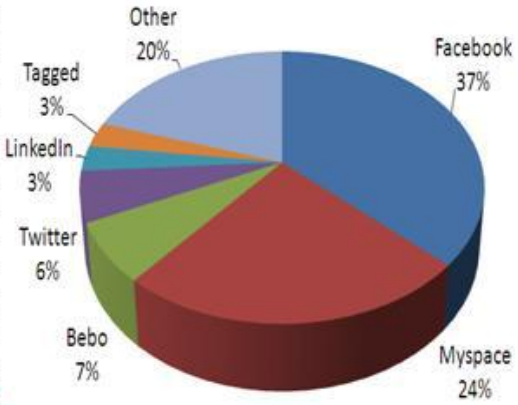

Figure 2. Representation of social networks in Serbia

Results and Discussion

Businesses around the world are increasingly oriented to Internet communications because representatives of their target groups' participation. This is a relatively new business communication channel, but there are great opportunities for expansion of new “green“ knowledge in order to raise awareness of the population to actively join the fight for nature conservation (World Bank, 2006).

“Green“ business has been a top priority for the EU for a decade now. Nine out of ten Europeans are aware that losses in biodiversity, i.e. reduction and potential disappearance of animal and plant species, natural habitats and ecosystems in Europe, are a serious problem (World Journalism Observatory for EU, 2013).

Europeans almost completely agree (93%) that it is important to halt losses in biodiversity since well-being and quality of life are based on nature and biodiversity (Kutz, 2013).

In order to raise people's consciousness about the importance of nature conservation, foresters of SE "Srbijašume" have introduced into their daily practice Internet communications in the form of a website and profile on the social networking site Facebook.

SE "Srbijašume" uses conventional and Internet business communication, as shown in Figure 3 (http://www.srbijasume.rs/basicdata.html, 2015). When it comes to Internet communications, first the website was applied.

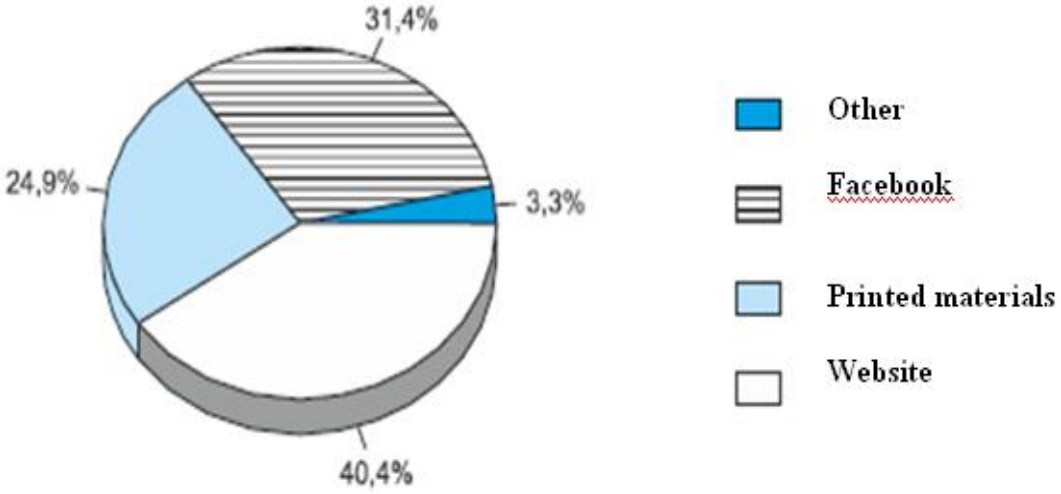

Figure 3. Types of Business Communication at SE “Srbijašume“

With the introduction of Facebook into communication, the number of website users has increased because young people who use Facebook every day have also accessed "Srbijašume's" profile, and from there have linked to the website and become regular users and our followers. With the introduction of multimedia content into Internet communications, the number of users has rapidly increased.

For efficient Internet communication it is necessary to fulfill three basic demands: updatedness, diversity and respect for the user. Data and information must be continuously changed, the materials placed must be from different areas of interest of the target groups, and every question or request of the user must be given adequate and quick response.

For the organization of in-field activities, the most effective communication is on Facebook, because large numbers of people can be quickly gathered for the purpose of extinguishing forest fires or collecting plastic bottles etc. Facebook is also effective for the placement of environmental education content.

Conclusion

Linking of social structures, economic entities and citizens is of crucial importance for the quality of the environment. In order to raise awareness about the importance of nature conservation for further socio-economic development, SE "Srbijašume" has introduced into their work practice, Internet networking to exchange information in the fight for a healthier and better environment. Internet communication has been chosen, because the Internet is a technological communication medium containing numerous services that make communication simple and accessible from any place and at any time.

INFLUENCE OF LIGNIN CONTENT ON HIGHER HEATING VALUE OF BURLEY TOBACCO STALKS FROM DIFFERENT PRODUCTION AREAS IN SERBIA

Olivera EĆIM-ĐURIĆ*, Nemanja MANDIĆ, Vesna RADOJIČIĆ

Faculty of Agriculture, University of Belgrade, Belgrade, Serbia
*Corresponding author: nera@agrif.bg.ac.rs

Abstract

Tobacco stalks make up a significant proportion of the total biomass in agricultural production in Serbia. They have no economic value yet, but may represent a large potential as a biofuel with amount of 70 000 tons per year.

The aim of this study is correlation between lignin content and higher heating value (HHV) of Burley tobacco stalks from two different production areas, Šabac and Čoka (Serbia). Lignin content determination was performed according the Zadražil and Brunnert method. The HHV of tobacco stalks as a function of lignin content (L, wt %) was calculated using the following equation:

HHV=0.0889 L + 16.8218

Statistical interpretation was performed SPSS v. 18. Statistical analysis showed that the lignin content and HHV of tobacco stalks are significantly different depending on the production areas. There was a higherly significant correlation between HHV and lignin content. Considering the high levels of HHV (19, 98 – 20, 51 MJ kg^{-1}) it is possible to use tobacco stalks as biofuels.

Key words: *higher heating value, lignin, tobacco stalks, Burley.*

Introduction

Reducing of fossil fuel reserve in the world encourages the much more implementation of renewable energy, which has great economic and ecological importance (Demirel, 2012). The use of renewable energy sources becomes significant energy issue in Serbia, and in particular will become important in the time of accession to the European Union. It is estimated that total of 12.5 million tons of biomass is produced in Serbia each year, of which 9 million tons in Vojvodina. The major part of agricultural waste in the Republic of Serbia makes corn stalks, wheat straw, and then sunflower remains (Malnar et al., 2014). A significant share of the crop residue makes also tobacco stalks (Kulić and Radojičić, 2011). According to the Statistical Office of Serbia (Statistical Yearbook of the Republic of Serbia, 2013), tobacco was planted on 6.200 hectares in the year 2013. After harvesting of large leaves tobacco on the fields remains a significant amount of crop residues, or an average of 22.000 stalks of tobacco per hectare. This means that about 76.000 tons of tobacco stalks remains in Serbia each year. These tobacco stalks have no economic value yet. It should be noted that this energy potential in our country is little used, because most farmers burn agricultural waste after harvesting, and the rest of biomass is plowed. Burning of crop residues in the fields adversely affects on land and on the ecosystem in generally, as it causes the release of large amounts of gases and from the other side, large amount of heat energy is lost in the atmosphere. This data indicates that unused tobacco stalks, which are classified into green tobacco waste (Radojičić et al., 2009), represent the potential that can be used in energy purposes.

It can be said that use tobacco stalks in energy purposes in the world is still unexplored in generally. In recent years researchers in Serbia are increasingly interested in the possibility of using these raw materials for energy purposes (Ećim-Đurić et al., 2014; Kulić and Radojičić,

2011; Malnar et al., 2014; Mijailovic et al., 2014; Radojičić et al., 2014a; Radojičić et al., 2014b). Based on these results the researchers agree that tobacco crop residues should be included in the energy balance and used it as biofuel.

The most important indicator of the possibility of using some organic raw materials as a fuel is its heating value, which depends on the type and chemical composition of biomass, as well as relative humidity. Thus, the tobacco stalks heating value, as well as for other biofuels, significantly depends on the content of organic compounds (Sheng and Azevedo, 2005; Yin, 2011). HHV of lignocellulosic fuels is a function of the quantity of lignin (Demirbas, 2001). Generally, HHV of lignocellulosic fuels increases with increasing lignin content in the fuel. The lignin HHV is from 23.26 to 25.58 MJ/kg. Pesevski et al. (2010), agree that high lignin content in tobacco stalks provides an opportunity for their use as biofuels.

Due to the increase in lignin content increases biomass heating value in the same time, defining the content of this substance (Demirbas, 2001) is quite important. The cell walls of the tobacco stalks can contain 40-45% of lignin, which is approximately the same amount as in softwood stalks. The only difference is that tobacco stalks have a significantly lower density of perennial trees wood.

Since the amounts and structure of lignin differ from one to the other types of biomass, it can be concluded that HHV vary from one to the other kinds of biomass. HHV can be obtained experimentally by determining in the bomb calorimeter. Experimental determination of HHV requires special equipment, and the element analysis data can be easily obtained with available laboratory equipment. Thus HHV fuels from renewable sources can be calculated using data on the content of lignin obtained by ultimate or proximate analysis. The aim of this study is determination of correlation between the lignin content and HHV from the organic material suitable for energy use, cultivated at different production areas.

Materials and methods

As a material for this research, Burley tobacco stalks from production area of Šabac and Čoka were used. Stalks were taken after tobacco leaves harvesting, at the beginning of October. Samples for laboratory analysis are prepared by grinding and homogenization. Lignin content was determined by Zadražil-in and Brunnert-in (Radojičić, 2011). For calculation of higher heating value, following formula was used (Demirbas, 2001):

$$HHV = 0{,}0889\ (L) + 16{,}8218 \quad (1)$$

Moisture was determined gravimetrically after drying the materials in an air circulation dryer, till constant weight, at 93±2°C (Radojičić, 2011).

Based on the moisture content, the results are expressed relative to the samples dry weight. All analyzes were performed in five replicates.

Data obtained from the experiments were analyzed and the results were expressed as mean ± SD. Statistics was performed using SPSS 18.0 software ANOVA. Pearson coefficient of correlation was used to determine correlation between variables (De Coster, 2004).

Results and discussion

Descriptive statistics indicators of pH and organic matter content in the soil from two production area, as well as the lignin content and higher heating value of Burley tobacco stalks are shown in Table 1.

Based on the data from Table 1, it is clear that the lignin content in Burley tobacco stalks is greater from Šabac production area than from Čoka. Given that the lignin content is in direct correlation with the HHV (Demirbas, 2001), the greater HHV was obtained for tobacco stalks from Šabac tobacco production area.

Table 1. Soil pH value, organic matter content in soil, lignin content and HHV of Burley tobacco stalks from Šabac and Čoka production area

	Origin	Average	SD
pH	Šabac^{SL}	6.1	.0707
	Čoka^{L}	5.6	.1225
Organ.matter %	Šabac	2.4	.1342
	Čoka	2.3	.0837
Lignin %	Šabac	41.56	.44816
	Čoka	35.48	.25456
HHV (MJ kg^{-1})	Šabac	20.51	.04099
	Čoka	19.98	.02490

Soil texture: L –loam; SL – sandy loam

Table 2. The significance of the difference in the observed parameters from two locations

	F	Significance
pH	62.500	.000
Organ.matter	2.880	.128
Lignin	695.773	.000
HHV	624.557	.000

Applying univariate analysis of variance (Table 2) it was established a significant difference in soil pH (** F = 62.5, p = 0.000), lignin content (F = 695.8 ** p = 0.000) and tobacco stalks HHV (F = 624.6 ** p = 0.002), but not in the organic matter in the soil between these two locations.

The relationship between soil pH, organic matter in soil, lignin content and HHV of Burley tobacco was investigated by using Pearson's coefficients of correlation (Table 3 and Table 4).

Table 3. Pearson's Correlation between soil pH, organic matter in soil, lignin content and HHV of Burley tobacco from Šabac production area

		pH	Organ.matter	Lignin	HHV
Šabac	pH	1	.264	.339	.345
	Organ.matter	.264	1	-.511	-.536
	Lignin	.339	-.511	1	.999**
	HHV	.345	-.536	.999**	1

**Correlation is significant at the 0.01

Table 4. Pearson's Correlation between soil pH, organic matter in soil, lignin content and HHV of Burley tobacco from Čoka production area

		pH	Organ.matter	Lignin	HHV
Čoka	pH	1	-.732	.000	-.082
	Organ.matter	-.732	1	-.423	-.336
	Lignin	.000	-.423	1	.994**
	HHV	-.082	-.336	.994**	1

**Correlation is significant at the 0.01

Based on the results shown in Tables 3 and 4, it can be concluded that there is a statistically very significant positive correlation between the lignin content and tobacco stalks HHV from selected production area (r = 0994 – 0999). Correlations among other examined parameters from both production areas are present, but they are not significant.

Organic matter content in the soil and the lignin content in stalks are negatively correlated, which is not statistically significant (r = -.423 – -.511). Since, there is no significant difference in organic matter content in the soil between locations (Table 2), it was concluded that organic matter did not affect on the lignin content, and therefore neither on HHV.

Based on the data in Table 3 and Table 4, it is evident that there is no statistically significant correlation between soil pH and lignin content in tobacco stalks, as well as between soil pH and HHV. However, applying the univariate analysis of variance (Table 2) it was found that there are significant differences in soil pH (F = 62.5 **) and lignin contents of tobacco stalks (F = 695.8 **) from selected production areas. Based on these results, it can be generally concluded that these two variables had an impact on tobacco stalks HHV.

Conclusion

Results obtained from this study indicate there is a significant difference between soils pH, lignin content and HHV of Burley tobacco stalks from different production areas. There is no difference between organic matter content in soil. The results also showed a statistically significant strong positive correlation between lignin content and HHV of tobacco stalks.
Considering the high levels of HHV (19, 98 – 20, 51 MJ kg-1) it is possible to use Burley tobacco stalks as biofuels.

Abstract

The paper presents the results of analysis of the content of hazardous and harmful substances in the water used for irrigation, sampled during July, August and September in 2013, in the basin of the part of the Drina River, which flows through Serbia from Salaš Crnobarski to Bajina Bašta (Bušinsko polje). The study included 12 selected sites belonging to agricultural area under irrigation.

During the mentioned period it was determined the values of pH, ECw, TDS (total dissolved solids) and content of trace elements and heavy metals Cr, Ni, Pb, Cu, Zn, Cd, B, As, Fe, Hg in the water samples. The content of trace elements and heavy metals in the studied samples was generally below the maximum allowable concentration (MAC).

Based on the data obtained, it can be concluded that the water from the Drina basin is usable for irrigation of agricultural crops and soils, but with frequent quality checks during the summer months.

Keywords*: agricultural soil, hazardous and harmful substances, irrigation water*

Introduction

This paper presents the study of quality of irrigation water from the River Drina, based on the requirements of FAO (Food and Agriculture Organization of the United Nations) and U.S. Salinity Laboratory classification (Doneen and Westcot, 1988; U.S. Salinity Laboratory Staff, 1954), and designed for evaluation of usage of irrigation water. Irrigation is the artificial watering the soil in order to increase the moisture in the rhizosphere layer at a time when the amount of available soil moisture is insufficient to meet the optimum for the crops. Irrigation is a hydro-reclamation measure that aims to improve the physical properties of the soil by adding water to achieve optimum moisture during the growing season and thus achieve optimum yield. It may be applied during part of the growing season or during the whole growing season. For irrigation of cultivated plants on agricultural soil, water must have appropriate physical, chemical and biological properties, so it is very important to examine the quality of water for irrigation purposes. Intensification of irrigation depends primarily on the provision to the required amount of water of adequate quality.

Anthropogenic impacts and natural processes can affect the quality of surface waters and threaten their use as drinking water, and for use in industry, agriculture, and for other purposes (Carpenter et al., 1998; Jarvie et al., 1998; Simeonova et al., 2003).

The aim of this study is to assess the current water quality of the River Drina in order to be used for irrigation of agricultural soil near the streams and estimate the possible pollution risk. Pollution risks are mainly the direct consequence of the discharge of waste water from industrial plants, agricultural intensification or anthropogenic factors.

The major pollutants of surface water in the country are industrial enterprises, farms and settlements with sewage systems, without built facilities for waste water treatment, and such with acting, but technically outdated (Konstandinova et al., 2013).

Agricultural lands used for intensive agriculture and fertilized with nitrogen and phosphate, treated with pesticides, and manure from livestock farms are one of the major sources of diffuse pollution (mainly nitrogen, phosphorus and biodegradable organics).

Description of the study area

In geographical terms, the basin of Drina River in the flow through Republic of Serbia lies between 43°00' and 44°52' of north latitude and 19°15' and 19°20' of east longitude Drina River basin and locations of sampling are presented on Figure 1.

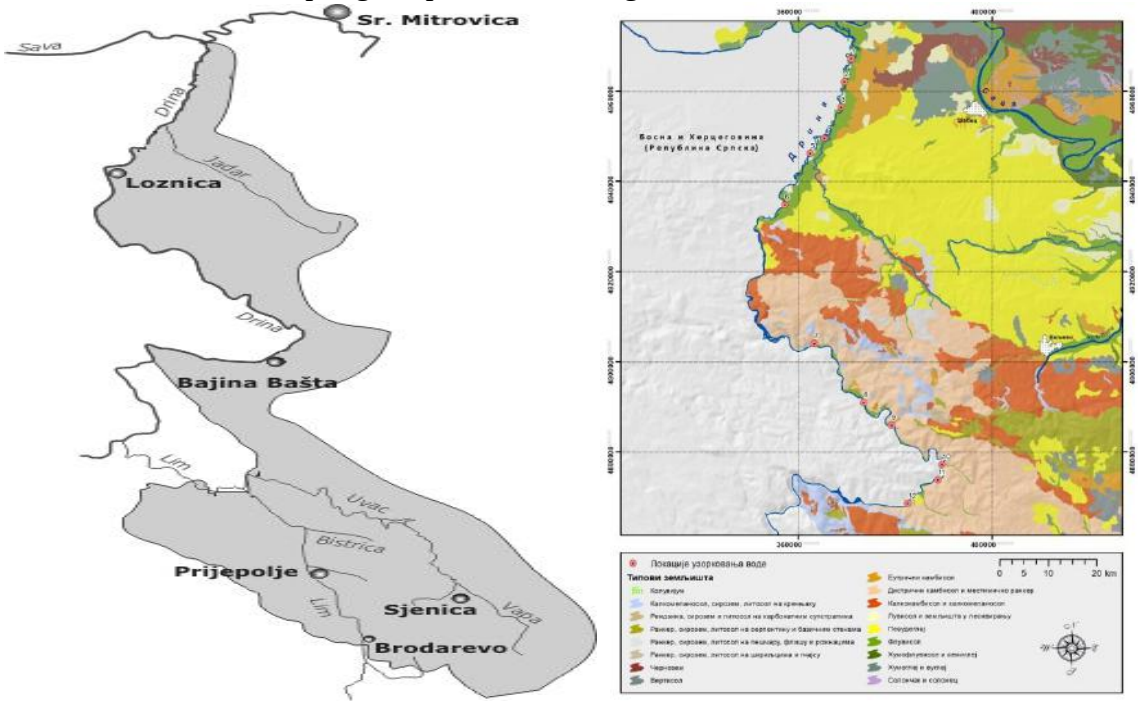

Figure 1. Location map of Drina River basin with selected sample sites.

The Drina is a 346 km long international river, and presents natural border between Bosnia and Herzegovina and Serbia. It is the longest tributary of the Sava River and the longest karst river in the Dinaric Alps which belongs to the Danube River watershed (Marković J., 1990 and Pivic et al., 2014).

River Drina basin covers the southwestern and western part of Serbia, the northern part of Montenegro and the eastern part of Bosnia and Herzegovina. Direction of its flow is from south to north and has a lot of tributaries. Water regime of the River Drina belongs to the typical modes of type snow-rain, with the primary peak of the water level in April and a secondary peak in December. Most of the stream is running through the mountains, while the entire upper stream is located in the high mountains of the Dinaric Alps, creating conditions that heavy precipitation and snows melting are leading to high flows. Decline of River Drina flow is very high, almost 2000 meters for less than 350 km of length, (spring is at about 2000 meters above sea level, while the confluence is on 80 meters above sea level). With an average flow of 395 m³ / s at the confluence, Drina is richest tributary of the River Sava.

Soils suitable for irrigation are primarily alluvial soils along the River Drina and meadow soils that are heavier texture from alluvium. Water physical properties of the soil along the Drina are very heterogeneous composition. Represented are applied gravel, sandy gravel, sandy, loamy and clay composition. All of these can be irrigated land varying amounts of water. The basic soil types of the studied area are Fluvisols, Eutric Cambisols and Distic

Cambisols (WRB, 2014. http://www.fao.org/3/a-i3794e.pdf, Accessed on 12/08/2015), presented by Figure 1.

Sampling and collection of water samples

Water samples were collected in three cycles of sampling, in July, August and September 2013, using 2000 ml plastic bottles from 12 (twelve) sampling points (Table 1), a total of 36 water samples were collected.. The sampling bottles for heavy metal determinations were pre-soaked overnight with 10% HCl, rinsed with distilled water and also rinsed using river water before sample collection. Sampling bottles for the determination of physicochemical parameters were cleaned and rinsed using distilled water only. Preservation of water samples was done by adding 2 drops of concentrated HNO_3 to each water sample before storage below 4°C until it was analyzed.

Table 1 Sampling points along the Drina River

Sampling point	Easting	Northing
1	7370890	4968150

12	7382590	4869580

Analytical methods

Parameters were determined by the following methods: temperature is determined *in situ* by a calibrated thermometer, pH-potentiometric (SRPS H.Z1.111:1987), electrical conductivity (ECw)- conductiometric (SRPS EN 27888:1993), TDS-gravimetric (Greenberg et al., 1998), The acid-available fraction of heavy metals and other toxic elements (As, B, Cd, Cr, Cu, Fe, Ni, Pb, Zn) was determined using EPA 200.7 methods, as well as an ICAP 6300 ICP optical emission spectrometer (ICP-OES). The concentration of Hg was determined by a flame atomic adsorption analyzer SensAA Dual (GBC Scientific Equipment Pty Ltd, Victoria, Australia).

Data processing methods

The experiment data were presented with mean of three tests with the presented summarized basic statistics of the dataset. Analysis of the interdependence of variables was carried out by calculating linear Pearson correlation coefficients. It has been assumed that the regression modeling of the potential usefulness of the selected variable (explanatory) to model another variable (explained variable) determines the absolute value of the high correlation coefficient between these two variables. The statistical analysis usually assumes that if the correlation coefficient is >0.9, a very strong linear dependence exists; 0.7-0.9-significant linear dependence; 0.4-0.7-moderate linear dependence; 0.2-0.4-distinct linear dependence, but low; <0.2-no linear dependence (Nelson and Sommers, 1996).

Results and discussion

The seasonal and annual averages of physicochemical characteristics are given in Table 2. The recorded water temperature in all three cycles of monitoring is in compliance with the prescribed values of national standards (Official Gazette of Republic Serbia, 23/94, 1994 and #50/12, 2012).

The pH value is a measure of alkalinity and acidity of the water. If the value is less than seven, the water or the aqueous solution is acidic, and if it is higher, then it is alkali. Plants for growth and development favor the slightly acidic solution, or the pH should be around 5.5. The pH is an important factor that determines the suitability of water for a variety of purposes, inter alia, for irrigation.

The tested samples showed pH values from neutral to slightly alkaline. In all series of monitoring the pH of the samples were in the range permitted by the classification USGA (Duncan et al., 2000), while in relation to the classification (Ayers and Wescot, 1994), is in the first series of monitoring.

Conductivity is a measure of the ability of an aqueous solution to carry an electric current. Increasing levels of conductivity and cat ions are the products of decomposition and mineralization of organic materials (Begum and Harikrishnarai, 2008). The aqueous salt solution and dissociated are broken down into positive and negative ions. Electrical conductivity in natural waters is generally with values less than usual. Measurement of the conductivity is performed at a specific temperature and it corresponds to the presence of dissolved salts. These are most commonly sodium chloride, and may be present, and sodium sulphate, calcium chloride, calcium sulfate, magnesium chloride, etc. Salts dissolved in the water influence on increase of the water conductivity values.

TDS are an important characteristic for determination of the quality of water for irrigation because it expresses the total concentration of soluble salts in water. Dissolved solids in water include all inorganic salts, silica and soluble organic matter. Pure water must be free from most suspended particles, which are responsible for turbidity. TDS was the highest in summer due to evaporation and reduced intake, which contributed to an increase in concentration, and had the minimum value in the rainy season, due to the increased entry of rain and a corresponding reduction in concentration at all locations.

*References (listed below in reference list); bdl-below detection limit

ə - in me/l = mill equivalent per liter (mg/l ÷ equivalent weight = me/l); in SI units, 1 me/l= 1 mill mol /liter adjusted for electron charge.

The contents of trace elements and heavy metals in the samples of water are generally below the MAC, maximum allowable concentration (Official Gazette of Republic Serbia, 23/94, 1994 and [#]50/2012, 2012).

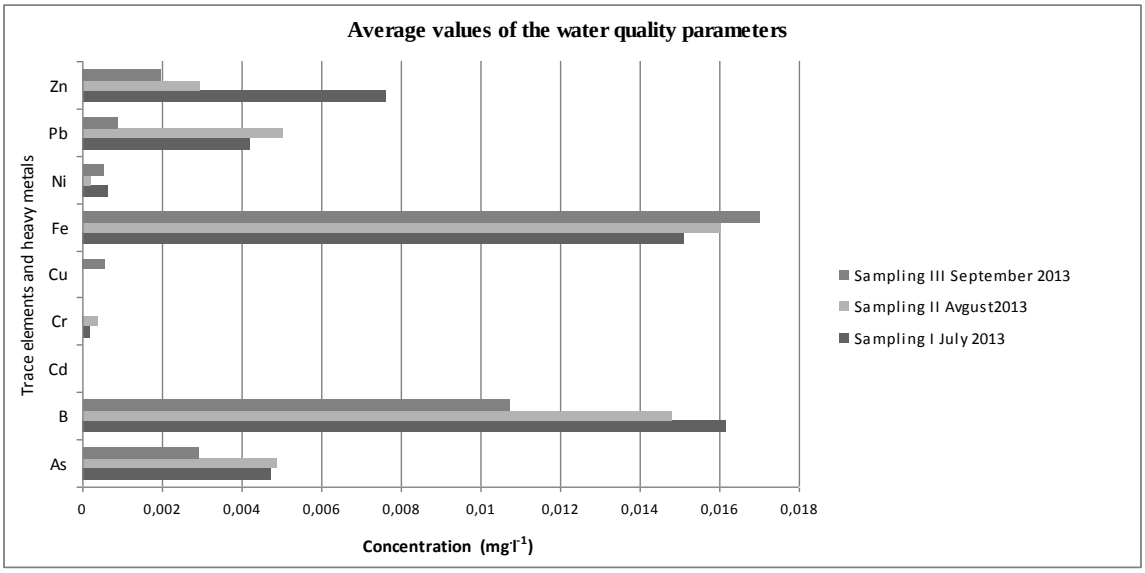

Figure 2. Average values of the water quality parameters of Drina River

The sources of metal pollution of natural water are: industrial and domestic wastewater, agricultural activities, mining, waste and intermediate products from power plants, factories for the production of non-ferrous metals, sludge from sewage treatment plants for municipal and industrial wastewater, as well as the processes of natural erosion and sedimentation (Aktar et al., 2010).

The diversity in the results and demonstrated dynamic variations, suggests impact of a number of various environmental factors on the pattern of metals distribution in the water. In this regard (Ozmen et al., 2004), reported that the concentration of metal ions strongly depend

on the biological processes, redox potential, ionic strength, pH, the activity of organic and inorganic chelators and the purification processes in water.

By analyzing of correlation parameters the conclusion is that the correlation between the samples and the characteristics of the water where the pH value has a significant negative correlation to all studied parameters except to the concentration of ECw and Cr (Atekwana et al., 2004; Gong et al., 2013). ECw values were negative correlated to all study parameters except to the concentration of TDS, B, Ni, Pb and Zn. TDS values show a positive correlation to the concentration of As, Pb and Zn, and a negative to the concentration of B, Cr, Cu, Fe and Ni in the samples of water.

The obtained results also implies on very strong linear correlation for As-Cr; As-Cu; B-Cu; Cu-Zn in the studied water samples, significant linear correlation for As-Fe; As-Zn; Cr-Fe; Cr-Zn; Fe-Zn, moderate linear dependence for B-Pb; B-Cr; B-Fe; Cr-Pb, and distinct linear dependence for ECw-As; ECw-Pb; TDS-As; As-Pb; while for the rest of observed parameters there is no linear dependence.

Conclusion

Results from obtained from water samples showed that the concentration of heavy metals in the water of the Drina River in most of the samples analyzed is within the MAC values. Variations of the heavy metal concentrations in the water are the result of a wide range of anthropogenic activities (primarily agriculture) in the study area throughout the year.

Based on the obtained and analyzed results of testing, the quality of water for irrigation from the Drina River can be used for irrigation of crops and soil with frequent quality checks during the summer months.

In detailed examination of usage of water for irrigation purposes in the area, it is necessary to extent the research with detailed study of hydrological parameters (determining the biological minimum of each watercourse), analysis of the amount of organic pollutants, study of the influence of temperature and oxygen concentration in the water on wildlife, etc.

SEDIMENT QUALITY ASSESSMENT USING CULTIVATED PLANTS AS BIOINDICATORS

Sonja GVOZDENAC, Dušanka INĐIĆ, Slavica VUKOVIĆ

University of Novi Sad, Faculty of Agriculture, Trg Dositeja Obradovića 8, Novi Sad, Serbia

Abstract

During seasonal maintenance of irrigation canals large quantities of sediment are dredged and need to be properly handled. The possibility of sediment use in agriculture has been intensively studied during last decades. Prior to its use it is necessary to assess the quality, detect present contaminants and characterize pollutants bioavailability to plants because contaminated sediment can pose a risk for crops. This work aimed to assess the quality of sediment (in the form of interstitial water) from canals Feketić, the Great Bačka canal –GBC and Stari Begej - special nature reserve “Carska bara” using cultivated plants as indicators. Biological effects were evaluated on physiological (germination) and morphological (root and shoot lengths and weights) responses of maize (*Zea mais L.*), radish (*Raphanus sativus L.*), cucumber (*Cucumis sativus L.*) and beans (*Phaseolus vulgaris L.*) according to a standard filter paper method (ISTA Regulations book, 2011). In sediment from Feketić and Stari Begej Ni and Cu were present in amounts exceeding maximal allowable concentrations according to regulations, while sediment from GBC was contaminated with Ni, Fe and Zn. In biotest, sediment from Feketić and GBC significantly inhibited germination of maize, radish and beans compared to the control and sediment from Stari Begej (F=19.78*, 260.80**, 80.63**, p<0.01/0.05, respectively), but highly significantly stimulated germination of cucumber (F=466.76**, p<0.01). Root and shoo lengths, fresh and dry weights of all test plants except cucumber were inhibited by sediment from Feketić and GBC, while sample from Stari Begej stimulated shoot lengths, fresh and dry weights of all plants compared to the control (p>0,05/0,01).

Keywords: *sediment, contamination, bioindicators, cultivated plants*

Introduction

During seasonal maintenance and revitalization of irrigation canals, sediment dredging is one of the most important activities (Savić et al., 2008). Large quantities of sediment which are dredged need to be properly handled and the use in agriculture is the most promising one, because they are rich in organic matter and nutrients. But also, sediment can be considered as a potential source of heavy metals, especially due to the fact that they are not permanently attached and immobilized (Rajić, 2010) and can be desorbed on the surface of particles and become available to organisms or exhibit ecotoxicological effects (Wasserman et al., 2013). Re-mobilization of metals from sediments is a major problem for the environment, because released metals affect the aquatic ecosystem as well as agricultural activities in the area (Middelkoop, 2000; Dennis et al., 2003) because they are usually heavily loaded with nutrients, hazardous or other undesirable substances. Far-reaching consequences are manifested in the irrigation canals, coastal region and the wider environment, in the form of degradation of the quality of irrigation water and useful disposal of sediments on arable land along the canals. The possibility of the use sediment on agricultural land reflects the need for a risk assessment on the presence of certain pollutants to plants (Bedell et al., 2006). Mainly, for sediment quality assessment and contamination detection, chemical methods are used. However, they solely are not sufficient because they do not provide information on the direct impact of pollutants and interactions on living organisms (Leitgib et al., 2007). Therefore,

they must be complemented with toxicological i.e. biological methods (Vaajasaari et al., 2002; Leitgib et al., 2007). Such integrated methodology gives information not only about content of contaminants, but also about bioavailability and allows complete risk assessment of contaminated sites (Leitgib et al., 2007). Biological tests that include plants as bioindicators of contamination have become a useful tool in water risk assessment in the last few years, especially in agricultural regions. Bio-assays that involve agricultural plants as indicators are very important for the evaluation of water and sediment quality that is used for agricultural production, because the results of these studies directly show the suitability of water for irrigation and sediment for disposal on arable land (Gvozdenac et al., 2011, 2012a, 2014).
The aim of this work was to assess the quality of sediment (in the form of interstitial water) from canals Feketić, the Great Bačka canal –GBC and Stari Begej - special nature reserve "Carska bara", using chemical and biological methods, with special accent on cultivated plants as potential indicators of pollution. We also tended to estimate the potential use of these sediments in agricultural production.

Material and method

Sediment sampling. Sediment was collected during 2013 from canals Feketić, the Great Bačka canal –GBC and Stari Begej within the special nature reserve "Carska bara". At the investigated locations, composite sediment sample were taken from three deep samples. Immediately after taking, all samples were split and placed into plastic bags for the analyses. The samples were stored at 4 °C. Total concentration of particular metals was carried out according to the NEN procedures. Sediment was used in the form of interstitial water.
Phyto-toxicity test was carried out according to a standard filter paper method (ISTA, 2011) with slight modifications described by Gvozdenac et al. (2014). The most commonly cultivated plants in this area– maize (*Zea mais* L.), radish (*Raphanus sativus* L.), cucumber (*Cucumis sativus* L.) and beans (*Phaseolus vulgaris L*.) were used as test species. The effect of sediment quality on plants was evaluated according to changes in physiological (germination energy and germination - %) and morphological parameters (root and shoot length -cm and fresh and dry weight of root and shoot -g). Experiment was set in four replicates.

Statistical analysis. Data were analyzed using Duncan`s multiple range test, for 95% confidence interval, in software SPSS version 17.0 (SPSS, Inc., Chicago IL).

Results and discussion

The results of chemical analysis indicate that sediment from GBC is contaminated with Ni (46 ppb), Cu (130 ppb) and ammonium ion (460 ppm). Mentioned values exceed Maximal allowable concentrations (MAC) according to Regulation on limit values for pollutants in surface and ground waters and sediments (Official gazette, 50/12) for the II class of water. P (2504 ppb), Fe (10548 ppb) and Zn (315 ppb) are present in high amounts. Sediment from Feketić is heavily loaded with N (23 000 ppm), P (1024 ppb) and Mn (494 ppb) and from Stari Begej with Fe (7577 ppb) and Mn (247 ppb).
The results of phyto-toxicity test are presented in Table 1.
Maize. In biotest, sediment from Feketić and GBC significantly inhibited germination energy and germination of maize seeds, compared to the control (F=19.78*) while sediment sample from Stari Begej did not cause significant effects on physiological parameters of this species. Root length and fresh and dry weights of maize seedlings were significantly inhibited when treated with sediment from Feketić, GBC and Stari Begej (F=249.02**, 291.81**, 225.89**, respectively). The aboveground parts were also negatively affected by the sediment samples from Feketić and GBC (F=8.99*, 314.0**, 94.01**, p<0.01/0.05, respectively). Given indicates that maize seedlings were very sensitive to sediment pollution and total chemisam.

This is probably due to high amount of heavy metals detected in the samples which exceed MAC values. More significant inhibitions were recorded in treatments with interstitial water from GBC, which is heavily polluted with a variety of heavy metals. Maize responded in inhibition of all parameters which makes these sediments unsuitable for use in production of maize as fertilizer. Many authors have demonstrated that maize is sensitive to metal pollution, only Mahmood et al. (2005) emphasized that small concentrations of heavy metals are not responsible for *Zea mays* germination inhibition.

Radish. Germination energy and germination of radish seeds were significantly inhibited by interstitial water from sediments from Feketić and GBC, compared to the control ($F=260.80^{**}$, 260.80^{**}, $p<0.01$, respectively), while sediment sample from Stari Begej did not cause significant effects on physiological parameters of this species. Root and shoot length and fresh and dry weights of radish seedlings were significantly inhibited by interstitial water from Feketić and GBC sediment, but sediment from Stari Begej statistically significantly stimulated these parameters ($F=94.27^{**}$, 101.83^{**}, 97.89^{**}, 13.78^{*}, 242.48^{**}, 156.9^{**}, $p<0.01/0.05$, respectively). Thus only sediment originating from Stari Begej can potentially be used for irrigation of radish. However, prior to its use, it must be chemically analyzed again. Di Salvatore et al. (2008) presented different results that the presence of metals (Cu, Ni and Zn) in the substrates did not affect seed germination. However, when comparing these results the concentrations of metals present and varietal sensitivity should be taken in consideration.

Cucumber. Germination energy and germination of cucumber seeds were significantly stimulated by interstitial water from Feketić and GBC, while root length and fresh and dry weights of cucumber seedlings were significantly stimulated by interstitial water from Stari Begej ($F=23.60^{*}$, 24.21^{*}, 16.78^{*}, $p<0.05$, respectively). The aboveground parts of cucumber seedlings were also positively affected by the sediment samples from Feketić and GBC ($F=135.69^{**}$, 272.89^{**}, 97.90^{**}, $p<0.01$, respectively).These results indicate at possibility of using these sediments in the production of cucumber in the region. However, prior to application, the sediment should be re-analyzed, to avoid possible negative affects due to increase of some unfavorable substances because according to Rajić (2010) availability and concentrations of metals in sediment change seasonally. Previous findings of Gvozdenac et al. (2011) indicate that seed germination of *Cucumis sativus* L. was not affected by the chemical composition of water. On the basis of the results from bioassay, we could speculate that perhaps the presence and interaction of several compounds exceeding MAC in sediment (Cu, Zn and Ni) stimulated root elongation of cucumber seedlings. Some authors reached the different conclusions.

Beans. Germination energy and germination of beans seeds were significantly inhibited by interstitial water from Feketić and GBC sediments, compared to the control and sediment from Stari Begej which did not cause any effects on physiological traits ($F=70.80^{**}$, 80.63^{**}, $p<0.01$, respectively). Root length and fresh and dry weights of cucumber seedlings were significantly stimulated by interstitial water from Stari Begej but inhibited by sample from Feketić. Only sediment from GBC statistically significantly inhibited the above ground parts of beans ($F=26.75^{*}$, 292.13^{**}, 42.13^{**}, $p<0.01/0.05$, respectively). Only interstitial water from Stari Begej can be potentially used for irrigation of beans. However, prior to its use, it must be chemically analyzed again.

Table 1. Physiological and morphological parameters of tested plant species depending on the sediment sample quality

Results presented in this study indicate different sensitivity of tested plants to sediment quality, as well as different tolerance to heavy metals and inorganic pollutants detected in higher concentrations. This was previously reported by several authors pointing out that tolerance is species-dependant but there are also varietal differences (Ankley, 1993, Gvozdenac et al., 2011, 2012a, 2014). Sensitive species are successfully used as bioindicators of habitat contamination and for the detection of contamination in bioassays. When interpreting the results regarding plant reactions to sediment quality and contamination, the fact that metals like Cu and Zn are essential elements for plant cell development and catalyze certain physiological processes, should be considered. However, increasing concentrations in the environment can lead to morphological and physiological changes due to immobilization and inability to adopt other essential elements (Kastori and Petrović, 1997). On the contrary, Ni and Cr are noted as elements that have toxic effect on plants and are more frequent

pollutants of the environment. Also, the potential interactions of pollutants in medium should not be overlooked.

Conclusion

The results of chemical analysis indicate that:
sediment from GBC is contaminated with Ni, Cu and ammonium ion, and heavily loaded with P, Fe and Zn
sediment from Feketić is heavily loaded with N, P and Mn
sediment from Stari Begej is heavily loaded with Fe and Mn
The results of phyto-toxicity test indicate that:
sediments from Feketić and GBC had inhibitory effect on all physiological and morphological traits of maize, radish and beans
sediment from Stari Begej only inhibited some traits of maize seedlings but stimulated root and shoots traits of radish, cucumber and beans
tested sediments did not cause any toxic effects on cucumber seeds and seedlings, even stimulated certain parameters
due to sensitivity expressed in this assay, maize can be considered as good indicator of sediment quality and contamination with metals detected in high amounts (Ni, Cu, Fe, Zn, Mn)
The overall results indicate at possibility of using these sediments in the production of cucumber in the region. However, prior to application, the sediment should be re-analyzed, to avoid possible negative affects due to increase of some unfavorable substances

Abstract

The aim of this research was to investigate the tobacco waste composting with addition of different organic materials. Tobacco waste (TW) represents significan percent of industrial and communal waste in Serbia. If the nicotine content in tobacco waste is greater than 500 ppm of dry weight, according to European Union Regulations, this waste is classified as „toxic and hazardous”.

Virginia tobacco leaves, which remain after processing, were used as a waste. Two experimental samples are formed according to the following scheme: I 60% TW + 40% cabbage; II 60% TW + 10% soil +15% dry forest leaves + 15% cabbage. The comparison was made with the reference sample (only TW).

Experiment was set up in the indoor area at the Faculty of Agriculture, without automatic control of microclimatic parameters. The indoor area is periodically re-heating by electrical heater, and the relative humidity is controlled only by natural ventilation. During the process of composting, temperature and humidity in all samples and in the room was measured. Nicotine content in samples was determinate by HPLC method.

Initial nicotine content in tobacco waste was 17 363 mg/kg. By adding other organic material to the tobacco waste, nicotine content was decreased in the range of 37.5 – 46.5%. At the end of the research, nicotine content has dropped below 10 ppm in both experimental samples. Reduction of the nicotine content showed that organic materials can be used in the composting of hazardous tobacco waste.

Keywords: *tobacco waste (TW), Virginia, organic material, composting*

Introduction

A growing concern for the environment has resulted in the development of new technologies, materials and ways to reduce the amount of waste and environmental pollution in general. Increasing environmental awareness in recent years caused an increase in interest in the composting process in order to prevent or reduce environmental pollution, as well as sustainable management of waste generated as a product of the various activities of society (Jovičić, 2006).

Composting is the biological decomposition of organic matter under the influence of microorganisms in aerobic conditions. The composting process leads to stabilization of biodegradable waste (wet and solid organic matter, food waste, garden waste, paper, cardboard, etc.), in order to finally obtain a stable product, compost (Jovičić, 2006). This process can be conducted in a controlled, partly controlled and uncontrolled environmental condition.

In Serbia, agriculture is one of the major industries, so that generates large amounts of waste. The largest part of agricultural waste in the Republic of Serbia makes corn stalks, wheat straw and then the remains of sunflower (Jovanović and Parović, 2009). Tobacco waste, which is generated in all processes, from tobacco leaf production to the production of cigarettes, represents a significant percentage of agro-industrial and municipal waste in Serbia

(Radojičić et al., 2009). His elimination and/or recycling are mostly left to the initiative of individual companies for tobacco processing and manufacturing.

Tobacco waste includes waste remaining after breeding, processing and manufacturing of tobacco, but also after the consumption of tobacco products (cigarette butts, wrappers, cartons). The total global tobacco (Nicotiana tabacum L.) waste production in the year 2005 was more than 25.1 million metric tons (Jun et al., 2010).

According to Waste Catalogue issued by the Ministry of Environment and Spatial Planning and the Agency for Environmental Protection of the Republic of Serbia (Waste Catalogue, 2010), tobacco is classified as non-toxic waste. Although this waste is not classified as dangerous, it is not categorized as inert and therefore cannot be disposed of to landfill without treatment (Radojičić et al., 2009).

The main characteristics of the tobacco waste are a high value of the total organic carbon (TOC) and also a high content of nicotine, which is a toxic compound (Civilini et al., 1997). Its water fraction has a concentration of TOC above 200 mg/l and therefore cannot be disposed of in a sanitary landfill. According to the EU Directive nicotine content over 500 ppm declares this waste in the category of hazardous waste. Also, due to the nicotine high solubility in water, there is a serious risk in preservation that nicotine can be flushed out of the trash and end up in the groundwater, which is a particular dangerous for the environment and human health. For these reasons, tobacco waste cannot be disposed of together with urban waste (Pichtel, 2005), and must be destroyed under special conditions, which has a great economic impact for the tobacco producers and processors.

Tobacco waste recycling, or its preparation and reuse are very important, both because of the economic effects, but also due to the reduction of pollution or degradation of the environment (Novotny and Zhao, 1999; Okur et al., 2008).

Tobacco waste can be managed in the same way as other agricultural waste, by aerobic composting degradation (Felicita et al., 2003). Composting creates a stable product that can be used as an organic fertilizer.

The aim of this study was to examine the possibilities of tobacco waste composting with the addition of various organic waste materials, with the purpose of nicotine biodegradation until receiving the product that can be used and which is not dangerous for the environment.

Materials and methods

Virginia tobacco leaves, which are declared as waste after redrying process, were used for the purposes of the experiment. As components in experimental batches were used dry leaves of trees and soil, which were collected in the park around the Faculty of Agriculture, University of Belgrade and cabbage waste that is commercially available. Experiment was carried out during the period of three months: December 2014 - March 2015 at the Faculty of Agriculture, University of Belgrade. Experiment is carried out in several stages:

Preparation of experimental batches - Low humidity is one of the main characteristics of tobacco waste. Humidification was the process carried out in the first phase of experiment, and after that grinding and mixing tobacco with other biodegradable waste was performed. For the purposes of the experiment the following compost batches were formed (Table 1):

Table 1: Composting batches composition (%)

composting batch	TW	soil	cabbage	dry leaves of trees
1	60	/	40	/
2	60	10	15	15
control	100	/	/	/

Monitoring parameters of the composting process - Experiment was performed in a closed room, which is not equipped with devices for the automatic control of microclimate parameters. For this reason, the room periodically heated with electric heaters and the relative humidity is regulated only by natural ventilation.

During the experiment, in a period of three months, measuring the temperature and humidity in all samples was done every day (K-type thermometer 5115; microprocessor-moisture meter, model No. RS7825PS, CE ISO-2178), as well as temperature and relative humidity of the room (mini weather station Kestrel 4000, Nielsen-Kellerman).

Analysis of nicotine content in samples of experimental batches - Nicotine content in batches during the composting process was determined by High Performance Liquid Chromatography method (HPLC, Waters Breeze, USA).

The method applied in this analysis involves water extraction of the milled material followed by separation of the alkaloids on reverse-phase C18 column with a mobile phase of 40% methanol containing 0.2% phosphoric acid buffered to pH 7.25 with triethylamine. This procedure allows the quantitative analysis of four "major" alkaloid in tobacco and may be partially automated way to handle a larger number of samples (Saunders and Blume, 1981).

Results and discussion

Table 2 shows the results of nicotine content in experimental batches.

Table 2. Nicotine level in experimental batches (mg/kg)

R – Control sample

The initial content of nicotine in tobacco waste was 17 363 mg/kg. Nicotine content was reduced by 46.5% in sample 1 and 37.5% for the sample 2 at the beginning of the experiment, mixing with other forms of organic waste.

Both experimental batch showed solid results in the degradation of nicotine. At the end of the experiment, after three months (the results of 18.03.2014.), nicotine content has fallen below 10 mg/kg in both experimental batches. In order to check the effectiveness of the experiment, after 15 days, it was performed another analysis of nicotine content in the samples.

Although the process of composting was carried out successfully in both experimental batches, the sample 2 showed better results in the nicotine degradation. In the sample 2 (addition of 15% dry leaves of trees + 10% soil + 15% cabbage waste) nicotine degradation was occurred below the limit of 500 mg/kg (393,3 mg/kg) after two months from the experiment beginning. It took 15 days to decrease the nicotine content below 500 mg/ kg in the sample 1.

The results of this experiment, which refer to the nicotine content, confirm that the organic material, which also presents the waste, can be successfully used for the composting process of tobacco waste.

During the experiment, the dynamics of nicotine decomposition depended of the temperature and the humidity in the experimental samples. From the results shown in Table 2 it is possible to conclude that the increase in temperature and humidity patterns and dynamics of decomposition was higher, especially in the second half of the experiment. Temperature and humidity were measured daily. For better understanding of process, the results given in Figure 1 and Figure 2 are the average values of the process parameters.

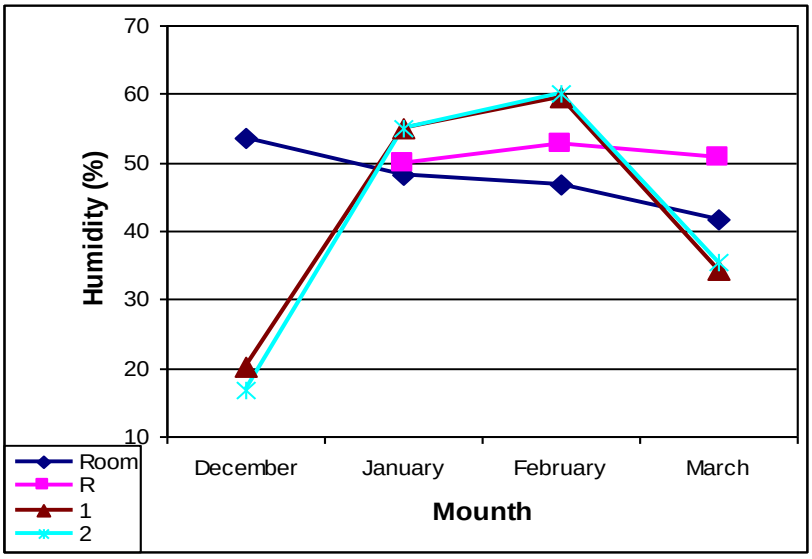

Figure 1. Humidity mean values during the composting process

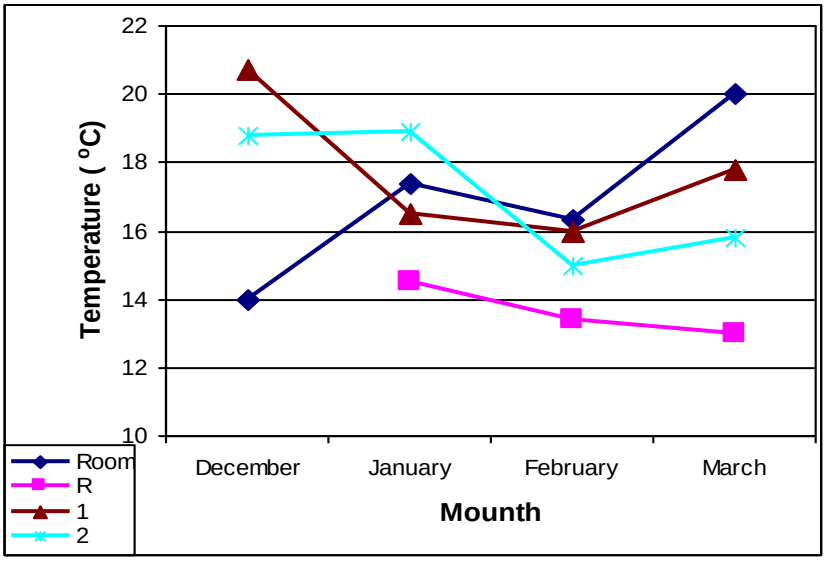

Figure 2. Temperature mean values during the composting process

With the progression of the composting process, it was observed that humidity had risen in experimental batches, due to intensification of the process. On the basis of the average

moisture content shown in Figure 1, it can be concluded that both experimental samples (1 and 2) had almost identical values. Sample 1 had a higher temperature at the beginning of the experiment, so the speed of nicotine degradation was higher at the beginning. After that, due to the rapidly temperature decreasing in the batches, speed of nicotine degradation in the second month of experiment was reduced. In the sample 2, in the first month of experiment, temperature was maintained at constant value, which resulted in a faster degradation of the nicotine in the later stages.

Low air temperature in the experimental room has slowed down the process of biodegradation. If the composting process would be conducted under controlled conditions, with automatic regulation of parameters, this could lead to significantly shorter process of duration.

Conclusion

Tobacco waste can be used as fertilizer due to its high content of organic matter. But first, it needs to be made applicable because in its original form it's still toxic. Effective implementation of the nicotine biodegradation of tobacco waste has great importance, both in terms of efficiency and maximum utilization of tobacco raw material and environmental protection.

From the presented results it can be concluded that the dynamics of acceptable nicotine degradation can be achieved by mixing the tobacco waste with other types of organic waste (cabbage, dry leaves of trees and soil). Therefore, by mixing tobacco waste with other types of organic waste, the nicotine content had already decreased in the range of 37.5 - 46.5% at the beginning of the experiment. At the end of the experiment nicotine content has dropped below 10 mg/kg in both compost batches, which is far below the values prescribed by the EU Directive.

Results of the experiment showed that it is possible to perform nicotine biodegradation of tobacco waste in order to archieve non toxic organic material that can be used without the risk of environmental pollution.

The importance of this experiment is the fact that the process of biodegradation can be carried out in natural conditions, regardless of the process duration, and it does not require a great economic investment. If the composting process would be performed in the summer months with high outside temperatures and adequate relative humidity, the natural process would be faster. In this case, available forms of organic waste in this period of the year must be taken in account. On the other hand, if the composting process would be carried out in controlled conditions, with automatic regulation of parameters, the duration of process would be significantly shortened. These conclusions open up opportunities for further research.

RESEARCHES ON DEMOGRAPHIC VARIATION OF NEW ARTIFICIAL YANARDÖNER (Centaurea tchihatcheffii Fisch. & Mey.) POPULATIONS

Ahmet Tansel SERİM*, Mustafa Selçuk BAŞARAN, Ayşegül YILDIRIM

Plant Protection Central Research Institute 06172 Yenimahalle Ankara, TURKEY
*Corresponding author: a_serim@hotmail.com

Abstract

Yanardöner (Centaurea tchihatcheffii Fisch. & Mey.), belong to Asteraceae (Compositae), is an annual endemic plant species and localized in an extremely narrow arable fields in Gölbaşı, Ankara, Turkey. C. tchihatcheffii, ranks among Critically Endangered Category with respect to IUCN criteria due to under pressure agricultural practices and urbanization. Some agricultural practices significantly affected natural populations, such as using herbicide, tillage and burning stubble. Creating new populations of narrowly endemic plant, like C. tchihatcheffii, in a suitable place protected from the outer pressure is an approach to protect of the plants. Demographic variations of new artificial population in the field conditions were keenly observed through the three years.

Field experiments were conducted in the Yenimahalle Agriculture Campus (YAC) to determine the establishment ability of C. tchihatcheffii population in a new area and the demographic structure of new population in the YAC. The factors that have influence on the population growing, such as the seedling time and number, the mature plant number and blossoming time, the maturation time of seeds and the seed numbers reach to the soil at the end of the season, were determined as the part of the demographic studies. The population established with 10 seeds per square meter in the soil reached considerable amount of seed number (2792 seed m-2) at the end of the trial. Death ratios of the germinated seeds were 11.7% at the cotyledon stage, 30.9% at the seedling stage and 5.6% at the blossoming stage. The rate of seed maturation ranged from 0.5 to 86.7% depends upon climatic conditions. Severe drought occurred after emergence of the seeds caused to decline about 99.5% of the population.

Keywords: *Demographic variation, Centaurea tchihatcheffii, artificial population, narrowly endemic plant*

Introduction

Turkey has hosted more than 10,000 plant taxa, approximately one-third of them is endemic. This high ratio of endemism can be explained by the variety of climate, geomorphological and soil diversity, the situation of the area at the junction of three flora region (Euro-Siberian, Mediterranean and Irano-Turanian) and ecological factors, and made Turkey a rich country for endemic taxa (Avcı, 2005; Davis, 1982). Asteraceae comprises 1,535 genera with 26,000 species in the world while it is represented by 1209 species in the Flora of Turkey, out of which 447 are endemic, with an endemism of 37% (Doğan et al., 2009). Among 134 genera of Asteraceae in the flora of Turkey, *Centaurea* L. is described as one of the largest genera (Wagenitz et al., 2005).

Centaurea tchihatcheffii (Fisch. & Mey.) is an annual endemic plant species and localized in an extremely narrow arable fields in Gölbaşı and Gölbek Village, Ankara, Turkey (Çakaroğulları, 2005; Vural, 2009). *C. tchihatcheffii* ranks among the Critically Endangered Category with respect to IUCN criteria due to herbicide applications and collection for ornamental purposes under pressure agricultural practices and urbanization (Ergüner-Baytok, 2008). Some agricultural practices significantly affected natural populations, such as using

herbicide, tillage and burning stubble. Creating new populations of narrowly endemic plants, like *C.* tchihatcheffii, in a suitable field protected from the outer pressure, is an approach to protect of the plants.

Conservation strategies of endangered species can be evaluated through two basic strategies called in-situ and ex-situ conservations (Brutting et al., 2013). In-situ conservation is a technique used for maintaining the viability of the populations in their natural habitats such as, national parks and gene management zones (Ergüner-Baytok, 2008) while ex-situ conservation is mostly used to be applied to the populations outside of their habitat in artificial conditions such as, botanical gardens, game farms, and gene banks (Primack, 1999). Ex-situ conservation encompasses not only the advantage of supplying new habitats for endangered plant species, but also it has some risks to adapt the species, such as genetic erosion, artificial selection and spontaneous hybridization (Volis et al., 2009). *C. tchihatcheffii* has also potential economic value as an ornamental plant because it has got remarkable flowers with shiny pinkish red (Ergüner-Baytok, 2008). Therefore, ex-situ conservation studies will contribute to maintain the viability of the species and to breed for ornamental purposes.

Some individual efforts have made to establish *C. tchihatcheffii* populations in protected areas, and they have promising results for the longevity of the species. The species have been established in Nezahat Gökyiğit Botanical Garden (İstanbul/Turkey) and successfully adapted in there (Vural, 2009). Savcı, (2007) also found that the species can survive in the protected areas where they have different type of soil. Demographic variations of *C. tchihatcheffii* populations in a new field condition were keenly observed through the three years to determine the establishment ability of new artificial populations.

Materials and Methods

The study on the establishment of the *C. tchihatcheffii* populations was performed in YAC 10 stable plots, each size was 1 m^2 (1m x 1m), were arranged on the two rows, and there was 0.5 m between adjacent plots. The seeds were sown in a depth of 2.5-3 cm in the late of December 2004 as a first step of 3-year study. Each parcel contained 10 matured seeds. Afterwards, the plots in YAC were keenly observed at 15 days intervals. The plants have been checked from the rosette stage to the mature plants. The parameters was monitored during the life cycle of plants were germination, mortality, phenology, achene output per plant, life stage transitions, fecundity and the number of seed included to the seed bank. Calculation of the plant's contribution to the seed bank in a plot was predicted by multiplying the number of mature capitulum by the average seed number of each capitulum.

The influence of seed burial depth on seed germination was performed during the trial in YAC due to the fact that the seed longevity of *C. tchihatcheffii* within the seed bank had not been known. Trial was conducted using the seeds collected from Gölbaşı in 27.05.2004. The seeds/sand mixture which were placed in nylon fabric bags were sown at depths of 5, 10, 15 and 20 cm in the clay pots. The efficacy of dry storage on seed germination was also carried out. For this aim, the seeds were put inside paper envelopes were stored at +5^{o}C during the same durations. The seeds sown at varies depths were exhumed of 1, 6, 12 and 24 months to determine germination rates in the laboratory conditions. At the same time, the seeds stored were taken off paper envelopes for the same purpose. The experiment was conducted according to the Rules of International Seed Testing Association using a total of 400 seeds (ISTA, 1985). The petri dishes were incubated at constant temperatures of 10°C and 12 h/12 h of light/dark photoperiod cycle to determine the effect of burial at various time on the germination percentages while the dishes put inside a growth chamber at constant temperatures of 5^{o}C and 10°C and darkness and 12 h/12 h of light/dark photoperiod cycle to determine the influence of dry storage duration on the germination percentages for 30 days.

Germinated seeds were counted and removed from petri dishes at 2-day time interval, and water was added as needed. Experiment was conducted with the use of a completely randomized design with four replicates. Data were subjected to ANOVA (α=0.01).

Results and Discussion

The biological cycle of *C. tchihatcheffii* in YAC, from the rosette to the mature plants, were keenly monitored from 2004 to 2007. Growing stages of the plants launched when the rosettes were appearance on the soil surface at the early of December. First rosettes were seen in plots 10-12 days after an effective rainfall was occurred. Although many of seeds emerged in December, it was observed that emerging of a small number of seeds continued in the spring months due to the irregularity of autumn rainfall. Rosette, flowering and maturity dates of populations in YAC are given in Table 1. The flowering stage followed emerging stage, heavily occurred in October, and continued from early of April to early of June (30-45 days). Maturity of the plants started at the late of May in 2006 and the second week of June in 2005 and 2007. Variation at the duration of biological stages can be caused by the climate, especially the amount of rainfall and its time. These results are in harmony with those of Çakaroğulları (2005) and Savcı (2007) except some little differences regarding the emerging, flowering and maturation times. These discrepancies may be related to climate and soil conditions.

Table 1. Emerging, flowering and maturation dates of *C. tchihatcheffii* from 2004 to 2007

Year	Emerging Date	Flowering Date	Maturation Date
2004–2005	15.01.2005-15.04.2005	25.04.2005-01.06.2005	08.06.2005
2005–2006	10.10.2005-15 02.2006	01.04.2006-15.05.2006	30.05.2006
2006–2007	01.10.2006-15.11.2006	15.04.2007-15.05.2007	11.06.2007

As it can be seen in the Table 2, more than two of three of seeds sown emerged in the first growing season (2005); however, emergency ratio of the seed in the plots approximately 2% in the second growing season (2005-2006) and 3.2% in the third growing season (2006). There was a huge disparity between the results of the first season and the second-third seasons, which can be caused by more number of immature and undeveloped seeds. Viable seed ratio of *C. tchihatcheffii* in natural seed banks were determined in 2005 using the soil sample taken from natural habitats of *C. tchihatcheffii*. This ratio was 25.37% in a natural habitat where didn’t any agricultural practise while the soil in cultivated field had high viable seed ratio (65.85%). Many researchers have found that using fertilizer, fine tillage of soil and weather conditions can improve seed viability (Jevdovic et al., 2013; Hay and Probert, 2013; Sveinsson and Björnsson, 1994) like *C. tchihatcheffii*.

Table 2. Settlement of *C. tchihatcheffii* in YAC

Plot	Seed Bank	Budding density (Plant number m^{-2})			Mature plant Density (Plant number m^{-2})			Seed Number included to seed bank			Sum
		2004-2005	2005-2006	2006-2007	2004-2005	2005-2006	2006-2007	2004-2005	2005-2006	2006-2007	
1	10	5	5	25	10	0	3	182	0	195	
2	10	4	32	90	10	31	1	650	1274	39	
3	10	6	-	39	10	-	0	1547	-	0	
4	10	10	11	61	10	9	1	1196	507	39	
5	10	5	90	60	10	83	0	1235	463	0	
6	10	9	13	117	10	9	0	5434	923	0

8	10	7	48	100	10	48	0	2067	689	0	
9	10	9	21	75	10	10	0	1495	819	0	
10	10	7	29	170	10	21	0	2236	1781	0	
Sum	**100**	**68**	**351**	**916**	**100**	**239**	**5**	**17.550**	**11.331**	**273**	**27.919**

The seed bank was established by starting with 10 matured seeds per square meter, and the number has reached to 2.791,9 seeds averagely at the end of three growing season (Table 2). Although there was a steady increase in the population size in two-years, a sudden decrease of the population size was observed in 2007. These dramatic declines were caused by severe drought in 2007 and more than 99% of budding couldn't reach maturity. Average seed number to include seed bank was calculated multiplying by the capitulum number of the mature plant and average seed number in each capitulum (13 seeds per capitulum). Calculation was only done using the plant emerged and matured because non-emerged seeds couldn't be observed. Approximately half of plants died before they reached maturity (Table 3). The highest mortality rate was observed at the budding stage of *C. tchihatcheffii* (30.9%). A study carried out by Çakaroğulları (2005) in Gölbaşı/Ankara (Natural habitat) reveal that percent mortality at rosette stage and budding stage ranged from 2.02 to 18.35 and from 1.39 to 6.06, respectively. These percent mortalities are very low compared with our results. This contrast may be related to natural environment because enemies in new habitats can be more destructive than natural habitat due to limited individual plants.

Table 3. Mortality ratio of *C. tchihatcheffii* at various growing stages

Year	Mortality Ratio (%)			Sum (%)
	Rosette	Budding	Flowering	
2005	-	8.8	4.5	13.3
2006	17.7	11.7	2.6	32
2007	17.5	72.3	9.7	99.5
Average	11.6	30.9	5.6	48.3

The efficacy of dry storage on seed germination was determined with a-24 month assay. Seed germination exhibited a steady increase depending on time (Figure 1). Although the germination rates were low initially, at the end of trials (24th month) the germination ratios were higher than 80%. No differences was found among germination rates in the darkness and in the dark-light cycle at 4 storage times ($P>0.01$). This results suggest that light is not required for *C. tchihatcheffii* seed germination, and the differences among germination rates at 5^oC and 10^oC are not significant statistically ($P>0.01$). The difference between germination rates at 4 storage durations are significant statistically ($P<0.01$).

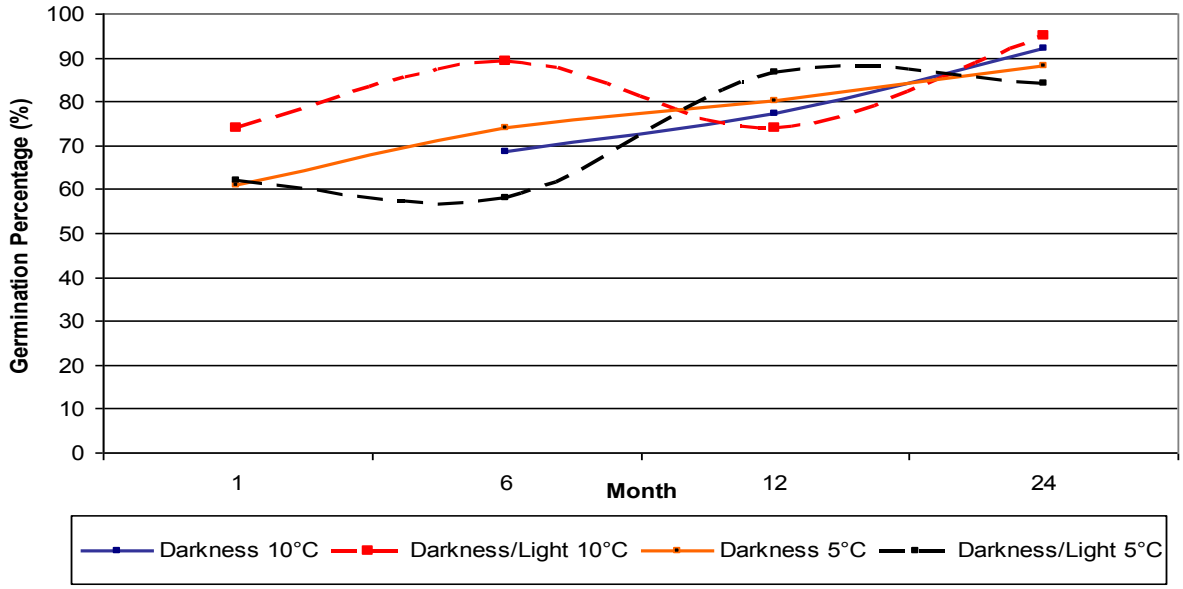

Figure 1. The influence of dry storage duration on the germination percentages of *C. tchihatcheffii* seeds

Seed are exposed the effects of many biotic and abiotic factors, such as microorganisms, pests, water, salt and pH when they included into soil. These factors influence viability of seed, and germination percentage are getting down day by day. Germination percentage of the seeds was influenced by seed burial depth (Figure 2). This percentage was higher for seeds placed at near the soil surface than for seeds buried at more depth. Statistical analysis of trial results has demonstrated that interaction between Time and Burial Depth is significant ($P<0.01$). Decreasing of germination percentage was very high compared with the results obtained from the seeds 1 month stored in dry conditions (Figure 1). This sharp declining can be caused by secondary dormancy, is induced by unfavourable environmental conditions. Some reports have indicated that extreme temperatures and high soil moisture significantly influence the occurring secondary dormancy (Anderson and Milberg, 1997; Jursík et al., 2010). Our findings are in agreement with the previous studies, buried *Bifora radians* seeds couldn't germinate at favourable environmental conditions in laboratory if the season wasn't suitable to her (Taştan, 1988) and duration and burial depth has got negative effect on the viability of *Boreava orientalis* seeds (Taştan et al., 1997).

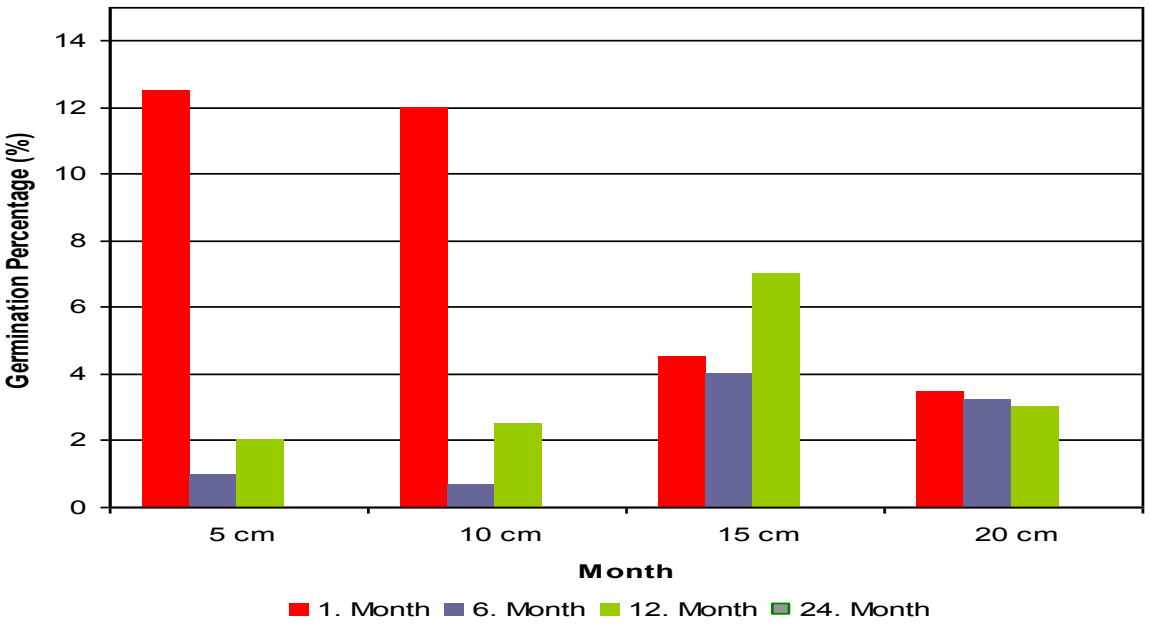

Figure 2. The effect of burial at various times on the germination percentages of *C. tchihatcheffii* seeds

Conclusion

The creation of new populations is one the most important solution to decrease the risk of extinction of *C. tchihatcheffii*. Our results indicated that *C. tchihatcheffii* can easily settle in the new habitats although the populations more vulnerable to outer factors compared with natural habitat. The present study also confirmed that the new populations may create strong seed banks for establishment of viable populations. These seed banks are the key factor to generate the new offspring and for population viability. Although the study finished eight years, the individuals of *C. tchihatcheffii* have been seen in study area. New populations and also seed banks for *C. tchihatcheffii* should be created at some protected areas if anthropogenic pressures on the populations continue in its natural habitats. Production of *C. tchihatcheffii* for ornamental purposes in new cultivation fields not only support the longevity of the species, but give an economical opportunity for florist as well.

Abstract

Nowaday, the increasing importance given to human health, and the impact of legislation prepared for it, more environmentally friendly clean residue-free disinfection methods have been developed. One of these applications is ozone application. Ozone in its gaseous form kills insects in various commodities and this activity has been thoroughly evaluated by many researchers under laboratory and field conditions, with various application techniques. But oxidation of ozone gas does not usually result in complete mineralization, but rather in the formation of oxidation by-products (e.g. aldehydes, ketones, alcohols, bromate and more) can also be generated from the reaction of ozone with according to the type of contaminants. Ozone treatments on studies have recently focus on kept at allowable value of these by-products will be formed, increasing the effect of ozone, ensuring more economical production and more. This review provides answers to the following questions: What is the level of effectiveness of generated ozone gas? What are the effects on the environment, food and human health produced ozone gas? Is there any advantage from other disinfection methods? Is it true that ozone gas some of the claims of destroying bacteria and viruses types, and which extends the shelf life of the food? Lastly, which combine methods can be increased the effectiveness of ozone gas?

Keywords: *Ozone gas application, desenfection, food, human health.*

Introduction

Ozone, the triatomic form of oxygen (O_3), is highly reactive and a strong oxidizing agent, which is classified as “GRAS” (Generally Recognized As Safe) by the United States Environmental Protection Agency (FDA, 1982). To be used in bottled water and in food processing (Graham, 1997). Moreover, the Food and Agriculture Organization (FAO, 1994) recognizes the potent disinfectant characteristics of O_3.

Ozone is toxic to all forms of life, and governmental regulations have been established to protect people from excessive exposures to this gas. This reason, the effects of ozone treatment on the quality and physiology of the commodities mainly depends on ozone doses, exposure time and environmental conditions such as treatment medium and temperature.

The human threshold limit values vary from 60 to 100 parts per billion (ppb) in air, depending on the agency or country involved. Ozone can be generated by exposing normal diatomic oxygen gas to energetic electrons, X-rays, nuclear gamma rays, short-wavelength ultraviolet radiation (UV) and corona discharge (electrical field) and more recently by electrochemical methods. Other disinfection methods outside the ozone gas application are ultraviolet light, ultrasound, electrolyzed oxidized water, high pressure carbon dioxide, and bacteriophage. Other novel technologies like high pressure processing, pulsed electric field processing and irradiation were not covered considering their vastness of literature and availability of published reviews (Mukhopadhyay and Ramaswamy, 2012).

Throughout the world, ozone has been used to purify drinking water, kill bacteria, sanitize food, deodorize, decolorize and decrease some contamination. The modern life-style of developed countries involves daily usage of artificial compounds such as active

pharmaceutical (such as human or veterinary) ingredients (API), personal care products, hormones, pesticides or biocides and other environmentally persistent chemicals. Many of these potentially harmful substances are not biodegradable and do not adsorb easily. As a result residues of these compounds become micropollutants in wastewater which leads to an insufficient elimination of them in wastewater treatment plants. During ozonation most organic micropollutants present in treated. Another source of wastewater is grey water has a huge potential to be treated, recycled and reused, especially when the availability of freshwater is a concern in many countries. (Oh et al., 2015). Wastewater are oxidized either by a direct reaction with O_3 or by secondarily formed hydroxyl radicals ($^{\cdot}OH$). However, undesired oxidation by-products from the oxidative transformation of matrix components can also be formed. The oxidative transformation of dissolved organic matter (DOM) leads to assimilable organic carbon (AOC) or biodegradable organic carbon (BDOC), which includes compounds such as aldehydes, ketones or organic acids. These compounds are typically removed during a subsequent biological treatment step. The oxidation of trace organic contaminants and potential microbial inactivation must be balanced with the formation of disinfection by-products, including bromate. However, during ozonation of saline waters such as sea water highly toxic and persistent by-products are formed, as ozone reacts rapidly with selected halogen ion such as iodide and mainly bromide to different secondary oxidants summed up as ozone-produced oxidants (OPO). It has been shown that brominated oxidants such as hypobromous acid/hypobromite($HOBr/OBr^-$). Same way, the carcinogenic N-nitrosodimethylamine (NDMA) can be formed during ozonation of wastewater from effluent organic matter or micropollutant precursors. Also, seawater electrolysis is also efficient in generating chlorine ($HOCl/OCl^-$). It is expected from a disinfection process both should provide sterilisation and by-product should not form as well as or remain within acceptable limits. Acceptible limits of bromate concentrations for ozonated wastewaters were above the drinking water standard of 10 mg L^{-1} (WHO, 2005). And the NDMA guideline value for drinking water of 100 ng L^{-1} given by the World Health Organization (WHO, 2008).

In order to increase the impact of ozonation process, reduce the formation of by-products, and reduce the cost of disinfection, scientists are trying to develop the different combine method can be used together with ozone gas. In this study has been mentioned developed in some combined methods.

Water and food desenfection application

The extensive use of Bisphenol A (BPA) in the plastics industry has led to increasing reports of its presence in the aquatic environment. Ozonation, have been shown to effectively degrade BPA(Umaret al.,2013). Ozone caused a decrease in particle stability and dissolved calcium concentration at pH of 6 (Sadrnourmohamadi and Gorczyca, 2015). Antoniou et al. (2013) investigated the ozone dosage required to remove active pharmaceutical ingredients (APIs) from biologically treated wastewater. 15 of the 42 investigated APIs could be classified as easily degradable ($DDO_3/DOC \leq 0.7$). Fenitrothion and deltamethrin insecticides are widely used on wheat grains in the storage units. The residues of fenitrothion were decreased after direct O_3 gas treatment for 180 min of exposure (Savi et al., 2015). Spices and herbs often contaminated with pathogenic bacteria and fungi. The results demonstrated that the gaseous ozone treatment is an effective alternative microbial reduction technique for dried oregano (Torlak et al., 2013). The ozone generation system is capable of reducing Escherichia coli O157:H7 in packaged spinach (Klockow and Keener, 2009). Segat et al.(2014)’s study demonstrates that water acting as carrier of spoilage icroorganisms can be successfully treated with ozone in order to reduce microbial cheese contamination in each processing step after stretching and shaping. Microbial growth and darkening rate of fresh noodles made from ozone treated flour were delayed significantly (Li et al.,2012).

Medical application and other applications

Medical ozone therapy is used for the treatment of inflammation, infected wounds, chronic skin disease and advanced ischemic illnesses, including burns, due to its antioxidant, antiflammatory and antimicrobial effects. Additionally, Ozone therapy has been successfully used in the management of diabetic foot, lumbar disc herniation, and vascular disorders, including myocardial infarction and stroke. The other techniques to supply O_3 therapy are rectal, vaginal, and ear insufflations; injection to veins, joints, muscles, and tumors; and bagging of the use of ozonated water and oil orally and externally(Case Report, 2015). Ozone was demonstrated to be a reparative substance against acoustic trauma and, in addition, it can be supplied and applied easily(Lopes et al., 2015). However, pure ozone is not used in ozone therapy owing to ozone toxicity. It is applied in the form of an ozone/oxygen mixture (Yenigun et al.,2013). Ozone might be a useful tool to reduce and control oral infectious microorganisms in dental plaque and dental cavity. However, Almaz and Sönmez, (2015) in their review study reported that the results of in vitro studies are controversial; while some researchers reported that ozone therapy had a minimal or no effect on the viability of microorganisms (Müller et al., 2007; Hauser-Gerspach et al, 2009), others suggested ozone to be highly effective in killing both gram-positive and gramnegative oral microorganisms (Holmes, 2003; Baysan and Lynch, 2004). In one study forty-four patients had intradiscal injections and were included in the analysis. After treatment, 75.0% showed significant improvement in pain based on the visual analog scale with using ozone (Murphy et al., 2015). Similarly, Teixeira et al.(2013), in their study on dogs, ozone had no measurable adverse effects and is an alternative option to promote pain relief. Ozone oxidative preconditioning attenuates experimental contrast-induced nephropathy. This effect is suggested to be mediated by reinforcement of renal antioxidant defenses and maintenance of renal nitric oxide levels by Kurtoglu et al. (2015). were shown to be effective in increasing bone healing using of hyperbaric oxygen and ozone, separately and in combination.

Zhang et al. (2011), in their review correlated different air cleaners (high efficiency particulate air (HEPA), adsorption, ultraviolet germicidal irradiation (UVGI), photocatalytic oxidation (PCO), thermal catalytic oxidation (TCO), plasma, botanic air cleaners, ion generators, and electrostatic precipitators). They concluded that none of the reviewed technologies was able to effectively remove all indoor pollutants and many were found to generate undesirable by-products during operation. Furthermore, particle filtration and sorption of gaseous pollutants were among the most effective air cleaning technologies, but there is insufficient information regarding long-term performance and proper maintenance. Finally, ozone is not recommended by Zhang et al. (2011) for indoor air cleaning because of the harmful by-products.

Method comparisons

Aday and Caner (2014) examined ozone and chlorine dioxide, alone and in combination, on strawberry storage life. Overall their findings suggest that combinations of ultrasound plus ozone and chlorine dioxide could be used for prolonging shelf life of strawberries. In the other study examined the effects of sonication, sanitizers and sodium dodecyl sulfate (SDS) on the quality of fresh-cut Iceberg and Romaine lettuce. As a result reached chlorine-treated samples had a significantly higher overall quality score than that from the other treatments(Salgado et al., 2014). In different reserch suggested by Crowe et al. (2012) that ozone treatments resulted in the greatest log reductions in mesophilic bacteria, yeast, and mold population. This impact was short-lived and only observable at time. The greatest microbial reductions in all populations were observed on chlorine-treated berries. On the contrary, in Olmez and Akbaş (2009)’s study, ozone treatment was found to be better than the chlorine and organic acid treatments in maintaining the sensory quality on Listeria monocytogenes counts and the

overall visual quality of lettuce. For compounds with low reactivity toward ozone, ozonation treatment could be insufficient in removing them from drinking water, therefore hydroxyl radical-based treatment techniques such as O_3/H_2O_2 or UV/H_2O_2 are recommended by Jin et al.(2012). NDMA(N-Nitrosodimethylamine) formation potential was significantly reduced by ozone and ozone/peroxide pretreatment (Pisarenko et al, 2012).When the comparison of the UV-based advanced oxidation processes (AOPs) VUV, UV/O_3 and UV/H_2O_2 under the experimental conditions, the combination VUV/O_3 is a good alternative to the other UV-based AOPs since it provides an economic treatment of raw waters containing taste and odour compounds and the minimization of undesired by-products (Zoschke et al., 2012). In the other study on O_3, UV, and O_3–UV were effective disinfection treatments on vegetable wash water, with a maximum microbial achieved by UV and O_3 treatments (Selma et al., 2008). The UV–ozone reactor is capable of removing most of the cyanide (66%) and of precipitating a significant amount of iron (46%) (Postigo and Richardson, 2014). The combined ozone–organic acid treatment was more efective than individual treatments in reducing initial population levels of Escherichia coli O157:H7 and Listeria monocytogenes pathogens on enoki mushroom (Yuk et al.,2007). The other study on atmospheric cold plasma device against Escherichia coli, Salmonella enterica Typhimurium and Listeria monocytogenes inoculated on cherry tomatoes and strawberries (Ziuzina et al., 2014). Resulted in reduction of E. coli, Salmonella and L. monocytogenes populations and also effectively reduced the background microflora of tomatoes. The antilisterial effects of coating formulation in combination with ozonated water, UV-C and C-ray treatments on inoculated samples ensured microbial safety during storage with a reduction of L. monocytogenes (Severino et al., 2014). Oxidation by ozone followed by sand filtration (SF) and powdered activated carbon (PAC) adsorption followed by either ultrafiltration (UF) or sand filtration. Despite its current higher costs and energy consumption PAC-UF treatment led to a good removal of most pollutants without forming problematic by-products, the strongest decrease in toxicity and a total disinfection of the effluent(Margot et al., 2013).As a sequential application, ozonation followed by electrolysis could be an optional process for the inactivation of some resistant microbial species, such as B. subtilis spore(Jung et al., 2013).

. Lastly, correlated UV, ozone and ionizing radiation methods by The ionizing radiation can be applied as an effective and economical alternative technique to conventional disinfection processes (Lee et al., 2015).

Conclusion

When exceeds a certain dose of ozone gas, damages to the environment and human health. Because of the harmful by-products, ozone is not recommended for indoor air cleaning. Hovewer, though significant reduction of bacteria and other contamination could be achieved by many of different emerging technologies when used alone or in combination, the disinfection of ozone appears to be successful administered at appropriate amounts and appropriate method even if many times they do not result in complete elimination.

Since the disinfection efficacy is greatly affected by the quality parameters of water itself, it is also important to understand the relation between the pH, temperature, turbidity and organic matter contents of substrates and the efficacy of disinfection.

Because of these reasons, discrepancies regarding the efficacy of ozone are often found in the bibliography and further research is still needed, to clarify and develop the inferences for its wider use, including the cost of its application.

LANDSCAPE-ADAPTIVE APPROACHES TO THE MANAGEMENT OF SALINE SOILS FERTILITY IN UKRAINE

Sviatoslav BALIUK, Elena DROZD*, Marina ZAKHAROVA

National Scientific Center «Institute for Soil Science and Agrochemistry Research named after O.N. Sokolovsky», Kharkiv, Ukraine
*Corresponding author: elena_drozd@ukr.net

Abstract

Saline soils of Ukraine are mainly formed in the Subboreal zone in the Forest-Steppe and Steppe natural zones. Conventionally they can be divided into two types - naturally saline and secondary saline. Secondary salinization is often an environmentally negative consequence of irrigation (during soil irrigation with mineralized water and during the rise of saline groundwater above the critical level). Naturally saline and secondary saline soils can be without morphologically indicated solonetzic horizon, their area is 1. 92 million ha and morphologically distinct solonetzic horizon (saline - alkaline) – 2. 8 million ha. Furthermore, among the irrigated lands 200 thousand ha of secondary saline of soils. The majority of saline soils in Ukraine are ploughed excluding strongly saline types and salt marshes. Fertility management of saline lands is aimed at building models of sustainable, environmentally safe and cost-effective land use. Effective use of saline soils in Ukraine is possible only with accounting soil properties (power and chemistry of salinity, salt balance of soil, etc.), the level of groundwater mineralization, climatic conditions (rainfall), the direction of agricultural use (arable land, hayfields, pastures, perennial plants). Depending on the genesis and properties of different types of saline soil for conditions of Ukraine, a landscape-adaptive set of measures to improve their fertility was developed. Herewith the reclamation is carried out in the following directions: chemical reclamation (soils and irrigation water), ameliorate plantation plowing, flushing, creating drainage systems, phytomelioration). Landscape-adaptive approach to the management of saline soil fertility ensures sustainable environmentally safe and cost-effective use of saline soils.

Keywords*:* *Saline soils, areas, properties, reclamation, fertility.*

Introduction

The general tendency of the agriculture development in the world at the present stage envisages the creation of conditions for the stabilization and increase volumes of agricultural production to solve the food problem. Year by year the Ukraine's role increases as an agricultural country in the food security of Europe and the world. According to the Land Registry of Ukraine, the land fund country makes 60.3 million hectares, of which agricultural lands – 41.6 million hectares (69% of the total area of Ukraine) in arable land - 35.5 million hectares (53. 9%) (Laktionova *et al*., 2015). Saline soils cover relatively small part of arable land area in Ukraine (about 7%), but require special attention in the management of agriculture for several reasons. Firstly, their agricultural development is closely linked to the need to perform a complex set of special reclamation measures for desalination. Secondly, soil salinity can occur during the exploitation of non-saline areas in irrigated agriculture as a result of the processes of secondary salinization. Thirdly, the range of saline soils is dynamic as soil salinity can be accompanied by the simultaneous appearance of the process of secondary salinization and alkalinization and new ranges of salinity on adjacent territories. Under the condition of landscape-adaptive scientifically substantiated use, saline soils are a significant reserve for increasing the production of various types of agricultural products.

Materials and Methods

Main research directions of saline soils in Ukraine: fixing manifestations and identification of patterns of sharing processes of salinization and alkalinization (depending on the structure of soil, ecological and reclamation land condition, irrigation water quality, existing farming technologies, etc.); spatial assessment of lands and directions for further development of the processes of salinization and alkalinization on the basis of their mapping and typing the territory; development of recommendations for the justification of measures to prevent or eliminate the salinity and alkalinity, protection and reproduction of soil fertility; formation of information support of management decisions systems in the context of monitoring and advisory - deliberative service (Baliuk *et al*., 2014).

The research was conducted in Forest-steppe and Steppe zones of Ukraine, where is disposed 98% saline soils. The objects of our research were:

naturally saline soils, irrigated soils and methods of its reclamation.

irrigation water. For irrigation in Ukraine are used basically water of main river arteries and created on their base water storage's and ponds.

agricultural plants, grown on saline soils in irrigating and none irrigating conditions (grains, vegetables, fodder's and technical cultures).

The main methods were field, model, analytical and statistical research.

Also were used

materials of large-scale land survey (1957-1961 yr.) and their correction;

the Land cadastre;

materials of agrochemical certification of the agricultural lands;

data of ecological-ameliorative monitoring;

data of scientific organizations National Academy of Agrarian Sciences of Ukraine, higher educational institutions and others.

For an accurate assessment of ecological and agromeliorative soil condition National Scientific Center «Institute for Soil Science and Agrochemistry Research named after O.N. Sokolovsky» created a regulatory framework for the monitoring of saline soils, developed agro-environmental criteria, parameters and diagnostics of saline soils (using thermodynamic parameters - the activity of hydrogen ions, calcium, sodium, magnesium). To establish the degree of alkalinity, including the processes of secondary alkalinization, it is used a set of criteria: the amount of absorbed sodium and potassium cations, the ratio of the absorbed sodium and potassium cations to the sum of all cations, the ratio of the activity of sodium ions to the square root of the activity of calcium ions, as well as indicator of thermodynamic potential (pNa - 0.5pCa). The system of irrigation water quality assessment is developed and put into effect, which includes agronomic criteria (evaluation on salinity risk, alkalinization, alkalinity) and ecological criteria (soil pollution by heavy metals and fluorine), taking into account their buffer properties.

The control (monitoring) of the soils condition include:

- the systematic observation of state, properties, regimes of soils;
- the analysis of the stability of soils to the diverse degradation processes;
- the evaluation of the different types of the human economic activity, its positive and negative influence on the soil cover - impact-analysis;
- the computer data bases creation and cartography;
- forecast and prevention of the degradation processes.

The estimation of the soils condition is achieved by the method of comparison of the parameters of the soils, which are fixed in the initial period of observations, or standard soils with the same parameters after the corresponding periods of the soils using. The criteria of evaluation of the development of degradation processes are carried out on the basis of these observations, the levels of their ecological danger and unprofitability are determined (table 1).

Table 1. The integral estimation of the soil soils according to the degree of the degradation

Indices	Soil without degradation	Degree of degradation		
		Low	Average	Strong
Salinization, 0-50 cm				
Toxic salts content, eCl^-, meqv/100 g of soil	less than 0.3	0.3-1.5	1.5-3.5	more than 3.5
Ca:Na in water extract	more than 2.5	2.5-1.0	1.0-0.5	less than 0.5
Solonetzization, 0-30 cm				
Na^++K^+, % from sum of cations, clay soils	less than 3	3-6	6-10	more than 10
Na^++K^+, % from sum of cations, sandy soils	less than 5	5-8	8-12	more than 12
aNa/√aCa	less than 1	1-3	3-7	more than 7
Factor of dispersivity by Kachinsky, %	less than 10	10-20	20-30	more than 30
Alkalinization, 0-30 cm				
pH_w.	less than 7.8	7.8-8,5	8.5-9,0	more than 9.0
HCO_3^--Ca^{2+}, meqv/100 g of soil	less than 0.5	0.5-1.0	1.0-2.0	more than 2.0
CO_3^{2-}, meqv/100 g of soil	less than 0.1	0.1-0,3	0.3-0,9	more than 0.9
pH-pNa	less than 4.0	4.0-5.0	5.0-5.5	more than 5.5
Humus state, 0-50 cm				
Decreasing of humus content, % from initial	0	0-10	10-20	more than 20
Agrophysical state, 0-30 cm				
Content of air-dry aggregates 0,25-10 mm	more than 70	60-70	40-60	less than 40
Content of water-proof aggregates > 0,25 mm	more than 45	35-45	25-35	less than 25
Equilibrium density of composition, g/sm^3, clay soils	less than 1.3	1.3-1.4	1.4-1.6	more than 1.6
Equilibrium density of composition, g/sm^3, sandy soils	less than 1.3	1.3-1.5	1.5-1.7	more than 1.7
Pollution, 0-100 cm				
Heavy metals content, in zinc equivalents, mg/kg of soil	less than 25	25-50	50-100	more than 100
Water-soluble fluorine, mg/kg of soil	less than 6	6-10	10-20	more than 20

For today on the basis of the long-term comprehensive study of the soil processes dynamics and regimes in saline soils there are identified common landscape-zonal patterns and spatially differentiated features of orientation, and the prevalence rate of soil processes. For a more accurate spatial assessment of the saline soils state, a series of electronic maps of the regional and local levels is created.

At the regional level there are solved issues of spatial differentiation of land on the main factors of the formation and the degree of manifestation of salinity and alkalinity, the directions of further development of processes for determining a set of preventive and prophylactic measures. At the local level - the solution both monitoring tasks, and tasks related to the needs of the targeted land users. The main attention is paid to the definition of local variability of salinity and alkalinity manifestations, obtaining the characteristics of the soil condition and the dynamics of its performance. This approach allows creating a unified system of information and mapping support for measures to control environmental and agromeliorative state of naturally and secondary saline soils and solonetzic soils, developing the principles of their rational use based on technology adaptability to soil - climatic and social conditions.

Results and discussion

Naturally saline soils of Ukraine are confined to the two tectonic cavities - the Dneprovsko-Donetskaya (Forest-Steppe zone) and the Black Sea (Steppe), where the total lack of areas

drainage creates favourable conditions for the accumulation of salts (Novikova, 1984; 1996). (Fig.1).

Fig.1 Dissemination of saline soils in Ukraine

According to the soils classification of Ukrainian, they are presented by chernozems saline and solonetzic, chernozem meadow, meadow - chernozem, meadow-chestnut, meadow, alluvial - meadow, dark -brown and brown alkaline soils, solonetzes and salt marshes (Polupan *et al*., 2005).

Manifestation of secondary salinity is often the environmentally negative consequence of irrigation. Considering the fact that in Ukraine every two years from the five are arid, irrigated lands are the insurance fund of the country, as 75% of the territory of Ukraine for natural hydration are in unfavourable or partially favourable for agricultural production conditions, which greatly affects the efficiency.

Most often, secondary salinity in Ukraine occurs in conditions of inadequate drained low-lying areas by the absence of the collector-drainage network and / or by using for irrigation of saline water (more than 1 g / l) (Fig.2).

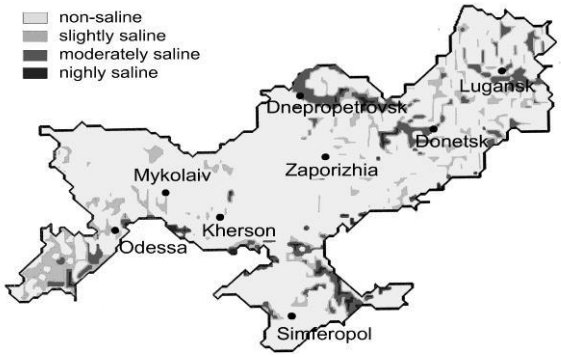

Fig.2 Dissemination of secondary salinity in Ukraine

Herewith it is set a positive salt balance in excess of accumulation of salts over their removal (Baliuk *et al*., 2009). The causes of secondary salinity in Ukraine can also be:

adverse chemical composition of the irrigation water in which the content of alkaline salts of sodium, potassium, in an equivalent ratio exceeds the content of salts of calcium, magnesium, iron and other two-and trivalent cations;

rise to the surface of the ground water with the same adverse chemical composition and so secondary salinity can be stored for a long time. Then, during salt flushing by precipitation or irrigation water in soils secondary alkalinization process can be developed;

special flushing of saline soils, as well as the development of the rice systems based on naturally saline soils (the early years).

According to the soils classification of Ukrainian, secondary saline soils are represented by chernozem ordinary, southern and dark chestnut soils (Polupan *et al*., 2005).
Until 1991 fertility improvement of saline soils in Ukraine was carried out mainly with the use of chemical amelioration on the area 2 million ha. After 1991, the reclamation of saline soils has been given insufficient attention mainly due to high energy consumption and the lack of adequate state financial support. During this period, the agriculture of Ukraine in general has gone on the way of extensive development, which inevitably leads to the loss of soil fertility, reduced yields and volatility of gross yield of agricultural products. This has contributed to changing attitudes, principles, methods and technological solutions to problems of land reclamation (Baliuk *et al*., 2015).
The feasibility of reclamation, its kind, technology are defined by agro-climatic resources, modern ecological and land improvement state of solonetzic soils, tasks of agricultural production and its resourcing. The main requirement for rational use of solonetzic soils in Ukraine in modern conditions should be considered a necessity of landscape-geochemical assessment of their formation and distribution and adaptive application of different types of reclamation. It provides protection and increase effective fertility of solonetzic soils, optimization of living conditions of the crops.
The State Agency of Ukraine for Land Resources has developed and approved a procedure for land conservation, based on which the saline soils containing toxic salts more than 0,4% are subject to transfer from agricultural lands to other land uses. The system of measures on re-naturalization of landscapes provides also removal of strongly solonetzic lands from arable land.
Chemical reclamation in Ukraine is recommended to carry out on saline and alkaline soils, which lend themselves well to this reclamation measure (chernozems saline and solonetzic, chernozem meadow, dark -brown and brown alkaline soils with share of solonetzes spot 10-30 % and 30-50 %, soils that irrigated by bonded suitable water). Continuous chemical reclamation is recommended to replace by the sample (contour) application of meliorant on solonetzes stains or by local application of gypsum in rows during sowing, providing economic- and material resources savings. According to this approach, areas of lands needing chemical reclamation could be significantly reduced compared to those that were reclaimed in previous years. This method of chemical reclamation provides increasing yields of grown crops at 15-20%. According to research, chemical reclamation should be repeated every 5-7 years. For the reclamation of secondly saline soils it is recommended to apply the gypsum directly into the soil or with irrigation water.
In the dry conditions of Steppe, where the chemical reclamation in unirrigated conditions is ineffective, it is recommended the use of reclamation plantage ploughing. It is expedient to apply for dark chestnut and chestnut saline soils in combination with steppe solonetzs (25%) with 40-50 cm deposition of carbonates and / or gypsum and alkali-saline brown soils in meadow-chestnut. With the research of the properties of agrotransformed solonetzic soils of Dry Steppe of Ukraine in irrigated and non-irrigated conditions, conducted by NSC ISSAR, was determined that the result of the aftereffect of reclamation plantage ploughing is the formation of highly environmentally sustainable agro transformed soils which are unique in nature on their morphological, agrophysical and physico-chemical properties and are able to

provide high productivity of agricultural crops, that are able to provide high fertility in agro-climatic conditions of the Steppe zone of Ukraine. A single conducting reclamation plantage ploughing provides a positive after-effect on soil properties and productivity of agricultural crops for 50-60 years and the discontinuation of its positive aftereffect is unmarked. Gain yields are 20-25% in unirrigated conditions and up to 40% under irrigation.

Large areas (92.2 thousand hectares) are occupied by solonetzic soils, where the reclamation is inefficient n and bringing them to arable lands is economically unfeasible. It is mainly saline alluvial chernozem and its complexes, with medium to high degree of salinity and the level of ground water occurrence of 1.0-1.5 m and alkali-saline chernozem soils and solonchaks. Cost-effective and environmentally safe using such soils is appropriate through selection of adapted economically valuable kinds of crops to create productive perennial multicomponent agrocenoses.

Saline soils with not deep mineralized groundwater with adequate natural drainage of areas are recommended for usage under rice systems. For reclamation of slightly saline soils it is recommended to use technical measures: application of organic and mineral fertilizers, the introduction of perennial grasses in crop rotation, phytomelioration.

To separate group it should be attributed saline soils, which in the present shortage of resource expenditure do not require radical reclamation. Increasing their fertility is advisable to make with farming practices and application of increased amounts of organic and mineral fertilizers, involvement in crop rotation perennial grasses and solonetz-stable crops. It is chernozems and dark chestnut soils with a low degree of salinization without solonets spots or their complexes with solonets spots 10%.

Conclusion

On the basis of generalization and systematization of long-term research there were highlighted the issues of the genesis of saline soils in Ukraine, the main directions of research, the main approaches to their rational use and fertility management. Landscape-adaptive approach to the management of saline soil fertility is proposed. The proposed system of reclamation activities, differentiated by features of different types and kinds of solonetzic soils, environmental and economic aspects of reclamation can reduce the area of chemical reclamation of solonetzic soils to 1.0-1.1 million hectares compared to 2.0 million hectares in previous years and receive economic benefit by increasing crop productivity and improving product quality. Thus obtained results will serve as for securing the sustainable development of agriculture in Ukraine.

IMPACTS OF CLIMATE CHANGE AND ADAPTATION ON THE AVAILIBILITY OF WATER: A CASE OF AGRICULTURE IN PAKISTAN.

Samina KHALIL

Applied Economics Research Center,University of Karachi, Karachi, Pakistan
*Corresponding author: samina.khalil@gmail.com; skhalilpk@yahoo.com

Abstract

Climate change is a major issue faced by the world today. It is proved that activities by mankind are the main cause behind it. Among them Energy is the main activity that is responsible for most of the green house gases that cause climate change. Climate of a region is a key factor that ascertains the availability of water resource. The global phenomenon of climate change has increasingly instigated rise in average global air and temperature of oceans. Mounting global sea levels and pervasive melting of glaciers are evident consequences of climatic changes in the last few decades. Changes in atmospheric temperature and radiation balance are closely linked to the hydrological balance. The hydrological cycle gets intensified due to higher temperature of climate, which in turn results into increasing rate of evaporation and liquid precipitation. It is quite evident that these processes along with the changing pattern of precipitation have profound impact on the spatial and temporal distribution of soil moisture, groundwater reserves and runoff etc. This could trigger the intensity and regular occurrence of floods and droughts. Agricultural demand, particularly for irrigation water is considered more sensitive to climate change. A change in field-level climate may alter the need and timings of irrigation. The demand for water for irrigation purpose may increase with the increase in dryness and on other hand it may reduce if soil moisture content rises at critical times of the year. It is projected that most irrigated areas in Pakistan would require more water around 2030 and global net irrigation requirements would increase relative to the situation without climate change by 3.5–5% by 2030, and 6–8% by 2075. The effect of climate change on water resources may be mitigated through better water harvesting and by micro-storage facilities in watersheds. These would not only provide supplemental irrigation but also recharge the groundwater aquifers.

Key words: *Hydrological balance, radiation balance, liquid precipitation, atmospheric temperature, watersheds*

Introduction

Pakistan is one of the important South Asian countries with total geographical area of 796,095 km^2 and population of 19 million people that is 2.56% of the world population. The land area of Pakistan is 97.13% and water is 2.87%. Over 70% of Pakistan’s population is rural and agriculture oriented for whom these rivers are the source of their livelihood and prosperity.

The source of main water in Pakistan is canal irrigation system. The Indus valley, comprising the planes of Punjab and Sindh is mainly dependent on the water of river Indus and its tributaries, as the area is mostly arid because of annual precipitation. The river Indus is the life line of Pakistan's agriculture. Nearly 450,000 sq.m, Himalayan watershed of Indus and its tributaries includes the world's biggest glaciers outside the Polar Regions.

The distribution of rainfall in Pakistan varies on wide ranges, mostly associated with the monsoon winds and the western disturbances, but the rainfall does not occur throughout the year. Like, Khyber Pukhtonkhuwa (northern mountains) and Balochistan provinces receive maximum rainfall in the months of December to March while Punjab and Sindh receive 50 - 75% of rainfall during monsoon season (Kazi, S. A. and Khan, M. L 1951). The precipitation received in the country can be divided into two main seasons, summer or monsoon and winter

precipitation. The monsoon rainfall enters Pakistan from east and north east during the month of July to September. During this duration a good amount of rainfall is received in the north and northeastern areas of the country. Winter precipitation (December to March) are mainly received from western disturbances entering from Iran and Afghanistan. Table 1 depicts the major river basin system of Pakistan with their origin and catchment areas and average annual potential in river.

Table 1: Major river basins of Pakistan

River	Origin	Catchment area	Average annual potential in river (Bm3/yr)
Sutlej River	Western Tibet in the Kailas Mountain range and near the source of Rivers Indus, Ganges and Bramaputra	47,100 Sq.miles/75,369 Sq.km (70% in India)	45.67
Ravi River	Originates from the lesser Himalayas Range in India	15,600 Sq.miles/24,960Sq.km	65.87
Chenab River	Forms at the confluence of streams Bhaga & Chandra which join at a place called Tandi in Occupied Jammu & Kashmir state. -Upper most part is snow covered and forms the North East part of Himachal Pradesh -From Tandi to Akhnur the river traverses through high mountains	26,100 Sq.miles/41,760 Sq.km	34.59
Jhelum River	Originates in the Kashmir Valley about 34 miles (54 km) east of Anant Nag.	24,500Sq.miles/ 39,200Sq.km	58.76
Indus River	One of the largest rivers of the world and the main river of the Indus valley; -Originates near lake Mansarowar on north of Himalayas range in the mountain of Kailash Parbat in Tibet at an elevation of 18,000 ft.;	1,80,000 Sq.miles/2,88,000 Sq.km	647.45

The Indus River Basin is of major importance to the economy of Pakistan as well as other countries in South Asia. Indus River System consists of six main rivers (the Indus, Jhelum, Chenab, Ravi, Sutlej, and Kabul rivers) originating from glaciers in the Western Himalayas and provides irrigation to more than 16 million hectares of agricultural land and generates up to 13 giga Watts of electricity through hydropower plants in Pakistan, India, and Afghanistan. Glacial retreat and changes in precipitation patterns from anthropogenic climate changes are expected to alter significantly river basin behavior and jeopardize hydropower generation and irrigated agriculture production. Initial short-term increases in water flow may endanger the sustainability of downstream infrastructure. Expected long-term reduction in water flows will

reduce power generation potential and irrigation supply, with dramatic impacts on overall agriculture yields of these countries, consequently altering people's livelihoods. This will be particularly catastrophic for Pakistan where an estimated 50 % or more of river run-off flowing into the Indus Basin Irrigation river basins. Table 2 present the water resources and their composition in terms of availability and utilization as well as various end uses of sectors in the economy. It is quite evident that agriculture is the main sector which has major share of consumption of water for irrigation purpose.

Table 2: Water resources of Pakistan

Parameters	**Amount**
Annual precipitation	< 100 mm in parts of the Lower Indus Plain to > 750 mm near the foothills in the Upper Indus Plain
Utilizable water	169,384 billion m^3
Available water resources per capita	3,420 m^3
Surface water (storage and diversion)	147 MAF
Ground water (replenishible)	50 MAF
Present utilization (surface water 63%, ground water 37%)	176 MAF
Water use for irrigation (out of 169,384 billion m^3)	83%
Water use for domestic purposes	2%
Water use in industry, energy and other sectors	5%

Increase in persistency of drought requires a re-examination of our assumptions, operating norms and contingency measures for existing and planned water-management measures. Droughts produce the additional burden of migration of population from neighboring regions into lands that are already stretched to the maximum. Besides the social disruptions, there is the cost of the degradation of the natural resources due to the over-exploitation.

The United Nations report in 1997 determined each member country's ratio of water-consumption to water-availability, in order to gauge the overall pressure on its water-resources. The report predicts that moderate to high water-stress translates to consumption-levels that exceed 20 per cent of available supply. In Pakistan, this ratio has already exceeded 65 percent! Water-use in agriculture is projected to increase as our food-demand rises. World-wide, agriculture accounts for about 70 per cent of water-consumption; in Pakistan, its share is already 95%. Future projects show a 50- to 100-percent increase in demands for irrigation water by 2020. Figure 2 depicts the water requirements of the country in different sectors.

Water Requirements

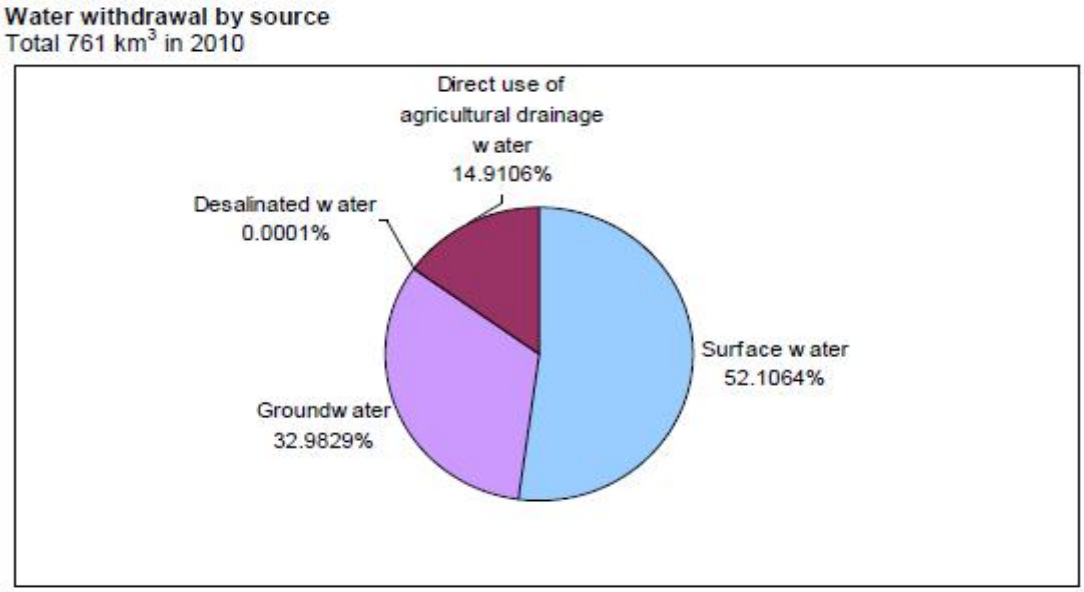

Fig 2: Water withdrawal by source

Agricultural Demands

Pakistan is a country, which is required to double its annual food production every 15 years, in order to maintain its statusquo in meeting requirements of food. This target, on the surface, may not look so demanding, as the country is bestowed with enough fertile and productive lands and sufficient freshwater-resources. Despite the availability of these basic resources, unfortunately the country has to import large quantities of food commodities every year. With the current population of about 140 million people growing at the rate of almost 2.5% per annum, the country would have to feed 120 million additional mouths by the year 2025. Table-3 shows the production and water-requirements of some major crops needed to maintain self-sufficiency in these food grains, which may be compared with future water needs.

Table 3: Agriculture Water Demands (MAF)

Crops	**1990**	**2000**	**2025**
Wheat	26.27	28.8	56.91
Rice	18.78	22.24	16.68
Cotton	13.68	15.71	19.35
Sugarcane	11.35	13.41	13.93
Other Crops	28.93	30.59	46.74
Total with Losses @70%	168.32	188.28	261.14

Domestic and Industrial Needs

Table - 4 shows the domestic present and future domestic requirements, based on a per-capita demand of 46m3 per annum. The corresponding industrial water-demand is considered negligible when compared with the domestic and agricultural demands.

Table 4: Water Demand for Domestic Use

Year	**1990**	**2000**	**2025**
Population (Million)	110	140	260
Water Demand (MAF)	4.1	5.2	9.7

Pakistan is highly vulnerable to climate change as its economy is heavily reliant on climate-sensitive sectors like agriculture and forestry, and its low-lying densely populated deltas are threatened by a potential risk of flooding. In Pakistan, annual mean surface temperature has a consistent rising trend since the beginning of 20th century. Considering Table 5, rise in mean temp. of 0.6-1.0°C in arid coastal areas, arid mountains and hyper arid plains, 10-15% decrease in both winter and summer rainfall in coastal belt and hyper arid plains, 18-32% increase in rainfall in monsoon zone especially the sub-humid and humid areas is observed. There is 5% decrease in relative humidity in Balochistan, 0.5 to 0.7% increases in solar radiation over southern half of country.

Table 5: Temperature Change during 1951 – 2000

S.No	**Region**	**Trend during last century**	**Range (°C)**
1	Over the Thermal Low Region	(Increased)	0.2 to 1.0°C
2	Coastal Areas (Balochistan)	(Decreased)	0.5 to -1.5°C
3	Monsoon belt	(Generally decreased)	2.0 to 0.0°C
4	Northern Mountains (Greater Himalayas)	(Generally increased)	1.5 to 1.5°C
5	Thar region	(Increased)	0.3 to 1.0°c
6	Sindh Coast	(Generally Increased)	0.0 to 0.5°c

There is 3-5% decrease in cloud cover in central Pakistan with increase in sunshine hours, 3-5% increases in ETo due to 0.9°C temperature increase. 5% Increase in net irrigation water requirement with no change in rainfall. Expanding aridity in Northern parts outside monsoon range and arid regions. During last 100 years, 7 strong, 10 moderate and 7 weak EL-Nino events 17-64% departure of rainfall from normal during strong events.

Projected Changes in Precipitation and Temperature

SCHENGEN model was used for generating climate change scenarios during next half of 21st century in Pakistan, based on 1931-2010 data. Results indicate a progressive change in temperature during the period. However changes in rainfall pattern may not be uniform and south-western coastline and western Balochistan may experience low rains.Results indicate that during monsoon, temperature change over seasonal low is relatively slow compared to other arid and hyper arid region due to windy conditions?

Potential Impacts of Climate Change

Global weather changes and water- resources are deeply inter-related. The largest source of freshwater is rain. Global climatic changes will have major effects on precipitation and runoff. In the relatively arid and semi-arid regions, modest changes in precipitation can have proportionally large impacts on water supplies. In mountainous watersheds, higher temperatures will increase the ratio of rain to snow, accelerate the rate of spring snowmelt, and shorten the overall snowfall season, leading to more rapid, earlier, and greater spring runoff. Because the temperature projections of climate models are less speculative than the projections of precipitation, temperature-induced shifts in the relative amounts of rain and snow and in the timing of snowmelt in mountainous areas are considered highly likely. Climate-induced changes in hydrology will affect the magnitude, frequency, and costs of extreme events, which produce the greatest economic and social costs to humans. Flooding could become more common and extreme. Recent reports of the Intergovernmental Panel on Climate Change (IPCC) suggest that a greenhouse warming is likely to increase the number of intense- precipitation days as well as flood-frequencies in northern latitudes and snowmelt-driven basins. These reports also suggest that the frequency and severity of droughts could increase in some areas, as a result of a decrease in total rainfall and more frequent dry spells.

According to the climate change scenario, the global warming should be reflected in the river-flow data of Pakistan, especially in the nineties. From the data available from 1975 to 2000, the following picture emerges. In the post-Tarbela era, the water diverted from the rivers to the canal system has remained constant around 104 MAF per year (128 bm).
The fresh-water outflow to the sea may, therefore, be considered to be a good indication of the total river flow for this period. From the year 1975/76-1989/90 the average flow into the sea per year has been 34.13 MAF/year. However from the year 1990/91 to 1999/2000, this flow has been 47.88 MAF/year i.e. about 40 % greater. For the winter season for the same period, the average flow into the sea from the year 1975/76-1989/90 was 1.86 MAF/year. However from the year 1990/91 to 1999/2000, this flow has been 3.28 MAF/year, i.e. about 76 % greater. Although other factors may also be contributing, nevertheless the change visible in this time-frame is quite large. This increased river-flow could be taken as evidence for local effect of global warming. The global warming impact is expected to impact initially on the river-flow to increase, as the glaciers melt, then decrease as they recede.

Diminishing flows in Indus Basin

Glacial melt water is a key source of water for river system in Pakistan. However, along the eastern slopes of the Himalaya, glacier cover has decreased rapidly in recent years, and total cover is now approaching the lowest experienced in the past 10 000 years.

The Gangorti glacier is retreating 98 feet per year. At this rate scientists predict the loss of all central and eastern Himalayan glaciers by 2035. As the glacial cover has decreased, so have the downstream flow volumes. Analysis of precipitation and inflow data shows a direct relationship indicating that, in dry years inflows are reduced despite the fact that temperatures were higher in upper watersheds. This finding appears to contradict projections of the Intergovernmental Panel on Climate Change that warmer temperatures will cause glacial contributions to downstream flow regimes to increase in the short term. However, historical stream flow data indicates that this increased flow phase has already passed, and that the basins have entered a potentially long-term trend of declining flows. The continuation of this trend would exacerbate water shortages that were already apparent across the country during recent severe drought. Increased temperature with or without any change in precipitation, over

the last few decades is causing glacier melting leading to higher rates of sliding and sediment loads in the upper watershed.

Quality of Fresh Water

Water quality would suffer from the projected impacts of climate change. Poor water quality effectively diminishes the availability of potable water, and increases the costs associated with rendering water suitable for use. Changes in water quantity and water quality are inextricably linked. Lower water levels tend to lead to higher pollutant concentrations, whereas high flow events and flooding increase turbidity and the flushing of contaminants into the water system.

Conclusion

The developing countries of Asia, like Pakistan, where impacts of climate change are likely to be felt most severely because of resource and infrastructure constraints, need to develop and implement incremental adaptation strategies and policies to exploit no regret measures and stressing the importance of considering climate change in planning, designing and implementing development activities.

The first is a macro strategy and involves rapid sustainable and equitable development that will increase income levels; education and technical skills; improve public food distribution, disaster preparedness and management and health care systems and reduce vulnerability. The second strategy is a micro strategy and involves the management of sectors most sensitive to the climate change. This means developing new institutions or modifying existing ones to promote adaptation to climate change. It would also involve modifying climate-sensitive infrastructures already planned or implemented or other long-term decisions that are sensitive to climate.

Abstract

Work contains materials on helminthes, parasitizing at predatory mammals in the conditions of the urbanized territories of the Voronezh region. In the studied territory at predatory 33 helminthes species is revealed. Among them nematodes (17 species) dominate, further follow cestodes (9 species) and trematode (6 species), the minimum number of species is noted among acanthocephalan (1 species). In the urbanized territories, more than 20 species of activators zoonotic helminthosen circulate. Results of these researches show that the red fox plays important role in maintenance of functional stability of the natural centers zoonotic helminthosen. In the urbanized territories, the red fox actively joins in circulation zoonotic helminthosen.

Keywords: urbanized territories, zoonotic, predatory mammals, helminthosen

Introduction

Circulation helminthosen is represented as difficult structured process caused by a combination of various ecology-biological factors. A specific variety and number of local populations belong to these factors helminthes, secondly, a biodiversity of animals owners, thirdly, structure and quantitative parameters of biotic and abiotic components in ecosystems, first. Interaction of the listed factors influences features and regularities of realization of life cycles and functional stability of helminthes parasitic systems, respectively, circulation helminthosen (Galaktionov, Dobrovolskij, 2003; Roitman, Beer, 2008).

Now considerable influence on shape and a condition of ecosystems renders anthropogenous factors, which can change the qualitative and quantitative status of certain species of parasitic worms. Due to the features of ecology helminthes, three main forms of circulation helminthosen are allocated: natural, anthropogenous and natural and anthropogenous. Natural forms are dated for natural ecosystems where circulate helminthes in populations of wild animals. Parasitic worms are considered as important components of natural ecosystems which influence an organism, populations and communities of animals hosts (Hechinger et al., 2008). Anthropogenous forms are connected with the urbanized territories where the leading role in circulation helminthes is played by pets and the person. The natural and anthropogenic form arises in adjacent (buffer) territories of natural and anthropic ecosystems. These conditions influence formation of a certain biodiversity helminthes and specialized ecological communications. There is a system of optimum factors for transfer of activators helminthosen on the urbanized territories and their subsequent adaptation in a format of anthropogenic circulation (Romashov, 2009).

In circulation of numerous group zoonozny гельминтозов wild predatory mammals have importance. Predatory (Carnivora) - one of the most representative on a specific variety and number of groups of animals among mammals. They occupy the highest levels of an ecological pyramid and have wide tropology-horology communications. At predators the numerous fauna on a specific variety helminthes as a part of which the considerable share is presented by activators zoonotic helminthosen was created. Predatory mammals as the integral components are built in process of circulation of activators of the majority natural

centre helminthosen and play a role of obligate owners and reservoir (Pozio et al., 2001; Deplazes et al., 2004; Romashov et al., 2006; Denzin el al., 2009).

Taking into account ecological and ethological factors between wild and house predators there are various trophic communications which cause an active exchange helminthes. House predatory (dogs and cats) are carriers of a large number helminthes and important links in ecological chains of circulation zoonotic helminthosen (Dyachenko V. et al., 2008). It is established that with participation of wild and house predatory more than 70% zoonotic helminthosen circulate.

Now concerning considerable number zoonotic helminthosen strengthening of epizootic intensity in connection with big number of vagrant dogs and cats in the cities and in rural settlements is registered. On the other hand separate species of wild predators, for example, a fox and a wolf, possess high ecological plasticity. These types successfully adapt in anthropogenic conditions and actively participate in circulation zoonotic helminthosen. In this regard. researches on fauna and ecology studying helminthes in the conditions of the urbanized territories have scientific and practical value and are directed on the solution of tasks in the field of applied medicine, veterinary science and ecology.

Results of research are given in the real work helminth fauna and ecological aspects of circulation zoonotic helminthosen in the conditions of the central part of the European Russia (Voronezh region). The quantitative analysis of fauna and contamination of predatory mammals of helminthes, with an assessment of their number and occurrence is carried out.

Materials and methods

Original materials of helminthes are collected from predatory mammals in various regions of the Voronezh region on an extent more than the 20-year period (1990-2014). The method of complete helminthological openings (Ivashkin et al., 1971) investigated over 200 individuals of the predators relating to 12 types: the canidae - 4 species (a wolf, a fox, a raccoon dog, a house dog), marten – 7 species (a badger, an otter, a wood marten, a stone marten, steppe polecat, the american mink, caress), cat's - 1 species (a house cat). Materials are received from animals at carrying out regulation actions, registration researches and from victims of animals. Quantitative indices of contamination and distribution helminthes in owners estimated on the following indicators: occurrence (extensive of infection), intensity of an infection, abundance index (Beklemishev, 1970).

Results and discussion

The received helminthological materials are analyses in the following directions. First, the modern helminth fauna wild and house carnivorous is investigated quantitative data on contamination helminthes owners are secondly obtained the differentiated assessment of quantitative parameters concerning epidemiologically significant species helminthes, circulating with participation wild and house predators is thirdly made.

By results of researches at wild predators 33 helminthes species, presented by four taxonomic groups - Trematoda, by Cestoda, Nematoda and Acanthocephala is revealed (tab. 1). The maximum number of types is noted as a part of nematodes (17 species), further follow cestodes (9) and trematodes (6), the minimum number of species is revealed among acanthocephala (1). Among predators the highest indicators of a helminthes species variety are noted at a fox - 24 species (tab. 1). At other species of predators a helminthes species variety is essential below: at a wolf it is revealed - 12 species, a stone marten - 11 species, a raccoon dog and a wood marten - on 9 species, the american mink - 8 species, a badger - 7 species. The minimum number of helminthes species is revealed at an otter - 3, caresses - 3, steppe polecat - 1.

Table 1 Helminth fauna at wild predators in the territory of the Voronezh region

The helminthes species	The host species

The leading role in circulation zoonotic helminthosen is played by a fox of which share the maximum number of species in structure helminth fauna predators is the share. Quantitative parameters of occurrence and number helminthes, parasitizing at a fox are analyses, the measure of representation of separate species helminthes is inadequate (tab. 2). Taking into account occurrence indicators (extensiveness of an infection) and an abundance (number) among helminthes four groups are allocated: dominants, subdominants, intermediate and rare (casual) species.

Table 2. Distribution helminthes at a fox on extent of domination

Helminthescategory	Helminthes species	Contaminationindicators	
		Extensiv of infection%	Index abundances (number), specimen
Dominants	*A. alata*	75,0	82,0
	T. canis	71,4	8,2
	E. aerophilus	62,5	4,3
	C. plica	53,6	3,25
Subdominants	*T. leonina*	34,0	2,2
	T. nativa	33,9	18,4 (in 1 g of muscles)
	T. crassiceps	33,3	3,2
	C. vulpis	25,0	3,7
	T. hydatigena	25,0	3,62
	U. stenocephala	23,2	2,5
Intermediate	*D. caninum*	17,8	3,9
	T. mystax	17,8	0,46
	M. lineatus	12,5	5,5
	O. felineus	11,1	0,5
	P. truncatum	11,1	0,4
	C. putorii	8,9	0,48
	H. taeniaformis	5,4	0,07
	E. boehmi	3,6	0,09
Casual	*T. pisiformis*	1,8	0,26
	T. krabbei	1,8	0,2
	E. multilocularis	1,8	0,2
	D. immitis	1,8	0,09
	M. catulinus	1,8	0,07
	M. bilis	1,1	0,8

The numerous helminth fauna at a fox is caused, in our opinion, by two major ecological factors, first, high number of this predator, secondly, its wide ecological valence. If to estimate a contribution of separate species of predators to formation process of helminth fauna and at maintenance of its «status quo», the leading role in this process belongs to a fox. Among registered helminthes (tab. 1, 2) a considerable part have epidemiological and epizootological value. In turn it assumes an active exchange helminthes with other types both wild, and the house carnivorous.

Let's note that in the territory of the Voronezh region, the fox, among predatory mammals, is the most numerous both in natural ecosystems, and on recreational and farmlands. In this regard the fox plays important role in maintenance of functional stability and circulation of a large number natural center zoonotic helminthosen. In this regard we analyses the original helminthological materials characterizing ecology-epizootology aspects circulating zoonotic helminthosen where the fox is an active and important link of this process.

By consideration of these materials the main accent is made on activators zoonotic helminthosen which taking into account literary data and own researches are registered as at pets, first of all dogs and cats, and at the person. Besides, across the Voronezh region there are

not numerous materials on fauna and distribution helminthes among the house carnivorous. At present for the studied territory from among zoonotic helminth species, found in a fox, it is necessary to consider the most part as "potential" activators zoonotic helminthes.
By results of the real researches at a fox 22 species of agent zoonotic helminthosen as a part of which each of taxon (at level of classes) is presented by various quantity of species are registered. The greatest number of species is revealed among nematodes - 10 species: *Toxocara canis, T. mystax, Toxaskaris leonina, Trichinella nativa, Dirofilaria immitis, Uncinaria stenocephala, Capillaria putorii, C. plica, Eucoleus aerophilus, Crenosoma vulpis* (fig. 1).

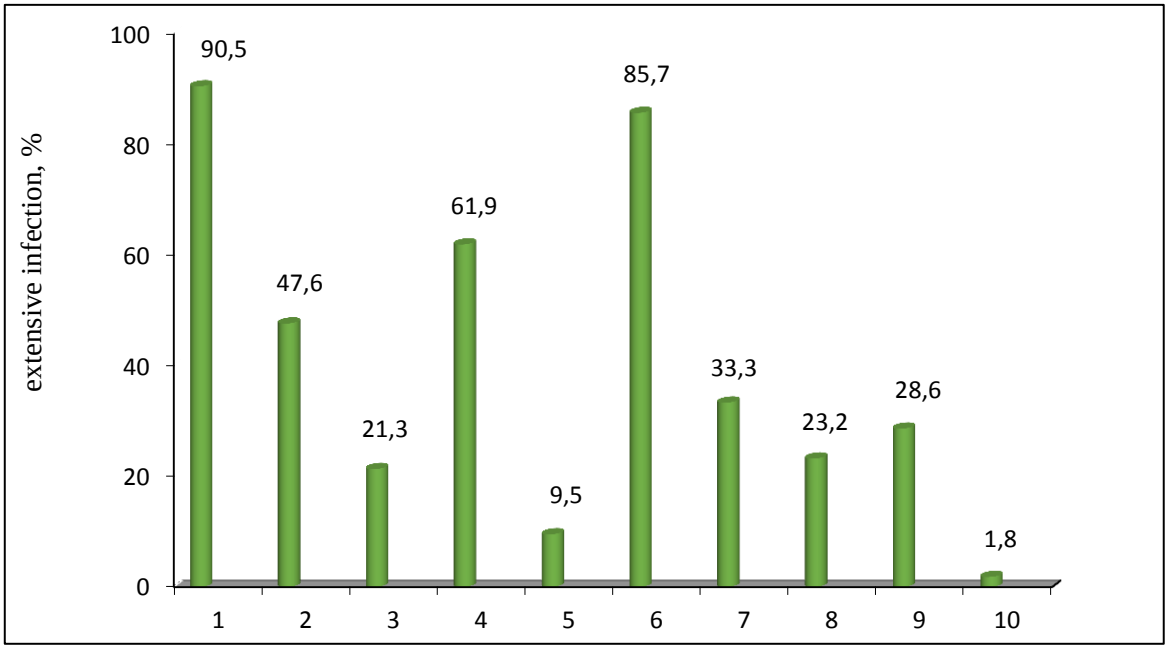

Fig. 1. Contamination of fox (extensive infection) nematodes (agent zoonotic helminthosen) in the urbanized territories of the Voronezh region:
1-Toxocara canis, 2 - T. mystax, 3 – Toxaskaris leonina, 4 - Capillaria plica, 5 - C. putorii, 6 – Eucoleus aerophilus, 7 – Trichinella nativa, 8 – Uncinaria stenocephala, 9 – Crenosoma vulpis, 10 – Dirofilaria immitis.

The highest index of extensive infection are noted at 4 species: *T. canis* (90,5 %), *E. aerophilus* (85,7 %), *C. plica* (61,9 %) and *T. mystax* (47,6 %). The second level is occupied by 3 species of nematodes, contamination with which hesitates from 20 to 30 %, including *T. nativa* (33,3 %). For other 2species of nematodes index of extensive infection less than 10 % are noted (fig. 1).
From among the registered nematodes from the point of view of applied medicine and veterinary science in the territory researches nematodes of the genus *Trichinella*, *Toxocara*, *Toxaskaris*, *Dirofilaria* and *Eucoleus* are the most actual. Now study of epidemiological and epizootological intensity in the relation nematodosis, which agent are nematodes of this group is observed. In particular, over the last 10 years trichinellosis and dirofilariosis got the status endemically circulating natural очаговых invasions in the territory of the Voronezh region (Romashov et al., 2006; Volgina et al., 2013).
By rather numerous group of number zoonotic helminthosen are presented trematodes - 4 species and cestodes - 8 species. Among trematodes registration at a fox of three opisthorchidae species (*Opisthorchis felineus, Pseudamphistomum truncatum* and *Metorchis*

bilis) (fig. 2) is remarkable. These facts indicate active participation of a fox in circulation of the natural centers opisthorchosis.

From number трематод the highest index of extensive infection and index of abundance are noted at *Alaria alata* (75,2 % and 82,0 specimen) (tab. 2, fig. 2). Now the increase in a hostal component of this trematode is observed, the range of definitive hosts, which actively include also the house carnivorous extends.

Contamination cestodes varies, including the highest indicators (from 25 to 30 %) are revealed at two species: *Taenia hydatigena* and *Taenia crassiceps*, *Mesocestoides lineatus*, the second level (from 10 to 20 %) occupy three look: *Dypilidium caninum*, *Mesocestoides lineatus* and *Hydatigera taeniaformis*, the minimum indicators are noted at *Echinococcus multilocularis*, *Taenia pisiformis* and *T. krabbei* (fig. 2).

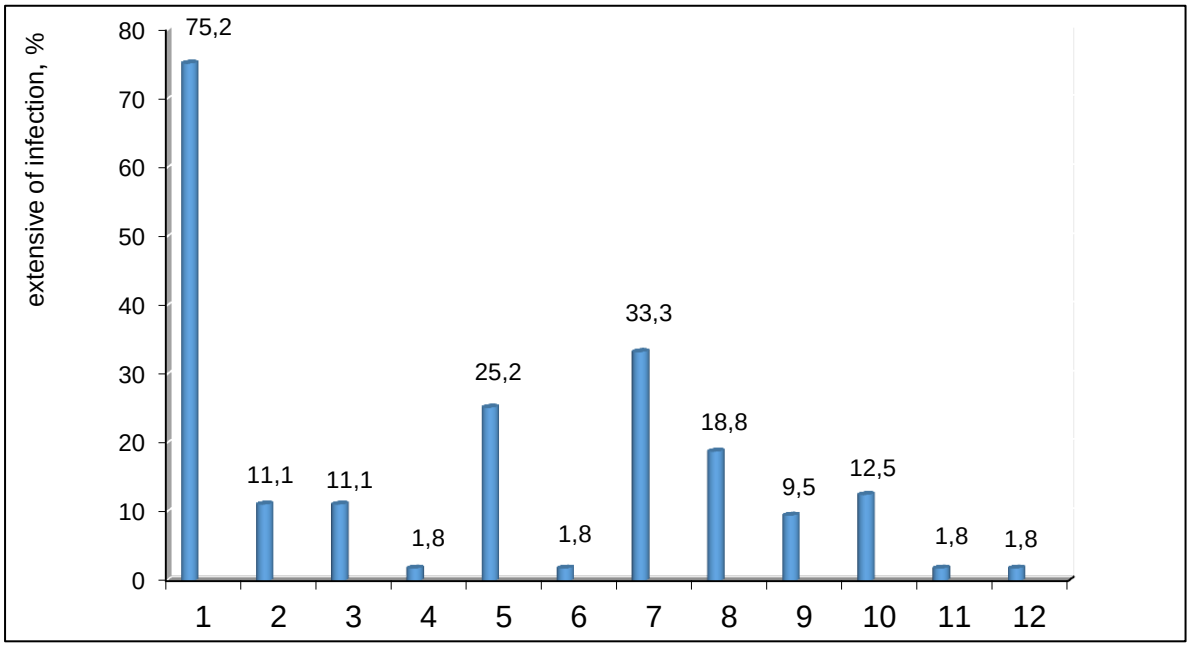

Fig. 3. Contamination of fox (extensive of infection) trematodes and cestodes (zoonotic helminthosen) in the urbanized territories of the Voronezh region: *1-Alaria alata, 2 – Opisthorchis felineus, 3 – Pseudamphistomum truncatum, 4 – Metorchis bilis, 5 – Taenia hydatigena, 6 - T. pisiformis, 7 - T. crassiceps, 8 – Dypilidium caninum, 9 – Hydatigera taeniaformis, 10 – Mesocestoides lineatus, 11 – Echinococcus multilocularis, 12 – Taenia krabbei.*

Results of these researches show that the fox plays important role in maintenance of functional stability of the natural centers and circulation of a large number of zoonotic infection. On the other hand in the conditions of anthropogenic ecosystems, for example, farmlands and rural settlements, the fox actively joins in circulation zoonotic helminthosen. In these conditions the anthropogenic component presented helminthozoonosen, which are dissemination mainly among housedogs and cats, is dominance. The fox in this case can play a role of an additional ecological link, as a source and a factor of accumulation and distribution of activators of these infections in the conditions of urbanized territories.

Abstract

Distric cambisols are very abundant in the Vlasenica area which is located in the eastern part of Bosnia and Herzegovina (BiH), occupying ¾ of the municipality's areas. They were formed on different parent substrates where the different properties of soil are inherited. The characteristics of dystric cambisols formed on sandstones and shale, and under different types of land use: arable land - maize, orchards - plum and meadows, were analyzed in this paper. The aim was to determine the influence of land use and management practices on the basic parameters of dystric cambisols on various substrates. The following physical properties were also analyzed in this paper: texture, real specific weight and bulk density, porosity, water retention capacity, permeability to water and air capacity. The chemical characteristics were analyzed as follows: active and substitution acidity of soil, humus and nitrogen content, availability of phosphorus and potassium. Profiles are open one per each land use, both on the sandstones (profiles 2, 3 and 8) and on shale (profiles 4, 10 and 11) parent substrates. The most favorable physical and water-physical properties were observed in land under plum orchards that are covered with grass and meadows on both substrates. The highest content of humus on shale in the Ah soil horizon was also recorded under arable land, and on sandstones in the Ah soil horizon under orchard. In the surface horizon in the soil under maize in both examined parent materials, the highest content of available phosphorus and potassium is recorded in comparison to the other tested variants of land use.

Keywords: Distric cambisol, land use, the parent substrate, the physical and chemical properties.

Introduction

Distric cambisols occupy a substantial part of the territory of BiH (28.73% of the area is distric cambisole which is formed on different parent material of the total land area in BiH), including the Vlasenica area, with 3/4 of the entire surface.

Parent material of substrate has a twofold impact on the process of soil formation with both physical properties of rocks (compactness, binding, looseness, the degree of dispersion) and mineral composition of rocks (impact on soil fertility), which has been confirmed in many scientific papers (Szafranek and Sklodowski, 2006; Knezevic et al., 2011).

Soil quality is significantly dependent on its natural origin and conditions of their origin, but it also depends on changes caused by its use (Kastori and Milosevic, 2011).

The aim of this study is to determine the impact of land use and management practices on the basic parameters of distric cambisols on various substrates.

Material and method

A total of 6 of the profile, the profile 3 on sandstones (sections 2, 3 and 8) and the profile 3 on the shales (sections 4, 10, 11) were analyzed. Profiles are open in the soil under different modes of use: arable land - maize, orchards - plum and meadows.

Area under meadows was previously used for growing field crops, 7-10 years ago. Manure is introduced to the land under maize every three years in the fall, and the fertilizer is used as a starter fertilizer and as a top dressing (urea, KAN). Plowing of crop residues is not performed. On the land that is under orchard, 5 years old, previous culture was a meadow (sections 8 and 4). In the row, and between the rows of orchard, land is under grass cover.

For laboratory analyzes, the soil samples in disturbed and undisturbed condition of all genetic horizons were collected.

Laboratory analyzes of soil were performed as follows:

Texture of soil is determined by the modified pipettes B method where the coarse sand is separated in sieve. Sample preparation for analysis was performed with Na pyrophosphate by Thun, and the texture class based on the classification by Ehwald.

Albert - Boggs's method was used to determine real specific mass of soil (S_{mp}, g/cm^3) with xylol, and the bulk density of soil (S_{mv}, g/cm^3) in the Kopecky´s cylinders of 100 cm^3 volume, by moistening to the retention capacity, weighing, drying at 105°C and re-weighing.

Total porosity (%) is determined by calculation of the difference between values of real and bulk specific soil mass ($P_{vol\%}=S_{mp} - S_{mv}/S_{mp}$ x 100).

According to the Kopecky method water retention capacity (% volume) was determined. Filtration coefficient (K-Darcy) is defined in the natural undisturbed soil samples (in the cylinders by Kopecky).

Air soil capacity is determined by calculation of the difference between the value of total porosity and water retention capacity.

pH value in H_2O and KCl were determined in a suspension of 1:2.5 on the pH meter electrometrically, and humus content was determined by Tjurin method in Simakov modifications in the calorimeter.

The total nitrogen content was determined by the Kjeldahl method in modification by Bremner. According to the Al method by Egner–Riehm–Domingo was determined content of available phosphorus and potassium

Results and discussion

Textural composition of soil

The fraction of silt is in average dominant in the Ah horizon profile of the sandstones and shales (Table 1).

In (B) horizon of the profile on the sandstones slightly higher average content of the sand fraction was recorded (40,18%) compared to the fraction of the silt (37,46%), while in (B) horizon of the profile on shales showed highest average content of clay (43,02%).

On both analyzed parent substrates, content of silt decreases with depth, while the clay fraction content increases.

The content of sand fraction increases with profile depth in the sandstones, and in shales profiles it decreases with the depth of the profile.

Table 1. Texture composition of soil

Parent substrates	Profile	Land use.	Sand (%)		Silt (%)		Clay (%)		Texture class (classification by Ehwald)	
			A_h	(B)	A_h	(B)	A_h	(B)	A_h	(B)

Physical properties

Physical properties of dystric cambisols are mainly related to the parent substrate. The higher value of bulk density in the sandstones profiles compared to the shales profile is a consequence of different mechanical composition that is inherited from the parent material (Table 2).

Because of the large amount of humus, higher aggregation and porosity and lower subsidence of Ah horizon compared to deeper horizon, the value of bulk density in the analyzed profiles increases with depth. The maximum value of bulk density in the Ah horizon in the profiles of the sandstones and is observed in the profiles under maize. Increased bulk density in the soil which is cultivated in relation to the uncultivated is the result of continuous tillage (Idowu, 2005).

Real specific weight in both horizons profiles on sandstone and shales are slightly different in average.

The soil is porous in all samples, except in the (B) horizon of the profile 3 (maize) where low porosity is recorded. Somewhat higher average value of total porosity was recorded in both the horizons of the profiles in relation to the profiles on sandstones. Due to the increased presence of organic matter in the Ah horizon, total porosity in all tested profiles is higher in Ah horizon in relation to the horizon (B) (Tilahun, 2007).

Profiles under maize and shales in the Ah horizon have the lowest porosity. The tillage increases compactness within the arable layer and destroys most of the secondary pores; therefore, the lowest total porosity in the test soil was observed in the soil under maize.

The maximum porosity in the profiles on sandstones and shales in the Ah horizon was recorded in sections 3 and 11 under orchard. In all the tested samples, mean water retention capacity was recorded, except in both horizons of the profile 10 (meadow) and (B) horizon of the profile 11 (maize), where high water retention capacity was recorded.

There is s minor difference in average water retention capacity of the profiles of the sandstones and shales, while cambic horizon has high water retention capacity due to greater presence of clay fraction, the average value of retention of water capacity profile in shales is higher compared to average value water capacity retention of in the profiles of the sandstones.The highest retention of water capacity value in Ah horizon profile of the sandstones was recorded in the profile 8 under orchard, and profiles on shales in the profile 10 under meadow.

In Ah horizon of the analyzed profiles the soil is very permeable, and in (B) horizon the permeability is medium. The average permeability coefficient of Ah horizon in the sandstones and shales profiles and are slightly different, while in (B) horizon the permeability is greater in sandstone profiles than in shales profiles.

Table 2. Water-physical properties of soil

Parent substrates	Profile	Land use.	Bulk density (g/cm^3)		Real specific weight (g/cm^3)		Total porosity (%)		Water retention capacity (vol. %)		Filtration coefficient (m/day)		Air capacity (vol. %)	
			A_h	(B)	A_h	(B)	A_h	$(B)_h$	A_h	(B)	A_h	(B)	A_h	(B)
Sandstones	2	meadows	1,17	1,35	2,60	2,73	55,00	50,55	41,00	39,00	1,42	0,82	14,00	11,5
	3	maize	1,25	1,59	2,65	2,74	52,83	41,97	42,50	36,00	1,45	0,78	10,33	5,97
	8	orchards	1,13	1,49	2,64	2,79	57,20	46,59	44,50	36,00	1,20	0,49	12,70	10,5
Average value			1,18	1,48	2,63	2,75	55,01	46,37	42,67	37,00	1,36	0,70	12,34	9,37
Shale	4	orchards	1,05	1,40	2,62	2,71	59,92	48,34	43,50	42,50	1,40	0,55	16,42	5,84
	10	meadows	1,16	1,19	2,66	2,82	56,39	57,80	45,50	50,50	1,46	0,39	10,89	7,30
	11	maize	1,23	1,27	2,67	2,80	53,93	54,64	39,00	45,50	1,30	0,40	14,93	9,14
Average value			1,15	1,29	2,65	2,78	56,75	53,59	42,66	46,16	1,39	0,45	14,08	7,43

Air capacity in the examined profiles is highly variable. The air capacity in Ah horizon is medium (profiles 3, 10), very high (profiles 2, 8 and 11) and very high (profile 4). In (B) horizon in the profiles 3, 4 and 10 there was a low air capacity, and in profiles 2, 8 and 11 medium air capacity was recorded. The lowest air capacity value in Ah horizon of the sandstones profile was recorded in the profile 3 under maize (10.33 vol. %), and the highest in the profile 2 under meadow (14.00 vol. %). Air capacity is variable which is rapidly changing in the upper layers through tillage, increasing with loosening and reducing compaction due to trampling and natural subsidence. In the profiles of the shales in the Ah horizon the minimum value of air capacity is recorded in the profile 10 under meadow (10.89 vol. %), and the highest in the profile 4 under orchard (16.42 vol. %).

Chemical properties

Parent substrate with its mineral composition is the most important pedogenetic factor which forms chemical properties. Apart from being the result of type of organic matter transformation, the acidic reaction of soil is also the product of parent substrates which are poor with alkali (Knezevic et al., 2011).

On the basis of the recorded values of the pH in 1 M KCl in Ah horizons the analyzed soil was generally very strongly acidic (profiles 4, 8 and 10) and very acidic (profiles 2, 3 and 11). In all (B) horizons of the tested profiles the soil was very acidic (Table 3).

The pH in H_2O and KCl decreases with depth of profiles. The lower average value of pH in H_2O and KCl in Ah horizon was recorded on the shales profiles in relation to the profiles in sandstones. The highest pH value in H_2O and KCl in profiles of the sandstones in the Ah horizon was recorded in the soil under meadow, and then in the soil under the maize, and the lowest pH in H_2O and KCl was observed in the soil under orchard. The highest pH value in H_2O and KCl in profiles of the shales in Ah horizon was recorded in the soil under maize and the lowest in the soil under orchards.

Ah horizon of the analyzed soil is a poor to moderate humus content, while (B) horizon in all tested profile has poor humus content. The average value of humus in the profiles on the sandstone is slightly higher in comparison to the profiles on the shales. The humus content rapidly decreases with depth in all profiles. In the profiles of the sandstones in the Ah horizon the highest humus content was recorded in the soil under orchards (2.35%), and slightly lower in the soil under the maize (2.08%). The lowest humus content is recorded in the soil under meadows (1.74%). In the profiles of shales the highest humus content was recorded in the Ah horizon land under maize (2.33%), as a result of the application of manure and fertilizers. The minimum content of humus in the Ah horizon in the profiles of the shales was recorded in the profile 4 under orchard (1.30%).

Table 3. Chemical properties of soil

Parent subtrates	Profile	Land use	pH in H_2O		pH in KCl		Humus (%)		Total nitrogen (%)		P2O5 mg/100 gr soil		K2O mg/100 gr soil	
			A_h	(B)	A_h	$(B)_h$	A_h	(B)	A_h	(B)	A_h	(B)	A_h	(B)
Sandstones	2	meadows	5,45	4,66	4,64	3,93	1,74	0,30	0,09	0,02	2,30	0,50	18,4	14,3
	3	maize	5,08	4,57	4,56	3,87	2,08	0,32	0,10	0,02	3,26	0,00	27,1	10,5

Average value			5,14	4,63	4,4	3,88	2,00	0,44	0,10	0,02	2,42	0,20	16,9	9,80
Shale	4	orchards	4,20	4,02	3,54	3,49	1,30	0,15	0,06	0,01	0,62	0,00	9,00	6,60
	10	meadows	5,19	5,31	4,23	4,02	2,02	0,25	0,10	0,01	2,10	0,11	13,4	5,90
	11	maize	5,46	4,83	4,57	3,81	2,33	0,36	0,12	0,02	2,63	0,50	22,9	18,3
Average value			4,95	4,72	4,11	3,77	1,88	0,25	0,09	0,01	1,78	0,20	15,1	10,26

Ah horizon soil profiles are moderately to well supplied with nitrogen, while the (B) horizon is poor with nitrogen. The reduction of total nitrogen with increasing depth is due to a decrease of humus content. Average values of total nitrogen in the studied profiles are uniform in both the horizon profiles on sandstones and shales. In all soil samples, readily available forms of phosphorus are low. The content of available phosphorus in the profiles on sandstones and shales in the Ah horizon is the highest in the profiles under maize, which is the result of fertilization of this soil with phosphorus fertilizers, while the lowest content of available phosphorus is observed in profiles under orchard. Provision of readily available potassium in the Ah horizon is poor (profiles 4, 8), moderate (profiles 2, 10) and good (profiles 3, 11), while in (B) horizon the soil is poorly (profiles 4, 8, 10) to moderately provided (profiles 2, 3 and 11). In average, the content of readily available potassium in Ah horizon is somewhat higher in the profiles on the sandstones compared to the shales profiles, while in (B) horizon the average content of readily available potassium is the higher in the profiles on shales compared to sandstones. The content of easily available potassium decreases with the depth of profile which is, according to Ashok (1998) result of a higher content of organic matter in the Ah horizon in relation to the adjacent horizon and due to the fertilization of the surface horizon. The profiles of the sandstones in the Ah horizon the highest content of readily available potassium was recorded in the profile 3 under maize (27.1 mg/100 g soil), and the lowest in the profile 8 orchard (5.30 mg / 100 g soil). Also, in the Ah

horizon of profile on shales, the highest content of readily available potassium was recorded in the profile 11 under maize (22.9 mg/100 g soil), and the lowest in profile 4 under orchard (9.0 mg/100 g soil). The application of organic and mineral fertilizers, the availability of physiologically active phosphorus and potassium was improved in soil under maize. From the aspect of crop production the soil under maize is well provided with potassium, which means that the application of potassium fertilizers compensated the losses of potassium which resulted from removal of the crop, fixation by clay minerals and leaching. Providing of soil with readily available phosphorus for crop production has remained poor.

Conclusion

Profiles on the sandstones have a lighter texture composition in relation to the profile on the shales as a result of the influence of parent material. The textural composition of the soil affected the water-physical properties of the soil which are favorable for plant production. Chemical properties are characterized by acid reaction of soil. The analyzed soil is poorly to moderately composed of humus in the surface horizon, and in cambic poorly. The content of humus in the Ah horizon profile on sandstones is somewhat higher than in the profile on the shales, while in horizon (B) there is higher humus content in the profiles on shales with respect to the profiles on sandstones. In the profiles on sandstones in the Ah horizon the highest content of humus is recorded in the soil under orchard, followed by soil under maize, whereas in the Ah horizon profiles on the shales, the highest humus content is recorded in the soil under maize. In the surface horizon in the soil under maize in both examined parent materials, the highest content of available phosphorus and potassium is recorded in comparison to the other tested variants of land use. Fertilization increased readily available potassium content in the tested soil, while the availability of phosphorus remains poor.

Abstract

This study is designed to determine total phenols and flavonoids and to evaluate the antioxidant activity of pomegranate peel and guava leaves methanolic extract as well as to assess the effects of pomegranate peel and guava leaves methanolic extracts against ethanol induced fatty liver in wistar rats. Both two extracts showed a good amount of phenols and flavonoids and appeared antioxidant activity in reducing power and total antioxidant capacity assay. Twenty-four male albino rats were used over a 30 day period. The animals were divided into 4 groups, where group (A) represents the negative control which was a fed basal diet, while group (B) administered by stomach tube with ethanol (2g/Kg body weight) to serve positive control. The other two groups were given ethanol supplemented with methanolic extracts of pomegranate peel and guava leaves. Group (C) was treated daily with pomegranate peel extract (200 mg/ Kg body weight), while group (D) was treated with guava leaves (200 mg/ Kg body weight). The plasma lipid profile and liver functions in the different groups were determined. The rats in the treated groups (C and D) showed significantly lower levels of total cholesterol, triglycerides, LDL- cholesterol, HDL-cholesterol, LDL-cholesterol, VLDL-cholesterol, ALT, AST and ALP activities as well as high levels of total protein in comparison with the positive control group. Our results suggests that both two plant extracts haves anti fatty liver effect which induced by ethanol treatment, and pomegranate peel extract showed highly significant effects compared with guava leaves extract.

Keywords: *Pomegranate peel, guava leaves, fatty liver, ethanol.*

Introduction

Guava (Psidium guajava) is one of the most effective edible plants and it has been used for a long time in traditional medicine. It has several biological activities such as antidiabetic (Oh et al., 2005), anticough, and antibacterial (Jaiarj et al., 1999). Recently, it has been reported to possess high potential for antioxidant activity (Guo et al., 2003). The leaf is the most effective part of guava plant (Tachakittirungrod et al., 2007).

Pomegranate is an important source of bioactive compounds and it has been used for folk medicine for many centuries. Pomegranate juice has high antioxidant activity and it is effective in the prevention of atherosclerosis (Li et al., 2006). Pomegranate peel extract could effectively protect (after oral administration) against CCl_4 induced hepatotoxicity, in which reactive oxygen species (ROS) damage was intensively involved (Murthy et al., 2002).

Purpose of this research is determination of the antioxidant activity and evaluation of the anti-fatty liver effects of guava leaves and pomegranate peel extracts on ethanol-exposed rats.

Materials and methods

Determination of total phenolic compounds, total flavonoids and reducing power

The amounts of phenolic compounds in different extracts were determined with Folin-Ciocalteu reagent using the method of (Spanos and Wrolstad, 1990) and aluminum chloride colorimetric method was used for flavonoids determination according to (Aiyegoro and Okoh,

2010) while the reducing power of different extracts was determined according to the method of (Ebrahimzadeh et al., 2008).

Biological experiment

Twenty four Male albino wistar rats weighting between 150 - 200 g each were used for this experiment. They were procured from Research Institute of Ophthalmology, Giza, Egypt. The animals were divided into 4 groups with 6 rats in each group. Group (A) served as Control. Group (B) treated with 2g/Kg body weight of ethanol. Group (C) treated with 2g/Kg body weight of ethanol plus 200 mg/Kg body weight of Pomegranate peel extract, and Group (D) received 2g/Kg body weight of ethanol plus 200 mg/Kg body weight of guava leaves extract.
Blood samples were collected after 30 days in tubes contain heparin as an anticoagulant from the eye plexuses under diethyl ether anesthesia and then centrifuged at 3000 rpm for 20 min. to obtain plasma, which was kept frozen until analysis. The total cholesterol (TC) was analyzed calorimetrically according to (Richmond, 1973). HDL - cholesterol was determined according to (Lopez et al., 1977). LDL – cholesterol and VLDL -cholesterol were calculated according to (Friedewald et al., 1972). The triglycerides (TG) were analyzed according to (Bucolo and David, 1973). The both of alanine-aminotransferase (ALT) and aspartate-aminotransferase (AST) activities were measured according to the method described by (Reitman and Frankel, 1957). Alkaline phosphatase (ALP) activity was measured by (Hausamen et al., 1967).Total protein was determined according to (Tietz, 1976), and albumin was determined according to (Doumas et al., 1971).

Statistical analysis

To determine statistical difference between means ($p < 0.01$), ANOVA and Duncan's test were calculated using SPSS statistical software package v.11. Results were expressed as mean values ± SD.

Results and discussion

Total phenolic, total flavonoids contents and in vitro antioxidant activity of plant extracts:

The antioxidant activity of plants is mainly contributed by the active compounds present in them. The phenolic contents of guava leaves and pomegranate peel extracts were found to be 98 and 187 (mg/100g), respectively, while total flavonoids content were 35 and 46 (mg/100g) respectively (Table 1). These results of pomegranate peel is agree with (Li et al., 2006) who determined total phenols and total flavonoids of Pomegranate peel and pulp, while guava leaves results is agree with (Nantitanon et al., 2010) who studied total phenols in different guava leaves extracts.
From our data we can reported that methanolic extract of Pomegranate peel have high concentration of both total phenolic compounds and total flavonoids compared with the methanolic extract of guava leaves.

Table 1. Total phenolic and total flavonoids contents of guava leaves and pomegranate peel extracts

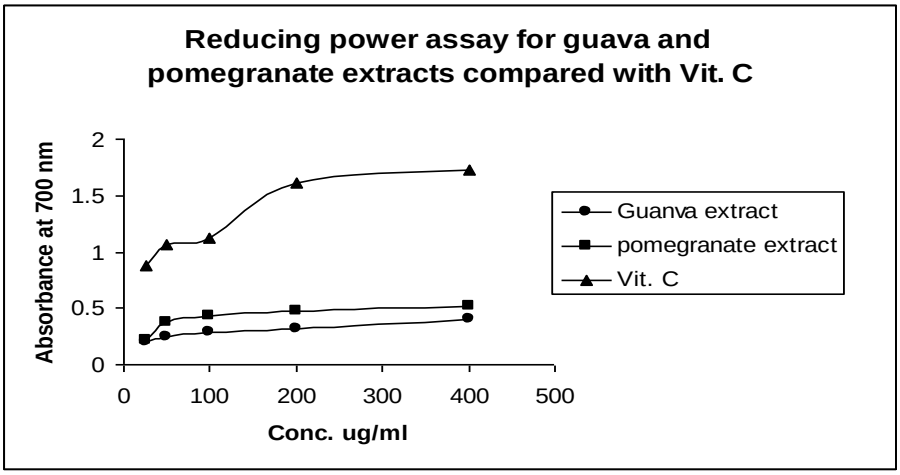
Plant extract	Total phenolic content (mg/100g)	Total flavonoids content (mg/100g)
Methanol extract of guava leaves	98	35
Methanol extract of Pomegranate peel	187	46

Figure (1) showed the dose– response curves for the reducing powers of the guava leaves extract and pomegranate peel extract. It was found that the reducing powers of extracts also

increased with an increase in their concentrations. At the highest concentration (400 ug/ml) pomegranate peel extract showed highest activity (0.521) while guava leaves extract was (0.4), at the same concentration.

Pomegranate peel extract evaluated by Ferric reducing antioxidant power (FRAP) assay, was found to be the richest source of antioxidants among peel extracts of the most commonly consumed fruits. Similarly, pomegranate peel extract demonstrated 2.8-fold higher antioxidant activity compared to pomegranate seed and leaf extracts (Tehranifar et al., 2011).

Fig. 1: Reducing power assay for guava leaves and pomegranate peel extracts



Effect of pomegranate peel and guava leaves extracts on liver function in ethanol-treated rats

The results of biochemical indicators of liver function are summarized in Table (3). The administration of ethanol caused severe hepatotoxicity in the rat, as evidenced by the significant elevations of plasma total bilirubin, direct bilirubin content, aminotransferases (ALT and AST) and ALP activities in experimental rats compared with normal control group. The levels of plasma total bilirubin and direct bilirubin in the plasma of the ethanol treated group were 1.6 and 0.8 mg/dl, respectively. Also the activities of ALT, AST and ALP in the same group were 96.5, 88.43 and 79.34 U/L, respectively. However, the activities of ALT, AST, and ALP in rats administrated with pomegranate peel and guava leaves extracts were significantly decreased. Also our data sowed significant decreased in both plasma total protein and albumin levels in ethanol treated group compared with control. The levels of total protein and albumin in the plasma of the ethanol treated group were 4.07 and 2.28 g/dl respectively. However, the levels of total protein and albumin in rats administrated with pomegranate peel and guava leaves extracts were significantly increased.

Ethanol-induced liver damage progresses through alcoholic fatty liver, alcoholic hepatitis, fibrosis and cirrhosis (You et al., 2010). Liver damage due to ingestion of alcohol is a well known phenomenon in animals. It is well-established that ethanol inhibits the mitochondrial electron transport chain, resulting in increased ROS production (Song et al., 2008). So the oxidative stress plays an important role in the development of alcohol liver disease (Yurt and Celik, 2011). Hepatic injury also results in the leakage of cellular enzymes into plasma (Baldi et al., 1993).

Increased activities of serum enzymes such as ALT and AST and decreased levels of albumin have been observed in alcohol-treated mice or rats, indicating increased permeability, damage, steatosis and inflammation (Ki et al., 2007).

Our results showed that pomegranate peel and guava leaves extracts treatments protect the liver by significantly inhibit the ethanol-induced ALT, AST and ALP activities. At the same

time increases total protein and albumin levels. And we can notice that pomegranate peel extract showed highly significant effect compared with guava leaves extract due to highly phenolic and flavonoids contents and highly antioxidant activities

Table 3. Effect of pomegranate peel and guava leaves extracts on liver function in rats treated with ethanol for 30 days.

Liver function	Group A	Group B	Group C	Group D
ALT (U/L)	34.24 ± 2.96 a	96.5 ± 3.1 d	64.83 ± 3.6 b	75.47 ± 1.28 c
AST (U/L)	22.87 ± 2.08 a	88.43 ± 1.4 d	45 ± 2.58 b	54.75 ± 2.68 c
ALP (U/L)	33.41 ± 3.6 a	79.34 ± 5 d	52.61 ± 2.16 b	62.63 ± 2.15 c
Total protein (g/dl)	5.69 ± 0.17 d	4.07 ± 0.1 a	4.94 ± .065 c	4.55 ± 0.96 b
Albumin (g/dl)	3.64 ± 0.22 c	2.28 ± 0.046 a	3 ± 0.061 b	3.2 ± 0.02 b

Values represents mean ± standard deviation (6 rats).

and when the values followed by different letters differ significantly at $p \leq 0.01$.

Effect of pomegranate peel and guava leaves extracts on plasma lipid profiles in ethanol-treated rats:

Accumulation of fat is the earliest and most common response to heavy alcohol intake. Alcoholic fatty liver is usually characterized by the enlargement of the liver, the increase of the serum and hepatic TG levels, together with a lot of fat droplets in the liver sections.

Plasma triglycerides, total cholesterol, HDL-cholesterol, LDL-cholesterol, VLDL-cholesterol levels and risk ratio were significantly increased in ethanol administered rats compared to that of control animals. In rats co-treated with pomegranate peel and guava leaves extracts along with ethanol all these parameters levels were significantly reduced compared to rats treated with ethanol alone (Table 4). Although our data appeared that, pomegranate peel extract showed highly significant effect compared with guava leaves extract and we can notice that clearly in risk ratio which showed not significant changes between co-treated pomegranate peel group and normal control rats.

In recent years, the positive effects of flavonoids on human health have attracted more attention. Especially, quercetin, a flavonoid found in many plants, is widely distributed in fruits and vegetables. Most of the biological actions of quercetin seem to be associated with its potency as an antioxidant. The antioxidant effect of quercetin has been reported by different studies (Kalender et al., 2012 and Sanchez-Gallego et al., 2011).

This is in accordance with the previous study where flavonoids presented the largest percentual reduction of cholesterol in the triton induced hyperlipidemic rats (Ricardo et al., 2001), and restores the lipid profiles to normal (Krishnaveni et al., 2010). The hypolipidemic effect may be due either to the retarding effect on lipid fraction absorption or the increase in the LDL receptor mediated cholesterol rein oval (Lieber, 1994).

Table 4. Effect of pomegranate peel and guava leaves extracts on plasma lipid profiles in rats treated with ethanol for 30 days

Lipid profiles	Group A	Group B	Group C	Group D
Triglycerides (mg/dl)	119.3 ± 6.16 a	213.05 ± 2.9 d	168.6 ± 5.79 b	192.8 ± 3.69 c
Total cholesterol (mg/dl)	89.5 ± 1.72 a	194.5 ± 5.86 d	123.25 ± 6 b	147.7 ± 5.55 c
HDL-cholesterol (mg/dl)	32.4 ± 0.57 a	52.76 ± 2.8 c	42.6 ± 1.8 b	46.28 ± 0.56 b
LDL-cholesterol (mg/dl)	33.28 ± 2.6 a	99.17 ± 4.5 d	46.9 ± 4.7 b	62.8 ± 6.4 c
VLDL-cholesterol (mg/dl)	23.86 ± 1.23 a	42.6 ± 0.59 d	33.73 ± 1.16 b	38.57 ± 0.74 c

Values represents mean ± standard deviation (6 rats).
(a, b, c, d) means in the same column followed by the same letters do not differ significantly, and when the values followed by different letters differ significantly at $p \leq 0.01$.

Effect of pomegranate peel and guava leaves extracts on liver triglycerides and total cholesterol in ethanol-treated rats:

The tissue total cholesterol and triglycerides levels were found to be significantly increased in rats administered ethanol alone. Rats co-treated with pomegranate peel and guava leaves extracts along with ethanol registered a significant decreased in tissue cholesterol and triglycerides levels compared to rats treated with ethanol alone (Figure 2). The hypolipidemic effect may be due prevention of liver from damage caused by ethanol dose.

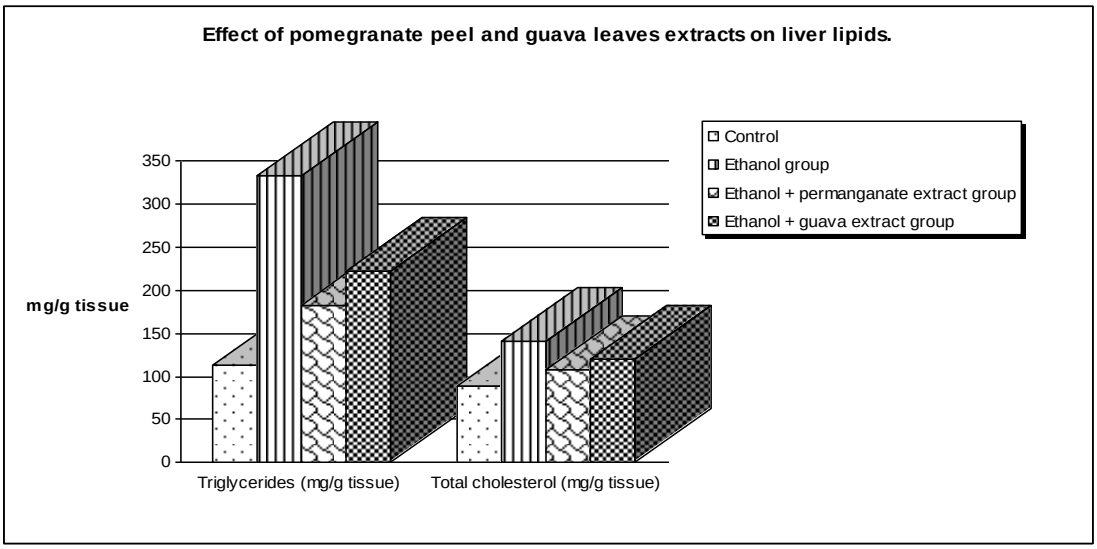

Fig.2. Effect of pomegranate peel and guava leaves extracts on liver lipids in rats treated with ethanol for 30 days.

Conclusion

From our study it is obvious that ethanol induced alteration in the lipid profile, and liver damage can be ameliorated by pomegranate peel and guava leaves extracts co-treatment and

pomegranate peel extract showed best effect. Our study advocates the use of natural plant extracts (pomegranate peel and guava leaves) in diet to reduce toxic effects of ethanol.

Abstract

The present study was conducted in order to determine ^{90}Sr radionuclide migration in the agricultural soil within the long-term field experiment at the Rimski Šančevi in Novi Sad (Republic of Serbia). This radionuclide is one of the most hazardous fission products. The downward migration of ^{90}Sr anthropogenic radionuclide in soil is a key factor in the understanding of behavior of this radionuclide in natural systems. The validated radiochemical analytical procedure for separation and determination the activity of ^{90}Sr in soil samples was applied. The measurements were performed by α/β low level proportional counter. The activity concentrations of ^{90}Sr at 4 sampling locations and 3 depths of soil are reported. The obtained results showed that the activity concentration of ^{90}Sr in the chernozem soil ranged from 0.2 (minimum detectable activity) to 1.1 Bq kg^{-1}. It was concluded that exists uniform distribution of ^{90}Sr in agroecosystem of the chernozem zone. Also, the obtained results showed that the highest concentrations of ^{90}Sr radionuclide were found in the arable horizon.

Keywords: *^{90}Sr radionuclide; soil; agroecosystem*

Introduction

^{90}Sr is the artificial long-lived radionuclide, so-called fission product created in nuclear reaction (^{235}U (n,f) ^{90}Sr), which is released in the environment not only from global fallout, already and accidents involving nuclear materials (Kavasi et al., 2015). This radionuclide belongs to the group of the extremely toxic radionuclides and it is one of the most significant radioecological factors because it has a high fission yield, a long physical (28.6 y) and biological half-life (Grahek and Rožmarić-Mačefat, 2005; Friberg, 1997). Thus, the investigation of ^{90}Sr translocation in the environment is very important for determination of radiobiological effects in each part of ecosystem. The artificial radionuclide once released in the environment can find their way into the food-chain leading to contamination of food (Sandeep et al., 2009).

The downward migration of anthropogenic radionuclides in the soil depends on several factors such as the way and chemical form in which they were deposited on the soil, the climatic conditions of the ecosystem, soil characteristics (Guillen et al., 2015). One of the major factor of influence on radionuclide mobility in soil is the pH value of soil (Koch-Steindl and Prohl, 2001). Sorption on clay minerals, oxides and organic matter are the main processes that have an impact on radionuclide mobility in soil (Vukašinović et al., 2010).

According to the degree of mobility in the soil, anthropogenic radionuclides with long half-life can be divided into the following series: ^{90}Sr>^{106}Ru>^{137}Cs>^{144}Ce>^{129}I>^{239}Pu. For contamination of soil and live organisms, hazard effects have only radionuclides with a long biological half-life, of which the most significant are ^{90}Sr and ^{137}Cs. Sorption of these

radionuclides in the soil has a great significance, because of sorption determines their migratory ability, as well as their penetrating in the root system of plants (Gajić, 2006).
The main objective of this study is to analyze the downward migration of ^{90}Sr in soil of experimental field in the northern province of the Republic of Serbia. A tendency for the accumulation of ^{90}Sr was observed in the soils subjected to a long-term fertilization with NPK. This study will contribute to the better understanding of ^{90}Sr migration in the agricultural managed systems.

Material and Method

In order to measure the content of ^{90}Sr, the soil samples were collected from a long-term experiment (LTE) „Plodoredi“ at the Rimski Šančevi experimental field of the Institute of Field and Vegetable Crops in Novi Sad (45^{o}19’ N, 19^{o}50’ E, *Figure 1*).

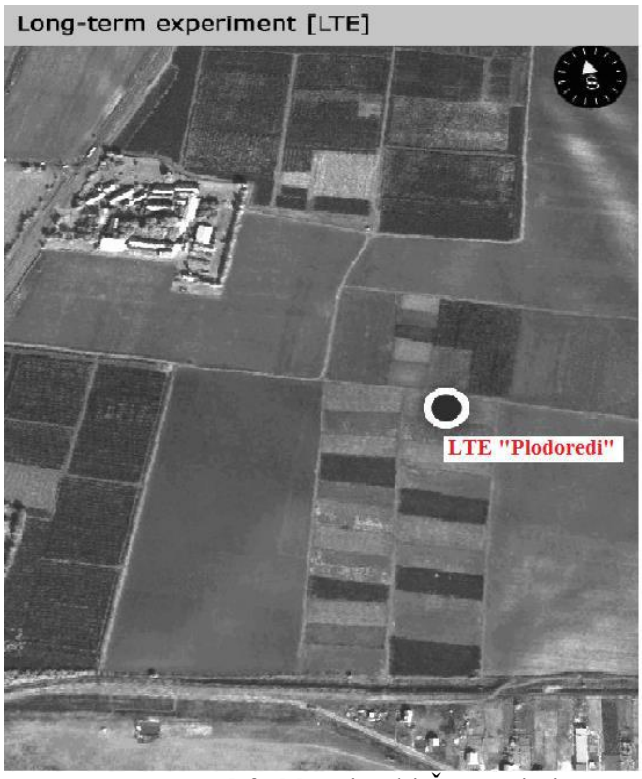

Figure 1. Experimental field „Rimski Šančevi“ in Novi Sad

The soil sampling was conducted in the autumn season of 2013 year. The each sampling locations and ambient dose rates are given in *Table 1*. The measurement of the ambient dose rate at sampling locations was performed using a scintillation probe (Model 6150 AD-b produced by Automess, Germany) 1 m above the ground.

Table 1. The sampling locations and the corresponding ambient dose rates

Location code	Treatment of soil	Ambient dose rate (nSv h^{-1})
L1	2-year crop rotation (maize-**winter wheat**) from 1970 120 kg ha^{-1} N per year+PK	125
L2	2-year crop rotation (**maize**-winter wheat) from 1970 100 kg ha^{-1} N per year+PK	105
L3	**Winter wheat** monoculture from 1970 100 kg ha^{-1} N per year+PK	110
L4	2-year unfertilized crop rotation (winter wheat-**maize**) from 1946	100

About 2 kg of soil samples were taken from three depths (0-10, 10-20 and 20-30 cm) at each sampling location. This soil is slightly alkaline with nearly equivalent percents of fine sand and silt.

The preparation of soil samples involved the following: removing plant residues from the basic soil mass, samples drying at 105 ^{0}C during 24 h and sieving through a stainless steel sieve (diameter 3 mm) followed by grinding to powder (according to MARLAP 2004). 300 g of dry soil was mineralized at 500 ^{0}C during 24 h by the method of dry burning for further radiochemical analysis of ^{90}Sr.

The procedure of validated radiochemical analytical method (Sarap et al., 2014) was applied for the determination of ^{90}Sr activity concentration in agricultural soil samples. This method is based on the radiochemical separation of ^{90}Y from the sample using aluminium collector. After the establishment of radioactive equilibrium between ^{90}Sr and daughter radionuclide ^{90}Y during 18 days, ^{90}Sr is determined via ^{90}Y. The measurements were performed using α/β low-level proportional counter Thermo Eberline FHT 770 T (ESM Eberline Instruments GmbH, Erlangen, Germany).

The activity concentration of ^{90}Sr (*A)* expressed as Bq kg^{-1}, was calculated using the Equation:

$$A = \frac{(N-B)\times \exp\left(\frac{\ln 2 \times t}{T_{½}}\right)}{P_{Al}\times P \times Ef \times m} \qquad (1)$$

where N is the count rate of the sample (s^{-1}), B denotes the background (s^{-1}), t - the time elapsed from ^{90}Y separation (h), $T_{1/2}$ is the half-life of ^{90}Y (h), P_{Al} - the yield of aluminium which is determined for each sample separately, P - the yield of the used method, Ef - the efficiency of the detector and m is the mass of the sample (kg).

Results and discussion

Agricultural soil which is the subject of this investigation belongs to the Haplic Chernozem (CHha) type (typization according to IUSS Working Group WRB, 2006) and its chemical reaction is slightly alkaline. In 4 experimental variants with different levels of fertilization (120 kg ha^{-1} N per year+PK, 100 kg ha^{-1} N per year+PK and without of fertilization, marked as L1, L2, L3 and L4 in *Table 2*), 2-year crop rotation (maize-winter wheat) and winter wheat monoculture were included. The ^{90}Sr activity concentrations for different depths of investigated soil are presented in *Table 2.*

Table 2. The ^{90}Sr activity concentration (*A*) in agricultural soil, expressed on dry matter.

Location code	Depth of soil (cm)	A (Bq kg^{-1})
L1	0-10	1.1 ± 0.4
	10-20	0.6 ± 0.1
	20-30	< 0.8
L2	0-10	0.8 ± 0.2
	10-20	0.6 ± 0.1
	20-30	< 0.2
L3	0-10	0.4 ± 0.1
	10-20	0.5 ± 0.1
	20-30	0.4 ± 0.1
L4	0-10	0.5 ± 0.1
	10-20	0.5 ± 0.1
	20-30	0.4 ± 0.1

The obtained values of ^{90}Sr activity concentration in agricultural soil are ranged from 0.4 to 1.1 Bq kg^{-1} and 0.5 to 0.6 Bq kg^{-1} for 0-10 and 10-20 cm depths of soil, respectively. The ^{90}Sr activity concentrations for 20-30 cm depth of soil at locations 1 and 2 are below of the minimal detectable activity, while for locations 3 and 4, the values were identical and amounted to 0.4 Bq kg^{-1}. The differences in activity concentrations of ^{90}Sr radionuclide by the soil layers are evident for locations 1 and 2, while for locations 3 and 4 are insignificant. Anyhow, the highest content of ^{90}Sr in investigated soil profiles is obtained for location 1, where the maximum quantity of fertilizer is used. Based on the obtained results it can be seen that the distribution of ^{90}Sr is uniform in examined agricultural soil profiles. Also, it can be said that ^{90}Sr shows tendency to retention in the upper soil layers, apropos in arable horizon.

Conclusion

The downward migration of anthropogenic radionuclide of ^{90}Sr in agroecosystem was analyzed. Investigation of the vertical migration of ^{90}Sr radionuclide in agricultural soil showed uniform distribution. The highest ^{90}Sr activity concentrations are obtained in topsoil layer of the chernozem at 0-10 cm of depth. The obtained results are confirmed the literature data that the most of ^{90}Sr retains in the arable horizon of agricultural soil.

Abstract

As world demand for water grows, water reclamation and reuse becomes increasingly important and an indispensable component of integral water resources management to enhance water supply reliability. Now a days, politically and technically it is well recognized the important role the treated waste water and its reuse could play in reducing the enormous gap between the increasingly water demand and the limited fragile water supply particularly in many arid and semi arid developing countries. In the future, it is certain that water reuse will increase worldwide not only with a view to countering problems already known, but also to counter a new threat arising from climate change and the expected changes it could have on the available water resources. (IPCC 2007). Water reuse is meant to help close the water cycle and therefore enable sustainable reuse of available water resources. When integrated to water resources management, water reuse may be considered as an important component of the national research policy and as an integral part of environmental pollution control and water management strategy. It may present benefits to public health, the environment and economic development. Reclaimed water may provide significant additional renewable, reliable amounts of water and contribute to the conservation of fresh water resources. To obtain maximum benefits and to minimize the risks from water reuse, we are in need to better understanding of the advantages, the drawbacks and controversial opinions about planning, methodologies, appropriate technologies, implementation challenges and opportunities. Those are some of the fundamental issues beside others to be fully discussed in this paper.

Keywords: *waste water, water scarcity, water reuse, water management and research policy*.

Introduction

Nowadays, politically and technically the important role of treated wastewater and its reuse could play in reducing the enormous gap between the increasing water demand limited fragile water supply particularly in many arid and semi arid developing countries is well recognized. In dead for some water scarce regions including those of the Mediterranean and the Middle East, treated wastewater is becoming a common source for additional water and is already included in their master plans (Bahri, 2002; Bazza, 2002 and Hamdy, 1999).As a matter of fact, for many countries, wastewater reuse is recognized as an encouraging solution to cope with the problem of water scarcity, the big challenge many countries are now facing (Collinos *et al.,* 2009). In order to cope with water scarcity, one of the most promising supply management practices to be explored is the reuse of wastewater (Periera et *al.,* 2002). Technological advances in the treatment field have enabled treatment facilities to obtained reclaimed water quality suitable for urban and even potable supply (Maliva and Missimer, 2012). However, several obstacles have hampered the implementation of this type of projects for instance, the tight compartmentalization of sanitation and supply sectors has limited the development of reuse schemes and consequently resulted in a mismanagement of water resources. Bridging supply and sanitation sectors into a more integrated approach is vital for achieving sustainable management of urban water systems (Lazarova *et al.,* 2001; Bixio *et al.,* 2006). With issues of climate change, increase in urban population and increased demand for

water from competing sectors, wastewater recycling is becoming an important strategy to complement the existing water resources for both developing and developed countries and there are lessons, experiences data and technology that can be shared for mutual benefit.

Wastewater: a growing source

By 2015, 88% of the one billion person growth in the global population will occur in cities, the most majority of this growth will occur in developing countries (UNDP, 1998). An increase in urban water supply ensures an increased wastewater generation. The growing wastewater volumes render a cheap and reliable alternative to conventional irrigation systems. In this context wastewater is a resource that could be of increased national and global importance, particularly in urban and peri-urban agriculture. According to Hussein *et al*., (2001), there is at least 20 million hectares in 50 countries irrigated with raw or partial treated wastewater. After reviewing many overseas recycling projects, Radcliffe 2004 concluded that worldwide, water reuse is becoming an increasingly common component of water resources planning as the costs of wastewater disposal rise and the opportunities for conventional water supply development dwindle. In many developing countries particularly those in arid and semi arid regions the use and recycling of wastewater is always increasing with time due to a combination of factors among them: urban population increase, decrease in rainfall, water scarcity, environmental concerns, need for greener water strategies and improved technology. **Figure (1)** illustrate the increase in urban water supply coverage have been and will continue to be the highest in Asia and Africa, where absolute population figures as well as population growth are the highest. In this context wastewater is a resource that could be of increased national and global importance.

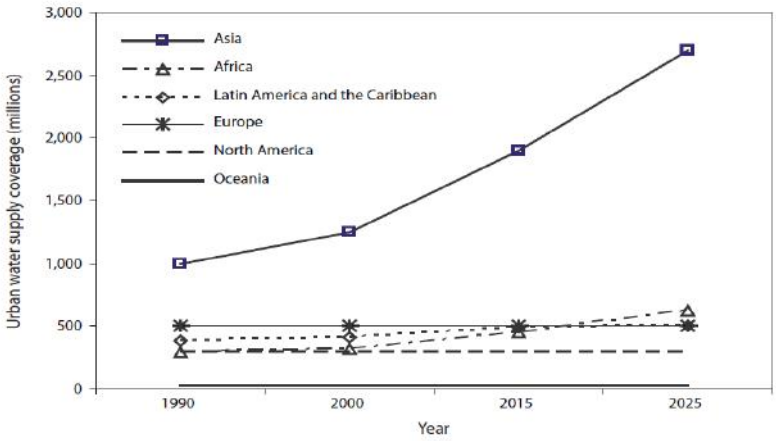

Figure 1. Growth in urban water supply coverage by regions of the world.
Source: Scott et al., 2004

Water reuse: the main drivers

Main drivers for reusing water are: drought and scarcity of water supplies; resource efficiency and protection of existing water supplies.

Drought and water scarcity: treated wastewater is commonly used for irrigation purposes around the world due to drought and scarcity of water supplies. This is the case in Europe and especially in the southern Europe as well as the arid and semi arid countries of the Mediterranean and Middle East regions.

Resources efficiency: Not all water that is consumed in industry, agriculture or in municipality needs to be drinking water quality. Producing clean water from waste water in the long term can be more economical and sustainable than over consuming fresh water sources or desalinating sea water. Treated wastewater can be used in many applications. For instance in the pulp and paper industry the water is reused several times and water

consumption has dropped significantly over the years. In the 1970s producing 1 tonne of pulp required as much as 250 m^3 of water – now it only takes 5-50 m^3. The past decade saw water consumption of paper machines being reduced by 1/3 as a result of more efficient water circulation.

It is well recognized that, insufficient financial and coping capacities constrain the establishment of comprehensive wastewater management systems The use of untreated wastewater is not limited to the countries and cities with the lowest gross domestic product (GDP), but is also a common practice in many middle-income countries as well (Raschid-Sally and Jayakody, 2008).

Wastewater reuse: the benefits

The most relevant reuse benefit of wastewater is making a new water supply source available. Besides, this new resource guarantees a high level of supply relatively constant between years (Friedler, 2001), which may bring increased benefits to users that suffer from constant water shortages (Mesa- Jurado *et al.*, 2012). Increasing the resource availability entails decreasing on water stressed bodies (Miller, 2009). The reuse of treated wastewater can provide the following benefits:

Economic benefits: Designed correctly, recycling can help achieve considerable savings because water only needs to be treated for its purpose. For example, desalinating sea water for irrigation would be more energy demanding and expensive than using reclaimed water for the same purpose. **Social benefits**: Water reuse can ensure the safeguarding of existing water supplies and to manage the imbalance between water demand and supply. **Ecological benefits**: Water reuse can help to decrease the amount of waste water discharged into the environment. Ground water levels can be kept; overutilization of water from lakes can be avoided and in some cases nutrients in wastewater can be directly reused in agriculture. Direct wastewater reuse provides also an effective means of coping with nitrogen and other nutrients and pollutants present in effluents (Hernandez-Sancho *et al.*, 2010). At the same time, direct wastewater reuse may reduce the dependency on other sources of fertilization (Toze, 2006, and Fonder *et al.*, 2010). **Environmental benefits:**In addition to providing dependable, locally controlled water supply, water recycling provides tremendous environmental benefits including the following:

- Decrease diversion of freshwater from sensitive ecosystems: people who reuse water can supplement their demands by using a reliable source of recycled water, which can free considerable amounts of water for the environment and increase flows to vital ecosystems and thereby avoid the diversion of freshwater from sensitive ecosystems that can cause deterioration of water quality and ecosystem health.
- Enhance wetlands and riparian (stream) habitats: experiences gained demonstrate clearly that streams that have been impaired or dried from water diversion, water flow can be augmented with recycled water to sustain and improve the aquatic and wildlife habitat.
- Prevent and reduce pollution: A clear demonstration for such benefit can be seen with recycled water containing higher levels of nutrients, such as nitrogen. Application of recycled water for agricultural and landscape irrigation can provide an additional source of nutrients and lessen the need to apply synthetic fertilizers (El-Motaiam and Abdel Monem, 2001).
- Saving energy: recycling water on site or nearby reduces the energy needed to move water longer distances or pump water from deep within an aquifer. Tailoring water quality to a specific water use also reduces the energy needed to treat water using recycled water that is of lower quality for uses that don’t require high quality water saves energy and money by reducing treatment requirements.

In addition, to the environmental benefits achieved due to the reuse and recycling of wastewater, other several benefits could be obtained including:

1. Conservation of fresh water resources for other uses.
2. Reduction in the need for wastewater infrastructure for treatment and disposal of sewage
3.Reduction in the need for nitrate and phosphate removal by the treatment system since these elements have added value in agriculture (Hamdy and Ragab, 2005); Papadopoulos (1995).
4. Reduction of pollution from disposal of sewage into the environment (Fridler, 2001).
5. Combating desertification (Al-Shreideh, 2001).
However, in spite of the benefits gained by reusing treated wastewater in irrigation, there are associated health risks due to contact with reclaimed wastewater. Consequently, it is of utmost importance to make sure that these risks are minimized and monitored (Toze, 2006).

Wastewater use: The risks.

Hussain *et al.,* (2001) developed an overview of the potential benefits and risks arising from the use of wastewater in agriculture. Selected potential impacts are summarized as follows: Public health: Wastewater has the potential to cause diseases as it contains bacteria, viruses and parasites. Also, the inclusion of heavy metals in wastewater can be very dangerous for human health. Wastewater use in agriculture causes risk to the population living within and outside the wastewater irrigation zone. **Crops:** Wastewater is attractive and economically valuable for farmers because it contains important nutrients for crop growth. However, a high concentration of chemical pollutants in wastewater may be toxic to plants. **Soil resources:** Accumulation of nitrogen, phosphorus, dissolved solids and other constituents such as heavy metals in the soil affect its productivity and the sustainability of land use for agriculture. Salt accumulation in the root zone may have harmful impacts on crop yields. **Groundwater resources:** Leaching of nutrients and salts included in wastewater has the potential to affect the quality of groundwater. The degree of impact depends on several factors, including the quality of groundwater, depth of water table, soil drainage and the amount of wastewater applied for irrigation. **Ecological impacts:** Drainage of wastewater from irrigation schemes into water bodies may indirectly affect aquatic life and negatively influence overall biodiversity, e.g., the presence of water birds. **Social impacts:** The use of wastewater in agriculture has different social impacts such as food safety, health and welfare, impaired quality of life, loss of property values and sustainability of land use.

Wastewater – reuse and recycling: Environmental and public health

The main issue derived from wastewater reuse is the health and environmental risk in agriculture and urban uses or ecosystems enhancement purpose. Reclaimed wastewater involves a certain amount of risk because it may contain dissolved solids, heavy metals, pesticides, pathogens and other substances which may cause damage to ecosystems, crops or human beings (Norton-Branduo *et al.,* 2013). In regard to urban uses pathogens (bacteria, virus, protozoa, and parasitic worms) are the most concerning risk since this can cause disease spread. It is worthy to emphasize that an important parameter to decide on the economic feasibility of a reuse plan in agriculture is salinity, as this is not reduced by regular treatments, but requires environmental and economic costly solution such as reserve osmosis (Haruvy, 1998). The impact of effluent disposal on ecosystems has been well documented (Garcia and Pargament 2015). The presence of organic and inorganic nutrients can cause eutrophication and algae bloom, a worldwide environmental problem that causes hypoxia and fish kills, as well as a nuisance to city dwellers and visitors (Gibbs *et al.,* 2002). Beside nutrients, emerging contaminants such as organic wastewater derived compounds might be recognised as one of the most relevant stressors in ecological rehabilitation (Plumlee *et al.,* 2012).

Wastewater recycling: the barriers

A number of factors influence wastewater recycling. These include:

Centralized wastewater treatment systems, the location of the treatment plants, the availability of space in and around cities and the topography – all of these factors restrict the use of wastewater to certain areas and for specific purposes..

There are substantial barriers to entry in the field of wastewater recycling. Wastewater is often operated and owned by a single entity, like the Water Board or sewage treatment plant, which is often the retailer. Also, wastewater recycling often requires a dual reticulation system that is inefficient to duplicate (Muir, 2006).

There are both positive and negative externalities associated with wastewater recycling. The positive externality is: environmental benefits from reduced discharge of saline wastewater into natural water bodies. The negative externalities include potential groundwater pollution and increase in soil salinity if used for irrigation and potential unknown ill effects on human health if used for potable uses..

Public perception is the main barrier for a reuse scheme implementation (Miller, 2006). Without the acceptance of the public, it would be complicated for any utility to locate, finance develop and operate any reclamation plant for the purpose of water reuse (Bdour *et al.,* 2009)

The wastewater challenges

In many parts of the world, wastewater is already used for agriculture. This practice should be encouraged, but, it must be done safely. The challenge is to establish appropriately national and regional guidelines for wastewater reuse in view of the characteristics of the wastewater and the prevailing socio, economic and environment prevailing conditions. Furthermore it is needed to identify practical and safe uses that do not threaten those communities which are dependent on wastewater, accounting the importance that this resource plays in achieving food security in growing urban areas. The fact that right now more than 90% of world's wastewater in discharged untreated into oceans, rivers, or wherever else it can go is indeed a disaster in slow motion that will grow in proportion and impact. In this context the challenge is having solutions for wastewater management not only of human sewage, but also of industrial, agricultural and urban wastewater. According to the World Bank, "The greatest challenge in the water and sanitation sector over the next two decades will be the implementation of low cost sewage treatment that will at the same time permit selective reuse of treated effluents for agricultural and industrial purposes" (Green Arth, 2012).

Wastewater reuse and recycling: supportive policy and institutional setting.

The divers impacts that wastewater use has on the environment, public health, local economies and food security, combined with substantial secondary impacts, highlight the complexity and cross-cutting nature of wastewater management. Proper wastewater management requires collaboration and dialogue between partners and stakeholders involved in wastewater issues, for example, farmers, public health officials, municipal and waste managers, planners and developers. The management of wastewater use in agriculture involves many of the following actors which need to cooperate these actions and regulations: ministers of water resources, agriculture, health, the environment, energy and development; research institutions and universities, NGOs, farmers' groups, consumers, water operators and municipal and local water management institutions. To facilitate the safe management of wastewater in agriculture in this complex context, appropriate policies, legislation, institutional frameworks and regulations at international, national and local level need to be in place which brings these actors together. Scountries have already established platform for these actors to exchange knowledge at national level, there is little structure and opportunity for across sectoral approach and issues of safe use wastewater for agriculture. Important aspects to address this gap such be analysed such as the followings: institutional roles and responsibilities, economic instruments, and education and social awareness.

Concluding remarks and recommendations

Technology selection should focus on the type of reuse anticipated, proximity to source of effluent, environmental sustainability, local conditions, and affordability. Simple solutions that are easily replicated, that allow further up-grading with subsequent development and that can be operated and maintained by the local community are often considered the most appropriate and cost effective

An important element in sustainable water reuse is the formulation of a framework of realistic, achievable and enforceable standards for treated wastewater quality and applications. Monitoring and evaluation of water reuse programs and projects are fundamental and thus must overcome challenges of weak institutions, shortage of trained personnel, lack of monitoring equipment and the relatively high cost required for monitoring processes.

The establishment of clear policies with regard to wastewater management and water reuse is required in order to guide programs, projects and investments relating to wastewater collection, treatment, reuse and disposal in a sustainable manner. These policies should be compatible with other local policies including those on national water management and irrigation, health, sanitation, agriculture and the environment. Policies of water reuse and strategies for its implementation should be part of water resources planning at the national level. At the local level, individual reuse projects should be part of the overall river basin planning effort.

The responsibilities of the various organizations involved in wastewater collection, treatment and reuse must be considered and reconciled by improving coordination among stakeholders and the donor community. Improved participatory approaches (especially with farmers) are further needed including raising the awareness of the general public on the benefits of water reuse.

Furthermore efforts are needed to allocate the required funds to support applied research to find sustainable wastewater treatment processes adaptable to the socioeconomic and climatic conditions.

That the safe use of wastewater in agriculture is an important water resource issue that needs to be addressed, efforts are still needed to advance it in national policies and to implement safe use guidelines and practices. The lack of implementation of guidelines and safety standards can lead to another wise avoidable aggravation of health risks that could result in significant secondary impacts.

INFORMATION AND COMMUNICATION TECHNOLOGIES IN SMART WATER MANAGEMENT

Atef HAMDY[1]

[1]Emeritus Professor, Water Resources Management, CIHEAM/Mediterranean Agronomic Institute, Bari-Italy
*Corresponding author: hamdy@iamb.it

Abstract

For most Countries in arid and semi arid regions including those of the Mediterranean water scarcity and water stress are among the dominant crucial problems, seriously affecting any type of development. Indeed, the majority of those countries are subjected to both economic and physical water security. Institutional constraints, aging infrastructure, ICTs gap, lack of investment, poor data and lack of quality services are just some key challenges that the water sector faces. Smart water management (SWM) has become a key policy issue for the 21st century, as a solution to a number of a factors those are impacting the delivery of water to the affected people. Moreover a number of issue linked to climate change, such as lengthy drought and extreme weather variations are worsening the situation. SWM seeks to alleviate challenges in the water sector by promoting the coordinated development and management of ICT products, solutions and systems in order to maximize economic and social welfare without compromising the sustainability water as a resource of the environment. Today ICTs have become pivotal in very day life. Though there is many initiatives designed to enhance water sustainability, efficiency and accessibility via ICTs to address the water crisis and the increasingly surrounding problems. Nowadays ICTs, therefore, are increasingly becoming a key enabling tool for data acquisition, early evaluation, communication or automated management in the water sector. However, in spite of the progress in promoting the integration of ICTs in water resources management yet, there is still a need for the development of standards policies and proper ICTs governance to ensure that there is integrity in the water resources management.

Key words: *Smart water management, ICTs, Security, Sustainable development, Mediterranean*

Introduction

Today, we are faced with an unprecedented number of global water issues. As a solution to these, SWM in connection with ICTs has emerged as stable and efficient water management system. However, for the realization of SWM, it is needed to move forward and strengthen and expand the cooperation systems the implementation of water technology standardization in order to respond effectively and accelerate the resolution of global water issues (ITUT, 2010), Vital solution to relieve water stress caused by climate change and pollution growth can be achieved by applying state-of-the-art technologies using ICTs. SWM could have an important role to resolve water issues by intelligent integrated-technologies and water information generated in the process of the whole water cycle (Al Sheikh, 2011). In addition, it can maximise the efficiency of water management in terms of water resource management, treatment, distribution and energy consumption. The world at it was known, 30 years ago is not what it is today; neither will be the same 30 years from now (FAO, 2011; WWAP 2009; UNEP, 2008). Such dramatic change in such a short period of time is mainly attributed to the develop0ment of ICTs. Modern ICTs have provided today's society with a vast array of innovative communication capabilities and have transformed the world into a global village.. Harnessing ICTs technology within the water sector creates a more intelligent means to manage and protect the plant's water resources (DeLange *et al.*, 2013). Indeed ICTs can play

a special role in this respect through a number of technologies that help in better distribution, management and allocation of water. Unfortunately, the role that ICTs play to help in measuring, monitoring, and distribution of water as result of environmental issues has not been fully defined and completed.

Smart water management: meaning and objectives

Smart Water management (SWM) is a future-oriented water management strategy integrating and managing the entire process of the water cycle from analysis of current situation to purification, distribution, use and recycling of water resources scientifically and systematically. Indeed, it is an integrated management model covering the entire water cycle securing the stability, safety and efficiency of water (IBM Research, 2013). SWM can be seen as an intelligent water management model covering all aspects from water supply infrastructures to the production and distribution of water resources, digital data to manage water scientifically,. SWM seeks alleviate challenges in the water sector by promoting the coordinated development and management of water, through integration of ICT products, solutions and systems (Hope and Thomas, 2012).

Why do need smart technology for water?

Recently stakeholders in water sector are trying to incorporating ICT technology into water management extensively, pursuing smart water management to satisfy a variety of demands based on regional needs and economic conditions (Acqua, 2014). Smart technology for water management provides alternatives to the traditional solutions by applying intelligent ICT (Kappor, 2006). Today's water supply industry in faced with many imminent problems such as aging water supply infrastructure, supply and demand imbalances of water, water pollution and rising energy costs.

Smart Water Management: What it can provide with respect to conventional methods

Unlike conventional methods, SWM initiatives is not dependent on the supply capacity of water sources. It provides the optimal utilization system by combining every water resources available including underground water sea water and rain water. Therefore water can be provided and reused whenever necessary without a large scale infrastructure such as dams. Furthermore, it is to be added that SWM is capable of accurately predicting the needs and appropriate coordination of production and supply through ICT-based analysis of consumption patterns. As such, water quality and quantity and be ensured and saving can be promoted.

Smart Water Management: the tools

SWM tools fall into these main categories, data acquisition and integration (e.g. sensor, networks, smart pipes, smart meters, etc.), modelling and analytics (e.g. radio transmission, WiFi. Internet, etc., data processing and storage; (e.g. Cloud computing); management and control (eg. SCADA Optimization tools), and visualization and decision supporting (e.g. Web-based communication tools. Flow data from one end of a river without the use of stream digital geographical data can be used to create digital topography models, and videography have made it possible to store and retrieve large volumes of ground information (Mauree, 2010).

Water Smart Grid WSG

WSG is one innovative approach to addressing water scarcity, promoting efficient water use, updating existing water infrastructure, improving water quality and reducing water related energy consumption (Brozowski, 2011). The development and implementation of smart grid systems for water are similar to those that have been used for electricity distribution. A WSG

system would direct an innovative technology suite, including smart water meters, sensors, advances modelling, water mapping, smart irrigation, autonomous robots, and other technologies, that would work together to create a data-drive system for intelligent management of water resources.
These systems would be comprised of network of hardware and software that continuously monitors municipal water use ad agricultural irrigation systems; water treatment plants; individual ground water withdrawals and delivery and allocation schemes to provide consumers and utilities with real-time information on water consumption from consumer, commercial, industrial and agricultural endpoints and users (Culter, 2013).

Changing the Concepts of Water Management

The purpose of conventional water management is to ensure smooth water flow from water sources to consumers while smart water management is to transform flowing water to communicating water as it is aiming to realize water management system equipped with scientific assessment and constant communication smart water management through providing information on the whole water cycle from water source to production, supply to consumers, and re-sues (**Figure 1**) The application of the innovative smart water management approach will ensure not only stability but also both safety and efficiency of water.

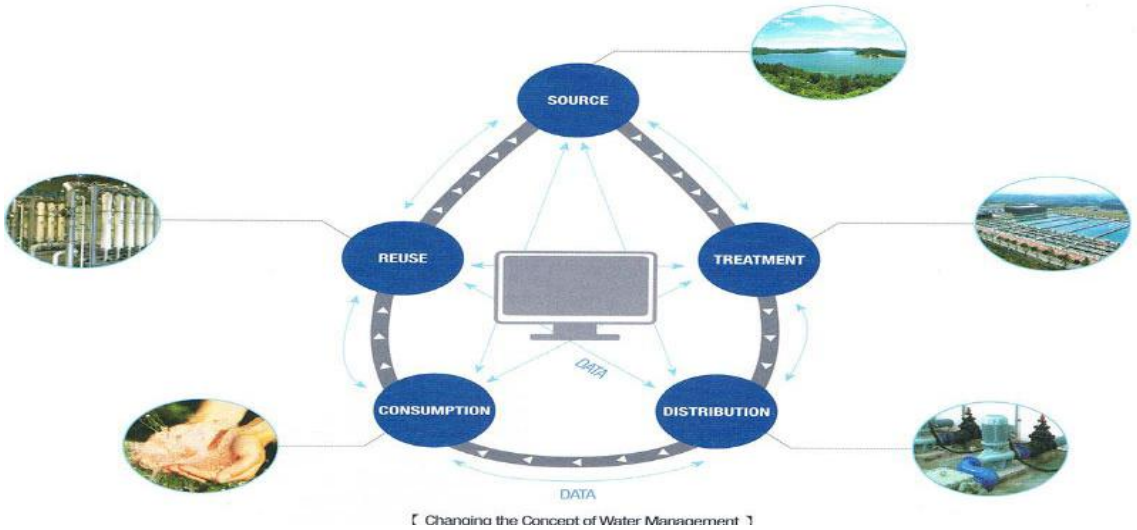

Figure 1: Changing the Concept of Water management
Source: K water , the WWF (2015)

SWM is it the water management for tomorrow management?

Smart Water consists of an information architecture and intelligent infrastructure that enable automated sensing, monitoring and decision support for water management operations. This approach includes a combination of Smart Sensors, modelling, connect and facilitate information flows. It enables continuous monitoring of physical, water infrastructure and environments, It also provides a foundation for more robust, reliable and strategic water management capabilities. With data integration, data from various sources can be combined to show the entire management domain. According to (Meena and Singht 2012), the water management projects should be based on:
- Combining science-driven conservation with IT expertise and computing power
- Building a novels software modelling framework for stimulate the behaviour of river basin around the world

- Informing policy and management decision that conserve the natural environment and benefit the people who rely on these resources. In this regard:

People technologies will be essential to successful implementation of smart system
People should be viewed as active participants of systems: sensors, decision makers , actors
People should play key role in the reflection, and reshaping of.

SWM: managing and protecting water resources. Can we implement smart Water management?

In our opinion the answer to the raised question should be not just we can, but should be we must. This is because we have the followings.
Instrumented: we now have the ability to measure, sense and see the exact condition of practically everything
Interconnected: people systems and objects can communicate and interact with each other in entirely new ways.
Intelligent: we can respond to changes quickly and accurately, and get better results by predicating and optimizing for future events.
Tackling the case of managing and protecting water resources we can think and act in more intelligent ways concerning the followings:
Eliminate data drought by improving access and delivery of the right information to drive a new era of smarter water management.
Build and repair water infrastructure whilst adding intelligence and instrumentation into the network to maximize return or investment well into the future

Water resources challenges and use of ICT

Many developing countries including those of Mediterranean are facing a series of challenges : ongoing urbanisation, resource depletion and CO_2 emission, an ageing and deteriorating urban water supply infrastructure and the effect of climate change.
Water scarcity is a real issue which will grow in importance in the near future compounded by the effect of climate change, rising population and economic growth.
To meet these challenges and to be able to drive sustainable economic growth, those countries need to tap their innovation potential through the use of Information and communication Technologies (ICTs). The use of relevant ICT and social computing can instrumentaly raise awareness of stakeholders on the significance of water sector in sustainability and in changing behaviours and attitudes among citizens. ICT can help water managers drive aggressive information campaigns and integrate the water sector with other country services in order to deliver sustainable service sand quality citizens life. The problem of future water security-including flooding and droughts is not going to go away and we must look across the whole water cycle from abstraction and treatment to use and sewage, to help address the infrastructures and attitude changes which are needed. This clearly characterize the role ICT can play in smart water management. The (OCED ,2008) in their environmental outlook to 2030 (www.oced.org) states that water demand is expected to rise globally by 55% between 2000 to 2050, by 2050 up to 3.9 billion people, 40% of the world population, may be living in water stressed area. ITCs and collaborative innovation are instrumental in helping of water management.

ICT in smart water management

In 2013, the international telecommunication Union (ITU) decided to establish a Focus Group on Smart Water Management (SWM). This initiative, aims to promote the use of ICT for

better distribution/management and allocation of water as there is lack of attention being paid to smart water management resulting in low investment level. The fact that SWM is critical to sustainable water future, nowadays the demand for intelligent and automation through ICT is increasing. The ITU has found that it is necessary for ICT to be imbedded into smart water management systems to get timely data and react to change quickly. However for smart water management, we need deeper collaboration, collective input from stakeholders to empower affected communities and to mange water and energy related challenges with an extremely high rate (Laspidou, 2014). For the energy sector ICT can enable energy network in a reasonable and sustainable way (Pagani and Aiello, 2012).

ICTs opportunities

ICT use in SMW have wide application and clear set of benefits, which, in general, increases water use efficiency and therefore decrease consumption. (Gourbesville, 2011, Martinez Liado, 2013, Savic, 2013). Some of major areas where improvement is evident could be outlined in:

Real-time monitoring: Technologies such as smart metering, SCADA, GIS, telecommunication sensors and decision support systems, all are effective tools for the provision of real-time reliable data. This means that water utilities have the opportunity to make improvements in demand response and in reducing water losses in the water distribution system;

Reduction in water consumption: ICTs provide the tools needed to create advanced water use efficiency in all sectors. Incorporation of sensors in the agricultural sectors ensures that crops are watered when needed reducing large volumes of water normally lost due to over irrigation;

Reduction in operation costs: Improvement in operational efficiencies mean that administrations costs can be reduced, creating an optimization of expenses. (Culter, 2013).

Greater public involvement: One of the benefits of ICTs is the improvement in communication between water utilities and the public which will lead to an enhancement in public awareness with respect to consumption and water usage (Alsheikh, 2011);

Integration of smart water management in smart sustainable cities (SSC): Practically, SWM is highly incorporable into SCC and it safeguards economic growth and sustain a higher quality of life as well as it maintains ecological and environmental resources for future generations (Mizuki *et al.*, 2012).

Environmental flow integration: The use of ICT products, solutions and systems in the proper monitoring and assessment of environment flow can lead to better decision-making in sustainable management of water resources (OECD, 2008)

ICTs Challenges

Although there is sustainable opportunities of ICTs use in SWM, global development in this area are currently insufficient and are mainly due to:

Lack of standardization: In spite of the efforts carried out by ITU in this field, there still need for further standardization. Standardization maintains integrity, and adherence ensures that there is compatibility, interoperability, and certain level of quality. Therefore reduction of risks (UNESCWA, 2013).

Lack of policies: Generally in most Countries there is no coherent multi-sectors and or multi-stakeholder coordinated policy on water management and /or conservation. For those Countries, it is needed to have an integrated policy formulation approach that integrates different governmental sectors, NGOs, CBOs, Academia, and the private sector for the success and adoption of water resources management policies on the national and regional level (UN-Water, 2012) .

Lack of awareness: Awareness, proper education as well dissemination are essential for proper water resources management. Many Countries are not necessary conscious on the role of ITCs can play in water management or of it is usefulness, with little attention on how ICTs can act as an enabler of SWM on large scale.
Proper ICTs governance: Lack of ICTs governance impacts investments as well as prevents stable coordinated and comprehensive planning to address future requirements and proper integration (WGF, 2012).

Key stakeholders involved in ICTs and SWM

For SWM to effectively tackles global water issues, stakeholders engagement is imperative. The type of ITCs used in SWM plan or project, is as effective and efficient, as the understanding of the roles and responsibilities played by the stakeholders. SWM stakeholders fall into diverse groups according to their roles (advising, producing solutions, making decisions.etc.). Stakeholders engagement typically involves the main areas are represented in **Figure 2**. For successful integration and implementation of SWM within countries, stakeholders involvement is necessary and should not be conducted in parallel but rather as an interactive process strategically woven throughout to determine priorities, increase support for remediation programmes and generally enhance the livelihood of success..

Figure 2. Good Stakeholders Engagement

Concluding remarks and recommendations

ICT is the indispensable enabler to achieve the necessary level of control and management of water networks. What is impressive, however, is that there is no standard for data management and no data interoperability of systems across the providers, practically. Everything needs to be built. This will require a massive research effort from the ICT industry to adopt solutions to the water sector, develop adequate standards and interoperability.
One of the biggest drivers for change to smart water networks is leakage and conservation, especially in countries facing serious water scarcity issues. Leak detection is one of the most active areas of smart networking. Network monitoring, combined with analytics software, are helping to reduce the impact of leakes and identify areas in need of repair before a burst become visible and is reported.
Proper integration and stakeholders involvement prevents fragmented and uncoordinated approaches to water management issues, and therefore leads to a smarter way for water management. Appropriate intelligence adoption is SWM can only be achieved if there is focus on partnering the right technologies with the right stakeholders.

Information from utilities, municipalities, regulators, investors technology provider and academia must be bridged and are properly harnessed. This allows for the development of innovative partnership, creating the right solutions for all.

ICTs can bring enormous benefits to water authorities in mapping and monitoring of natural water resources, aquifer recharge as well as in forecasting river flows and advanced warming in water related emergency situation.

ICTs have the capability of:

Providing reliable real-time information needed for monitoring, measuring, modelling, and managing of water resources, Reliable data leads to better decision making and consequently clearer projection to cope with water scarcity and water stress problems.

To enhance water allocation by ensuring it is done in a more fair and equitable manner

To be strategic enabler to drive SMW policies and assessment.

Abstract

The area of the protective forest of the Glogow Copper Smelter (GCS), Poland, has been exposed to industrial emissions for many years. A large amount of dusts has been deposited in the topsoil. The paper presents results of the vulnerability assessment of poplar trees (*Populus robusta* L.) of the GCS protective forest to phytoaccumulation of lead. The bioconcentration factor (BCF), counting as the relation of Pb concentration in plant to this noted in soil, established for the poplar organs was 0.45-0.69 for leaves and 0.02-0.03 for stem. The relative small differences was observed for locations around the smelter – Zukowice I, Zukowice II and Bogomice, but very clear between them and the control site Stypulow (BCF 0.81 for leaves and 0.57 for stem). It should be taken into account absolutely different level of lead deposition in soils of the following investigation points – 175-347 $mg \cdot kg^{-1}$ in GCS protective forest against 10 $mg \cdot kg^{-1}$ in the control place. Presence of Pb in poplar leaves was about 20 times higher in the GCS protective forest comparing to the control site. There was not observed significant differences between the sites counting Pb concentration in the poplar stems. In the described situation more accurate for leaves analysis may be the average amounts described for the investigated plant species (plant pollution index – PPI).

Key words *Lead pollution, poplar tree, BCF, PPI*

Introduction

The possibility of long-term effects of emissions to the environment was the reason for the creation of the special sanitary zones around the main Polish industrial plants. An example of such a zone is the protective forest (former Glogow Sanitary Zone – GSZ) of the Glogow Copper Smelter (GCS), established in the year of 1987. The main plant species occurring on this area is Hybrid Poplar *Populus robusta* L.

For many years only the values described heavy metals concentration in soils and plants were presented. In the second half of the XX^{th} century, this situation has been changed, mainly in plant physiology and general environment elaborations. It was connected mainly with the natural values estimation for soils, waters and living organisms, including plants (Adriano 1986; Eikmann et al., 1993, Kabata-Pendias and Pendias, 2001). There were provided many researches to establish geological level of the following elements concentration in soils. As a consequence there were established the indices of state of the environment– index of geo-accumulation (Muller 1969), ecological risk index (Hakanson 1980). The next works have been focused on the threshold limits estimation and legal regulation (Eikmann and Kloke 1991, Soil and ground water criteria used in The Netherlands for contaminated land ("Dutch List") 1995, 2000, IUNG in Pulawy basis of assessment of chemical contamination of soils – Kabata-Pendias 1995, Bachmann et al. 1995, Milani et al. 1995) and evaluation of the different remediation techniques (Chaney et al. 1997, Robinson et al. 2000, Schnoor 2000, Stoltz and Greger 2002, Komárek et al. 2007, 2008).

Nowadays are discussed many problems connected with multifactorial analysis of the environment. One of the part of such analysis is the elements flow direction and intensity estimation, counting following parts of the entire environment. Thereby it became necessary to develop and apply indicators of movement of elements in soil-water, soil-plant, soil-air and others systems.
The aim of this work was to present the biosorption of Pb from the soil by the poplar plant organs – leaves and stem. Different factors were calculated to illustrate biological risk of such Pb transport in the environment.

Materials and methods

The research sites were placed in the former sanitary zone of the Glogow Copper Smelter (Lower Silesia Province, the western part of the Poland). The individual investigation sites Zukowice I (N $51^0$40’50.00” E $15^0$58’46.80”) and II (N $51^0$40’43.80” E $15^0$58’45.30”) are located about 0.1-0.3 km SW from the smelter, and Bogomice (N $51^0$41’41.60” E $16^0$00’26.50”) about 1 km NE from the smelter . The control site (Stypulow N $51^0$41’44.30” E $15^0$36’13.70”) was located about 15 km NW from the smelter.
According to Leśniczak (2005), investigations about the choice of tree species for the area were carried out from the 1973. It was tested 440 species and varieties of trees, including 287 of poplar. From the 70th of XX century the most of the area was afforested with *Populus robusta* L.Soil samplings were taken from the forest root-zone (up to 50 cm). Each sample was collected as a mixed one, representing material from the whole depth of the horizon. Soil material was air-dried and sieved with a mesh diameter of 2.0 mm.
Averaged samples of unwashed leaves of *Populus robusta* L. and stems – wood without bark, taken from saw-cut discs at a height of 1.3 m from 3 selected trees at each site. After drying, samples were ground in a mill.
Particle size distribution was determined by the Casagrande-Proszynski areometer method. Textural classes were established according to FAO procedure (2006). Sorption properties (hydrolytic acidity – HA and total exchangeable bases – TEB) were determined by the Kappen method, pH in H_2O and 1M KCl – by the potentiometric method, TOC concentration using a Shimadzu analyser, and the Pb concentration in aqua regia using atomic absorption FAAS. Extracts in Aqua regia (HCl + HNO_3 in a 3:1 ratio) were prepared according to PN-ISO 11466:2002. All analyses were performed in triplicate. All statistical analyses were conducted using Statistica 10 for Windows. The basic statistical figures were defined together with correlations between soil condition indices at levels α=0.01 and 0.05.
Contamination factors were calculated as the ratio of the Pb in plant tissues to its average soil concentration (Starck 2012) – BCF (bioaccumulation factor) and the ratio of the Pb in plant tissues to its average concentration given for analysed plant species and variety (Diatta et al. 2013) – PPI (plant pollution index).

Results and discussion

The particle size distribution of the soils covering the sanitary zone is mostly sandy loam and loamy sand. TOC concentration is not high – from 0.8% in Zukowice I locality to 1.7% in Zukowice II (Table 1). Because of this situation the soil sorption capacity reached just over 20 cmol·kg^{-1}. The soil reaction for the tested sites varies from acid in Zukowice I and Bogomice, neutral in Stypulow to alkaline in Zukowice II. Soil properties are showed in table 1.

Table 1. Selected properties of soils

SITE		Zukowice I	Zukowice II	Bogomice	Stypulow
Particle size distribution (%)					
2 mm-50 µm		78	55	53	77
50-2 µm		19	44	42	21
<2 µm		3	1	5	2
Texture class (FAO 2006)		loamy sand	sandy loam	sandy loam	loamy sand
Physic-chemical properties					
TOC (%)		0.80	1.70	1.11	0.77
pH	in H_2O	5.5	7.6	6.0	6.5
	in 1M KCl	5.0	7.2	5.5	5.5
EC ($dS \cdot m^{-1}$)		0.40	0.45	0.42	0.38
HA ($cmol \cdot kg^{-1}$)		1.38	0.21	2.47	0.66
TEB ($cmol \cdot kg^{-1}$)		10.2	12.5	25.1	14.3
CEC ($cmol \cdot kg^{-1}$)		11.5	12.5	27.7	14.9
BS (%)		87.4	98.2	89.8	94.4

TOC – organic carbon, HA – hydrolytic acidity, TEB - total exchangeable bases, CEC – cation exchange capacity, BS – base saturation

The lead concentration was similar both in soil and in plant tissues in the sites Zukowice I and Bogomice, much lower in the soil and poplar trunk of the Zukowice II (Table 2). Control site in the Stypulow locality was characterised by the low concentration of Pb in soils and in poplar leaves. The lead concentration in stem of poplar trees from the control site was higher than in Zukowice II site but smaller than in other sites.

Table 2. Pb concentration in soils and plants

SITE	Zukowice I		Zukowice II		Bogomice		Stypulow	
soil								
Minimum ($mg \cdot kg^{-1}$)	4,74		7,50		14,04		1,80	
Maximum ($mg \cdot kg^{-1}$)	328.5		175.3		347.6		9.60	
Mean value ($mg \cdot kg^{-1}$)	95,7		72,4		140,4		4,80	
Standard deviation ($mg \cdot kg^{-1}$)	37,68		30,50		58,35		1,23	
Standard error ($mg \cdot kg^{-1}$)	12,56		10,17		19,45		0,41	
plant	stem	leaves	stem	leaves	stem	leaves	stem	leaves
Minimum ($mg \cdot kg^{-1}$)	5,49	66,6	0,98	67,5	5,06	108,1	3,64	6,50
Maximum ($mg \cdot kg^{-1}$)	14,0	181,1	7,71	210,9	14,5	212,2	10,4	8,60
Mean value ($mg \cdot kg^{-1}$)	8.50	146.6	2.90	120.6	7.80	158.6	5.50	7.70
Standard deviation ($mg \cdot kg^{-1}$)	3,55	47,7	2,76	57,7	2,07	50,1	0,98	0,95
Standard error ($mg \cdot kg^{-1}$)	0,25	9,55	0,20	11,5	0,10	10,0	0,04	0,24

BCF shows very different situation (Table 3). For stem the highest result was noted for control site in Stypulow. These calculating for the GCS surrounding were lower and almost equal. The similar situation was obtained for leaves from the control site – the highest BCF values were calculated. The GCS sites were not unified, BCF in leaves for Zukowice II site was higher than these calculated for the other two sites.

PPI for stem of poplar trees was not very different for the following sites, ranging from 1.5 to 4.3. Other one situation for the leaves was noted. PPI 3.9 was characteristic for

uncontaminated control site in Stypulow locality. For the GCS surrounding PPI for leaves was between 60.3 and 79.3 (higher values for Zukowice I and Bogomice sites).

Table 3. Contamination/pollution factors for the poplar trees growing on analysed sites

SITE	stem	leaves
Bioconcentration factor (BCF)		
Zukowice I	0.03	0.45
Zukowice II	0.02	0.69
Bogomice	0.02	0.46
Stypulow	0.57	0.81
Plant pollution index (PPI)*		
Zukowice I	4.3	73.3
Zukowice II	1.5	60.3
Bogomice	3.9	79.3
Stypulow	2.8	3.9

* - as the reference value was taken 2 mg $Pb \cdot kg^{-1}$, acc. to Kabata-Pendias and Pendias (2001)

The physic-chemical condition of soils do not raise any comments about the terms of the growth and development of plants, especially for the Hybrid Poplar. *Populus robusta* L. is the tree with a wide ecological grow spectrum – soil texture: clay loams to sandy loams, soil pH 5.5-7.5 (USDAFS 1990, Seneta 2009).

Under conditions of moderate pollution of soils with heavy metals it can be observed the positive effect of mycorrhizas, limiting the heavy metal intake by plants (Christie et al. 2004). Against this, the high level of heavy metals concentration in soil can inhibit the growth of mycorrhizas (Coral del Val et al. 1999). As an effect of local conditions, the concentration of TOC in soil ranged from the 0.8 to 1.7% is described as average for Robusta stands and smaller than typical when compare with the Hybrid 275 stands (Jonczak et al. 2010).

The main problem is a purity of soils from the chemical point of view. The obtained results for areas located near the GCS ranged from 175.3 to 347.6 mg $Pb \cdot kg^{-1}$ are 18-36 times higher than this one for the control site (9.6 mg $Pb \cdot kg^{-1}$). Kabata-Pendias and Pendias (2001) described the values from 3 to 189 mg $Pb \cdot kg^{-1}$ as natural for the top horizon of different soils of the world (mean value 10-67 mg $Pb \cdot kg^{-1}$, average 32 mg $Pb \cdot kg^{-1}$). The higher values illustrate regions of the world with high developed industry and communication. Estimated Pb geometric means for soils of Poland indicate a growing Pb level with increasing concentration of clay fraction; for example, in sandy soils, 12.6 ppm; medium loamy soils, 16.4 ppm; and heavy loamy soils, 20.9 ppm (Kabata-Pendias and Pendias 2001).

As a result of industrial emissions the most vulnerable to deposition are plants and a topsoil layer. Plants absorb soil compounds by the root system. Many researchers point this part of plants as the largest store of pollutants, including heavy metals (Kabata-Pendias and Pendias, 2001; Lakhdar et al, 2010). Heavy metals absorbed by roots can be transported to the aerial parts of plants. Greszta (2002) states that in the case of poplar the concentration of lead reaches about 10 mg $\cdot kg^{-1}$ d.m. in the roots and about 33 mg kg^{-1} d.m. in branches.

The natural concentration of Pb in plants ranging from 0.1 to 10 mg $Pb \cdot kg^{-1}$ with average value 2 mg $Pb \cdot kg^{-1}$ (Kabata-Pendias and Pendias 2001). In the control site the values higher than given as average were noted, but fitted within a range (5.5-7.7 mg $Pb \cdot kg^{-1}$). Also in the GCS surrounding presence of Pb in poplar stem was not very high – 2.9-8.5 mg $Pb \cdot kg^{-1}$. Very different situation was noted for the Pb concentration in leaves – 121-159 mg $Pb \cdot kg^{-1}$. It's a typical situation for the contaminated industrial, urban and traffic areas. The most of urban areas in Poland don't reach so high Pb concentration in plant leaves. Typical levels for *Tilia*

cordata L. ranging from 7 to 32 mg Pb·kg^{-1}, for *Robinia pseudacacia* L. 4 to 31 mg Pb·kg^{-1} and for *Ligustrum vulgare* L. 3 to 20 mg Pb·kg^{-1} (Greinert 2010).

Highly significant positive correlation between the concentration of lead in the stem of trees and Pb concentration in the soil from areas of former sanitary zone has been found during the correlation analysis. There was also negative correlations between Pb in the stem and the soil reaction and organic matter concentration. The lead concentration in leaves of tested trees were highly significantly correlated with the concentration of lead in the soil, soil pH and soil clay fraction (Fig. 2). In the control area a significant correlation between the lead concentration in the leaves and stems and the Pb concentration in soil, HA and CEC has been found.

The value of accumulation factors in the analysed area varies widely – depending on compared tissues and the concentration of heavy metals in soils. The higher concentration of lead in the leaves may be due to the sedimentation of contaminants from the atmosphere. Studies conducted on *Populus alba* (Madejón et al 2004) and *Populus robusta* (Mertens et al. 2007) showed much lower concentration of lead in the leaves (about 4-5 mg·kg^{-1} d.m.) and close to the trunks of the respondents (about. 1-2 mg kg^{-1} d.m.) receiving only lead from the soil. The BCF values – comparable between areas contaminated in varying degrees, may indicate the limits of plants in the absorption of lead. This thesis study appears in Lakhdar et al. (2010).

The values of BCF for stem in contaminated sites were smaller than in control site. Additionally the values of BCF were many times smaller for stem than for leaves (Tab. 3). This observation is confirmed in studies with poplar growing in conditions of Zn, Cu, Cr and Cd soil contamination (Sebastiani et al. 2004).

Conclusion

Bioconcentration factor (BCF) was always smaller than 1, what illustrates the less of tendency to hyper accumulation of Pb by the poplar trees; BCF for leaves were higher and more different than for stem.

Plant pollution index (PPI) shows significant difference between the clean and contaminated sites, when analyse Pb concentration in leaves. For the concentration in stem PPI was found not to be a good indicator of sites contamination with Pb.

BCF is a factor which requires additional description whenever to use, because for the different situations it can show similar values.

PPI index is more accurate than BCF, but requires more detailed determination of the chemical composition of the various species, varieties, hybrids and parts (organs and tissues) of plants.

Abstract

Through the implementation of the idea of sustainable development, is one of the priority objectives of the EU is (defined in the Action Plan on Sustainable Development Strategy for 2014-2020 with a strategic outlook to 2050) to ensure the society in the case of environmental care.This can be achieved by applying of appropriate tools of crisis management, which, due to the risk assessment will create space for application o protection instruments. There is necessity to continuously improve security by the systematic risk assessment of environmental and human impact. The aim of this paper is to show the risks arising from the application of extinguishing agent used by emergency services for disposal fires. The result is an overview of extinguishing agents and monitored parameters which have a negative effect of chemical substances as extinguishing agents.

Study in first part discusses the issue of forest fires that have occurred over the past decade in the Slovak Republic. Data are obtained from statistical yearbooks PTaEU Ministry of Interior of Slovak Republic and from the Statistical Office of Slovak Republic. Where as forest fires represent burning uncontrolled and undesirable negative impacts on society and the environment (including natural and cultural heritage), it should be paid to these issues still more attention. The analysis of the number and incidence of forest fires in Slovakia, the average value of forest fires of the total represents 2,5%.

The second part of study deals with observation of extinguishing by the foam which was prepared from the 3 % Sthamex foam agent water solution. The foam was applied on the Fire model A. The foam application was followed by the environmental parameters evaluation of extinguishing substance – foam, and the soil on which it was applied.

Key words: *fire, extinguishing substances, environmental impact*

Introduction

Slovakia may be a small country but with a large forest area, which represents 41% of the total country area (for forest land), which represents about 2 million hectares (Forest – natural heritage of our country is). The above data puts Slovakia among the countries with the highest rate of forestation (Kohútová, 20014). Slovak’s forests are the part of the West- Carpathian Mountains. Most forested land is in the central region of Slovakia, while 47,6% is forested area, representing almost half, followed by the East Slovak region, which has a third of its forested areas – 33,2% of the territory. Western Slovakia has the smallest forest area, around 19.2% of the territory. Listporous trees predominates the coniferous. The beech is most common tree naturally occurring in the Slovak Republic. It grows most often with fir and spruce. Such a mixing of talking trees "Carpathian mixture". Spruce in our country is represented 26.4%, while the coniferous trees are among the most common (Chromek, 2006).

The Fire and Rescue Corps (FRC) of the Slovak Republic fulfills assignments related to the fire fighting, providing the assistance and carrying out the rescue operations during

emergencies, natural disasters and other emergencies and protecting the environment, etc. Firefighters work in specific conditions. Security conditions firefighter ´s working requires a specific approach. The last decade has seen a change in the principal activity of firefighters, fire & technical interventions, as evidenced by statistics. For the purposes of evaluation and head to head comparison of exit activities of corps in Slovakia were selected data from statistical yearbooks of Fire and Rescue Corps (Official Reports, 2004-2013). For purposes to evaluate was use the statistical evaluation (descriptive statistics) in Excel. Over 10 years have been implemented 314,365 exits within the framework of FRC. The highest number of exits was in 2010 (35 654). Fig. 1 represents comparisons of individual years in terms of total number of exits of Fire and Rescue Corps compared to the number of exits to the fire. Process of the results of the total number of exits and exits to fire can be compared, except in 2004 and 2011. In 2010, the exits were to the technical intervention. That year was one of the coldest and the most raining year in Slovakia for last 140 years, which led to a significant reduction in the number of forest fires.

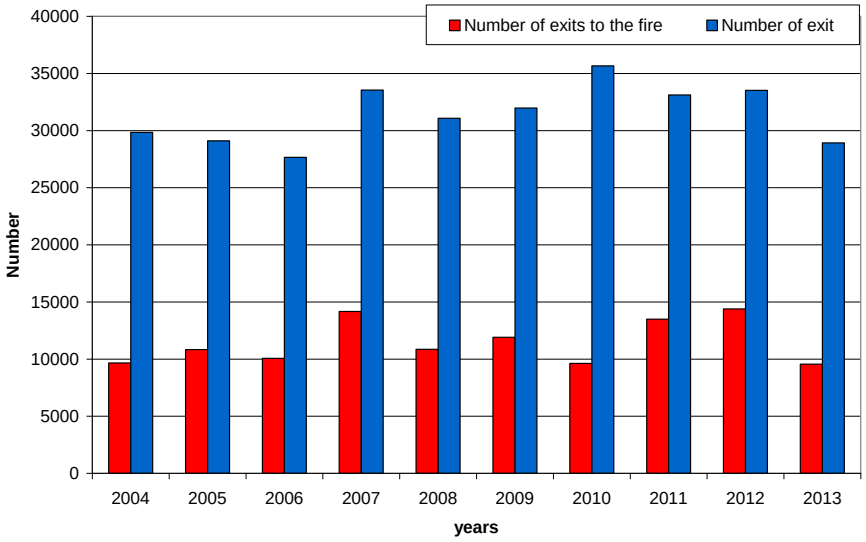

Fig. 1 Head to head comparison of the total number of exits to the number of exits Fire and Rescue Corps to the number of exits of Fire and Rescue Corps to fires from 2004 to 2013.

Forest fires on the forest ecosystem cause direct and indirect damage. Forest fires detrimental to all the components of forest biota such as habitat as well as flora and fauna (Fernandes, 2014). According to the cause of forest fires is distinguished between anthropogenic and natural harmful factors. Direct damages relate to the impairment of living trees, processed and unprocessed timber, lost growth and deterioration of wood raw material. Indirect damages related to the operation of other secondary pests, as well as the increase in the cost of the consequences of fires (Hlaváč, 2007). In the forest fire burning the whole set of organic materials that make up the forest cover. The generated heat halls in the environment affects the plants and leads to partial or complete dying back of part or the whole tree (Fernandes, 2014, Fitzgerald, 2005, Lotan et al. 1985).

Fire protection of forests against fire has to solve also the problem of used fire extinguishing substances appropriateness except the preventive precautions. The fact, that the forest fire liquidation is not easy is also confirmed by the theoretical analyses of this problem (Shaffer, 2002). Forest as well as the fires of agricultural land is extinguished by their perimeter. In previous years, the specialists from the sphere of forest fire extinguishing refer to the insufficient extinguishing efficiency of water as a extinguishing substance. (Hlaváč, 2007. Chromek, 2007). Into the water, due to the increasing if its utility parameters as well as for the fire extinguishing purposes, mainly the increasing of extinguishing efficiency of water, there

are added the additives – tensides called foam concentrates in the fire fighting practice (Marková, 2006). In the previous years, there was large market supply of the A3F Dr. Sthamex foam concentrates in our conditions. These were specialized for the extinguishing of “A” and “B” group fire, and were advised by the specialist from fire extinguishing sphere. Since the acquired results showed the excellent extinguishing parameters of these concentrates, the aim of this article is to verify the extinguishing efficiency of selected A3F foam agent on the Fire model A and to evaluate this area from the ecological aspects point of view. The above mentioned preparations show according to producer data excellent extinguishing properties, but our goal was to prove their effects on the environment after their application. *Sinapis alba* toxicity test together with two alternative ecotoxicity tests, *Thamnotoxkit* and *Daphtoxkit*, were employed for this purpose.
In order to evaluate the effectivity of extinguishing agent STHAMEX-AFFF 3% FL the experiment based on the application of extinguishing foam prepared from this agent was realized. The preparation was according to the producer data classified as dangerous chemical compound with identification as is physiologically harmless and easily biodegradable (Data sheet). Subsequently, the toxicity of the fire residuals was evaluated using three selected tests.

Material and method

The experimental ”Fire model A” is composed from wooden prisms (40 x 40 x 500 mm from spruce wood with moisture 10,5%) creating the stack, which is put on the metal frame base with the height of 250 mm, width of 900 mm and the length equal to the experimental fire model. The metal frame is made of squares of 50 x 50 mm by the ISO 657-1 standards. The scheme of the experimental ”Fire model A” is introduced in Fig. 2. According to the material economy, the fire model was constructed based on the EN ISO 14520-1 standard. For the fire ignition the flammable liquid mixture (water : fuel : kerosene in ratio 3:1:1) was used.

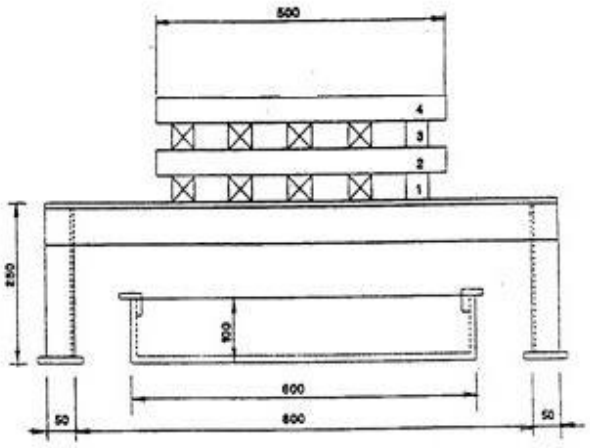

Fig. 2 Scheme of Fire model A by EN ISO 14520-1.

The extinguishing foam was produced by the use of HIRO, the water aerosol extinguishing system. From the top of the vat, there is terminated another hose, through which the compressed air flows to the branch to aerate. Owing to the STN EN 3-1 (92 0501) standards, the experiment started with the incendiary mixture lightning and parallel starting-up of a timer and the above apparatus HIRO. The Fire model A had been burning next 6 minutes that represented the total burning time of 8 minutes and creation of the experimental fire model itself. Next the fire extinguishing followed. To evaluate this experiment positively, it was important to extinguish all the fire flames not to occur repeatedly in the 3 minutes time interval of the survey. The way of extinguishing and time of fire put out was surveyed.

Extinguishing solution prepared as 3% water solution of the synthetic foaming agent STHAMEX F-15 based on surfactants was used.
For the purpose of ecotoxicological evaluation of fires and extinguishers effects artificial controlled fires were realized which were after flaring up quenched by extinguishing foam prepared from synthetic surfactants based agent STHAMEX F-15 as 3% water solution. Samples of soil and vegetation from the place after application of extinguishing foam were taken for comparison. After cooling of the fire places the samples of fire residuals were taken into the 50-liter plastic bags. All samples were transported to the ecotoxicological laboratory of the Institute of Chemistry and Technology of Environmental Protection, Brno. Ecotoxicity of extinguishing agent and samples from the fire places was evaluated using tests employing water invertebrate organism *Thamnocephalus platyurus*, which is wide-spread in our nature, and tiny crustacean *Daphnia magna*. Another applied test was the phytotoxicity test using representant of higher plants - white mustard (*Sinapis alba*). All these tests are described in details in literature Vávrová et al. (2011), Vávrová et al. (2012), Hříbová (2014).

Results and discussion

Experiments of Fire model A were especially evaluated. Among the important parameters of the measurements belonged the extinguishing time, consumption of extinguishing concentrate and the decrease of the air pressure. It follows from the obtained results that the model fire was extinguished in short time (in 9 seconds) using 4,5l of extinguishing solution. Using the 3% concentrate, the STHAMEX F-15 concentrate consumption reached the value of 0,135l. Heavy foam was prepared from the concentrate with foaming number 10,7. In other cases we concentrated on the eco-toxicological evaluation of fire places.
For the evaluation of toxicity three tests were selected. Test organisms *Daphnia magna* and *Thamnocephalus platyurus* assessed the load of the water compartment of the ecosystem when water solution of STHAMEX F-15 foaming agent was used. Another test used for the evaluation of toxicity of the STHAMEX F-15 water solution was phytotoxicity test using test organism *Sinapis alba.* Obtained results are presented in Table 1.

Table 1 Ecotoxicological evaluation for the STHAMEX 15. (Vávrová et. al., 2014)

Evaluation	Exposure	Foam Concentrate STHAMEX F-15
Daphnia magna	24h EC50	24 ml/l
Thamnocephalus platyurus	24h EC50	8 ml/l
Sinapis alba	72h IC50	32 ml/l

EC50 is concentration causing death or immobilization of 50 % of tested organisms *Daphnia magna*,
IC50 is concentration causing 50% growth inhibition of the algal culture or 50% growth inhibition of the *Sinapis alba* root in comparison with reference sample during the test duration.
Based on the performed experiments, there was tested the extinguishing efficiency of the foam, which was prepared from the STHAMEX F-15 foam agent (concentration of 3%) in the water solution. Hříbová´s (2014) study evaluated of ecotoxicological influence of the most used foam extinguishing agents concentrates (FEAs) which are often applied in fires. There were selected follows Sthamex F 15, Finiflam F 15, Expyrol F 15, Moussol APS F 15 and Pyrocool B (by effective concentration 3 – 5%). To predict ecotoxicity for aquatic ecosystems tests in aquatic arrangement using animal organisms *Thamnocephalus platyurus* and also *Daphnia magna* and plant organism *Lemna minor* and *Sinapis alba* were conducted. Their results indicated subsequently leachates of soil were contaminated by fire fighting agents via the same organisms were evaluated with aim to assess possible influence of soil sorption complex on ecotoxicity reduction. Ecotoxicological tests in contact arrangement using soil

animal organism earthworm *Eisenia fetida* and plant organism lettuce seeds *Lactuca sativa* to predict the ecotoxic effect of FEAs on terrestrial organisms and possible influence of biodegradability on ecotoxicity reduction were also conducted (Hříbová, 2014). The results of ecotoxicological tests in aquatic as well as in contact arrangements should arouse attention because of the fire fighting agents exhibit high ecotoxicity. As the least toxic agent Moussol APS F 15 was assessed, although its toxicity is still considerable (Hříbová, 2014). Our obligation is to produce chemicals that are environmentally friendly. The company aims to apply chemicals to support sustainable development. Sustainable development means providing for human needs without compromising the ability of future generations to meet their needs (Doble, Kruthiventi, 2007). The sustainable matrix, as proposed by the ICHemE (Tallis, 2002) include 49 submatrix covering the environment (related to resource usage, emissions, effluents, and waste), economy (related to profit, value, tax and investments) and society (related to workplace and society). In 2000 Young et. al. developed environmental impact factors (Tab.2) calculated using the Waste Reduction algorithm.

Table 2 Environmental factors of chemical substances

Environmental impacts	Important parameters	Several tools and methodologies are available for measuring environmental impact
Physical potential impact	ODP ozone depletion potential GWP global warming potential AP acidification potential POCP photochemical oxidation potential	LCA Life cycle assessment MIPS Material input per unit service ERA Evaluation risk assessment MFA materials low accounting CERA cumulative energy requirement analysis MFA materials flow accounting Eco Desing Life- cycle costing Total cost accounting Cost –benefit analysis
Human toxicity effects (air, water and soil)	PI human toxicity potential by ingestion TPE human toxicity potential by exposure both dermal and inhalation	
Eco – toxicity effects	ATP terrestrial toxicity potential, calculate by $ATP = \frac{1}{(LC_{50})_i}$ ATT aquatic toxicity potential calculate by $TTP = \frac{1}{(LD_{50})_i}$,	

Long-term effects of chemicals on the environment are very difficult to obtain. Thus, we have to make several assumptions and approximations while using these impact factors. This verdict relates extinguishing substances yet.

Conclusion

Based on the performed experiments, there was tested the extinguishing efficiency of the foam, from STHAMEX F-15 foam agent (concentration of 3%) in the water solution. For the evaluation of ecotoxicity only the organisms were available. From the values presented that the extinguishing agent STHAMEX F-15 doesn’t show the dangerous property H14 Ecotoxicity. Testing organism *Thamnocephalus platyurus* shows higher sensitivity to this agent. If the ecotoxicity tests were demanded using this organism, the effects of this extinguishing agent on the environment would be evaluated more strictly.

EFFECT OF CONSERVATION PRACTICES ON SOIL MOISTURE BALANCE FOR SORGHUM YIELD UNDER RAINFED CONDITIONS OF NORTHERN INDIA

Abstract

Field experiments were carried during rainy seasons of 2011 and 2012 in split-plot design at New Delhi, to study the impact of conservation practices on soil moisture balance for production of sorghum [*Sorghum bicolor*] under rainfed conditions. Sorghum variety ‘CSH 14’ was planted using two tillage types (minimum and conventional) and two planting methods (ridges and furrows, and flat-bed). For each type of tillage and method of planting three levels of fertilizer were applied. Soil moisture content was monitored periodically throughout the seasons by both TDR based FieldScout 300 in three soil depths (8, 12 and 20 cm), and gravimetric method for the depths (0-15, 15-30, 30-45, 45-60 and 0-60 cm) to study the soil moisture retention in each treatment. Soil moisture balance was determined periodically throughout the crop growing season. The results showed that the ridges and furrows planting method in conventional tillage retained the highest soil moisture content leading to the highest grain yield of 2.03 and fodder yield of 9.42 tonnes/ha. Flatbed sowing in minimum tillage was found to retain the least soil moisture content. The ranking of treatments in grain and fodder yields were similar to the ranking of retention of soil moisture content. The increment and decrement of the soil moisture balance was according to the effective rainfall and the total crop evapotranspiration (ETc) during normal rainfall season. The study suggested adoption of ridges and furrows method of planting in conventional tillage with 100% recommended dose of fertilizer for sorghum production as the one of best conservation technology.

Keywords*:* *Sorghum; Ridges and furrows; Conventional tillage; Soil moisture balance*

Introduction

The soil water balance is widely assumed to be the primary factor limiting crop yield. Water shortage and stress were the most important abiotic constraint to effect crop production globally and a major cause of yield instability and food insecurity. However, rain-fed agriculture is not coping for unreliable rainfall and recurrent droughts that leads to subsequent production failures (Zougmore *et al.* 2002). Low soil fertility and erratic rainfall are responsible for the low agricultural productivity of rainfed agriculture in African continent and India (Anonymous 2000). Climate change scenarios indicate that water shortage and shortening of the effective growing season will be increasing the need for short-duration cereals such as sorghum which is widely grown under rain-fed conditions in drought-prone regions of Africa and Asia. Sorghum (*Sorghum bicolor* Moench) is a drought tolerant cereal and has evolved various ecotypes that withstand an array of biotic and abiotic stresses (Elbasri *et al.* 2011). Sorghum should not be planted in a dryland situation unless the soil has stored moisture to a minimum depth of one meter (Jennie *et al.* 2005). Phil *et al.* (2004) indicated that moisture stress at any time after planting can affect plant development and reduce yield potential. The amount of yield loss is dependent on the growth stage of the grain sorghum when moisture stress occurs. Therefore, application of suitable soil and water management practices such as tied-ridging tillage should be integrated with fertilizer to improve the soil

water and soil fertility at the same time for production enhancement (Gebreyesus, 2012). Planting of crops can be either in the furrow or on the ridge based on the expected soil moisture required for a particular crop (Gebreyesus *et al.,* 2006; Gebreyesus and Wortmann, 2008; Tewodros *et al.,* 2010). Soil moisture accounting is used to calculate the soil-water balance in the root zone throughout the growing season (Phil *et al*. 2004). Despite the above facts, however, so far, there have been insufficient published results that estimate the role of ridges and furrows and other tillage practices as part of soil moisture harvesting technique integrated with fertilizer at small fields using hybrid varieties of sorghum. Thus, the aim of this research was designed to evaluate the effect of tillage practices on soil moisture balance and effect of retention of soil moisture and inorganic fertilizer concurrently on the productivity of CSH 14 variety of sorghum at small scale cultivation for precise evaluation.

Materials and Methods

The field experiment was conducted during rainy seasons of 2011 and 2012 at Water Technology Centre, Indian Agricultural Research Institute, New Delhi, (28° 38' 23" N of 77° 09' 27" E, at an average elevation of 228.61 m above the mean sea-level). The site has semi-arid and subtropical climate with hot dry summer and severe cold winter. Average annual rainfall is about 650 mm, 75% of which is received in July, August and September. The experiment was laid out in 3 replications in split-plot design for sorghum variety ‘CSH 14’. The treatments consisted of 2 types of tillage, viz. minimum and conventional, in main plots, 2 methods of planting, viz. ridges and furrows and flatbed, in sub-plots, and 3 levels of fertilizer. The full recommended dose of fertilizer (100%RDF) was 50 kg/ha of urea (46% nitrogen), 25 kg/ha single superphosphate (16% P_2O_5) and 25 kg/ha muriate of potash (60% K_2O). Sowing was done manually by labourers for the both seasons on 24 June 2011 and 11 July 2012. The delayed onset of autumn was the main reason of the delay in seeding process in the second year. Meteorological data, periodic volumetric soil moisture content for the soil depths 8, 12 and 20 cm using Time Domain Reflectometry (TDR) model FieldScout TDR 300 and gravimetric soil moisture content, were recorded throughout the growing season. Soil samples were taken from 0-15, 15-30, 30-45, 45-60 and 0-60 cm soil depth by adopting recommended sampling techniques and analyzed for gravimetric soil moisture content. The total rainfall received during the sorghum growing seasons of 2011 and 2012 were 574.0 mm and 483.2 mm respectively. The effective rainfall was estimated by fixed percentage approach, which is an empirical formula developed by Food and Agriculture Organization of the United Nations (FAO) and Agricultural, Land and Water Division (AGLW) based on analysis carried out for different climatic data to determine the dependable effective rainfall, i.e., the dependable rainfall at 80% probability corrected for assumed losses due to runoff and percolation (Smith, 1988). Reference evapotranspiration (ETo) and the crop water demand (ETc) were estimated using climate and soil data with CROPWAT 8.0 software (FAO, 2008). The soil moisture content on dry weight basis was determined using the following equation:

$$Soil\ moisture\ content\ (\%) = \frac{Weight\ of\ Wet\ soil\ (g) - Weight\ of\ Dry\ soil\ (g)}{Weight\ of\ Dry\ soil\ (g)} \times 100$$

Conversion of soil moisture content (%) to mm of moisture per m of soil was done by the following expression (Ratliff *et al.* 1983**):**

$$Soil\ moisture\ content\ (mm/m) = Soil\ moisture\ content\ (\%) \times \left[\left(\frac{1000\ (mm)}{1\ (m)}\right) \div 100\right]$$

The effective root zone was assumed as 1.20 m. Data on sorghum crop coefficients (K_C) are provided by the software (Some L. *et al.* (2006); FAO, 2008; R. Balaghi, 2010; Anonymous, 2010). Water balance was estimated by:

$$Soil\ Water\ balance = Ef\ rainfall - ETc$$

The data on volumetric and gravimetric soil moisture content were analyzed statistically by using analysis of variance according to Gomez and Gomez (1984) procedure for a split-plot design (3 factors) and the means separation were identified by least significant differences (L.S.D) at $P \geq 0.05$, by using MSTAT-C Package, version 1.47.

Results and Discussion

Soil moisture conservation

From Tables 1, 2, 3 and 4 the results revealed that there were significant differences in volumetric and gravimetric soil moisture content (at 5% level of significance) of the both seasons between the treatment of the ridges and furrows sowing in conventional tillage (T_{21}) and with each one of the other treatments for the all soil depths. The differences were highly significant between the ridges and furrows sowing in conventional tillage and flatbed sowing in minimum tillage. These results confirmed that the ridges and furrows sowing in conventional tillage have a significant impact on the ability of the soil to conserve moisture, followed by ridges and furrows sowing in minimum tillage (T11), flatbed sowing in conventional tillage (T22) and flatbed sowing in minimum tillage (T12) respectively.

These results are in conformity with the finding of Memon, 2007 who reported that soil moisture content after tillage operation showed highly significant difference in all the treatments and it was conserved more in ridge plot as compared to other treatments.

Soil water balance

Soil moisture monitoring for determination of soil moisture retention and soil water balance was taken for 60 cm soil depth. Positive value of soil moisture balance indicate that the effective rainfall is adequate to meet the crop water demand and the negative value indicate that the effective rainfall is inadequate to meet the crop water demand and supplementary

irrigation was needed. The total water balance of 73.3 and 155.7 (Table 5 and 6) respectively for the both season as per growing stages, should be supplemented by precise and efficient supplementary irrigation to achieve optimum yield under these conditions of tillage types and planting methods treatments with 100% RDF.

Total		386.6	301.0					

These results concluded that the increment and decrement of the soil moisture content naturally balancing according to the effective rainfall and the total ETc, when the rainy season is normal. The results are in close conformity with the finding of Some L. *et al.* (2006), which stated that soil water reserves naturally increase according to rainfall which generally decrease at the onset of the rainy season and sharply increase during the period of heavy rains to reach a maximum value in early September in regions of Bobo and Gaoua in Burkina Faso. Generally the values of water avilable in the soil for the crop were higher in the first season than the second one. The rainfall distribution in the first season was better than the second season leading to better crop production in the first season as compared to second season. The water stress in the end of this season did not affect the yield, because the crop was at the last stage of panicles and grain drying and did not need much water (Table 5). But the water stress

in the end of the second season was caused some yield reduction, because the crop was at the begining of the late stage of the grain filling process which required water to proceed normally (Table 6). The ridges and furrows method of planting in conventional tillage with 100% RDF recorded the highest grain yield of 2.03 and fodder yield of 9.42 tonnes/ha, and the ranking of treatments in grain and fodder yields similar to their ranking in soil moisture retention(Gabir et al., 2014).

Conclusions

The results of the present study concluded that, Adoption of conservation tillage practices for sorghum production proved optimum for higher soil moisture retention in the two growing seasons. Amongst the different planting systems, ridges and furrows in conventional tillage for the two growing seasons gave the highest soil moisture retention which constituted 32.5% more of the soil moisture retention in flatbed planting in minimum tillage. Adoption of ridges and furrows planting in conventional tillage with 100% recommended dose of fertilizer led to higher soil moisture retention and higher yield of 55% more as compare to flatbed planting in minimum tillage. The increment and decrement of the soil moisture content naturally balancing according to the effective rainfall and the total crop evapotranspiration under normal rainy season. Sorghum did not require supplementary irrigation under normal rainy season. The water deficit at grain filling stage should be supplemented by precise and efficient supplementary irrigation to prevent reduction in yield.

Abstract

Pesticides are important element of modern agriculture. Although pesticides are designed to kill harmful organisms, their environmental risks are important, especially soil applicated ones. Small amount of pesticides is reached to targeted organisms, rest is still in the ecosystem. Adverse effect to bees, birds, fish and microorganisms are also important issue.

Earthworms provide key soil functions that favour many positive ecosystem services. They represent a large fraction of soil living biomass in many temperate ecosystems and play an important role in soil functioning. As ecosystem engineers they influence organic matter dynamics, soil structure and microbial community. They participate in soil aeration, water infiltration and mixture of soil horizons, and they represent an important source of food for many other organisms like birds. These services are important for agro ecosystem sustainability, but can be degraded by intensive use of pesticides.

In this original research, we aimed to investigate the effect of two pesticides on behaviour of earthworms. For this aim chlorpyrifos and glyphosate treated soil was placed to the 2D (2 Dimensions) glass apparatus (Din–A4/ 21.0 x 29.7 x 0.4 cm). Then earthworms were released to the top of apparatus. Application rates were recommended dose and its two fold. Tunnel (gallery) opening performance and other behaviour of worms compared in the control and treated ones. Tunnel areas measured by using Sketchup program, then the results evaluated statistically. According the our findings there is no statistically significant diffrences between treated (recommended dose and twice) and control experiment.

Key Words: *Pesticide, environmental, risk, earthworms*

Introduction

Although pesticides are designed to kill harmful organisms, their environmental risks are important, especially soil applicated ones. Small amount of pesticides is reached to targeted organisms, rest is still in the agro ecosystem (Tiryaki and Temur, 2010). Use of pesticides often result in a loss of biodiversity. Their adverse effect to bees, birds, fish and microorganisms are also important issue. The effects of pesticides on different taxa and especially on soil organisms are not very clear (Pelosi et al., 2014).

Earthworms provide key soil functions that favour many positive ecosystem services. They represent a large fraction of soil living biomass in many temperate ecosystems and play an important role in soil functioning. Because of the major role, they play in soil functioning, the effects of pesticides on these soil organisms should be investigated further. As ecosystem engineers they influence organic matter dynamics, soil structure and microbial community. They participate in soil aeration, water infiltration and mixture of soil horizons, and they represent a source of food for many other organisms. These services are important for ecosystem sustainability, but can be degraded by intensive use of pesticide (Pelosi et al., 2014)

It is underlined the importance of earthworms for assessing the general impact of pollution in soil. Since then, earthworms have sometimes been used as bio indicators for soil

quality and the environmental impacts of cropping systems and pollutants (Callahan, 1984). Since then, earthworms have sometimes been used as bio indicators for soil quality and the environmental impacts of cropping systems and pollutants. Earthworms are impacted by pesticides at all organisation levels, such as the infra-individual level, the individual and population levels and the community level. For example, pesticides disrupt enzymatic activities, increase individual mortality, decrease fecundity and growth, change individual behaviour such as feding rate and decrease the overall community biomass and density (Pelosi et al., 2014). For instance, mortality and/or reproduction of *Eisenia fetida* are currently used to assess the effects of pesticides under laboratory conditions before marketing authorisation (ISO, 1998). Capowiez et al. (2010) worked on earthworm behaviour as a biomarker**.** Casabé et al. (2007) investigated the effect of chlorpyrifos and glyphosate on earthworm.

The aim of this original research is to investigate the effect of 2 pesticides on behaviour of earthworms (*Eisenia foetida).* For this aim commercial formulation of them used in this study. Both pesticides mostly used as soil applicated insecticide and herbicide in Turkey.

Materials and Methods

Materials

The earthworms known as California earthworm *Eisenia foetida,* are obtained from Siyah Altın Compnay- Edirne, Turkey. Sandy-loam soil is used in this study. Further properties of soil are shown in Table 1. Pestban 25 WP (commercial formulation of chlorpyrifos active ingredient from Organophosphate group) and Boxer (commercial formulationt of glypohosate active ingredient from Phosphonoglycine group) are used in the experiment. Detaily properties of both pesticides are given in Table 2. Other basic laboratory glass equipment and solvent were used in the study.

Table 1. Properties of soil used in the experiment

Properties	Value	Review
pH (1:2.5)	8.1	Mild Alkali
Sand (%)	56	Sandy loam

Experimenteal procedure

2D (2 Dimentions, Din–A4/) apparatus was constructed with 21.0 x 29.7 x 0.4 cm diamentions glass. 4 mm wooden rods were put between 2 glass plate, and small cloth were placed bottom of the apparate to absorb water, then apparatus was fixed with 4 clamp with 4 corner (Türkmen et al, 2013). Boxer 48 SL herbicide and Pestban 25 WP insecticide were

registrated with the application dose of 1000 ml/da and 1000 g /da, respectively. Generally weigh of 1 da soil is known 250 tones. After necessary calculations, 500 g sandy-loam soil is treated with pesticides. 2D apparatus divided 2 equal part with wooden rod. 100 g of pesticide applicated soil was transferred through right part of system, and 100 g untreated control soil was transferred through left part. Soil moisture was equilibrated to the field capacity (Figure 1). Later on 3 earthworms, weighed approximately 0.75 g, were released mid of the system and the top of the apparatus were taped to prevent escape (Figure 2).

Experiment were carried out 3 replication for each pesticide application dose. With 3 application dose (recommended dose x 1, recommended dose x 2 and control), 9 2D apparatus were used for each pesticide in the experiment. Totaly 18 pieces of 2D glass apparatus were incubated 3 days at 18 ºC.

Figure 1. Placing of pesticide treated soil on the top of 2D (2 Dimensions) glass apparatus and water absorption of soil

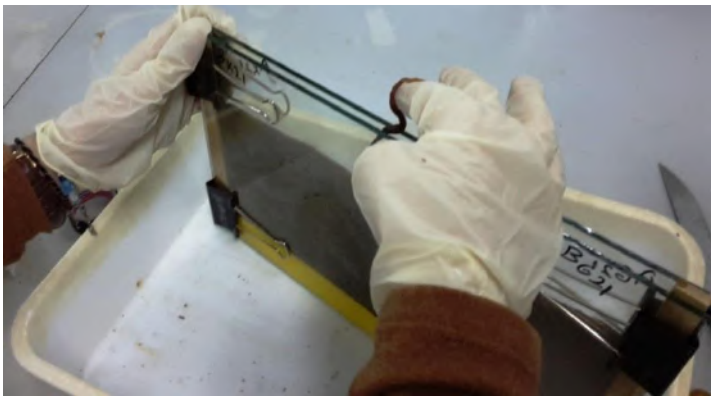

Figure 2. Releasing of earthworm on the 2D (2 Dimensions) glass apparatus.

Results and Discussion

After 3 days incubation, galleries of earthworm were fixed on acetate film with different colour marker (Figure 3). Area of each gallery was measured by using Sketch Up drawing program. Gallery areas in left (treated) and right (control) side were calculated separately. Average area of front and back side was used for calculation.

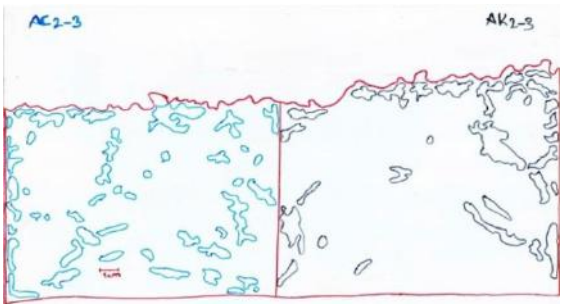

Figure 3. Fixed galleries on the acetate film.

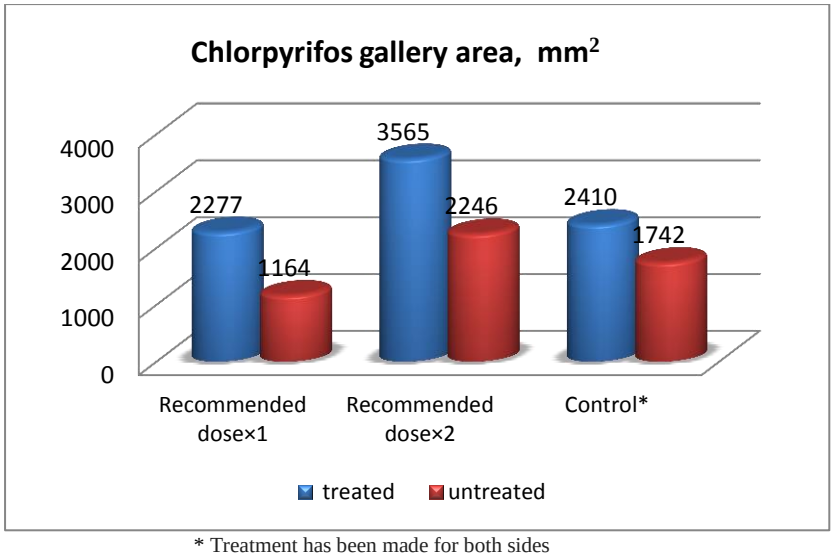
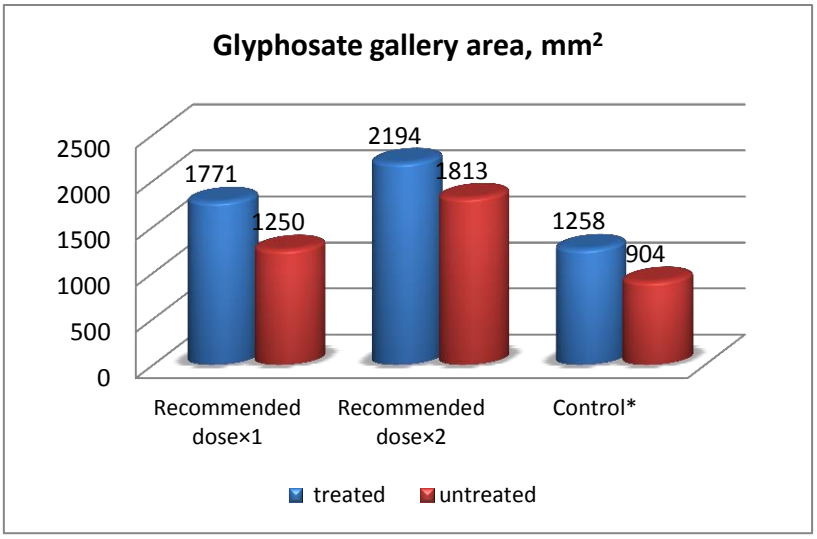
Graphical presentation of gallery area is shown for both chlorypyrifos and glyphosate for recommended dose x1, recommended dose x2 and nontreated in Fig 4, Fig 5 respectively.



* Treatment has been made for both sides

Figure 4. Gallery area of chlorpyrifos experiment



* Treatment has been made for both sides

Figure 5. Gallery area of glyphosate experiment

Statistical assessment was performed with SASV8 variance analysis program. Variance analysis table and calculated data is shown in Table 3. Mean square of replication and treatment, error and CV can also be seen in the table.

Mean gallery arae of chlorpyrifos and glyphosate experiment and statistically significant group, Least Significant Difference (LSD) and F value were given in Table 4. There was no significant differences between recommended dose x1 application and untreated ones, for both active ingredient. At the recommended dose x2 application, there is significant differences at 5% level between treated and untreated ones for chlorpyrifos, where as differences is not significant for glyphosate and control (both side is untreated) experiment. The another interesting finding for both pesticides is that the gallery area of treated (recommended and its twice) experiment is less than untreated control experiment

Table 3. ANOVA data for experiment.

Pesticide dose	Mean square		Error	CV%*
	Replicate	Treatment		
Chlorpyrifos				
Recommended dose x1	63.375	1858153.500	286512.875	31.11125
Recommended dose x2	502515.167	2609641.500	6162.000	2.701098
Control	218080.6667	669002.0417	65740.667	12.34817
Glyphosate				
Recommended dose x1	317217.3750	409770.6667	50895.542	14.92066
Recommended dose x2	13275.2917	216980.1667	130770.5417	18.04652
Control	282706.7917	187797.0417	334726.292	53.49152

*Co-efficient variation

There is a contrast between literature findings and our findings for both pesticides. The main reason of it, 3 days incubation is not enough for this kind of experiment. Booth et al (2000) examined effect of chlorpyrifos and diazinon on *Aporrectodea caliginosa* earthworm and they applied 12 weeks incubation. Capowiez et al. (2006) and Pelosi et al. (2014), applied 1 month incubation for imidacloprid-earthworm experiment. It was stated that high herbicide dose are toxic for soil living organisms (PSU, 2003). The another reason may be the pesticide amount is not enough for affecting earthworms. There is more than one application in the field condition. There is only one application at both dose and its twice in our experiment.

Table 4. LSD and F values of mean areas for chlorpyrifos and glyphosate experiment

Pesticide döşe	Untreated average area, mm^2	Treated average area, mm^2	LSD	p>F
Chlorpyrifos				
Recommended dose ×1	1164.00 a*	2277.00 a	1880.5	0.1258
Recommended dose ×2	2246.67 b	3565.67 a	275.77	0.0024
Control	1742.50 a	2410.30 a	900.76	0.0858
Glyphosate				
Recommended dose x1	1250.7 a	1773.3 a	792.56	0.1050
Recommended dose x2	1813.7 a	2194.0 a	1270.4	0.3266
Control	904.7 a	1258.5 a	2032.5	0.5320

*figures followed by different letters in same line differ significantly at $p< 0.05$. LSD: Least Significant Differences.

Conclusion

Our experiment was performed at controlled conditions in the laboratory. Pesticides is applied more than one in practices. Pesticide amount in the soil is an important factor in earthworms and pesticide relationship experiment.

Abstract

The selection and use of the most effective disinfectants in the post-milking teats disinfection process has a great importance in the reduction of teat infections, and this is what pushed us towards this undertaken study.

The assessment of the antimicrobial activity of the chlorhexidine based disinfectants, in the post-milking teats treating process was done throughout an “in vitro” method. The disinfectants efficacy was assessed with different active principles to the most common mastitis causes, preliminary defined in some cattle farms of Korca region.

The disinfectants Alpha Blue, Chlorhexidine digluconate 20%, used as solution with 5000 ppm active principles digluconate 20% used as solution 4500 ppm active substance.

The disinfectant effectiveness was defined as a percentage ratio between the destroyed microorganisms and those recovered by control teats. The chlorhexidine based disinfectants tested in our study resulted well and concretely their efficiency of Alpha Blue for four pathogenic microorganisms (Streptococcus agalactie, Staphylococcus aureus, Escherichia coli and Pseudomonas aeruginosa) was: 93.4%; 98.4%;97.6%;96.0% and Deosan: 97.3%;96.1% 95.4%; 94.0%. Chlorhexidine disinfectants have a very good antibacterial effect against mastitis causes. Results obtained through out this study match the nowadays literature data.

Key words: *Mastitis, in vitro, teats, disinfectants.*

Introduction

Mastitis, mastos in Greek, *μαστός*=teat and itis=inflammation, can be defined as an inflammatory state of the mammary gland that is accompanied with pathological changes of her tissues as well as with physical, chemical, cytological and bacteriological milk changes. Bovine mastitis is a mammary gland caused mainly from bacteria and favored by certain environment circumstances. Great economic loss in livestock farms come as a result of the reduction of milk production and changes in its physic-chemical composition as well as the treating cost.

Mastitis is called clinical when clinical signs are present in mammary gland tissues. For sub-clinical mastitis, the only indicator is the high number of somatic cells in milk, without any apparent anomaly in teats issues and milk. It can be said that for each clinical-mastitis in stall there are 10-20 sub-clinical mastitis.

Practically, all bacteria are mastitis causes in case all hygiene conditions favor their development. Main bacteria are classified in: infective Streptococcus agalactiae, Staphylococcus aureus, Corynebacterium bovis and Mycoplasma sp. s, environmental streptococcus and Gram-negative and opportunistic Coagulase negative.

Staphylococcus aureus. It is faced in a half of sub-clinical mastitis and about one third clinical mastitis.

Streptococcus agalactiae is one of the most widespread pathogenic germs. It could be found in a half of clinical mastitis and one third of sub-clinical ones.

Bibliographic facts show that mastitis epidemiology is changing, such as, e.g. Streptococcus uberis actually represents a redeemable clinical mastitis case. It was considered such an environmental microorganism but now shows contagious abilities as well in stalls. While Pseudomonas species are rapidly becoming prevailing mastitis in stalls.
Despite the antibacterial barrier of teat sphincter, the transfer of some microorganisms is inevitable.
Factors that favor mastitis are:
Improper environment hygiene, of: stall, animal, milkmaid, milking apparatus.
The neglect of post-milking teats disinfection.
Use of not effective disinfectants.

Material and Methods

The control and prevention of mastitis, is also the aim of this study. Animal teat health preservation through the sink of post-dipping teats with the most effective disinfectants prevents mastitis. There can be used a lot of disinfectants but the most common ones according to the consulted literature are the iodine and chlorhexidine.
The used disinfectants are: Alpha blue, chlorhexidine digluconate 20%, is used as a solution with 5000 ppm active principles (chlorhexidine based product).
Deosan, contains chlorhexidine digluconate 20%, used as a solution 4500 ppm active substances.
Disinfectants antibacterial activity was tested for the most frequent mastitis causes in some cattle farms in Korca region and concretely:
Streptococcus agalactie, Staphylococcus aureus, Pseudomonas aeruginosa, Escherichia coli.
For each of the above microorganisms we got clean microbial culture.
36 samples (teats) were taken in the slaughterhouse slaughtered for various reasons, with healthy mammary glands and were preserved at a temperature of -20 ° C.
The antibacterial activity was evaluated through laboratory tests using teats experimentally contaminated with pathogenic microorganisms described above.
Microorganisms were obtained from a former cultivation and they were transferred in triptosio agar in 200 ml PBW (peptone broth water) and stored at: 37 ° C for 48 hours “Streptococcus agalactie” and 24 hours “other organisms”. After incubation, suspension was obtained through centrifugation 4000 rpm (rotations / minute); it was cleaned 2 times with Peptone-based water and then diluted (10 based dilution) till a concentration of 10^8 CFU / ml broth was reached. After the dilution, it was made the cultivation 0.1 ml in blood agar ground/ land. In addition, the broth culture obtained was melted in sterile milk dive in which there were merged all the previous melted (in warm water at a temperature of 40^{o}C) teats. Thus, all the teats became infected.
For each microorganism there were used 3 controlled dovetail/ teats and three experimental dovetail/ teats for each disinfectant (3x2). Just the experimental teats (6 for each microorganism) were plunged, 3 in each disinfectant.
After 10 minutes, all the nipples were cleaned with 5 ml broth Bacto- lethen liquid; the cleaning liquid was collected for each disinfectant. It was taken 0.1 ml liquid from the cleaning of the controlled teats for each micro organism and it was made cultivation on blood agar at 37^{o}C for each disinfectant. Likewise the controlled teats, it was made the cultivation of 0.1 ml of the cleaning liquid of experimented teats separately for each microorganism and for each disinfectant. After 24-48 hours, the colonies were counted.
The effectiveness of disinfectants action was determined by the percentage ratio between the microorganisms destroyed in the teats treated with disinfectant and those recuperated in control teats

Results and discussion

Table 5.The destroying percentage of mastitis causes from disinfectants in test

Disinfectans	**Streptococcus agalactiae**	**Staphylococcus aureus**	**Escherichia coli**	**Pseudomonas aeruginosa**
Alpha Blue	93.4%	98.4%	97.6%	96.0%
Deosan	97.3%	96.1%	95.4%	94.0%

Conclusions

Deosan, containing chlorhexidine digluconate 20%, used as solution 4500 ppm active substance. (17500 ppm), is more efficient in our case. Alpha blue, that contains a large amount of active principles chlorhexidine digluconate 20%, is used as a solution with 5000 ppm active principles (chlorhexidine based product).

Experimented method (in vitro) can define the antimicrobial action of used products in the post-milking teats disinfection. Data obtain from this study match to the nowadays literature data in this field.

Chlorhexidine based products tested possess a high antibacterial activity against the routine agents that cause mastitis in cattle.

Abstract

The study was conducted at seven commercial intensive broiler farms in Albania, respectively in the area of Fier, Lushnja, Kavaja, Durres, Tirana, Vlora and Kruja, during April – May, 2012. All farms were growing Cobb-500 chicken. Number of chicken at the start of growth was the same for all farms (5000 chicks). At the end of the growth period (age 38 days), performance indicators and technical efficiency of growth were assessed. The lower values of mortality rates and feed conversion ratio (FCR) were obtained in the farm located in Kruja. Vlora farm headed for final body weight (BW), the average daily gain (ADG), higher values of performance index (PI), European Production Efficiency Factors (EPEF) and European Broiler Index (EBI). Higher economic efficiency of Vlora's broiler farm was influenced by performance indicators BW, ADG as a result of the strong correlation (0.84) among them. In all farms, subject of this study, performance indicators proved to be inferior compared to hybrid's standard. In Vlora's farm, the value of BW, ADG and FI (feed intake) were respectively 3.6%, 3.7%, and 4.5% lower than the standard, while the value of FCR was 10% higher.

Keywords: *performance indicators, technical and economic efficiency*

Introduction

Intensive/commercial broiler production is considered an important source of provision of animal origin protein. Broilers provide have a good meat quality and a high rate of productivity (FAO, 1999). Genetic improvement in terms of improving broilers' performance has substantially shortened their finishing time (Gunasekar, 2006). Because of the short growing cycle, broiler production ensures high returns and income (Kleyn, 2002; Grepay, 2009). In the next decade poultry meat will be the cheapest and most favored one, being marketed to customers in cuts. But this requires the finished broilers to be of higher body weights, higher meat yield, and consequently higher value added (Schmidt, 2008). In the past, poultry industry mainly focused on the dynamics of growth and feed conversion. Feed conversion rate (FCR) is considered as one of the most important parameters to assess the capacity of hybrids, or their nutrition program (Leeson, 2005). Researchers are studying options to improve feed conversion and growth indicators, in order to minimize the cost of production (Ghazi AM et al., 2012). Due to the substantial changes occurred in this area, to better evaluate the performance of broilers it is real important to take into consideration both biological performance and economic parameters. In order to accurately measure the broilers' performance several indices are calculated. Many of them represent only the biological performance of the birds; they can be used to measure the genetic capacity of birds, food quality and technical efficiency of the farm (Samarakoon S.M.R et al., 2012). Although there are many commercial broiler farms in Albania, full details regarding technical and economic indicators of production as well as an analysis of these indicators are not available. Therefore, the ***goal*** of this study is the evaluation of production and economic performance indicators in several commercial broiler farms.

Materials and Methods

The study was conducted in seven commercial broiler farms in Albania (in areas of Fier, Lushnja, Kavaja, Durres, Tirana, Vlora and Kruja), during April – May, 2012. Inclusion in the study of these farms was not random. Farms were selected considering their technology related conditions, growing broilers of the same hybrid (Cobb 500). In each farm for this study's purpose, a unit with the same number of heads - 5,000 birds was targeted. In all farms the chicken were kept in floor. The study was conducted during one growing cycle, from 1 to 38 days. Each farm had its specific conditions in terms of growing conditions and technology's implementation.

Performance parameters investigated during the monitoring for each unit were: final body weight (BW), average daily weight gain (ADG), feed conversion ratio (FCR), the mortality, as well as the economic efficiency of growth, through the calculation of PI (performance index), European Broiler Index (EBI) by Van, I. et al., 2003, and European Production Efficiency Factor (EPEF) by Broiler Management Manual Ross-308, 2009, and Van, I. et al., 2003.

Mortality was recorded daily, while based on the obtained data the percentage of viability was calculated. For analysis of performance indicators such as:

BWG (body weight gain), ADG (g/chicken/day), FCR, viability, PI, EPEF and EBI the following formulas were used:

BWG (grams on period) = BW (g) at the end period - BW (g) in first day;

$$\text{ADG (g/chick/d)} = \frac{\text{BWG}}{\text{days number of growth period}}$$

$$\text{FCR (kg feed/kg gain)} = \frac{\text{Feed intake (kg)}}{\text{BWG(kg)}}$$

Viability (%) = chicks remaining at the end of period (%);

To better judge on the performance of each farm, the index of production (IP) was computed. The Performance Index (PI) (Jahan MS, M. Asaduzzaman and AK Sarkar, 2006) was calculated as follows:

$$\mathbf{IP} = \frac{\text{Live Weight}}{\text{FCR}} \text{x} 100$$

European Production Efficiency Factors (EPEF)

$$(\mathbf{EPEF} = \frac{(\text{Flock Livability x Average Live Weight}) \text{ x } 100}{(\text{Average Kill Age x Feed Conversion})}$$

European Broiler Index (EBI)

$$\text{EBI} = \frac{\text{Livability (\%)x ADG (g/chicken)/day)}}{\text{FCRx10}}$$

EBI values are always lower than EPEF values, because for calculating the ADG, the Body Weight at age at day 1 day is excluded (Van, I. et al., 2003).

The obtained results according to the methodology were statistically processed for average values. To study the linkage between technical and economic indicators several correlations were calculated.

Results and discussion

Growth Indicators:

Throughout the growth period of the chicken, the mortality in each farm was monitored. At the end of growth (38 days) the number of chicks in each farm was recorded as in the following table:

Table 1: Mortality in each farm

	Fier	Lushnja	Kavaja	Durres	Tirana	Kruja	Vlora
Housed chicks in the Day 1	5000	5000	5000	5000	5000	5000	5000
Mortality (%)	9,12	3,96	5,62	6,48	4,96	1.68	3.92
Finished broilers	4544	4802	4719	4676	4752	4916	4804

Table1, clearly shows that the lowest mortality was demonstrated in Kruja's farm,followed by that of Vlora, Lushnja, Tirana, Kavaja, Durres and Fieri.

Analysis of performance indicators (i.e. BW, ADG, FCR and Mortality) is calculated based on the economic efficiency of broilers'growth.

Table 2: Broilers' growth performance indicators according to the respective farm (unit)

	Fier	Lushnja	Kavaja	Durres	Tirana	Kruja	Vlora	Standard
BW kg/chick	1.840	2.060	1.930	1.840	1.990	1.800	2.200	2282
ADG (g/day)	47.4	53.2	49.7	47.4	51.3	46.3	56.8	59
FI kg/chick	3.434	3.653	3.580	3.432	3.607	3.190	3.420	3.826
FCR	1.96	1.81	1.91	1.93	1.86	1.79	1.90	1.71
PI (%)	93.88	113.81	101.05	95.34	106.99	100.56	115.79	136.16
EPEF	224.52	287.56	250.90	234.76	267.51	260.26	292.77	
EBI	219.78	282.28	245.59	229.68	262.13	254.31	287.23	

The highest Finished Live Weight and Gain were received in ***Vlora's*** farm, followed by Lushnja's, Tirana's, Kavaja's, Fieri's, Durres' and Kruja. Although the broilers grown in Kruja's farm showed a satisfactory vitality, we can't say the same about the growth dynamics. Although Vlora's farm had 24.2% higher mortality than the Kruja's one, its broilers had an average weight of 400g (or 18.2%) higher.

The data obtained from this monitoring related to the production indicators were compared with the standard Cobb 500 (Broiler performance and Nutrition supplement; Cobb 500, 2008) for the same age (38 days).

It turns out that the closest to the standard body weight and gain were achieved at Vlora's farm. However, the values obtained in this farm were respectively 3.6% and 3.7% lower than the standard.

During the cycle, less feed per bird (FI = feed intake) is consumed in Kruja's farm, followed by Vlora's, Durresi's, Fier's, Kavaja's and Lushnja's ones. The same can be said for FCR, which shows a lower value in Kruja's farm, followed by Lushnja's, Tirana's, Vlora's, etc. FCR is strongly related to vitality (-0.88) which is clearly demonstrated in Kruja'sfarm (Table 3).

In all farms is consumed less feed per bird compared to the hybrid's standard. Closest to the standard is Lushnja's farm, with 173g (or 4.5%) less. In all farms, chicken were fed ad-libidum. Lower feed consumption in all monitored farms, should be connected with its quality (nutritional values, of the feed formula).

Kruja's farm broilers have used the feed per unit of weight more effectively, but in comparison with the standard have a higher FCR (4.5%). Given that in all farms, chicken have not received sufficient amount of feed, their growth dynamics and hence the final weight

has not been satisfactory. This has led to the acquisition of higher values of FCR than the standard's one. So feed is not used effectively.
As a result, the recorded values received by this study in all farms were inferior compared to the hybrid's standard.
Out of the data on growth performance: BW, ADG, FI, FCR and vitality, the values for the economic efficiency of growth, were obtained, through the calculation of PI, EBI (Van, I. et al., 2003) and EPEF (Van, I. et al., 2003 and Broiler Management Manual ROSS-308, 2009; Marcu, A., et al, 2013).
The highest IP was in Vlora's farm, followed by Tirana's, Lushnja's, etc. As lower the FCR's value is and the greater the body weight, the greater will the value of PI. Because in the calculation of this index, the relations between the IP and the Body Weight are the strongest (0.92), the farms that have the highest indicator will lead. However, at the farm of Vlora there is a blizzard of 14.96% in the IP's value compared with hybrid's standard.
In many countries the EPEF is used to measure the growth performance of broilers (Ross Broiler Management Manual 308, 2009; Van, I. et al., 2003). The EPEF value describes the overall production profile (Szollosi L, et al, 2014). This simple index facilitates the comparisons within a farm and among farms and can be used to assess changes in the application of the microclimatic and management parameters (Samarakoon S.M.R et al, 2012). The higher the value of EPEF is, the better is the technical performance of the birds. In our case, Vlora's farm has demonstrated the highest EPEF values, followed by Lushnja's, Tirana's and Kruja's ones. A broilers' flock with acceptable growth parameters and vitality should reach the EPEF values of 200-225 (Ross Broiler Management Manual 308, 2009). According to Reenivasaiah P.V.S, 2008, the optimal EPEF should have a value over 250. In our case, only four farms (Vlora's, Lushnja's, Tirana's and Kruja's) demonstrate to have this value over 250. Since EPEF includes the body weight and the finishing age at slaughter, (as well as the dynamics of growth), but the vitality and FCR as well, this indicator will also reflect any negative or positive effect related to health, environmental stresses or quality of feed. Lower values of EPEF in Kavaja's, Durresi's and Fieri's farms, show the necessity for a more accurate assessment of production parameters, including a study of data concerning the management and the health problems, in order to be able to determine the possible causes of a low output.
Vlora's farm has demonstrated to have the highest value of EBI. EBI is used to predict the efficiency of broiler production. Economic analysis based on EBI is used to predict farm income as well (Reenivasaiah P.V.S, 2008).
The highest value of the two indexes (EPEF and EBI) in the holdings of Vlora, Lushnja, Tirana and Kruja shows that their performance is better than the other farms. In both indices (EPEF and EBI) the highest influence belongs to the respective factors: Body Weight (0.84), ADG (0.84), Vitality (0.71) and finally FCR (-0.60).

Table3: Correlations between performance indicators and technical efficiency of growth

	FCR	Livability	BW	ADG	PI	EPEF	EBI
FCR	1						
Livability	-0,87936	1					
BW	-0,09084	0,257548	1				
ADG	-0,09046	0,254393	0,999962	1			
PI	-0,47436	0,564477	0,919443	0,919456	1		
EPEF	-0,60922	0,714302	0,840247	0,839545	0,980835	1	
EBI	-0,60294	0,706183	0,84526	0,844629	0,983	0,999927	1

Vlora’s farm and the one of Tirana and Lushnja are characterized by better indicator of technical efficiency of growth. This statement is verified and supported by the strong positive correlation (0.98-0.99) between these three indices (EPEF, PI and EBI). The higher is the productivity efficiency factor (EPEF) and European Broiler Index (EBI), the more rentable and the more profit will be farms.

Conclusion

Based on the results obtained out of the seven farms involved in this study, the following might be concluded:

Although Kruja’s farm is differentiated for best indicator of vitality and FCR has not managed to meet the desired performance because of insufficient feed consumption;

Vlora’s broilers demonstrated to have higher body weight and higher gain compared to other farms, but these parameters were lower compared to the standard (3.6 and 3.7% respectively).

Lower feed consumption/bird on all farms during the growth period can probably be linked to its quality, which led to inferior body weights and higher FCR, compared to the hybrid’s standard;

Vlora’s farm has shown a better technical performance (PI), EPEF and EBI (respectively 115.79, 292.77 and 287.23), compared to other farms subject of this study, resulting to be the most profitable farm.

For farms with poor indicators of technical efficiency of growth, one should make a fair assessment of production indicators related to growing/keeping conditions, feeding and health management of the flock.

Abstract

In Algeria, coccidiosis constitutes one of the main constraints which hinder the development of the poultry production and is responsible for major losses to the poultry industry, reducing performance and increasing production costs, especially increase of mortality and misuse of antibiotics. These molecules have fatal effects on the animal and public health, Thus, alternatives were introduced, in particular the extracts of plants. The present study, conducted in October 2013, was carried out in five hundred broiler chicks (Hubbard F15 strain). The chicks were monitored from birth to the 52nd day. These animals with homogeneous weight of 93 g, and mixed sexes, came from the same hatchery and underwent the same environmental conditions. Animals of the first lot, identified as "Control lot" received a food exempt from any additive but water added of antibiotics. The animals of the second lot, identified as "Experimental lot" received a water exempt from any additive and the same food added with the *Yucca Schidigera* extract. The objective of this study was the evaluation of the oocystale excretion by Mac Master's method to estimate the activity of the *Yucca Schidigera* extract. The results highlighted an increase of oocystale excretion until 82250 oocysts.g^{-1} of feces in the control lot and 22950 oocysts.g^{-1} of feces in the experimental lot. The average levels of oocysts were significantly lower during three weeks from J14 to J35 in the experimental lot, then remained comparable for the rest of the experiment period (J36 to J51). These results showed that this additive considerably reduced the coccidian eggs elimination and proved its efficiency in the coccidiosis control.

Keywords: *Yucca Schidigera, coccidiosis, broiler chicken, antibiotics.*

Introduction

Poultry is a significant economic protein source, especially for developing countries, which justified its rapid development across the globe for thirty years (Sanofi, 1999).

Poultry farming in Algeria has experienced spectacular growth and expansion through the various development plans of the Ministry of Agriculture. The increase in production is due to a control of livestock management, improved nutritional optimization of diets (Langhout, 1998) and the control of the health status animals. Coccidiosis is the major problem in poultry production with a significant economic impact, estimated at 2 billion$ including mortality (6 to 10%), the cost of prevention and treatment. The etiologic agents is an intestinal parasitic protozoa, coccidia of Eimeria which 7 species infect chicken (Yvore 1992). The control of this disease in livestock is essential to the success of the poultry industry. In Algeria, the treatment of coccidiosis is based on the use of chemical anticoccidials (antibiotics) in the food and drinking water. However, because of the prohibition of these antibiotics, the concern to maintain a satisfactory level of production requires the search for non therapeutic solutions that replace antibiotics. Alternatives to antibiotics should be both effective on the zootechnical, health and economic parameters. Additives proposed, are organic acids, essential oils, probiotics and prebiotics (Dorman and Deans, 2000). The objective of this

study is to evaluate the effect of supplementation based on *Yucca Schidigera* plant extract having various biological activities, antioxidant, anti-inflammatory, antimicrobial and antiparasitic can intervene in maintaining the health of the animal.

Material and Methods

The experiment was conducted for a period from November 2013 to January 2014. Five hundred day-old chicks of Gallus gallus domesticus belonging to the broiler strain Hubbard F15, were put in place in November 2013 and followed from the 1st to 52nd day. Animals were raised in a traditional style building located in the wilaya of Tipaza, compartmentalized so as to provide two living areas of 180 m². Animal's weight were 48 g of mixed sex from the same hatchery in the same environmental conditions. Food formulation considers the three breeding phases (starting, growing and finishing). The water served to the animals came from a regularly treated drink. Animals of the first batch, identified as "control lot" were receiving free food, any additive but water with antibiotics, the most frequently antibiotics administered on Algerian territory, from 1 to 14th day (day 1 to day 14) Animals of the second batch, identified as "experimental lot" were receiving free food, any additive but a drink of water with a anticoccidial based *Yucca schidigera* (Yuquina XO) produced by the NORFEED company, Europe. A vaccination protocol chicks was established and followed by the veterinary livestock. Animals in both lots were vaccinated against Newcastle disease KINGDOM L CEVA® at D6 and booster with L NEW CEVA® to J19 and also against infectious bursal disease IBD L CEVA® at15th day.

Experimental Protocol

We realized a comparative study between two lots: o The control group (TEM) with 250 chicks, receiving a food and water containing antibiotics.

o The experimental group (EXP) 250 chicks fed with the same food that the control but water with the *Yucca Schidigera* liquid. Harvesting of droppings was conducted in the barn to make a Fecal examination by highlighting the presence of oocysts in the feces of broilers in order to diagnose coccidiosis (Mayot, 2005).

Feces several subjects were collected in sterile jars from the 14th day (because the oocyst excretion begins on the 8th day) until the 51st day. The operation is done every day in the morning, collecting fresh droppings spread around the breeding of two lots in order to have a representative sample. These droppings were put in pots identified on the date of collection, the letters "TEM" for the control batch and the "EXP" for the experimental group. Droppings samples were transported immediately to the laboratory for parasitological analysis.

Counting oocysts of Eimeria

In the laboratory, we proceeded to parasitological diagnostic by the quantitative method. This method is based on counting oocysts in feces by Mac Master method. This method consists in counting the number of parasitic elements contained in 0.30 ml of a diluted fecal suspension at 1 / 15. This method relies on the use of Mac Master blade and has a flottation principe. Then, an amount of about 1 kg of salt is poured into a pan containing 1.5 liters of water. If necessary, add salt to saturation. We have carried out the preparation of the suspension of faeces.

The Mac Master blade is filled with the suspension of feces and placed under a microscope and retained about 10 min. The observation is made with a microscope (X10).

OPG of the two lots was calculated each day of the experiment (J14 to J51).

Results and discussion

Counting oocysts

The results of the count oocysts from 14th to 51st day show that the maximum values for each blade of the control group were 1645 and 658 oocysts, and from 21st to 31st they are 459, 198 and 237 oocysts J23, J27 and J41 respectively for the experimental group respectively.

b. Counting OPG

Results for both lots exhibit maximum values for the control group of 82250 and 32900 oocystes.g-1 faeces at 21st and 31st day respectively; these values were 35900, 9900 and 11850 oocystes.g-1 faeces at 23th , 27th and 41st respectively for the experimental group.

The results of the number of OPG of the two lots are illustrated in the following figure:

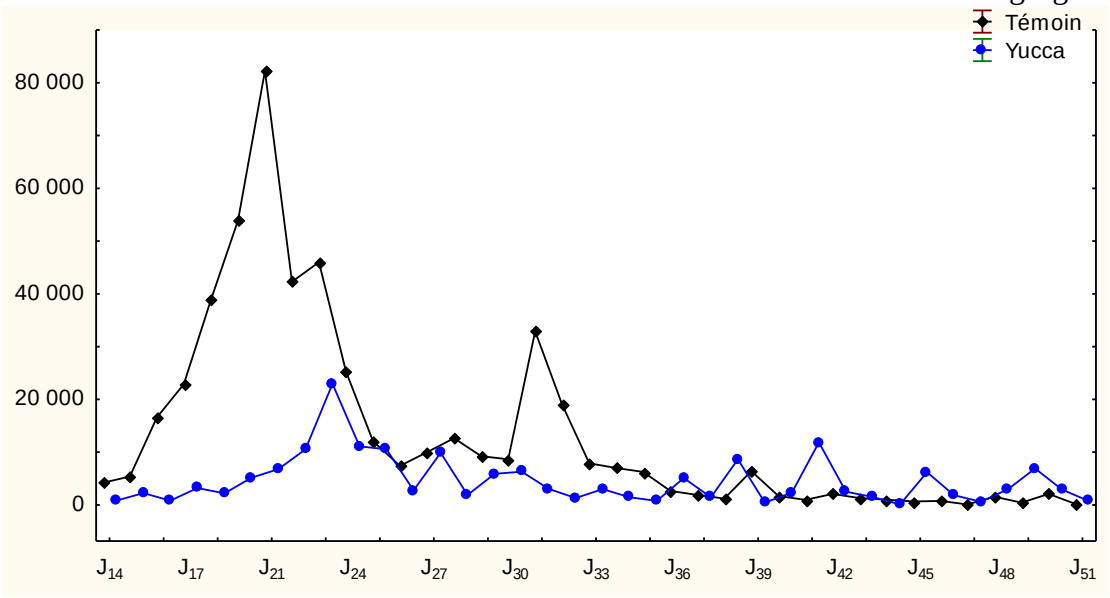

Figure 1: Evolution of oocyst shedding subjects of each lot.

Results show for the control group a progressive and significant increase in oocyst shedding from 14th (4200 OPG) and reach a first peak at 21st (82250 OPG) then decrease at 26th (7400 OPG) shedding then stabilized between 27th and 30th (9250 OPG) to move up to a second pic at 31st (32900 OPG). Then we have a lower concentration at day 33th (7900 OPG) and stabilize again from day 34th (7000 OPG).

For the experimental group, we have a stabilization of oocyst shedding between 14th (800 OPG) and 18th (2200 OPG) followed by a slow increase and reach a first peak at 23th day (22950 OPG) and then decease at 26th day (2750 OPG). The oocyst shedding present a second peak at 27th (9900 OPG), and decrease than at 29th (5900 OPG) followed by stabilization at day 30 (6300 OPG).

Comparison (2-2) the number of ovocytes.g-1 (mean ± SE) between control and experimental samples (paired samples) shows significantly differences for the first 3 weeks of measures (Table 1), corresponding to day 14-21, 22-28 and 29-J35.

Then levels ovocytes.g-1 was comparable for both samples at day36 to 51.

Table 1: Average weekly levels ovocytes.g-1of two lots

D_{43}-D_{49}	5ème week	829±188	2879±1013	0.10
D_{50}-D_{51}		1150±950	1800±1100	0.14

This difference in the number of oocystes.g-1 feces (OPG) between the two lots (TEM, EXP) is explained by the rise of OPG in the control group after a heavy infestation of coccidia. We registered a decrease in oocyst shedding after the administration of a chemical anticoccidial (Toltrazuril, Baycox®). This medication was made at the onset of clinical signs at D21 and D31.

Moreover, the number of OPG is weaker in the lot EXP with no symptoms compared to TEM lot. This seems to be explained by the incorporation of the extract of *Yucca schidigera* in their diet from day one.

However, Dahmani and Djaouchi (2013) made with the same additive and Trigonella Graecum in broilers report two relatively small peaks substantially similar for both lots between 18th and 20th day. These authors concluded that the use of the plant *Yucca Schidigera* and *Trigonella Graecum* extracted in broiler feed effectively protects animals against coccidiosis.

Various publications have reported efficacy studies of herbal products on the prevention of coccidiosis in vivo. Allen et al. (1997) demonstrated that the extract of wormwood leaves used as food additives would have a protective effect against intestinal lesions produced by the parasite. Recently, Naidoo et al. (2008) showed that the extract of this plant reduces significantly the production of oocysts to poultry, and restores their weight gain. Moreover, Saini et al. (2003a, b) and Giannenas et al. (2003) reported that the essential oil of oregano reduce the expression of coccidiosis in chickens. However, the mechanism responsible for these beneficial effects remains unexplained.

Mpoame et al. (2003) studied the effect of aqueous extracts of papaya seeds in older chickens (37 days), inoculated with a suspension having a oocyst who received 10 days later aqueous extracts based treatment papaya seeds administered for 3 days with doses of 0, 10, 20 and 40 gl-1; they revealed that the OPG were similar in all items and showed a reduction of OPG between samples before and after treatment.

The number of OPG 0 gl-1 was significantly higher ($p < 0.05$) for both post-treatment samples compared to the batch that received 40 gl-1, but comparable to lot wich receive 10 gl- 1. Conversely, the study Kouakou et al. (2010) using the aqueous extract of Thonningias anguinea revealed a presence of oocysts in the feces of all infected batches. This presence has been constant in the untreated batch infected with a higher excretion 1.2x105 OPG during the study. By cons, in both treated groups, we observed a reduction of oocysts excreted with OPG (contaminated and treated with conventional anticoccidial Super hipracox-p).

Conclusion

This study evaluate the effect of the *Yucca schidigera* plant extract on oocyst shedding in broiler chicken, we concluded that supplementation of this extract in the experimental group feed from the first days of life the chicks reduces significantly the elimination of coccidia eggs.

We also noted the absence of pathognomonic signs of coccidiosis, with this anticoccidial (*Yucca Schidigera*) introduced preventatively in broiler breeding. Whereas for the control group, we concluded that the use of anticoccidial early did not prevent the onset of the disease and its evolution.

Abstract

The aim of this study was to determine the value of fatty acids in the hump of camel. The fatty acid composition of the hump of 43 camels (*Camelus dromedarius*) with ages ranging from 1 to 13 years was determined by gas chromatography. The saturated fatty acids in the hump represented 64.4% of the total fatty acids, while the monounsaturated and polyunsaturated fats accounted for 33.1 and 2.5%, respectively. The main saturated fatty acids in the camel hump, namely the palmitic and stearic acid represented 49,6% and 38.8 % of the SFA (31.5% and 25.5% of the total fatty acids). The unsaturated fatty acids were mainly represented by the oleic acid, totaling 78.1% of the monounsaturated ones (25.9% of the amount of total fatty acids), the linoleic acid which accounted for 88.5% of the ω6 (1.17% of the total fatty acids) and the linolenic acid accounting for 63.9% of the ω3 (0.42% out of the total fatty acids).

The saturated fatty acid/unsaturated acids ratio have equalled 0.039 and that of ω6/ω3 equal 2.81.The results showed that the levels of fatty acids, saturated fatty acids and monounsaturated fatty acids were significantly higher in females, while the content of ω6, ω3, Linolinic Conjugate Acid (CLA), polyunsaturated (PUFA), as well as the PUFA/saturated fatty acid (SFA) and ω6/ω3 ratios were comparable in relation to both sexes.When reported to the breeds, the contents of ω6 and PUFA were higher in the Sahraoui, same as the ω6/ω3 ratio. The percentages of SFA, however, were higher in the Tergui, while the percentages of monounsaturated fatty acid (MFA) and ω6 were higher in the Sahraoui.

Keywords: *Hump, camel, fat acid, breed.*

Introduction

Camels store energy as fat deposits accumulated in various parts of the body, mainly hump and abdomen (Kadim et al., 2002). But their originality at this level resides in the preponderance of the hump. This one contains most of the subcutaneous fat, while the internal fat is mainly located around the kidneys (15% of the fat storage) and inside the mesentery (5%) (Kamili et al., 2006). As a whole, a dromedary weighing 750 kg contains more than 150 kg of body lipids. Changes in body fat are very little known in what concerns the dromedary. On average, the weight of lipids in the hump is estimated between 10 and 20 kg, but with a large variability associated to the physical activity and the nutritional and physiological status - age and sex- of the animal (Wilson, 1984). For example, the size of the hump increases during the rainy season, when the animal restores its fat deposits (Chilliard, 1989).

The lipid metabolism underlying fat store in dromedary is known (Mirgani, 1977). Its indicators are the same as in other species: determination of cholesterol, triglycerides, free fatty acids at serum levels, but also the fatty acids composition of the hump (Chilliard, 1989; Kadim et al., 2002).

Most of the studies performed to date on fatty acid composition of the hump in dromedary concerned animals raised in intense farms. In Algeria, dromedary is generally kept on natural pasture. Their diet includes foliage and desert vegetation. The dromedary is fed on *Acacia sp.*,

and *Artiplex sp.* and fatty acid profile of their fat must reflect the metabolism associated to poor vegetation from arid zone.
The aim of this study was thus to assess the fatty acid profile of hump fat from dromedary raised on naturel pastures in Algeria.

Material and Methods

Animals and sampling:

This study was performed on 43 animals slaughtered at the Ouargla abattoir (800 km South-Eastern from Algiers-Algeria) in 2011. Animals were represented by 7 females and 36 males aged 1 to 13 years old, belonging to two breeds, i.e., Sahraoui and Tergui.
Directly after slaughter, samples of 50 g fat were obtained from the center of each hump, carried out in ice to the laboratory and stored at -20°C in sealed plastic bags until analysis.
The fatty acids were analyzed based on gas chromatography with electronic pressure control Hewlett Packard type (HP 6890 series), equipped with a capillary column HP-5 (30 m x 0.25 mm) displaying a film thickness of 0.25 µm, an FID detector set at 260°C and fed with a H_2/Air mixture and a split/splitless injector set at 275°C. Injection by split method (split ratio: 1/50). The gas used was nitrogen with a flow rate of 1.7 $ml.min^{-1}$. The column temperature was set to 50 to 25°C at $4°C.min^{-1}$. The unit was controlled by a computer system "HP ChemStation" type, managing the operation of the device and enabling monitoring of the progress of the chromatographic analysis.

Statistical analysis:

The analysis was performed on Statistica 10.0, (Statsoft Inc., Tulsa, USA) and IBM SPSS 20 (IBM Corp).
Fatty acids (SFA, MFA, PUFA) were expressed as % of hump fatty acids (FA). The normality of the values distribution and the homogeneity of variances were evaluated by the Kolmogorov-Smirnov and Levene tests, respectively.

Results and discussion

Proportions of fatty acids:

Weight proportions of individual fatty acids in the hump of the 43 camels are shown in table I.

Table 1: Fatty acids composition (% FA) of hump fat, in algerian dromedaries.

SFA		**MFA**		**PUFA**			
				ω 6		**ω3**	
C14:0	4.90±0.21	C16:1cis9	2.33±0.18	C18:2n-6	1.17±0.07	C18:3n-3	0.42±0.05
C15:0	0.83±0.04	C17:1cis10	0.48±0.02	C20:2n-6	0.032±0.004	C20:5n-3	0.035±0.003
C16:0	31.5±0.7	C18:1trans11	2.63±0.26	C20:3n-6	0.025±0.005	C22:5n-3	0.19±0.02
C17:0	1.34±0.05	C18:1cis9	25.9±0.5	C20:4n-6	0.056±0.003	C22:6n-3	0.015±0.001
C18:0	25.5±1.0	C18:1cis11	1.74±0.06	C22:4n-6	0.043±0.003		
C20:0	0.28±0.02	C20:1cis11	0.009±0.001				
Total SFA	64.4±0.7	Total MFA	33.1±0.6	Total ω6	1.33±0.08	Total ω3	0.66±0.06

SFA represented for more than 60% FA hump. Palmitic acid was the most important of them with close to 31.5%, followed by stearic acid with about 25.5%. The two FA represented more than half of the fat hump (57%) and C14:0 represented a low value of 5% of total FA.
As concerns MFA, oleic acid, predominated with 25.9%. Far behind, was found the C16:1(9) with 2.33%. Two intermediate chain of fatty acid, C18:1 trans 11 and C18:1cis 11 showed closed levels and accounted for about 2.63 and 1.74% respectively.

When regarding PUFA, linoleic acid was predominant with 1.17% (88.5% of the total ω6), linolenic acid with 0.42% (63.9% of the total ω3). The cis-9, trans–11 CLA averaged 0.50%. In much smaller quantities followed C22:5n-3 (0.19%) and C20:4n-6 (0.056%).
Other fatty acids were found in very small quantities. However, PUFA/SFA was 0.039±0.003 and ω6/ω3 was 2.81±0.33.
According to an unpublished study reported by Faye et al. (2012), the dromedary hump stores on average 44% of the fatty reserves of the animal. It is the most representative organ in terms of importance of fatty reserves, before the perirenal and perivisceral regions. The fatty tissue is also deposited in different parts of the carcass like shoulder, sternum, flank, ribs, thigh and neck, subcutaneous and inter- or intramuscular tissues. In fatty animals, the tissue accumulates equally in the ano-genital area (Ollier, 1995; Faye et al. 2002).
The dromedary hump represents almost 13% of the carcass weight (Yousif and Babiker, 1989) and its tissue could contain 84% fat (Abu Tarboush and Dawood, 1993). In that species, half of the sirloin cut may be fat since hump is currently part of this cut (Yousif & Babiker, 1989). Its importance on a human dietary point of view could thus not be neglected.
Our results showed that the fat found in the dromedary hump was characterized by a high content, at about two third, in saturated fatty acids, the monounsaturated acids practically representing one third and the PUFA a level as low as 2%. More than half of the PUFA were from ω6 family, a bit more than a quarter was represented by the ω3 family, and the fifth was represented by cis-9,trans-11 CLA.
When regard to SFA in the hump prevailed palmitic (31.5%), oleic (25.9%), stearic (25.5%) and in a lower amount, myristic acids (4.9%). The same observation, in similar orders of importance, was reported by Mirgani, (1977) and Kadim et al. (2002), Mirgani (1977) having observed a slightly higher proportion in miristic acid (12%). Rawdah et al (1994), as for them, reported that the main fatty acids present in the fat stored in the dromedary hump were palmitic acid (34.4%), followed by oleic (28.2%), myristic (10.3%) and stearic acids (10.0%).
Comparing the saturated fatty acids present in the dromedary hump with those acids present in the milk shows very similar values. The findings of Gorban et Izzeldin (2001) showed that the camel milk is also rich in saturated fatty acids (66, 1%) and monounsaturated fatty acids (30.5%). Accordingly, the dominating saturated fatty acids are palmitic acid (34. 9%), myristic acid (14. 5%) and stearic acid (9. 7%).
It is remarkable to note that these four FA generally stem from a lipogenetic metabolism (Maier et al., 2006) or, in ruminants, from saturation of dietary fatty acids in the pre-stomaches (Kouba et Mourot, 2011). Owing to the fact that the diet from dromedary maintained on pasture is, as a rule, very poor in fat, it can be concluded that the very large proportion of the fat found in the hump derive from the lipogenesis in the animal.
In man, the saturated fatty acids consumed in excess increase plasma cholesterol, LDL and HDL levels (Mensink et al. 2003). However, not all saturated fatty acids bear the same cardio-vascular risk: the medium chain fatty acids such as myristic or palmitic acid have more deleterious effects than the long chain fatty acids such as stearic acid (Dubois et al., 2012). In our results, medium and long-chain FA accounted for similar amounts, and the mono-unsaturated fatty acids practically represented one-third of the total fatty acids (33.1%), with emphasis oleic acid, representing the very large part of the mono-unsaturated acids and also the second most frequently encountered FA after palmitic acid, i.e., more than a quarter of the total FA. Similar values have been reported by Mirgani (1977), Emmanuel and Nahapetian (1980) and Kadim et al. (2002). In lower quantities, but consistent when put in relation to the mono-unsaturated acids, trans-vaccenic, palmitoleic and vaccenic acids totalized close to 7% of total FA.

Mono-unsaturated fat acids are considered as beneficial for health owing to the fact it decreases the total cholesterol and LDL and, in the same time, increases the HDL blood levels (Hu et al., 1997).

Short chain PUFA levels were quite low in the present study. Besides similar features as ours for SFA and MFA, Emmanuel and Nahapetian (1980), as well as Kadim et al. (2002) also reported low levels of C18:2 w6 and C18:3 w3 in hump fat.

Polyunsaturated fat are protective against cardiac arrhythmias. A study of post-menopauseal women with a relatively low fat intake showed that polyunsaturated fat exert a protection against the progression of coronary atherosclerosis, by contrast to monounsaturated fat (Mozaffarian et al., 2004). However, it was known that polyunsaturated fats do are sensitive to lipid peroxidation. Vitamin E has been shown to be protective against this phenomenon (Leibovitz et al., 1990), as well as selenium, whose levels in meat from dromedary are rather high (Sahraoui et al., 2013). The unsaturated/saturated fatty acids ratio was 0.039 and that of ω6/ω3 2.81. These ratios could be judged small because the current recommendations for a healty diet are in favor of ratios close to 1 and 5, respectively (Renaud and de Lorgeril 1989; ANC, 2011).

Conclusion

This study showed that hump of two breeds of dromedary (Sahraoui and Tergui) raised on natural pasture in Algeria is especially rich in saturated fatty acids, followed by mono unsaturated ones, with modest levels of polyunsaturated onesThe fat of Sahraoui breed appeared to be richer in unsaturated fatty acids. Hump fat may be considered as a significant source of unsaturated fatty acids for nomadic populations.

Abstract

The purpose of this study was to investigate the effects of *Yucca schidigera* on animal and lipid parameters in broilers. For this, animals were divided into two equal groups of 950 chicks. Y*ucca schidigera* supplementation was incorporated into a standard diet of experimental group (0.5 kg/tonne) for a period of 52 days.

Zootechnical parameters (weight gain, feed conversion and mortality) and lipid parameters were determined at the end of each breeding phase (day 28, 42, 52) (total cholesterol, HDL-cholesterol-cholesterol LDL, triglycerides).

χ^2 test showed that mortality rates in 2 batches (control and experimental) were comparable for the 3 periods (p=0.26, p=0.11, p = 0.20). The results of weight gain obtained at the end of breeding showed a difference in weight between the animals of the ”control” and the “experimental" groups (2270 vs 2240 g), but without significant statistical difference.

In parallel, net decreases in triglycerides and LDL levels were observed in all supplemented animals. These results showed that dietary supplementation with *Yucca schidigera* interfered with the energy and fat metabolism of the animals.

Keywords: Yucca schidigera chicken production parameters, lipid profile.

Introduction

Poultry farming in Algeria has expansed through the various development plans (1).

Antibiotics as growth factors are among the most commonly used additives to improve feed efficiency and growth animals rate and consequently increase the productivity of farms. However, they have encouraged the emergence of antibiotic residues in the food chain and human health (antimicrobial resistance) (2). However, following the ban on the use of antibiotics as growth promoters from January 2006 by the European Union and in order to maintain a satisfactory level of production, more additional ingredients to the diet improves disease resistance and participate in their properties and bioactive molecules to improve health of animals, have been undertaken recently as an alternative of antibiotics, including enzymes, organic acids, extracts of natural plants, probiotics and prebiotics (3).

In Algeria, to fight against coccidiosis, we use the chemical coccidiostats in feed and drinking water.

The aim of this study was to evaluate the effect of dietary supplementation of anticoccidial containing the natural extract "*Yucca schidigera*" in our broiler farms.

Material and Methods

The aim of this study was to evaluate the impact of food supplementation *Yucca schidigera* extract, on growth performance and blood lipid parameters.

Our study was conducted during the period of February to April 2014, in a traditional farm, located in Tipaza (north of Algeria).

Zootechnical parameters:

1.1. Animals:

We used two thousand seven hundred (2700) day-old chicks of Gallus gallus domesticus, coob strain, mixed sexes, a homogeneous weight (93 g) from the same hatchery. These animals were weighed and divided into two (2) batches. Animals were put in place 10 February 2014 for a period of 52 days, in a traditional building, under the same conditions of environments.

1.2. Food:

The food used was produced especially for our experiment on the basis of a formulation into account the three breeding phases (starting, growing and finishing). Drinking water distributed to the animals came from a regularly treated well.

1.3. Preventive treatment:

Subjects in both lots were vaccinated against Newcastle disease KINGDOM L CEVA® to D7 and a booster with L NEW CEVA® j17 and j45 for and against Gumboro disease IBD L CEVA® at J9 and J20.

This study aims to compare the lipid profiles of two experimental treatments:

The first batch of animals (300), identified as "control group" received the food free of additives but water with antibiotics, the most frequently administered treatments on Algerian territory.

The second batch of animals (2400), identified as "experimental group" received a drinking water free from any additive and the same feed supplemented with *Yucca schidigera* extract in an amount of 0.5 g/kg (this is an anti-coccidian form of a powder "Yuquina" produced by the company NORFEED Europe).

From these two lots 23 subjects were sacrificed, the blood test was done at the age of 28^{th}, 42^{nd}, 52^{nd} days to determine the parameters of the lipid profile.

Biochemical study was to evaluate the effect of *Yucca schidigera* extract on some biochemical parameters of chick blood (total cholesterol, triglycerides, HDL and LDL).

Statistical analysis

Comparison tests of weights between batches "Experimental" and "Control" has been made based on the calculation of RC critical report.

The mortality rates were compared using χ^2 tests.

Otherwise, comparisons of total cholesterol, triglycerides, HDL and LDL were established between experimental and control groups for the three periods of experimentation with Student or Mann-Whitney tests.

The results are given as mean ± SE and differences were considered significant at $p<0.05$.

The analysis was based on SAS or Statistica 10, Statsoft Inc., USA.

Results and discussion

I. Zootechnical parameters:

1. The weight of chicks:

The average weight values (g) of chickens supplemented or not by *Yucca schidigera* extract were given in Table 1.

Table 1: Evolution of the weight of chicks two batches (g).

Lots		**D_{28}**	**D42**	**D_{52}**
Experimental (n = 1400)	Weight (g)	581±7,2	1575±8,7	2510±7,1
	Feed conversion	2.99	1,42	0.65
	Mortality rate (%)	3.25	**4.42**	**67,92**
Control (n = 300)	Weight (g)	862±13,8	1986±10,6	2775±6,9
	Feed conversion	1,72	1,85	1.90
	Mortality rate (%)	**1,66**	3	**49**
	p (Weight)	**<0.001**	**<0.001**	**<0.001**

Chickens from the control group had a higher weight than the experimental group during the three breeding phases with high significant differences ($p<0.001$).
Feed conversion ratios of supplemented group with *Yucca schidigera* extract is lower compared to the control group during the growth phase until age 52nd.

Indeed, the use of anticoccidial based on natural plant *Yucca schidigera* and probiotics in avian husbandry has been the subject of numerous studies where weight gain has improved as reported (Kucukkurt *a*nd Dundar, 2013).
Mortality rate:
Animal mortality observed in the first three days is mainly due to transportation and handling stress during the chicks installation. Therefore, we will not take into consideration, and we have registered mortalities between 4th and 52nd day.
The mortality rates at D_{28} were comparable between “Exp” and “Contr” group ($\chi^2=2.23$, $p=0.14>0.05$)
The mortality rates at D_{42} were comparable between “Exp” and “Contr” group ($\chi^2=1.26$, $p=0.26>0.05$)
There was a highly significant difference between the mortality rates at D_{52} between “Exp” and “Contr” group ($\chi^2=38.70$, $p<0.001$)
According to Villate (5) norms of mortality rates are below 5%, which shows a mastery of breeding practice.
Jang et al. (6) indicated that the weight, average daily gain, the amount of food ingested, and feed efficiency were not significantly improved due to the addition of plant extract

Biochemical parameters:
The samples of chickens supplemented in *Yucca schidigera* extract, showed a decrease in cholesterol levels (table 2) (the difference was not significant $p=0.25$).
At the age of 42nd day, the total cholesterol content in both batches was similar (1.23 and 1.24).
We can see that the voluntary cessation of supplementation *yucca schidigera* extract cause of increased cholesterol level, this might be explained by the positive effect of this extract (the difference was not significant $p=0.14$).
Triglycerides levels were reduced on the 42nd day (0.47 and 1.03) and also the 52nd day between supplemented and control groups (the difference was not significant $p=0.14$ and 0.34).
HDL: it was noted decreased HDL levels in day 42 in the batch supplemented but not significant $p=0.77$).

LDL: in this study, we observed lower levels of LDL cholesterol in supplemented lot. At 52nd day LDL-cholesterol level is high in experimental group compared to the control (1.43 and 0.54) which corresponds to the voluntary cessation of supplementation *Yucca schidigera* extract.

Thus, Zhao et al (7) saponins from Yucca schidigera decrease cholesterol, triglyceride levels, and LDL levels were significantly reduced, in contrast to HDL witch is increased.
However, Kaya et al (8) reported the same observation using *Yucca schidigera* extract, these authors noted a decrease in the cholesterol levels in chickens

Moreover, Kucukkurt and Dundar (4) have shown that supplementation of *Yucca schidigera* induced HDL concentration increase and a decrease of cholesterol rate, triglycerides and LDL lipoprotein.

Table 2: Biochemical parameters.

	D_{28}			D_{42}			D_{52}		
Parameters	**Control**	**Experimental**	**p**	**Control**	**Experimental**	**p**	**Control**	**Experimental**	**p**
Ch T ($g.l^{-1}$)	1.30±0.23	0.94±0.14	**0.25**	1.24±0.29	1.23±0.32	**0.98**	1.40±0.44	2.88±0.66	**0.14**

Ch T: cholesterol total, Trig: triglycerides.

Conclusion

Growth factors antibiotics used in animal feed are responsible of antimicrobial resistance in animals and human.
To preserve the quality of chicken meat (drug residues), which not require a waiting period and therefore consumer health. *Yucca schidigeraa* natural extract was studied on a broiler in order to better determine its effectiveness.

EFFECTS OF REMOVING VITAMINS AND TRACE MINERALS FROM CHICKEN FINISHER DIETS ON ASH CONTENT IN THE BREAST MEAT

Milanka DRINIĆ, Aleksandar KRALJ*, Nebojša SAVIĆ, Božo VAŽIĆ

*Faculty of Agriculture, University of Banjaluka, Bosnia and Herzegovina

Abstract

A chicken diet must consist of the following: energy, proteins, i.e. amino acids, fat acids, vitamins and minerals. Having in mind that broiler nutrition costs are high (55-70%), there are permanent searches of the opportunities to reduce them. In support of that, there are many researches aiming to remove some nutritive matters for a certain period of time from a diet with no bad impact on production parameters. The experiment was set up with 1400 chicken, divided into 7 groups, which vitamin additives or vitamin + trace minerals were excluded from the day 30 to 42. These additives were excluded 12; 8 and 4 days before the end of the fattening process. The assumption was that the body of chickens accumulate a sufficient amount of vitamins and trace elements and their exclusion from diet at the end of fattening period had no negative impact on the production characteristics. Great quantitative of water soluble vitamins cannot be generally accumulated, but broiler chicken will continue to use them from natural nutritive, after exclusion of premixes. The monitored production parameter was ash content in the chicken breast meat. The results show that exclusion of both, vitamin and mineral additives led to significantly lower ash content in chicken breast meat. The removing only vitamins did not have negative effects to the research parameter. Duration of the exclusion these substances (12, 8 and 4 days) had no effect on ash content in the breast meat of chicken.

Keywords: *removal, mineral, vitamin, ash content, breast meat*

Introduction

Vitamins and trace elements in the chicken body have important functions and therefore the feed must contain them in the sufficient concentrations. An excess of these substances in the body can be partly deposited in certain organs and tissues or removed from the body. The high concentration of vitamins and trace elements in the body can cause poisoning or depression, and the lack of these substances leads to the production decline and the appearance of characteristic deficiency symptoms. Many researches aiming to remove some nutritive matters for a certain period of time from a diet with no bad impact on production parameters.

Studies on pigs have shown that the exclusion of trace elements in the final stages of fattening had no adverse consequences on the production performance (Kim et al., 1997; Mavromichalis et al., 1999; Shelton et al., 2004). The studies that are linked to short-term exclusion of vitamins and/or trace elements from broiler chicken diet have shown the possibility of excluding these nutrients without harmful production consequences through some period of time (Summers, 1997; Ruitz and Harms, 1990).

Baker (1997) concluded that the concentration of trace elements in edible parts of the chicken meat will not be reduced as a result of a seven-day exclusion of trace elements from a chicken diet. The same author noted that the elimination of Fe from broiler diet for a period of 7 days did not reduce the concentration of this trace element in the muscle (Baker, 1989). Removing of a vitamin premix from broiler diet at 29 days did not have negative effect on the immune system (Alahyari-Shahrab et al., 2011). The research of Charuta et al. (2013) showed that in a group of male animals, reducing of relative bone mass from 1.03 to 0.79%, during post

hatching development can lead to deformities and fractures of the tibia, which could have negative effects on broiler production.
The removing of zinc from the chicken diet in the last 7 days led to a reduction of its concentration in the bones and intestines, but not in the muscle (Emmert and Baker, 1995).
Zapata et al. (1998) performed the studies on broilers in order to determine the effect of the exclusion of vitamins and trace elements from the chicken diet during the period 21-42 on the content of trace elements in meat. The conclusion was that the exclusion of vitamins and trace elements from the final chicken diet had no adverse effect on the mineral content in chicken meat. However, the calcium content was lower with the exclusion of these supplements.
Chicken breast meat has less fat and connective tissue in relation to other parts of chicken carcass, and because of that it is better digested. In addition, this type of meat is a good source of mineral substances, primarily richer source of K, Mg and P (Poltowicz and Doktor, *2013).*
The aim of this study was to investigate the effect of removing of vitamin-mineral or vitamin supplements from diet on ash content in the breast meat, only in the last stages of chicken fattening period. We should bear in mind the importance of chicken breast meat as a source of vitamins and minerals in human nutrition. On the other hand, the highest increase of chicken weight gain happens in the last period of fattening. Therefore, the possibility of exclusion of vitamin and mineral supplements without negative effects on the mineral content in meat could lead to significant financial savings.

Materials and methods

The experiment was set up in the building for chicken fattening, on the private "Vujat" farm, Srbac municipality. Total of 1400 one day old chicken, Cobb 500 hybrid, were divided into seven groups, each of 200. Chicken were fed with two mixtures whose nutritive matters were compatible with recommendations of the producers of line hybrids. The first mixture (PI) was identical for all chicken and it was used for the first 15 days. Afterwards, up until 30 day of fattening the second mixture was used (PII), which also was the same for all groups. From day 30 the same mixture as from 15-30 days were used, but vitamins and trace minerals or both were removed. After the day 30, the following mixtures were used: 1) full premix in concentration of 1% with vitamins and trace minerals according to the needs of this category (control group); 2) mixture with 0,5% premix, with only trace minerals (NV); 3) mixture with no premix, with no vitamins and trace minerals (NVM). Control group of chicken was fed with a full mixture, with vitamins and trace minerals up until day 42. NV mixture was given to the groups: II (30^{th} -42^{nd} day), III (34^{th} – 42^{nd} day), IV (38^{th} – 42^{nd} day). NVM mixture was used with following groups: V (30^{th} -42^{nd} day), VI (34^{th} –42^{nd} day), VII (38^{th} –42^{nd} day). On the day 30, each chicken was marked by a leg ring, groups were harmonised as per mass and sex. All health measures have been implemented as per veterinary program.
After completed fattening, 10 chickens was sacrificed from each group (5 male + 5 female) and ash content in breast meat was analysed.
The results were processed by Analysis of variance method using Statistical Programme STATISTICA 10, STATSOFT. Significance of differences between average values of individual groups was determined by F and t test. Because full diet was given to only one group for entire period (control), and NV and NVM mixtures were given in three different periods: 4; 8 and 12 days, it was not possible to make processing by using only one model of variance, it was done separately with using two Analysis of variance models, 3 X 2 (three mixtures, two sexes) and 2 X 3 X 2 (diet with no vitamins; diet with no vitamins + trace minerals; three removals in different times 12, 8 and 4 days; two sexes).

Results and discussion

Ash content was determined in in breast meat of chicken, bearing in mind different mixtures and sex, and it is shown in table 1.

Table 1. Ash content in breast meat of chicken (%), fed with different mixtures of concentrates, monitored depending on sex

Type of diet (F_A)	Sex (F_B)		Feed effect
	Male	Female	
Complete diet (control)	1.18	1.18	*1.18*
No vitamins (NV)	1.29	1.27	*1.28*
No vitamins and trace minerals (NVM)	1.10	1.15	*1.12*
Sex effect	*1.19*	*1.20*	
Analysis of variance			
F_A	F_B	F_{AB}	
25.47**	0.226^{NS}	0.918^{NS}	
t-test significance of differences between the different mixtures of concentrates			
Complete diet 1.18 % (X_1)	t^{1-2}	4.52**	
No vitamins (NV)1.28 % (X_2)	t^{1-3}	2.71*	
No vitamins and trace minerals (NVM) 1.12 % (X_3)	t^{2-3}	7.23**	

By looking data in table 1, it can be seen that statistically there is no a significant influence of sex to tested parameter. However, there is statistical significant impact of type of feed. Chicken that were fed with no vitamins-NV mixture had the greatest ash content in breast meat, 1,28%; chicken fed with complete mixture had ash content of 1,18%, while the lowest content was with chicken with no vitamins and trace elements-NVM, 1,12%. We can conclude that feed with no vitamins and trace minerals influenced the most depressive on the ash content in breast meat.
By monitoring the same parameter, only from the point of length of removal of vitamin-minerals, type of mixtures and sex has been shown in the table 2.

Table 2. Ash content in breast meat of chicken (%) fed with concentrates with no vitamin-minerals from 12; 8 and 4 days

Length of removal (F_B)	Sex (F_C)	Type of feed (F_A)		Effect of length of removal
		No vitamins (NV)	No vitamins and trace minerals (NVM)	
12 days	Male	1.21	1.14	*1.18*
	Female	1.17	1.22	
8 days	Male	1.26	1.10	*1.21*
	Female	1.34	1.13	
4 days	Male	1.40	1.08	*1.23*
	Female	1.32	1.11	
Effect of feed		*1.28*	*1.12*	
Effect of Sex		Male	Female	
		1.20	*1.21*	

Analysis of variance

F_A	F_B	F_C	F_{AB}	F_{AC}	F_{BC}	F_{ABC}
*29.33***	0.744^{NS}	0.191^{NS}	7.233**	1.104^{NS}	0.688^{NS}	1.114^{NS}

Interaction effects

	Type of mixture X length of removal of vitamin-minerals		
	12 days	8 days	4 days
NV mixture	1.19	1.30	1.36
NVM mixture	1.18	1.12	1.09

The above table clearly shows that the ash content in the breast meat of broiler was not depended on the length of the removal of vitamin and mineral supplements, but only on the type of mixture.

Moreover, significant interaction effect was determined by the type of feed and length of removal of vitamin-mineral additives.

These results are not fully consistent with the results of *Zapata et al. (1998),* who concluded that it is possible to exclude minerals without negative effects on meat quality. Also, this is not entirely consistent with the Baker (1997) who concluded that the concentration of trace elements in edible parts of the chicken meat will not be reduced as a result of a seven-day exclusion of trace elements from broiler diet. In addition, Emmert and Baker, (1995) claimed that the removing of zinc from the chicken diet in the last 7 days led to a reduction of its concentration in the bones and intestines, but not in the muscle. It can be said that the exclusion of these substances from the chicken diet in the last phase of fattening had no harmful production consequences, as well as in the researches of Summers *(1997);* Ruitz and Harms, (1990); Shelton et al., (2004). However, it should bear in mind that this type of meat is a good source of mineral substances, primarily richer source of K, Mg and P for human nutrition (Poltowicz and Doktor, 2013*).*

The results of this study show that the exclusion of both together, vitamins and minerals leads to a statistically significant reduction of minerals in the chicken white meat.

Adding mineral substances without vitamins gave even better results on the content of ash in the breast meat. Thus, the mineral content was better than in the group that received the vitamins and trace elements together.

Conclusion

Chicken breast meat has less fat and connective tissue in relation to other parts of chicken carcass, and because of that it is better digested. In addition, this type of meat is a good source of mineral substances, primarily richer source of K, Mg and P.

The highest increase of chicken weight gain happens in the last period of fattening. Therefore, the possibility of exclusion of vitamin and mineral supplements without negative effects on the mineral content in meat could lead to significant financial savings.

The results of this study show that the exclusion of both together, vitamins and minerals leads to a statistically significant reduction of minerals in the chicken white meat. The length of the removal of these substances (12, 8 and 4 days) had no effect on ash content in the breast meat of chicken. Adding mineral substances without vitamins gave even better results on the content of ash in the breast meat. Thus, the mineral content was better than in the group that received the vitamins and trace elements together.

POSSIBILITY TO USE THREE ACACIA PASTURES

Duska SLIJEPAC*

Faculty of Agriculture, University of Banja Luka, Republic of Srpska, Bosnia and Herzegovina
*Corresponding author: sljepac.duska@yahoo.com

Abstract

This study evaluated the possibility of using three acacia pasture, which contributes to an increased intake of nectar per hive. Based on field research and visits to 18 beekeepers at three site during the year 2012/2013, obtained results of the daily intake of nectar per hive, which are dependent on the use of one, two or three acacia pasture. The first location related to Bosnian mountainous area (Kotor Varos, Knezevo, Celinac municipalites), second to lowland areas (Srbac, Prnjavor, Banja Luka) and third to the river valleys (Mrkonjic Grad, Sipovo, Ribnik). Daily intake on pasture can be up to 15 kg of nectar, and the total yield from one pasture 70 kg per hive nectar. Acacia honey is of excellent quality, with very pleasant smell and taste. It is one of the most prized honeys. It is almost colorless, crystal clear, with a barely perceptible greenish hue. For a long time does not crystallize, sometimes several years.
Keywords*:* *acacia, beekeepers, bee pasture, nectar.*

Introduction

Honeybee cultivated because of honey, pollen, royal jelly, wax, bee venom and propolis (Đorđević et al. 2004). For production of these products the bee is necessary proteins, carbohydrates, fats, vitamins, minerals and water (Jiang-Guo, 1997). Meanwhile, in the last time, one of the reasons bee mortality is the lack of quality bee food (Mirjanić et al., 2005). Acacia is very extended species with; American origin which entered in 1601 in Europe entered (Maceljski et al., 2001). It blooms profusely, usually from early May until the end of June, 40-45 days after the first movement buds. Start of flowering depends on climatic conditions, altitude, variety, terrain, the degree of insulation areas under the acacia, soil composition, etc. At the time of flowering acacia significantly affect previous climatic conditions, so that the beginning of flowering in the same area year after year can vary up to 15 days. Due to these facts in one season can, with the same bee colonies, to use two, even three acacia pasture. In Hungary, which is a leading country by area under plantations of acacia, long years of work was done to create new varieties of black locust, whose basic characteristics are reflected in better yields nectar, somewhat later onset of flowering and greater resistance to winterkill (Klašnja et al., 2011). Acacia earliest starts to blossom at the lowest altitudes, in the valleys of large rivers. As the altitude increases the land, as a rule acacia on these grounds starts later and later to blossom. The optimum altitude for moving hives to another acacia pasture is 200-300 meters above sea level. Third acacia pasture should be used on hilly terrain, at 500-600 meters above sea level. At one location flowering acacia or nectar secretion usually lasts up to 14 days. Nectar secretion is most intense from the third to the tenth day of flowering. In the lower regions, with fertile soil, acacia blooms earlier and secretes more nectar, but in the mountain. In this case can be, in great part, in the course of a season, the same bee colonies to take advantage of the three locust pasture. The flowers of the acacia strongest secrete nectar on a daily temperature of 20 to 25°C, with optimum humidity and soil when the weather without wind, with the morning dew and temperatures above 16°C. The aim of this work is related to the possibility of three acacia pastures which affects on the increased daily nectar by hive, for the period 2012-2013 years.

Materials and Methods

The study was based on available literature data and an applied field research. Based on field research and visits to18 apiaries during the 2012/2013 at three sites, authors obtained results of the daily intake of nectar per hive, which are dependent on the use of one, two or three acacia pasture. The first location is comprised of six apiaries in mountainous areas (Kotor Varos, Knezevo, and Celinac), the other six apiaries in lowland areas (Srbac, Prnjavor, Banja Luka) and the third six apiaries in river valleys (Mrkonjic Grad, Sipovo, Ribnik).

Results and discussion

On the basis of the research on three sites: mountainous area (Kotor Varos, Knezevo, Celinac), lowland areas (Srbac, Prnjavor, Banja Luka) and in river valleys (Mrkonjic Grad, Sipovo and Pond), data were collected from beekeepers, on the amount of daily intake of nectar with 18 apiaries (locality six apiaries), which has 30 bee colonies, as well as the use of one, two or three acacia pasture during the acacia nectar production.

Tab.1. Daily yield (kg) per hive nectar at the first location and the use of three locust fits

Locality 1	Apiary	Yield (kg)
Kotor Varos	1	15
Kotor Varos	2	15
Knezevo	3	13
Knezevo	4	13
Celinac	5	14
Celinac	6	15

Beekeepers in the first location, mountainous areas used the three locust grazing, moving apiaries to the location where the acacia earliest starts to blossom at the lowest altitudes, in the valleys of large rivers and so use the first acacia pasture. By increasing altitude area, where acacia on these grounds begins later that blooms after 14 days beekeepers move hives to another acacia pasture (200-300 meters above sea level). Third acacia pasture used on hilly terrain (500-600 m above sea level) and so moving around the apiary in stationed. This way of Migration of the apiary, beekeepers exploit the possibility of using three acacia pasture with large living nectar yield per hive.

Tab.2. Daily yield (kg) per hive nectar on another site and the use of two locust fits

Locality 2	Apiary	Yield (kg)
Srbac	1	10
Srbac	2	10
Prnjavor	3	10
Prnjavor	4	9
Banja luka	5	9
Banja luka	6	10

Beekeepers in other localities in lowland areas they used two black locust fits, so that the first apiary moving to a location in the river valleys, where locust earliest starts to copper, and after 14 days apiary returning to the starting point of stationary and thus use two locust fits with smaller daily yield nectar per hive.

Tab. 3. Daily yield (kg) of nectar per hive at the third site and the use of a locust fits

Locality 3	Apiary	Yield (kg)
Mrkonjic Grad	1	5
Mrkonjic Grad	2	5
Sipovo	3	3
Sipovo	4	3
Ribnik	5	3
Ribnik	6	5

Beekeepers third locality in the river valleys moving bee gathering nectar close stationed, and use only a single acacia pasture which leads to a very small living nectar yield per hive. Using three acacia pastures during the year increase the enter of nectar by hive and till five kilograms, although using one or two acacia pastures by hive increases only for two since three kilograms by hive.

Conclusion

Based on the research that refers to the possibility of using three acacia pasture which contributes to an increased intake of nectar per hive for the period 2012-2013.godine can conclude the following:

The results clearly show that during the period of nectar daily intake depended on the possibility of using acacia pasture i.e. there are clear differences between the sites and how to use one, two or three acacia pasture.

The site of mountainous areas showing higher daily intake of nectar per hive from the lowlands and river valleys, due to exploitation of the three locust pasture.

Possibility of three acacia pasture increases daily intake of nectar and up to five kilograms per hive which can be clearly seen from the data collected from beekeepers in the field.

Abstract

The objective of this study was to evaluate chemical composition of eggs (whole egg, shell with membranes, egg white and yolk), a sample of twenty eggs for each stage of the production cycle, and originating from different age of hens during the production cycle (SN20, SN28, SN48 and SN72). Chemical analyses were carried out in two laboratories: the Laboratory of Faculty of Agriculture in Eastern Sarajevo and Food Laboratory Faculty of Technology in Zvornik, University of East Sarajevo. Water content, dry matter, crude protein, fat content, carbohydrates and mineral contents were assessed. Determination of moisture content and dry matter of the samples was made in accordance with current standards by drying in oven kept at a temperature of 105°C. Carbohydrate contents were determined computationally. The content of crude protein was determined by Kjeldahl method. The fat content was analyzed by acid hydrolysis according to the AOAC method, according to the accepted standard. Egg weight slightly increased with increase of hen´s age while the water content and dry matter content were decreased. The crude protein content in whole egg ranged from 12.01% (ALH20) to 12.21% (ALH28), in the yolk from 16.20% (ALH72) to 16.38% (ALH28), egg whites from 10.45% (ALH72) to 10.51% (ALH28). The whole egg fat content was 10.11% (ALH48 and ALH72) and 10.51% (ALH28) in the egg yolk 32.81% (ALH20) and 33.95% (ALH28). Mineral content was the largest in the shell membranes, what is understandable and ranged between 92.36% (ALH20) and 92.63% (ALH48). The chemical composition of eggs and its structural components (shell, egg white and yolk) was similar in all studied stages of the production cycle and was the standard for the chemical composition of eggs produced in commercial production.

Keywords: *table eggs, hens age, chemical composition of eggs, conventional production.*

Introduction

Eggs play an important role in our everyday food. In 2007 total egg production in the world was cca. 62.6 million tons, the European Union produced 9.9 million tons, representing 170 billion eggs (FAO, 2009).

Chicken eggs are one of the most versatile foods. They contain high-quality proteins, carbohydrates, easily digestible fats and minerals, as well as valuable vitamins (Huopalahti, 2007). The egg consists of four different main structures; shell, shell membranes, albumen and yolk. An average egg from domestic laying hens contains 64 % albumen, 27 % yolk and 9 % shell (Rose, 1997). Laying hen eggs are one of the most common and abundant foodstuffs in the human diet and they contain important compounds for human consumption such as lipids, amino acids and vitamins. The yolk is rich in saturated fat, cholesterol and other fatty compounds like lecithin. Small quantities of liposoluble (A, D) and water-soluble (thiamine, riboflavin) vitamins, and minerals like iron, phosphorus, zinc, selenium and sodium are found in eggs too (Belyavin, 1988). Egg quality encompasses several aspects related to the shell (external quality) and to the albumen and yolk (internal quality). The variability in the quality

and nutritional values of eggs has a significant impact on consumers' health; simultaneously, welfare and many other factors can affect egg quality (Sparks, 2006, Zita et al., 2009).
The objective of this study was to evaluate chemical composition of eggs (whole egg, shell with membranes, egg white and yolk), a sample of twenty eggs for each stage of the production cycle, and originating from different ages hens during the production cycle (SN20, SN28, SN48 and SN72).

Material and Method

Chemical analyses were carried out in two laboratories: the Laboratory of Faculty of Agriculture in Eastern Sarajevo and Food Laboratory Faculty of Technology in Zvornik, University of East Sarajevo. The individual is measured by the 20 eggs randomly sampled. Laboratory tests determined the chemical composition of eggs originating from hens of different ages (SN20, SN28, SN48 and SN72). Water content, dry matter, crude protein, fat content, carbohydrates and mineral contents were assessed. Determination of moisture content and dry matter of the samples was made in accordance with current standards by drying in oven kept at a temperature of 105°C (AOAC, 1990). Carbohydrate contents was calculated by using the following formula: 100% – (protein % + fat % + humidity % + ash %). The content of crude protein was determined by Kjeldahl method (mineralization, distillation, titration) described in ISO 59836-1:2006/AC: 2009. The fat content was analyzed by acid hydrolysis according to the AOAC method, according to the accepted standard. During the entire production cycle there were four control individual measurements of eggs (80 eggs in total) and statistical analysis waas donwe on 4 treatments and 20 repetitions (n). The results of analyzes were processed by using standard statistically methods (Hadživuković, 1991).

Results and discussion

Analysis of the chemical composition of eggs and its basic ingredients in the stages of production cycle is presented in Table 1.
Egg weight slightly increased with increase of hens' age, while the water content and dry matter content were decreased (tab. 1). The crude protein content in whole egg ranged from 12.01% (ALH20) to 12.21% (ALH28), in the yolk from 16.20% (ALH72) to 16.38% (ALH28), in albumen from 10.45% (ALH72) to 10.51% (ALH28). The whole egg fat content was 10.11% (ALH48 and ALH72) and 10.51% (ALH28) in the egg yolk 32.81% (ALH20) and 33.95% (ALH28). Mineral content was the largest in the shell membranes, what is understandable, and ranged between 92.36% (ALH20) and 92.63% (ALH48)

Nutritional quality of eggs can be assessed based on compositional quality, which includes crude protein content, ash, fat content, carbohydrates, mineral substances, etc. Commercial eggs are a significant source of fatty acids, cholesterol, and other lipid nutrients in the human diet (Cherian et al., 2002; Hidalgo et al., 2008). The proteins in eggs are easily digested and of good quality, because they contain all the essential amino acids to maintain life and growth. Eggs are a good source of iron, phosphorus, trace elements, vitamins A, E, K, B, D.

When it comes to egg albumen, the biggest constituent is water with a share of 84–89%, and most of the solid matter is represented proteins, 10–11% (Li-Chan and Nakai, 1989). Arias et al. (1993) found that the egg shell contains 3.5% of organic and 95.0% of inorganic matter. Meennicken and Waterloh (1997) in their work found that the dry matter content in egg albumen averaged 12.0%, according to Niewiarowicz (1991), the dry matter content in the egg yolk varied from 50.0% to 54, 5%.

Zanon et al. (2006) examined the chemical composition of egg albumen and egg yolk of two native Italian races of chickens. Albumen moisture content was from 88.27 to 13.29%, the share of albumen was 49.35–52.59% and the proportion of egg yolk was 34.96–32.35%. The

results were compared with the results of two commercial hybrids with white and colored egg shell. The differences were statistically significant ($P<0.05$) in favor of commercial lines. Dziadek et al. (2003) examined the effect of genotype on the chemical composition of table eggs of nine different lines (Lohmann Brown, Shaver 579, AK, ISA White, Mass 445 Mass 443, Astra W-1, W-2 Astra and Astra N), in the period of 63 and 66 weeks of age. The dry matter content in albumen of eggs ranged from 10.98% (Shaver 579) to 13.13% (Astra W–2), and in the yolk from 54.89% (Lohmann Brown) to 59.64% (Messa 443). So, with Lohmann Brown was found uniform, but the biggest moisture of albumen, with a standard deviation of 0.67% and coefficient of variation of 1.22%. The highest values of fat content in the egg yolk was in eggs of genotype Astra N (31.85%) and the lowest value in eggs of genotype AK (29.37%). All differences in chemical composition between the investigated genotypes were significant ($P<0.01$).

Approximate chemical composition of whole egg, according to Li–Chan and Kim (2007) includes 75.84 g of water; 12.58 g of protein; 9.94 g of total fats; 0.77 g of carbohydrates and 0.86 g of mineral substances. Similar results in terms of chemical composition of eggs and its components obtained Jurić et al. (2005), as well as Zanon et al. (2006) who, in addition to eggs produced in the intensive farming system (conventional) determine the chemical composition of eggs produced from indigenous pure breeds in semi–intensive or extensive farming system. Minelli et al. (2007) have reported different values for crude protein, in favour of organically produced eggs, (17.1% vs. 16.7%) compared with those from the conventional system. Many studies have investigated the fatty acid composition of the eggs of commercial layers reared in commercial production system, which include confinement facilities, highly productive hybrid layers kept in limited space (mostly in battery cages) and intensive feeding (Lopez–Bote et al., 1998). To maintain consistently good shell quality throughout the life of the hen, it is necessary to implement a total quality management programme throughout the egg production cycle.

Conclusion

During egg production, special attention was paid to the four main production stages, namely: 20^{th} week – SN20 (start load), 28^{th} week – SN28 ("peak" - maximum), 48^{th} week – SN48 (middle) and 72 week old hens – SN72 (the end of the production cycle). In this period, the adequate number of eggs for analysis the chemical composition of eggs (whole egg, shell with membranes, egg albumen and yolk), with sample of 20 eggs for each stage of the production cycle were taken by random sampling. It can be concluded: chemical composition of the egg and its structural components (shell, egg albumen and yolk) was similar in all tested stages of the production cycle and was the standard for the chemical composition of eggs produced in commercial farming.

Abstract

The experiment was carried out under natural condition to assess potential impacts of thiamine nutrition on hypopharyngeal glands (HPGs) development in Iranian honey bees (*Apis mellifera meda*). Twenty honey bee colonies, divided into 5 experimental groups, were used in the study. Control groups were fed sugar syrup (1:1). The experimental colonies were fed in the same manner but with syrup supplemented with different levels of thiamine (100, 200, 300 and 400 ppm). The experiment was conducted for 30 days in the summer. The result showed that the acinal area of HPG showed clear difference under feeding with difference diets. The largest area was recorded when honeybee workers fed the 100 and 200 ppm thiamine at 3 and 6 days of age.

Keywords: *Thiamine, Hypopharyngeal glands, Iranian honey bee*

Introduction

Hypopharyngeal glands (HPGs) consist of a pair of long glands coiled in the sides of the head. HPGs are the main organs responsible of royal jelly secretion. These secretions are fed to the larvae and queens (Crailshem, 1991, 1992). At normal condition they are well developed when bees are nursed and they degenerate when bees become foragers. The size of HPGs is correlated with glandular production and generally increases with age from 6 to 18 days in nurse bees (Hrassnigg and Crailshem, 1998; Deseyn and Billen, 2005). The diameters of HPG are often used to describe the physiological status of worker honeybees. For this reason, gland size and acini diameter have been used as indicators to test the effect of various food sources. The normal course of development of these glands (size of acini) is well known (Maurizio, 1954; Simpson et al., 1968; Moritz and Crailsheim, 1987; Crailsheim and Stolberg, 1989).

Little is known about the vitamin requirements of honey bees, although they are essential for all animals. It appears they are not linked to longevity of the adult bee (Pain, 1956) but are intrinsically linked to brood development (Haydak and Dietz, 1965). The B complex vitamins have been demonstrated to be essential for most insects. Four B complex vitamins, pantothenic acid, thiamine, riboflavin, and pyridoxine, plus vitamin A and K have been linked to development of the hypopharyngeal glands and brood rearing (Somerville, 2005).

Thiamine or vitamin B_1 is a water-soluble vitamin of the B complex. Its phosphate derivatives are involved in many cellular processes. The best-characterized form is thiamine pyrophosphate (TPP), a coenzyme in the catabolism of sugars and amino acids. All living organisms use thiamine, but it is synthesized only in bacteria, fungi, and plants. Animals must obtain it from their diet, and thus, for them, it is an essential nutrient (Du et al., 2011).

The purpose of the present paper is to study the effect of thiamine supplements on development of hypopharyngeal glands in Iranian honey bee (*Apis mellifera meda*) colonies.

Materials and methods

This investigation was carried out at Honey Bee Department of Animal Science Research Institute, Karaj, Iran. Twenty Iranian honey bee (*Apis mellifera meda*) colonies of the same strength and queen of similar age and quality were selected to carry out the study in summer season to test of different diets. Feeding started on July 5, 2012 and continued for 30 days. In this season we prepared five groups of four colonies fed with different levels of thiamine. Feeding treatments were assigned randomly to the colonies in trials. One-year old queens were used in this investigate. Recommended colony management practices were regularly followed in all these colonies.

Thiamine (Sigma Aldrich® thiamine hydrochloride T-4625) was used for feeding in the honey bee colonies. Control colonies received sugar syrup 1:1 (1Lit/day/colony). The experimental colonies were fed in the same manner but syrup supplemented with different levels of thiamine (100,200,300 and 400 ppm).

When the adults emerged, they were marked with atoxic paint and returned to the colony. Hypopharyngeal gland (HPG) was dissected to determine the acini surface at 3, 6, 9, 12 and 15 days old. The HPGs were dissected in sodium chloride solution (0.85%) isotonic to the hemolymph (Al-Ghamdi Ahmad et al., 2011). The glands were not covered by cover glass. For each treatment, we dissected 25 bees, five from each colony. The length and width of ten acini were measured in mm for each worker under stereomicroscope using a micrometer eye piece. The acinal surface was calculated according Maurizio's formula (1954).

$$\text{Acinal surface} = \pi \times \frac{a \times b}{2}$$

Where a = length, b = width, π =3.14.

Data were considered by a one-way analysis of variance for the response variable changes in acinal surface. Differences among means were determined by Duncan's multiple test SAS institute (1991). When the ANOVA indicated a significant effect, post hoc Duncan multiple comparisons test was used to determine individual differences between responses at each time considered, and differences over time for each treatment.

Results and discussion

Means of acinal surface of HPG of the Iranian honey bees after fed different levels of thiamine is presented in Table 1. The acinal surface increased significantly with the age and reached to the maximum at 6-9 days from emergence. These results agreed with those obtained by Hrassnigg and Crailsheim (1998). They reported that peak size is found at around 6 days in bees during the summertime, when workers are known to feed the larvae with royal jelly (RJ). Morphologically, acini size of the HPGs radically changes with age (Deseyn and Billien, 2005). In the present results, it is clear that the greatest acinal area was observed when bees were fed with 100 and 200 ppm thiamine at 3 and 6 days of age. The means area of the acini in the 100 and 200 ppm B_1+SS were 0.0921 and 0.0969 (mm^2) at 3 d, 0.2062 and 0.2147 (mm^2) at 6 d respectively. There was no significant difference between treatments in the acinal area after 6 d. These results confirmed the effect of vitamin B_1 or thiamine on the development of HPGs. The development of HPGs was studied with bees having direct access to brood over the whole period of 15 days. It has often been stated that access to brood is essential for the development of the hypopharyngeal glands (Brouwers, 1982; Moritz and Crailsheim, 1987; Lass and Crailsheim, 1996) but see Crailsheim and Stolberg (1989) who did not find an effect of brood rearing on gland development. Activity and developmental stage are age dependent and can be linked with the behavior of the worker (Wilson, 1971;

Michener, 1974). In conclusion, the gland is fully developed when the worker performs tasks inside the hive for feeding larvae.

Conclusion

Our study indicates that thiamine could be affective in development of the hypopharyngeal glands in Iranian honey bees.

Abstract

The Macedonian honey bee (*Apis mellifera macedonica*) is a subspecies of the most famous and also the most widespread type of honey bees in the world, the western honey bee (*Apismellifera L.*). Along with four other subspecies, Macedonian honey bee belongs to the central Mediterranean and Balkan Peninsula group of honey bees. In Republic of Macedonia *Apis mellifera macedonica* is an autochthonous subspecies (race) and is under special mode of protection, which provides continuous control of its subspecies purity which can significantly be compromised if honey bee colonies with queen bees from non autochthonous subspecies are being breed.

The purpose of this research was to determine the purity of *Apis mellifera macedonica* on the territory of Republic of Macedonia through morphological analysis of coloring of the abdominal rings. As a material for our research, we used young worker bees (n= 1440) from 15 apiaries from several regions in the country.

Results have shown that 66.3 % of the analyzed bees were with no colored abdominal rings, 9.5 % were with a single colored ring, 23.5 % with two and 0.7 % with three colored rings. The presence of honey bees with no colored ring indicates that they belong to the autochthonous subspecies *Apis mellifera macedonica*. This percentage of representation of autochthonous honey bee subspecies (greater than 50 %), puts it in the category of none threatened subspecies. But if we analyze the situation in individual apiaries and individual regions, in that case the situation changes significantly and the safety of the autochthonous subspecies is questioned.

Keywords: *honey bees, subspecies, purity, color, abdomen.*

Introduction

The diversity of honey bees (*Apis mellifera* L.), characterized by morphological, ethological and molecular differences in the so far determinate subspecies, is a result of their ability to adapt to the influence of numerous factors and ecological conditions.

Cosmopolitanism is a sufficient proof for the apparent capacity for adaptation of this biologically and economically important subspecies of insects, which during their evolution have gained ability for maximum usage of the existing resources in order to satisfy the rationally developed needs. Different geographic and ecological conditions have led to mutual differentiation of honey bee population and evolution of the subspecies which are best adapted to the given areas. The apparent fall in the number of colonies on global level (Neumann and Carreck, 2010; Van Engelsdorp and Meixner, 2010; Van der Zee *et al.*, 2012; Williams *et al.*, 2012) is a result of the influence of many ecological and anthropological factors. Despite the climate changes and its consequences, one of the most important factors is of course the lack of genetic diversity of the breeding populations (Ellis, 2007) which mainly originate from the limited number of commercial genetic lines for production of queen bees. Additionally, introducing the genotypes of non-autochthonous honey bee population, as a

result of the general communication and transport trends, can lead towards breeding colonies susceptible to various pathogens and stress-factors and obvious reduction of their number both on regional and global level. Therefore, breeding autochthonous honey bee subspecies, due to their adaptability and superior vitality, is the best way to fight against such factors.
In the Republic of Macedonia the autochthonous honey bee subspecies is "Macedonian honey bee" or *Apis mellifera macedonica (*Ruttner, 1988; Stevanovic *et al.,* 2010; Uzunov *et al.,* 2009, 2014) and according to the Law and amending the Law on Livestock Breeding (Official newspaper No 23 February, 14 2013) is under special protection regime. According to the State Statistical Office of Macedonia (2013), the overall population of honey bees bred in the period 2009-2013 ranged between 52 897 and 76 052 honey bee colonies, with a total annual production of 603 to 1 105 tons of honey.
The purpose of this paper work is to determine honey bee subspecies' purity bred in the Republic of Macedonia, since according to some results from morphometric, molecular and ethological researches done by Uzunov *et al.* (2007, 2009, 2013 and 2014), it is possible that there is an influence by other honey bee subspecies in certain regions. This type of influence is an opportunity for hybridization of the autochthonous subspecies, which can lead to a threat as in many northern European countries, where *Apis mellifera* subspecies have perished due to hybridization (Franck *et al.,* 2000; De la Rúa *et al.,* 1998, 2001a, 2001b, 2003; Ivanova *et al.,* 2007).
Studies on this subject, with similar results, previously were made by Kozmus (2011) on populations of Carniolan bees *(Apis mellifera carnica*) on the territory of the Republic of Slovenia.

Material and methods

For our research we used worker honey bees, as part of the 2014 collection from 9 locations of different regions in Republic of Macedonia, from 15 different apiaries and 48 colonies (Table 1). A sample of 30 honey bees has been taken from each colony which has been preserved in ethyl alcohol by the time it's been analyzed.

Table 1. Number of apiaries and number of colonies out of which the material for the analyses has been taken

No	Location	No of colonies
1	Vapila (Ohrid)	3
2	Ezerani (Resen)	3
3	Stenje (Resen)	1
4	Pehchevo	3
5	Josifovo (Valandovo)	2
6	Vinica	1
7	Gostivar I	5
8	Gostivar II	5
9	Gostivar III	5
10	Krstovi (Mavrovo)	5
11	Pelince I (Kumanovo)	3
12	Pelince II (Kumanovo)	3
13	Kumanovo	3
14	Mrshevci (Skopje)	3
15	Drachevo (Skopje)	3

To determine the subspecies' purity of the analyzed honey bees we used the method of morphological analysis on the coloring of abdominal rings.
The color of the abdominal segments (rings) is an indicator for the honey bees' subspecies affiliation. The analysis is done based on the description of the abdominal segments' color given in the Table for the comparison of the main external characters of the principal races of European Bees (http://www.beeworks.com/morphometry). There is no proper comparative table for the Macedonian honey bee with other honey bee subspecies, but since it most resembles to the Carniolan honey bee (*Apis mellifera carnica*) the analysis is done according to the description of this subspecies: the abdominal segments from the dorsum are quite dark with a red and yellow or orange pigment like spots (Figure 1-a, b and c), but at times even a whole colored ring – (Figure 1-d). According to Ruttner, 1988 *Apis mellifera carnica* was allowed to have honey bees with entirely colored ring to maximum 5 % within the colony. The presence of honey bees with two or three colored rings (Figure 1-e and f) shows possible hybridized population, most often with honey bees from the *Apis mellifera ligustica* subspecies, which are characterized by the presence of 1 to 3 yellow colored rings (Rihar, 2003) or hybrids with buckfast bees (Borsuk and Olszewski, 2010).

Figure 1 a) b) c) d) e) f)

The honey bees were analyzes visually, set on a white background, and based on the analysis we divided them into four groups: honey bees with no colored rings, honey bees with a single colored ring, honey bees with two colored rings and honey bees with three colored rings. We calculated the proportional representation of the overall population for each group.

Results and discussion

The morphological analysis of the honey bees from 48 colonies, according to the coloring of their abdominal segments (Table 2) showed that the percentage of honey bees with no colored abdominal rings, which means they belong to the *A. m. macedonica* autochthonous subspecies, is 66,3 %. This percentage of representation of the autochthonous subspecies of the honey bee (greater than 50 %), places it in the category of not endangered subspecies, but if we analyze their state in individual apiaries and regions, then the situation significantly changes and their endangerment is questioned.
The most characteristic example of an apiary is the one in the region of Vinica, where in a single colony all of the analyzed honey bees (100 %) are with colored abdominal rings, 10 % with single colored ring and 90 % with two colored rings.

Table 2. Percentage of honey bees with and without colored abdominal rings

No	Number of analyzed honey bees	% of honey bees with no colored rings	% of honey bees with colored rings			
			One colored ring	Two colored rings	Three colored rings	Total % of honey bees with colored rings
1	90	61,1	15,6	23,3	0	38,9
2	90	97,7	2,3	0	0	2,3
3	30	100,0	0	0	0	0,0
4	90	85,6	8,9	5,5	0	14,4
5	60	10,0	23,4	61,6	5,0	90,0
6	30	0	10,0	90,0	0	100,0
7	150	45,3	9,3	42,0	3,4	54,7
8	150	88,7	6,0	5,3	0	11,3
9	150	90,0	8,0	2,0	0	10,0
10	150	54,0	24,0	21,3	0,7	46,0
11	90	68,8	3,4	26,7	1,1	31,2
12	90	93,3	5,6	1,1	0	6,7
13	90	94,4	4,5	1,1	0	5,6
14	90	72,2	12,2	15,6	0	27,8
15	90	33,3	10,0	55,6	1,1	66,7
Total number of analyzed honey bees	1440					
Average		66,3	9,5	23,5	0,7	33,7

Honey bees with a very high percentage of colored abdominal rings were found in an apiary in the area of Valandovo (Josifovo). In this apiary the proportion of honey bees with no colored rings is 10 % whereas the other 90 % are with colored rings. Although the proportion of honey bees with colored rings is lower than the one in Vinica, yet it is interesting that we found 5 % of honey bees with even three colored rings and high 61,6 % of honey bees with two colored rings.

Except these two apiaries, larger percent of honey bees with coloring in terms of percentage of honey bees with no coloring is found in another two apiaries in the area of Gostivar and Drachevo in Skopje. In the apiary in Gostivar the percentage of honey bees with colored rings is 54,7 %, of which 42 % go to honey bees with two colored rings, 9,3 % honey bees with a single colored ring and 3,4 % honey bees with three colored rings. In the apiary in Drachevo the percentage of honey bees with colored rings is larger and amounts to 66,7 %, but the percentage of honey bees with three colored rings is lower than the one in Gostivar which is 1,1 %.

In the remaining 11 apiaries from which honey bees had been taken for the purpose of morphometric analysis the honey bees with no colored rings prevailed of which 9 apiaries with colored ring honey bees were established with presence of honey bees with a single and two colored rings, and only 2 honey bee colonies were established with presence of honey bees with a single, two and three colored rings.

From the apiaries in which honey bees with no colored abdominal rings prevail we can point out the ones in the area of Resen, where all the analyzed honey bees (100 %) from the apiary in Stenje are with no colored abdominal rings, and the one in Ezerani has 97,7 % of honey bees with no colored abdominal segments.

In the whole analyzed population of honey bees the proportion of honey bees with colored abdominal rings were 33,7 %, of which honey bees with two colored rings prevail (23,5 %), then the ones with a single colored ring (9,5 %) and 0,7 % go to honey bees with three colored rings.

Conclusion

Having in mind the results, the previous findings as well as the current state of the honey bee population in Republic of Macedonia, where the Macedonian autochthonous honey bee (*A. m. macedonica*) maintained the status of unthreatened population, it is necessary to take the following precautions and actions:

Education of beekeepers on the typical morphological characteristics of Macedonian honey bee (*A. m. macedonica*) and creating a practice for queen bees replacement in the colonies in which there is presence of honey bees with yellow colored rings is evident;

Breeding colonies with queen bees produced by the local genotypes of Macedonian autochthonous honey bee (*A. m. macedonica*);

Choosing local genotypes for noncommercial production of next generation queen bees from the Macedonian autochthonous honey bee (*A. m. macedonica*); which are characterizes by superior performances in term of vitality and economically important characteristics;

Providing queen bees from the registered queen bee breeding centers, preferably from their own region, whose breeding programs are focused on improving the genetic basis of local genotypes of the Macedonian autochthonous honey bee (*A. m. macedonica*);

This method is important because is very well applicable, and it can be used by the beekeepers directly on the bee yards. Beekeepers can easily notice the coloring on the abdominal rings, and they can and can respond appropriately on time;

Additional researches need to be done in future referring to the morphometric characteristics of *A. m. macedonica*, with the intention of her protection in the future.

Acknowledgement

We express sincere gratitude to our mentor Prof. Dr. Hrisula Kiprijanovska, for the given freedom and scientific support in relation for selection of the theme, the design and implementation of this research.

APPLICATION OF BACTERIOPHAGES IN VETERINARY LABORATORY PRACTICE

Elena CHUGUNOVA*, Natalya TATARNIKOVA, Tatyana PROHOROVA

Perm Agricultural Academy, city Perm, Russia
*Correspondent author: chugunova.elen@yandex.ru

Abstract

The article show using of bacteriophages in veterinary. Bacteriophages are viruses of bacteria. They are unique, nature antibacterial means. Bacteriophages have high specificity to cells owners. This property allows using ones in laboratory diagnostics, and for treatment of animal's infection diseases. The porpoise of our research is allocating bacteriophages to *Salmonella* and *Proteus*, and using them for indication and identification of the same bacteria in food of an animal origin. The objectives of research are poultry forcemeat. Two methods of research were used. First was bacteriological method with application of a standard technique, and second was diagnostics by bacteriophages. Before the start of researches bacteriophages for same bacteria were received, studied their sensitivity, specificity, and the range of lytic action. During the work the control and prototypes samples of forcemeat have been infected by different concentration of *Salmonella* and *Proteus.* After that samples investigated by standard technique and with application of bacteriophages. As a result of the researches sensitive bacteriophages against *Salmonella* and *Proteus* were allocated. Bacteriophages against *Salmonella* showed a wide range of lytic action on different strain of bacteria. Bacteriophages against *Proteus* were specific for *P.* vulgaris. The standard method of research took more time, then a diagnostics with application of bacteriophages. Besides, the bacteriological method of research was demanded a certain experience of work, and statement of diagnostics by bacteriophages was technically simpler for performance and higher sensitivity. Using of bacteriophages in laboratory diagnostics more inexpensive then standard technique of bacteriological method.

Keywords: *bacteriophages, veterinary, Salmonella, Proteus, diagnostics.*

Introduction

Bacteriophages are ultramicroscopic, intracellular obligate parasite, they are viruses of bacteria. For the first time the phenomenon of a bakteriophages was observed by N.F. Gamaley in 1898, later ones was observed by Tuort (1915) and by d'Errel (1917) (Timakov V., Goldfarb D., 1958). Bacteriophages have got heredity, variability, adjustment and properties of viruses. They possess of information necessary for process of their reproduction in the corresponding cells, but have no own mechanism for generation of energy and ribosomes for synthesis of proteins (Katter E., Sulakvelidze A., 2012, Timakov V., Goldfarb D., 1958). Specific interaction of bacteriophages with microorganisms gives chance to use them for identification of bacteria, including pathogenic. Bacteriophages were naturally occur during evolution and can identify owners´ receptors and contacts with cells of the owner only. This fact unlike them from artificially created systems for definition and differentiation of various structures of the bacterial cells. Thus bacteriophages are used in a number of various techniques of specific definition and differentiation of strains of bacteria. The research of objective is comparative analysis of standard bacteriological research and typification by bacteriophages. Bacteriophages to *Salmonella* spp. and *Proteus* spp. were allocated before and then used ones to identification of pathogenic microbes in foodstuffs.

Materials and methods

Materials of research are samples of poultry forcemeat (n = 40). These meat samples have been divided into two groups. The first group were control samples (n=20) and second ones were tests samples (n=20).

Two research methods were used. First is bacteriological standard method and second is identification by bacteriophages.

The bacteriological research directed on detection of bacteria of *Salmonella* spp. was carried out in according to standard (State standard 31468, 2013). The method is based on seeding of 25 g of a product on not selective and selective nutrient medium and the following reseeding on differential gelose substrate. Then it is essential to allocation of the pure cultures having typical for *Salmonella* spp. Morphological and cultural characteristics. Finally it is necessary to identification on biochemical properties and serological reactions.

Indication and identification *Proteus* spp. was carried out in according to standard (State standard № 7702.2.7, 2014). The principle of a method is based on starting raising by peptone-salt solution and then seeding of 0,5 cm^3 ones nutrient agar and 0,2 cm^3 on Ploskirev substrate. After that microorganisms were cultivation at a temperature of 37 ºC during 24-48 hours. In total perform allocation of typical or estimated colonies and identification on typical properties to *Proteus* spp.

Before the experiences bacteriophages against *Salmonella* spp. and *Proteus* spp. were received. For allocation of bacteriophages used horse manure. Placed it in peptone broth in the ratio 1:10 and added 0,2 cm^3 broth culture of *Salmonella* spp. and *Proteus* spp. which were grown to the logarithmic growth stage. Ones incubated at a temperature of 37 ºC during 18 hours, then cleanings of the lysate from impurity, bacteria and their fragments. At a final stage carried out the sterilize filtration by membrane of Millipore Millex-GP firm with a a diameter of time of 0,22 microns. After that sensitivity, specificity, a range of lytic action and a caption of bacteriophages were determination. Then samples of forcemeat were investigated by a classical bacterial method and with application of reaction of increase of phage titre. Estimated labor was input of performance of research; time spent for the analysis; sensitivity of both methods and costs of laboratory testing.

Results and discussion

As a result of the research we allocated sensitive bacteriophages against *Salmonella* spp. and *Proteus* vulgaris (fig. 1).

Fig. 1. Sterility spot on the bacterial lawn

The bacteriophage against *Salmonella* spp. showed a wide range of lytic action. The bacteriophage against *Proteus* spp. was specific concerning *Proteus* vulgaris (tab. 1).

Table 1-Range of lytic action of the allocated bacteriophages on bacterial lawns (according to Adams and Veyd)

Serotype of microorganism	Bacteriophage against *Salmonella* spp.	Bacteriophage against *Proteus* spp.
S.typhimurium	+	-
S.dublin	+	-
S.entritidis	+	-
S.choleraesuis	+	-
S.gallinarum-pullorum	+	-
S.hamburg	+	-
S.virchow	+	-
Proteus vulgaris	-	+
Proteus mirabilis	-	+-
Proteus morgany	-	-

For further work used lysate with the expressed sensitivity. A caption of the received bacteriophages established by Appelman and Gratsia methods. Both bacteriophages showed high titers (tab. 2).

Table 2-Titres of lysates

Serotype of microorganism	Titres	
	by Appelman method	by Gratsia method
S.typhimurium	10^{-9}	$2,1x10^{10}$
S.dublin	10^{-7}	$1,8x10^{11}$
S.entritidis	10^{-6}	$2,8x10^{8}$
S.choleraesuis	10^{-7}	$1,2x10^{8}$
S.gallinarum-pullorum	10^{-9}	$1,9x10^{10}$
S.hamburg	10^{-10}	$1,4x10^{11}$
S.virchow	10^{-7}	$3,5x10^{9}$
Proteus vulgaris	10^{-8}	$1,3x10^{9}$

Then the main objective of research were passed to performance. For this purpose everyone of empirical and control samples of forcemeat weighing 25 g to inoculated to suspension of bacteria in concentration from 10^{1} to 10^{10} cells in one gramme. After homogenized each sample by the laboratory blender and investigated according to State standard and reaction of increase of phage titre. Also obvious advantage using phages are their high sensitivity. (tab. 3).

Conclusion

As a result established that the standard method of research took more time and labor expenses, than bacteriophages used. The time saving when using phages made up 24-48 hours. Thus sensitivity and specificity of bacteriophages deliver of need to carry out morphological and biochemical identification of bacteria. Besides, it should be noted that the bacteriological method of research demands a certain experience of work, and statement of reaction of increase of phage titre is technically simpler for performance. Using of bacteriophages in laboratory diagnostics more inexpensive then standard technique of bacteriological method.

FATTENING AND MEAT QUALITIES OF BLACK-VARIEGATED BULLS OF DIFFERENT GENOTYPES

Irina GORDEEVA

Perm State Agricultural Academy named after Academician D.N. Pryanishnikov, Russia
*Correspondent author: gordeeva_i62@mail.ru

Abstract

Studies on the breeding of crossbred from different genotypes on the Holstein breed on fattening and meat qualities are topical. The aim of this work was to study fattening and meat qualities of bulls of different genotypes. Four groups were formed on the analogue method, 15 animals in each: control group crossbred bulls of genotype $^{3}/_{4}$ H$^{1}/_{4}$ BV; in I, II, III groups - genotypes $^{1}/_{2}$ H $^{1}/_{2}$ BV, $^{5}/_{8}$ H $^{3}/_{8}$ BV and $^{7}/_{8}$H $^{1}/_{8}$BV. Control slaughter of bulls in 18-month age (5 animals from each group) was conducted to study meat qualities. Yield of carcasses and body fat mass were higher than in peers. Weight after slaughter exceeded that of peers by 10.9 kg in the first experimental group. Carcass yield was higher in the control group (by 1.5-1.7%), mainly thanks to higher before-slaughter live weight of bulls. As a result of the research on morphological composition of carcasses and physical and chemical properties of meat of longissimus dorsi no significant differences between the control animals and experimental animals were identified. Thus, the study of fattening and meat qualities of bulls of different genotypes of the Holstein breed showed that breeding animals of the desired type ($^{3}/_{4}$H ¼ BV - control group) does not have a negative impact on meat productivity, and on a number of indicators such as body weight, daily gain, mass of hot and chilled carcasses, weight of flesh and meat of premium, hybrids in the control group outperform their peers in the experienced groups.

Keywords: *bleck-variegated bulls, Holstein breed, genotypes, fattening and meat qualities, slaughter qualities.*

Introduction

To ensure Russia food security it is necessary to reduce the country's dependence on imported food, particularly meat. For this the amount of domestic production of high-quality meat must be increased both for the food processing industry and for the population (Prahov et al., 2004). The main supplier of beef in Russia was and is dairy cattle (Ermilov et al., 2004).

Opportunities to increase beef production from dairy cattle, which produce more than 90% of this type of product, are now investigated. In Russia and CIS countries best domestic and foreign breeding resources of Dutch, Swedish and Holstein origin are widely used for improving black-variegated cattle. As a result, there is a certain genetic structure of herds in the leading breeding livestock farms, which allows working on the creation and breeding of highly productive types of herds, lines, and individual animals. Therefore, breeding of dairy cattle to improve its fattening and meat qualities is of a great economic importance (Prohorenko et al., 1985; Prohorenko et al., 1986; Prozora et al., 1987; Efimenko, 1991; Pashkin, 1998; Prohorenko et al., 2005; Gordeeva, 2005; Czerniawska-Piatrowska et al., 2005; Gordeeva, 2006).

Over the past three decades, a new type of black-variegated cattle was created on the basis of reproductive cross breedind with Holstein breed.

Therefore, studies on the problem of breeding hybrids of different genotypes of Holstein breed for fattening and meat qualities are relevant. The aim of the study was to investigate beef production of Holstein black-variegated bulls of different genotypes.

Materials and methods

Scientific and economic experiment conducted in agrofirm "Zorya", Rovenskaya region (Ukraine), which was one of the basic farms on breeding of a new type of highly productive black-variegated cattle. To create a herd in the farm, mainly Dutch and partly Estonian selections (breeding animals) were used. In recent years domestic production of Holstein breed imported from Canada were widely used.

During the study, all the flock of agrofirm "Zorya" was golshteinized.

Four groups of bulls aged 3 months, 15 animals each, were formed for this scientific and economic experiment by the principle of analogues based on origin, age and body weight. The control group included crossbred bulls of genotype of 3/4 Holstein breed (H) and 1/4 black-variegated breed (BV) which is set by the Ministry of Agriculture of Ukraine as the best for holsteinization. Experimental groups (I, II, III) included the following genotypes correspondingly: $^{1}/_{2}$ H $^{1}/_{2}$ BV, $^{5}/_{8}$ H $^{3}/_{8}$ BV and $^{7}/_{8}$ H $^{1}/_{8}$ BV.

During the period of the experiment (from 3 to 18 months of age) the conditions and feeding were the same for all bulls. Bulls growth monitoring was performed by monthly animal weighing and taking measurements at 6, 12 and 18 months. Diets were composed by growing periods (3-6, 6-12, 12-18 months) with monthly adjustments according to the All-Union Institute of Cattle Breeding norms of feeding (1985). Body weight before slaughter, weight of carcass and visceral fat, slaughter yield, carcass quality, weight of internal organs, and weight of fresh skin were determined according to the control slaughter (five animals in each group) by conventional methods. Morphological composition of animal carcasses was determined by dissection of the left half (three animals for each group) by sausage production technology. Fleshing index was calculated using standard practice. The chemical composition of an average meat sample (ground meat) and longissimus dorsi, and physical and chemical properties (amount of bound water, pH, softness of the meat) of the longissimus dorsi were examined using standard practice.

Results and discussion

Results of the control feeding showed that the level of food consumption did not differ by groups of bulls and was 2801.1-2848.1 food units and 296.1-297.1 kg of digestible protein. 7.04 (control) to 7.32 (I experimental group) food units were spent on 1 kg weight gain during the fattening period.

Analysis of the live weight dynamics in animals of studied genotypes shows some features of each of the experimental groups (Table 1).

Table 1-The dynamics of the live weight of the bulls, kg ($X \pm m_x$)

Age, month	Groups			
	Control	Experimental		
		I	II	III
3	105.4±1.64	102.2±1.60	101.7±2.70	103.9±2.57
6	196.9±2.55	191.5±4.30	189.0±5.05	194.6±4.47
9	309.6±3.48	296.4±5.19	298.4±4.71	305.1±4.55
12	397.0±5.04	382,7±6,36	386.2±6.84	386.6±5.97
15	451.6±5.71	441.9±6.84	439.4±7.33	449.4±5.98
18	490.6±7.07	486.2±7.81	478.7±9.69	485.6±8.24

Bulls of the control group surpassed their peers in the experimental group by 3.7-13.2 kg throughout the experiment. Significant difference in live weight was found between control group and experimental group I at 9 and 12 months, respectively: 13.2 (4.3 %) and 14.3 kg

(3.6 %) at P>0.90-0.95. Animals in experimental group II were inferior in live weight compared to their peers in other groups in all age periods and in 15 and 18 months respectively the difference was: 2.5-12.2 kg (0.6-2.8 %) and 6.9-11.9 kg (1.4-2.5 %).
In the final period of bulls growing and fattening (15-18 months) body weight varied by groups significantly from 478.7 kg to 490.6 kg, and there were no statistically significant differences. It should be noted that by the end of the experiment a slight superiority in bulls live weight (in 0.9-2.4%) in the control group remained.
Average daily gain was higher in the control group and experimental group I (for the period of experiment, 847 g and 845 g, respectively). The maximum average daily gain was obtained in the period of 6-9 months (1179-1265 g). During this period the superiority of animals in the control group over the peers in experimental group I was significant (at P > 0.95).
In general, during the experiment period, the highest absolute increase in body weight was in control bulls (385.5±6.84 kg) and experimental group I (384.3±6.71 kg). Significant difference in the relative growth rate of the animals was found between the control and experimental group I during the periods of 12-15 and 15-18 months (2.3 and 2.0 % respectively, P > 0.99) in favour of animals in experimental group I.
To study the fattening and meat qualities at the age of 18 months, we made a control slaughter of holsteinized bulls (5 animals per group).
Slaughter cattle grading (Table 2) showed that animals in the control group had pre-slaughter live weight 5.6-20.8 kg (1.1-4.2%) higher and fresh carcass weight 10-20 kg (3.3-6.7%) higher than their peers in the experimental groups. Their carcass yield was 1.4-1.8% higher and the weight of visceral fat was 0.1-0.9 kg (0.6-5.6%) higher. Slaughter weight exceeded the similar indicator at peers by value from 10.9 kg (experimental group I) to 20.4 kg (experimental group III), (3.5-6.5% respectively). Slaughter yield in the control group was 1.5-1.7% higher mainly due to a higher pre-slaughter live weight of the bulls.

Table 2-Slaughter qualities of experimental bulls ($X \pm m_x$)

Parameter	Groups			
	Control	Experimental		
		I	II	III
Pre-slaughter weight, kg	496.8±6.5	491.2±6.7	479.6±15.9	476.0±9.3
Fresh carcass weight, kg	299.0±6.7	289.0±6.8	280.0±9.8	279.0±7.1
Carcass yield, %	60.2±0.7	58.8±1.0	58.4±0.4	58.6±0.5
Weight of visceral fat, kg	16.2±0.7	15.3±0.8	16.1±1.2	15.8±0.2
Visceral fat yield, %	3.26	3.11	3.36	3.32
Slaughter weight, kg	315.2±7.4	304.3±6.9	296.0±10.6	294.8±7.1
Slaughter yield, %	63.4±0.8	61.9±1.0	61.7±0.5	61.9±0.4

It should be noted that the indicators of pre-slaughter live weight in holsteinized breed at 18 months of age varied insignificantly from 476.0 kg to 496.8 kg, and there was no statistically significant differences.
In general, animals in the control group had a superior slaughter qualities, somewhat inferior to them were experimental group I bulls that showed the lowest visceral fat yield - 3.11% (15.3 kg). The research showed the following trend: visceral fat content increases following blood increase in Holstein breed.
For a more complete characterization of meat qualities in experimental bulls, after 24 hours in the refrigerator, dissection of the left halves was performed followed by trimming of the meat by sausage production technology (Table 3).

Table 3 -Morphological composition of experimental bull halves (n = 3)

Parameter	Group							
	Control		Experimental					
			1st		2nd		3d	
	$\bar{X} \pm m$	%	$\bar{X} \pm m$	%	$\bar{X} \pm m$	%	$\bar{X} \pm m$	%

Meat weight, kg	109.7 ± 5.28	74.47	100.4 ± 3.63	74.54	98.8 ± 6.07	74.28	95.3 ± 4.86	73.88
Premium meat, kg	23.2 ± 1.67	15.77	19.6 ± 0.70	14.55	19.8 ± 1.63	14.89	19.6 ± 0.91	15.19
I grade meat, kg	43.3 ± 2.73	29.40	38.1 ± 1.10	28.29	41.3 ± 1.39	31.05	37.0 ± 1.52	28.68
II grade meat, kg	43.2 ± 1.42	29.30	42.7 ± 1.88	31.70	37.7 ± 3.38	28.34	38.7 ± 2.91	30.0
Bones weight, kg	30.3 ± 1.67	20.57	26.2 ± 0.44	19.45	26.0 ± 0.09	19.57	26.7 ± 1.20	20.7
Tendons weight, kg	3.7 ± 0.47	2.46	3.5 ± 0.09	2.60	3.8 ± 0.23	2.84	3.2 ± 0.17	2.46
Bones and tendons weight, kg	34.0 ± 1.43	23.08	29.7 ± 0.46	22.05	29.8 ± 0.15	22.41	29.8 ± 1.36	23.12
Weight of fat, kg	3.6 ± 0.60	2.50	4.6 ± 0.59	3.41	4.4 ± 0.07	3.31	3.8 ± 1.01	3.00
Fleshing index	3.63 ± 0.07		3.83 ± 0.12		3.80 ± 0.20		3.56 ± 0.03	
Fat, points	4.8		4.6		4.6		4.4	

Investigations of morphological structure of halves showed that in crossbred bulls except experimental group I the absolute meat weight and its yield decreased with blood increase compared to the control group by 9.3-14.4 kg (8.5-13.1%) and 0.3-0.6%. The carcasses of animals in the control group contained more bones (by 3.6-4.3 kg) and tendons (by 0.1-0.5 kg) due to greater weight. The relative mass of bones and tendons was also somewhat higher (0.7-1.0%) than that of peers in other groups. Premium meat yield was 0.6-1.2% (3.4-3.6 kg) higher respectively. There was 2.0-6.3 kg more I grade meat in halves of bulls in control group. II grade meat yield in halves of bulls in control group was 1.1% greater than in II experimental group but 2.4% less than in I and 0.7% less than in III. Fleshing index (the ratio of edible parts of the carcass to the bone mass) in animals was practically the same and varied from 3.56±0.03 to 3.83±0.12.

For the analysis of physical and chemical properties of meat we examined the longissimus dorsi at the 9-12 thoracic vertebrae. We also investigated the content of moisture in meat, pH and water retention capacity (Tables 4, 5). Water retention capacity is one of the most important indicators of the quality of meat, its juiciness and appearance.

In our experiment we haven't found significant differences in water retention capacity and pH (pH – 6.3-6.5, water holding capacity – 62.4-68.1%).

Table 4 - Chemical composition of meat in the longissimus dorsi, % (n = 3)

Parameter	Group			
	Control	Experimental		
		1st	2nd	3d
Water	75.99±0.32	76.18±1.09	75.65±0.40	74.90±0.42
Dry basis	24.01±0.32	23.82±1.09	24.35±0.40	25.10±0.42
Crude protein	21.85±0.23	21.33±1.05	21.75±0.41	22.34±0.35
Crude fat	1.33±0.27	1.71±0.24	1.48±0.08	1.98±0.12
Ash	0.82±0.08	0.78±0.18	1.12±0.06	0.78±0.04
Calorific capacity of 1 kg meat, kcal	1020	1034	1029	1100

. Table 5 - Processing characteristics of meat in the longissimus dorsi (n = 3)

Parameter	Group			
	Control	Experimental		
		1st	2nd	3d
Meat water capacity, %	62.4±2.52	65.3±1.93	68.1±2.21	65.5±2.28
pH	6.3±0.04	6.5±0.04	6.4±0.09	6.5±0.15
Boiled meat yield, %	59.0±2.70	62.9±2.41	59.3±1.03	65.0±1.30

Analysis of the data on the chemical composition of meat in the longissimus dorsi shows that no significant differences between experimental animals and control groups were observed. The protein content was high enough and ranged from 21.33% in the animals of experimental group I to 22.34% in the experimental group III.

The highest amount of fat contained in the meat of bulls in experimental groups (1.48-1.98%) and the lowest in the control group (1.33%). Experimental and control groups also did not differ significantly by meat calorific capacity (1020-1100 kcal).

Conclusion

Meat qualities of holsteinized bulls of $^{3}/_{4}$ H$^{1}/_{4}$BV genotype were higher than in animals of other genotypes ($^{1}/_{2}$H$^{1}/_{2}$BV, $^{5}/_{8}$H$^{3}/_{8}$BV and $^{7}/_{8}$H$^{1}/_{8}$BV). Thus, the control group animals had pre-slaughter live weight of 496.8 kg; fresh carcass weight of 299.0 kg; slaughter yield of 63.4%; internal fat content of 16.2 kg, which is higher than in bulls of other groups, respectively: on 5,6-20,8 kg (1.1 – 4.2 %); 10,0 – 20,0 kg (3.3 – 6.7 %); 1.5 – 1.7 % and 0.1 – 0.9 kg (0.6 – 5.6 %). Morphological composition of halves showed that, at an increase in the proportion of Holstein blood in the bulls genotype up to 62.5 and 87.5%, the absolute mass of the meat and its yield decreased slightly in comparison with the bulls of genotype $^{3}/_{4}$H$^{1}/_{4}$BV by 9.3 – 4.4 kg (8.5 – 13.1 %) and 0.3 – 0.6 %. No significant difference in chemical composition of meat was noted.

The research on the comparative study of beef production in black-variegated bulls of different genotypes of Holstein breed under the same conditions of feeding and management suggests that it is more efficient to fatten animals of $^{1}/_{2}$H$^{1}/_{2}$BV and $^{3}/_{4}$ H$^{1}/_{4}$BV genotypes as so as at the same feeding level they have greater live weight, relative weight of meat in the carcass and the fleshing index than their peers ($^{5}/_{8}$H$^{3}/_{8}$BV and $^{7}/_{8}$H$^{1}/_{8}$BV genotypes).

Thus, the study of fattening and meat qualities in bulls of different genotypes of Holstein breed showed that breeding the desired type of animals ($^{3}/_{4}$H $^{1}/_{4}$BV-control) achieved the best results in meat production, and by a number of indicators, such as live weight, average daily gain, fresh and chilled carcass weight and weight of meat and premium meat animals in control group outperform their peers in the experimental groups.

ASSESSMENT OF THE CARDIOVASCULAR SYSTEM IN SHEEP

Yury A. SHUMILIN, Dmitry A. STEPIN

FSBEI HPE «Voronezh State Agricultural University after Emperor Peter the Great», Voronezh, Russia
*Corresponding author: shumilin80@mail.ru

Abstract

It is considered that various changes in the body are caused by diseases that affect the operation of all systems and organs, including the myocardium. The difficulty in detecting heart disease makes this question even more relevant. Diagnostics of the sheep cardiovascular system is also of a specific scientific interest. This question has some difficulties connected with the anatomic features. In the scientific literature this issue is not described well enough.

Receiving quality electrocardiographic curve in sheep largely depends on the method of recording electrocardiogram. Therefore, in our work we paid great attention to the method of the ECG recording in sheep. We considered electrocardiographic changes in sheep of different age and with certain diseases. We also paid attention to the peculiarities of radiographic anatomy of the chest cavity in sheep. Radiography provides valuable data about the condition of the heart and large vessels. That combined with electrocardiographic and ultrasound assessment allows us to conduct a comprehensive assessment of the cardiovascular system in sheep.

Key words: *radiography, electrocardiography, instrumental diagnostics, sheep, goats.*

Introduction

Sheep breeding is one of the important branches of agricultural production in Russia. In recent years it has been gaining in economic importance. Periodic outbreaks of African swine fever in the Voronezh region have forced the population to develop alternative types of livestock. One of these types is the sheep, which can be used to provide the industry with wool and the population with food. The economic value of sheep is their precocity and rapid ability to reproduce.

The analysis of some scientific data [Kotarev V.I., Aristov A.V., Lopatin V.T., Kudinova N.A., Pronina E.A., Capkina N.I., 2014; Parshin P.A., Nikulin I.A., Shumilin Y.A., 2007] shows that the heart condition is often a reflection of the whole organism state. Meat and wool production of sheep depends on the stable operation of the cardiovascular system, therefore, timely detection of violations in this system is the key to successful prevention and treatment. It is considered that various changes in the body are caused by diseases that affect the operation of all systems and organs, including the heart. The difficulty in detecting heart disease makes this question even more relevant. Diagnostics of the sheep cardiovascular system, conducted by radiography, allows you to simultaneously assess the condition of the lungs and bronchi, which is also of particular scientific and practical interest. The solution of these problems has some difficulties connected with the anatomic features. In the scientific literature, they are not described well enough.

In connection with the above data, our goal was to assess the status of the cardiovascular system in sheep with clinical research methods that are available for practical use.

Materials and methods

The work was done in Voronezh State Agricultural University, faculty of Veterinary Medicine and Animal Husbandry Technology in 2015. The study was carried out on clinically healthy sheep Kuchugurovskaya breed (n=13) kept in the vivarium and facilities of the Department of Therapy and Pharmacology. Clinical study of the sheep was carried out according to conventional veterinary plan, taking into account species specificity in

accordance with the recommendations of some authors [Kotarev V.I., Aristov A.V., Lopatin V.T., Kudinova N.A., Pronina E.A., Capkina N.I., 2014; Kotarev V.I., Kryuchenkova N.V., 2003; Nikulin I.A., Shumilin Y.A., 2009; Parshin P.A., Nikulin I.A., Shumilin Y.A., 2007; Yerohin A.I., Kotarev V.I.., Yerohin S.A., 2014]. Special attention was paid to the cardiovascular system. The electrocardiogram was recorded with a three-channel electrocardiograph CARDIPIA 200. The electrodes used clamps of "crocodile" type. For best contact the skin and fur on the places of fixation of the electrodes were treated with electrode contact gel. ECG was recorded by system sagittal derivations suggested by M. P. Roshevskiy with a record of three bipolar body leads and reinforced Goldberg. X-rays of the lungs were performed on a portable x-ray machine DIG-360 using blue sensitive x-ray film and the intensifying screens on the basis of calcium tungstate. Photochemical processing of the films was carried out in the installation manual with reagents company Fudgi.

Results and discussion

A widely used method of studying the function of the heart is the electrocardiogram, which allows to study the functional manifestation of pathological processes affecting the heart, in particular breaches of its electrical activity. On this basis it is possible to develop evidence-based methods of diagnosis of heart disease that is of great importance to practice veterinary medicine. However, many issues of clinical electrocardiography, especially sheep one, are still open.

Receiving quality electrocardiographic curve in sheep and goats largely depends on the method of recording ECG. Therefore, in our work we paid great attention to the method of the ECG recording in sheep. Today, many scientists who study the condition of the heart in hoofed animals, consider theoretically correct and reasonable to carry out the ECG recording in sheep and goats in the sagittal leads, not leads from the limbs, as in humans and carnivores.

For the research a group of clinically healthy sheep Kuchugurovskaya breed (n=13) aged from six months to ten years were taken. We recorded ECG in ewes on the sagittal lead system, which is shared by all ungulates. It allows you to register a bipolar body abduction in the sagittal plane with the electrodes: 1) cranial part of the sternum; 2) the midpoint of the line connecting the caudal angles of the right and left scapulas; 3) the point of intersection of the perpendicular from the 13th thoracic vertebra, with the white line of the abdomen (figure 1). The fourth electrode is the ground electrode and is not involved in the recording of ECG leads, so it can be attached anywhere on the animal's body, at some distance from the 1, 2 and 3 electrodes. Usually we put it in the knee crease.

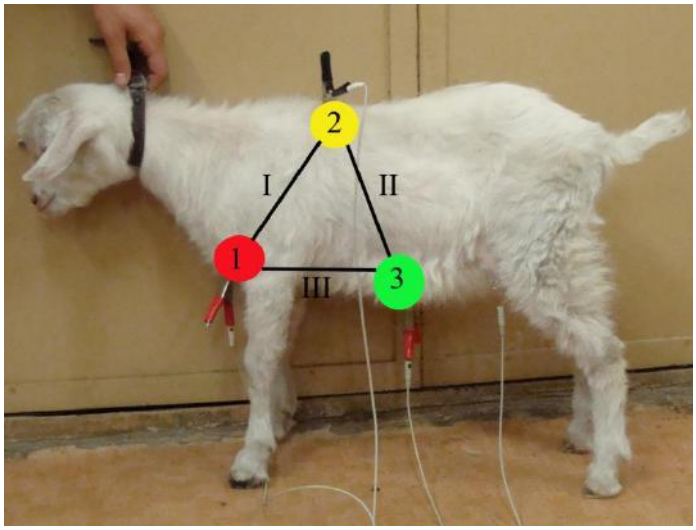

Figure 1. Scheme of electrodes during registration sagittal ECG leads in sheep and goats.

1 – the electrode with the red tip,
2 – the electrode with the yellow tip,
3 – the electrode with the green tip.

I – the lead ECG,
II – the lead ECG,
III – the lead ECG.

The choice of the speed of the paper

partly depends on the heart rate of examined animals. When working with sheep and goats, we recommend you to set the speed of paper movement 50 mm/s. In our opinion this speed allows you to get a good quality recording of cardiac cycles. Amplitude measurement of teeth were performed on unfiltered records because the filter reduces the amplitude of teeth.

In table 1 there are results of a normal electrocardiogram sheep Kuchugurovskaya breed. In the group there were animals (n=10) aged from six months to four years. The basic form of the ECG of the sheep of this breed registered by the system sagittal leads has the following characteristics. In the second lead, which is considered the main, there is a positive atrial prong P value of 0,18±0,01 mV. The initial activity of the ventricles of the heart in 50% of animals presented is Q - 0,54±0,12 mV. The R wave has a small value of about 0,11±0,01 mV. 60% of sheep for R-wave should be deep prong S value of 0,47±0,1 mV. The T wave in the investigated animals is very variable: so 70% of it is positive – 0,21±0,03 mV, in 10% of it is negative – - 0,2 mV, and in 20% of it is two-phase – -/+0,13±0,03 mV.

Table 1. Indicators of normal ECG in sheep Kuchugurovskaya breed (n=10).

Prong	The size of prongs, expressed in mV				
	I the lead		II the lead		III the lead
P	0,09±0,01		0,18±0,01		0,1
Q	80%	0,22±0,04	50%	0,54±0,12	-
	20%	-	50%	-	
R	0,23±0,03		0,11±0,01		0,08±0,01
S	-		60%	0,47±0,1	0,51±0,04
			40%	-	
T	70%	-0,16±0,03	70%	0,21±0,03	0,21±0,03
	20%	0,13±0,03	20%	-/+0,13±0,03	
	10%	-/+0,1	10%	-0,2	

Duration of basic ECG intervals were: PQ – 0,1±0,004 seconds, the wave P – 0,04 seconds, QRS – 0,04 seconds, QT was 0,26±0,01 seconds, and RR – 0,49±0,02 seconds. On the basis of the intervals duration, we can determine the systolic indicator. It shows the amount of electric systole, expressed as a percentage of the total duration of the cardiac cycle. And in our animals the value of systolic indicator is equal to 55%±2%. Knowing the duration of the RR interval, we can accurately identify the number of heart beats. It is 126±6 beats per minute.

The position of the ST segment in healthy animals corresponds to the position of the segment TP (the true isopotential line), i.e. they are located on the same level. ST segment elevation up or down from the true isopotential lines will indicate a violation of the coronary circulation. The ST segment was located at the level of the isopotential lines at all the sheep which we examined. Figure 2 shows a typical electrocardiogram for this group of sheep, which is typical for healthy animals.

The characteristic signs of cardiomyopathy were observed on ECG in three sheep. The electrocardiogram of one of them is presented in figure 3. There was a significant change of the QRS complex in the first lead. It changed its polarity and had splitting on the top of the R-wave. In the second lead QRS complex took the form of the letter W, with the presence of prongs Q, R, S small amplitude. At the same time the amplitude of the wave T was well above the norm, and most importantly it was several times greater than the highest wave of the QRS complex. Systolic indicator increased to 67%.

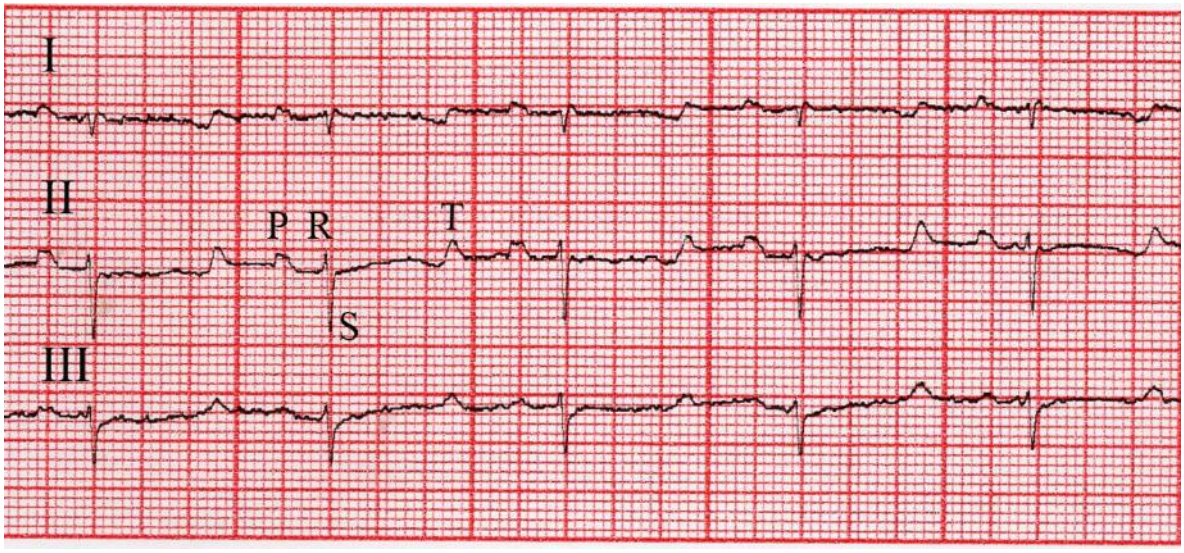

Figure 2. Electrocardiogram of the sheep №8 at the age of 3 years recorded by the system sagittal leads. 1 mV=10mm. The speed of the tape is 50 mm/sec. I, II, III - ECG leads. P, R, S, T – the prongs of the second lead.

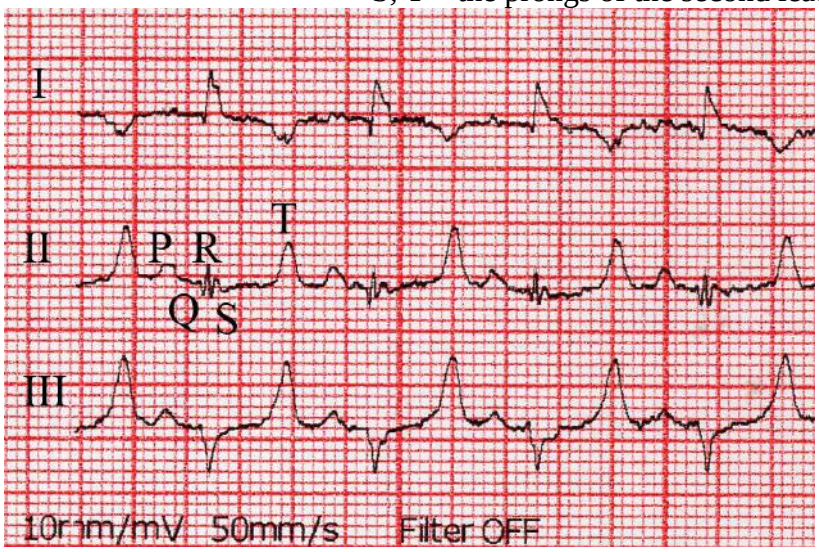

Figure 3. Electrocardiogram of the sheep №12 at the age of 10 years with symptoms of cardiomyopathy. 1 mV=10mm. The speed of the tape is 50 mm/sec. I, II, III - ECG leads. P, R, S, T – the prongs of the second lead.

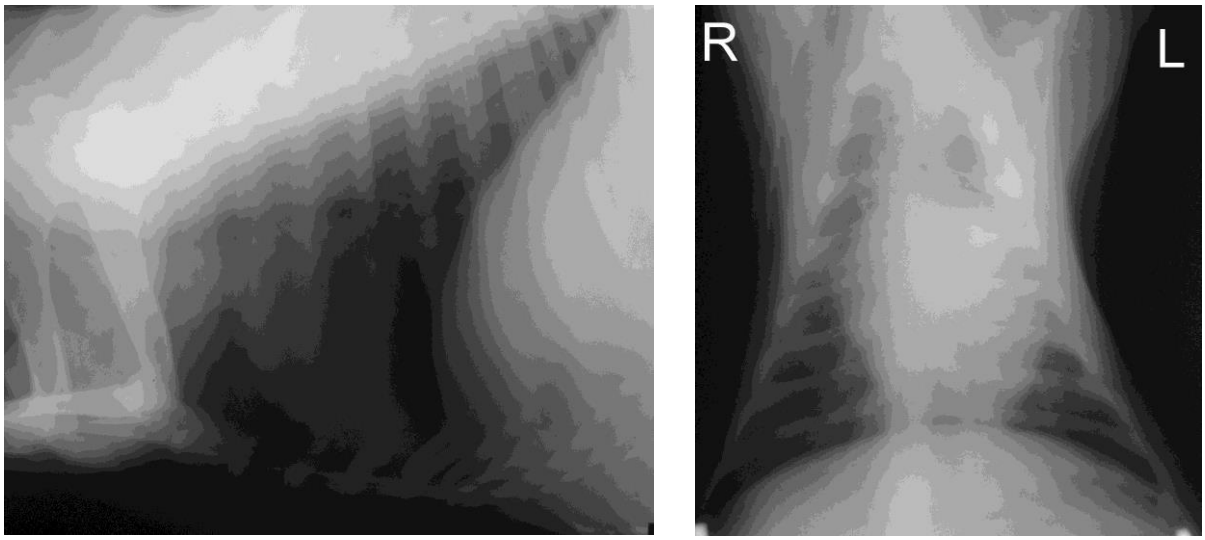
X-raying the chest in sheep we gave preference to the right lateral recumbent position, as this position is a more typical position of the heart, in this case between the heart and the lower chest wall there are more air lung fields, which enables the study of the elements of the heart and enhances the contrast. The diaphragm does not preclude consideration of the caudal lung fields.

When lying the animal tried to take the front legs forward and lock them to avoid the superposition of the main mass of the triceps on the cranial lobe of the lung.

The most important diagnostic decision is to determine whether the chest is characterized by an x-ray as normal or pathologically altered. To do this we identified key attributes of normal roentgen anatomy of the thorax in sheep (figure 4a, 4b).



a b

Figure 4. Chest x-ray, sheep aged 3 years. a – right lateral projection of the chest, b – ventrodorsal projection of the chest.

The trachea normally is rejected from the thoracic spine at an angle of approximately 40°, it is not visible in the direct projection because of the superposition with the spine.
The silhouette of the heart is egg-shaped with the base of the dorsal and ventral tip. The height of the heart from base to tip is about 2/3 of the height from the size of the chest cavity at the same level. The silhouette of the heart takes about three intercostal spaces laterally. In the direct projection the widest part of the heart is about half, the width of the chest measured at the level of the dome of the diaphragm. In the direct projection of the apex of the heart it is significantly shifted to the left from the middle line.
Caudal Vena cava enters the thorax through the diaphragm and tends cranio-ventral to the caudal border of the heart. Normally its sides are parallel. Cranial Vena cava is composed of the cranial mediastinum and is suitable at a right angle to the cranial border of the heart (figure 4a).
Lung fields are normal to the x-ray transparent in their background pulmonary vessels and the bronchial tree are all visible. The vessels of the lungs come in pairs: artery and vein, the branches of which are directed to the periphery of the lobes of the lung. Arteries and veins are normal, of similar diameter and are on each side of the bronchus. Arteries are dorsal and ventral veins. In the direct projection of the pulmonary vessels may be better seen in the caudal part of the thorax just before the liver.

Conclusion

Sagittal ECG leads applied to sheep meet all the requirements of the theory of electrocardiography for system leads. The shape of the electrocardiographic curve in the sagittal leads is constant when the right position of the body and forelimbs is found. We described electrocardiographic and radiographic indicators characterizing the state of the heart and thoracic cavity organs in sheep, which allow in the future to conduct evaluation the state of these organs in sheep. Knowing the criteria of the normal state different pathological changes can be distinguished. The description of the condition of the heart and lungs in sheep in different pathological processes such as pneumonia, ketosis and other we believe is important to improve diagnostic capabilities and performances of timely diagnosis. There is some prospect of further studies. Thus electrocardiography and radiography can find practical application in the diagnostics of pathology of the cardiovascular system and the lungs in sheep.

Abstract

Results of serological monitoring of echinococcosis in sheep using ELISA test with excretory-secretory antigens of *Echinococcus granulosus* (l) and *Echinococcus multilocularis* (l) protoscolexes were represented. 58 serum samples of slaughtered sheep with diagnosed parasitological status were tested including 23 from animals with cystic echinococcosis, 24 – without visible changes and 11 – with focal undiagnostic damages in livers. The results of our assay showed that antigens of the both types of echinococcus can be used in serologic monitoring of cystic echinococcosis of sheep. Sensibility of ELISA with *E. granulosus* (l) protoscolexes antigens was 74.3% and with similar antigen of *E. multilocularis* (l) was 73.9% respectively.

Key words: *echinococcosis, antigens, seroepizootology, sheep.*

Introduction

Cystic hidatid disease of sheep belongs to the widespread parasitic zoonoses causing significant economic damage and is dangerous for people. There are many publications about huge losses of animals caused by cystic echinococcosis in the Southern Federal Region where at some farms the extensity of infection exceeds 35-40%. Analysis of the data of slaughtered animals is trustworthy criterion for evaluation of epizootic situation. However in larval cestodoses including cystic echinococcosis the results of serologic studies allowing to conclude (on basis of the received information) about the activity of epizootic process can by an effective element for monitoring of epizootic situation. Considering all this we carried out serologic monitoring of cystic echinococcosis by analyzing serums serums of the slaughtered sheep from farms of Kabardino-Balkaria Republic.

Materials and methods

Serologic analysis was carried out by ELISA, using three-day products of metabolism of *Echinococcus granulosus* (l) and *Echinococcus multilocularis* (l) protoscolexes received by cultivation in RPMI-1640 with 2 ml of glutamine, 8 mg of gentamycin (4%) and 0.5ml of amphothericyn B as antigen. The viability of cultivating protoscolexes was maintained for 3 days in CO_2 incubator “Heraeus” at 37^o C. Serum samples from slaughtered sheep were taken from farms in Kabardino-Balkaria Republic. Helminthological status was determined by investigation of liver, lungs and other parenchymal organs. In total 58 serum samples from sheep were taken including 23 from animals with larval echinococcosis, 24 without visible parasitic changes and 11 - from animals with focal damages in livers. Previously using reference positive and negative control serums we determined an optimal concentration of excretory-secretory antigens for sensibilisation of solid phase and degree of serum solution and titre of conjugate for which rabbit antibodies affine cleared specific to immunoglobulines of sheep, marked peroxidase (“IMTEK”) were used.

Results and discussion

Previous investigations with reference positive and negative control serums by ELISA method showed that the optimal concentrations of excretory-secretory antigens from protoscolexes of *E. granulosus* (l) and *E. multilocularis* (l) for sensibilisation of solid phase were 9 and 11 mkg/ml, respectively. Serum solution was 1:100 and titer of conjugate was 1:6000.

Results of serological monitoring showed that out of 23 serum samples from echonococcus infected animals positive reaction was registered in 18 cases. Therefore, test sensitivity was 78,2% (table 1).

Table 1. Assessment of sensitivity and specificity of immunosorbent assay (ELISA) with 3-day excretory-secretory antigenes of protoscolexes of *Echinococcus granulosus* at echinococcosis of sheep

Serum samples	Number of tests	Results				
		Positive	Doubtful	Negative	Sensibility, %	Spesifisity, %
Larval echinococcosis	23	18	1	4	78,2	74,3
Focal damages in liver	11	5	1	5		
Absence of damages	24	3	-	21		

Positive results were in 17 samples from 23 in similar tests with excretory-secretory antigen from *E. multilocularis* (l) protoscolexes and the same serum samples that corresponded to sensibility of test as 73.9% (table 2). Specificity of assay after reaction with 35 serum samples from sheep with focal damages in liver and without visible damages in livers was 74.3% using homologous antigen and 77.1% using heterological one (tables 1, 2).

The false positive result in the first case was registered in 9 tests, in the second – in 8, and mainly there were serums of sheep with focal changes in liver of an unknown etiology.

Proceeding from the obtained data, we concluded that the both antigen preparations can be used in serologic monitoring of cystic echinococcosis in sheep that is confirmed by rather high sensitivity and specificity of the immunotest characterizing activity of epizootologic process of echinococcosis of sheep in this region.

Carrying out seroepizootologic monitoring of cystic echinococcosis in sheep with use of serums of animals with the known helmintology status and antigene preparations from protoscolexes of *E. granulosus* (l) and *E. multilocularis* (l) confirmed significant antigene relationship of these species of parasites and possibility of their interchangeability in the antigene relation; though there are data about presence of species-specific antigen components in each of them.

According to Ito et. al. for *E. multilocularis* (8) that is protein-antigen component with molecular weigh 18 кДа and for *E. granulosus* – 38 кДа.

Table 2. Assessment of sensitivity and specificity of immunosorbent assay (ELISA) with 3-day ekscretory-secretory antigens of protoscolexes of *Echinococcus multilocularis* at echinococcosis of sheep

Serum samples	Number of tests	Results				
		Positive	Doubtful	Negative	Sensibility, %	Spesifisity, %
Larval echinococcosis	23	17	1	5	73,9	77,1
Focal damages in liver	11	3	2	6		
Absence of damages	24	4	-	21		

Despite it, *Echinococcus multilocularis* (l) antigens were successfully used as diagnostical antigens at cystic echinococcosis in humans (7, 9). Potentially important diagnostic marker of cystic echinococcosis according to Zhang and Mc Manus (11), the component with molecular weight 38 kd, which, as well as component with molecular weight 25 kd, are a part of AG 5 representing the lipoprotein of cystic *E. granulosus* liquid containing subunits within 56-70 kd which at an electrophoresis in poliakrylamid gel with dodecylsulfat sodium dissociate on two components 25 and 38 of a kd.

However, earlier Feng et al. (5,6) reported that two components with molecular weight 52 и 38 кДа were registered in excrets and secrets of germinative cells and cystic liquid of E. granulosus, and the component with molecular weight 52 кДа showed highest specificity in immunological reactions. That dissociation maybe is connected with infective process as there are data that immune response to cestode infection is characterized by development of antibodies of various specificity, for which identification the diagnostic antigene containing molecules to antigene determinants for all synthesizable antibodies at all stages of development of a parasite is necessary.

Indirect confirmation about presence of antibodies with different specificity in serums of infected sheep is data of Ris et al. (10), which increased sensitivity and specificity of ELISA at echinococcosis to 80% at simultaneous holding of reaction with two polysaccharide antigenes of parasite – from protoscolexes and membrane *E. granulosus* cysts. That fact allowed to differentiate cross false positive responces with serums of the sheep infected with *T. hydatigena* (l) and *T. ovis* (l) more accurately.

Conclusion

The analysis of the results of seroepizootological monitoring at cystic echinococcosis in sheep with *E. granulosus* (l) and *E. multilocularis* (l) protoscolexes antigens gives the grounds to make the conclusion, first, about possibility of usage of antigene preparations of both types of echinococs in similar researches, and secondly to assess an epizootologic situation on this helminthosis on sensitivity and specificity of immunoreaction.

Abstract

Apple pomace was ensiled without additives and with the addition of dried beet pulp 15%, sunflower meal also 15% and 1% NPN substances, and each of these treatments was with and without inoculant. Certain parameters of suitability of biomass for silage were determined in the starting material, also DM, CP, content of ash, Ca and P. Also, the content of DM, pH, ammonia and soluble nitrogen were determined in the silage. The protein fractions in silage were determined according CNCPS (*Cornel Net Carbohydrate and Protein System*) system as follows: PA, PC and three protein fractions PB (PB_1, PB_2 and PB_3). Apple pomace is extremely suitable for ensiling, it has the most favourable WSC/BC ratio and can be a supplement used for ensiling of biomass that is difficult to ensile. Adding dry feeds such as dry sugar beet pulp and sunflower meal in the amount of 15% increases the content of DM. Sunflower meal provides the highest value of CP (227.5 gkg^{-1}DM) and PB_2 fraction in silage, while adding NPN substances (Benural S) provides the highest value of PA fraction (525.9 gkg^{-1}CP). Application of inoculants has contributed to reducing the PC fraction (214.64:239.47 gkg^{-1}CP), i.e. contributed to the increase of digestibility or nutritive value of silage. High and favourable WSC/BC ratio provided a slightly higher acidity (pH value 3.40 in the control silage, to 3.77 in the apple pomace silage + sunflower meal). The process of protein degradation in the silage expressed through ammonia and soluble nitrogen relative to the total nitrogen in the silage was low, so, the maximum points, i.e. an excellent score for all silage treatments by methods of Zelter and Weissbach and Hoing were awarded. The parameters of biomass suitability for ensilaging were determined in the starting material. Also were determined DM, CP, ash content, Ca and P.

Keywords: *apple pomace, sunflower meal, NPN substance, protein fractions, quality of silage.*

Introduction

The problem of the deficiency of animal feed for ruminants, especially in years of drought can be mitigated by using certain related products to the food industry, even in nutrition of dairy cows (Ghoreishi et al. 2007). Some by-products may have other uses as raw material for the production of compost, for the production of alcohol (Chatanta et al., 2008), but the best way of utilization is their preparation and conservation so that they can be used as part of the ruminants' diet.

Apple pomace is the residue remaining after pressing of apples and removing the juice and is composed mainly of fruit skin, seeds, and the rest of the juice. Fresh apple pommace, contains a low level of DM (Pavličević et al., 1988). In ruminants' diet fresh, ensiled and dehydrated apple pomace can be used. The use of fresh pomace in animal nutrition in the long run is not possible due to the rapid fermentation or spoilage. Dried apple and grape pomace has been previously used in ruminant nutrition, primarily in cattle fattening (Zeremski, 1982, Nikolić et al., 1986), however, presently such nutrition is not economically viable.

Taking into consideration that apple pomace is poor in protein (Abdollahzadeh et al., 2010), and rich in water soluble carbohydrates, it is necessary to apply a method of increasing the content of the CP, in order to optimize ruminant nutrition. One of the simple and extremely inexpensive methods is the addition of a suitable source of non-protein nitrogen in the silo mass or diet. Symbiotic bacteria in the rumen will, on the basis of added nitrogen, synthesize their own proteins of high biological value, which will be digested and used in the small intestine of ruminants together with dietary proteins (Đorđević and Dinić, 2011).

One of the potential problems related to the utility value of silage from apple pomace could be insufficient aerobic stability. The main reason for this is very broad relationship of water soluble carbohydrates (WSC) and the buffering capacity (BC), and any potential improper utilization and exclusion method of silage. Therefore, the use of the bacterial inoculant is planned, which in addition to homofermentative also contains heterofermentative bacteria of lactic acid fermentation.

The aim of this paper is to examine the possibility of ensiling apple pomace by adding NPN substances, sunflower meal, dried beet pulp to increase the dry matter content, determine the protein fractions according to CNCPS and increase the anaerobic stability of the silage.

Material and methods

Ensiling of apple pomace was performed on April 3rd 2013, in experimental containers holding 130 dm^3, in three replications. Study treatments in the present research of the apple pomace silage were: A_1 - ensiled apple pomace 100% participation (a_1b_1 - apple pomace without additives; a_1b_2 - apple pomace with inoculant; A_2 - apple pomace 85% + 15% dried beet pulp (a_2 b_1 - without additives; a_2b_2 - with inoculant); A_3 apple pomace 85% + 15% sunflower meal (a_3 b_1 - without additives; a_3b_2 - with inoculant); A_4 - apple pomace 84% + 15% dried beet pulp + 1% Benural S (a_4b_1 - without additives; a_4b_2 with inoculant).

Apple pomace is characterized by extremely high moisture content, yellow colour and pleasant smell. Dry sugar beet pulp and sunflower meal were purchased commercially and were according to their declaration.

As a NPN substance Benural S was used which contained 42% of urea, 56% of bentonite and 2% of sulphur. In contrast to the pure urea, this product contains the bentonite, which allows slower release of ammonia in the rumen, and more efficient utilization by the microorganisms of the rumen, it binds some gases and toxic substances, and contains certain important elements (K, Na, Mg etc.). The sulphur present in Benural S enables efficient synthesis of some essential amino acids that contain this macro-element (methionine, cysteine).

BioStabil Plus is an inoculant which contains homofermentative lactic acid bacteria (*Enterococcus faecium* and *Bacillus plantarum*) and heterofermentative lactic acid bacteria (*Bacillus brevis*) with a concentration of $5x10^{10}$cfu per gram of product.

Certain parameters of the ensiling suitability of the biomass were determined in the starting material (apple pomace, sunflower meal, dry sugar beet pulp). WSC (water soluble carbohydrates) were estimated colorimetrically by the method of DuBois et al. (1956), and the buffering capacity (BC) according to the method of Weissbach (1967). The following parameters were determined in the apple pomace and silage: content of DM, CP, ash, Ca and P; the content of DM in the silage, the degree of acidity (pH), ammonia and soluble nitrogen.

Protein fractions according CNCPS (*Cornel Net Protein and Carbohydrate System*) were determined by the method Licitra et al. (1996), and fractionated into 5 fractions (Snifen et al., 1992; Fox et al., 2003), as follows: PA fraction of CP – easy soluble proteins that comprise the non-protein nitrogen; PC fractions of CP - completely unavailable/inaccessible CP representing ADICP (*Acid Detergent Insoluble Crude protein*); PB fraction of CP - potentially degradable fraction is the difference between the total crude protein and the sum of soluble and unavailable crude proteins. PB crude protein fraction is further subdivided into:

PB_1 fraction which is rapidly degraded; PB_2 fraction that is of medium degradability and PB_3 fraction which is slowly degraded in the rumen.
The chemical analyses were performed in the laboratory of the Institute of forage crops in Kruševac, according to standard methods (AOAC, 1990). For evaluating the quality of silage - based on ammonia and water soluble nitrogen, two methods were applied - Zelter (Đorđević and Dinić, 2003) and Weissbach-Hoing (1997). The results of chemical analyses were analysed by analysis of variance, and the statistical significance of differences was tested using the LSD test.

Results and Discussion

In order for a biomass to be suitable for ensiling, it should contain as many as possible WSC, and at the same time as low as possible BC. In order to ensure successful lactic acid fermentation and obtain a stable silage without the presence of butyric acid, the WSC/BC ratio should be equal to or higher than 3.0 (Weissbach, 1967), and it is desirable that the level of dry matter in the biomass of roughages is 300 - 400 gkg^{-1}.

The low content of DM was determined in apple pomace - 170 gkg^{-1}, which forced us to use dry sugar beet pulp in order to increase the level of DM. WSC level was extremely high (498.6 gkg^{-1}DM, and the highest in the research so far with very low BC of 6.69 lactic acid (LA) to 100 g^{-1}DM (Table 1), which contributed to the highest WSC/BC ratio of 74.5 suggesting that apple pomace can be a great addition to all biomasses that are difficult to ensile. Dry sugar beet pulp is considerably less favourable in comparison with apple pomace and WSC content in the sunflower meal is a trace, below 1%.

Table 1. Results of the parameters suitability apple pomace and used supplements for silage

The starting material	DM, gkg^{-1}	WSC, gkg^{-1}DM	BC, meq LA $100g^{-1}$ DM	Ratio WSC/BC
Apple pomace	170.0	498.6	6.69	74.5
Dry beet pulp	869.7	28.1	14.1	1.99
Sanflower meal	901.8	8.93	76.9	0.12

Legend: BC - buffering capacity; LA - lactic acid; WSC - water soluble carbohydrates (sugars);

CP content and content of minerals in the starting material are given in Table 2. The lowest concentration of CP in apple pomace can be observed (79.0 g kg^{-1} DM), and the highest in sunflower meal (333.1 g kg^{-1} DM). A similar statement is in regard to mineral substances, sunflower meal contains close to 3.5 times and dry sugar beet pulp 3 times more compared to apple pomace.

Table 2 Concentration of protein and minerals in the starting material, gkg^{-1}DM

Treatments	CP	Ash	Ca	P
Apple pomace	79.0	20.8	2.7	1.3
Dry beet pulp	91.3	64.7	14.3	1.2
Sanflower meal	333.1	73.6	7.1	11.3

Ca concentration is the highest in dry sugar beet pulp, 2 times higher compared to sunflower meal and 5 times higher than in the apple pomace. The concentration of P is almost identical in apple pomace and dry sugar beet pulp, and over 10 times higher in sunflower compared to these feeds (Tab. 2).
The concentration of CP in silages depended on added nutrients. The lowest concentration of CP was established in silages of pure apple pomace - silages A_1 and A_2 (86.99and 89.75g kg^{-1}

DM) (tab. 3). Adding NPN substances to apple pomace in the amount of 1% (silage A_4) contributed to a significant increase in the content of the CP in the silage (140.25 g kg $^{-1}$ DM), and the highest values of CP in silage determined in A_3 to which 15% sunflower meal was added (227.52 g kg $^{-1}$ DM). Statistical analysis showed highly significant differences in the content of the CP between silages A_1 and A_2, on the one hand, and apple pomace silage with the addition of NPN substances (A_4) and sunflower meal (A_3) on the other hand. Statistically significant difference in the content of CP between silages A_3 and A_4 was determined, but no significance was established between silages with and without inoculant.

PA fraction of CP represents the easy soluble proteins that comprise the non-protein nitrogen. Values of PA fraction were in the range of 268.5 to 525.9 g kg $^{-1}$ CP (tab. 3). The highest value was found in silage where the NPN substance was added (Benural S). Statistical significance was established between silage A_3 and other silages, but no significance was established between silages with and without the inoculant in regard to the content of the PA (protein fraction).

$\overline{X}$ A_3		227.52a	286.5b	1.27a	566.4a	22.57c	123.23d
$\overline{X}$ A_4		140.25b	525.9a	1.22a	190.4d	106.98b	175.54c
$\overline{X}$ B_1		135.16a	334.0a	1.30a	322.5a	102.73a	239.47a
$\overline{X}$ B_2		137.10a	351.6a	0.83a	333.5a	99.43a	214.64b

PB_1 fraction of CP in silage that is characterized by rapid degradability, was present in a small amount and no statistical significance between the silage treatments was established (tab. 3). PB_2 fraction of CP is fraction of medium degradation, with the lowest values determined in the silages with NPN substance (190.4 g kg $^{-1}$ CP), and the highest value was found in silages with sunflower meal (566.4 g kg^{-1}CP). Statistical significance was established between silages of all treatments, except for the silages with and without the application of inoculants (table 3). Minimum value of PB_3 fraction of crude protein (22.57 g kg^{-1}CP), which degrades slowly in the rumen, was established in silages A_3 (with the addition of sunflower meal) and in control silages (37.17 gkg^{-1}CP), and the highest value (237.56 gkg^{-1}CP) was found in apple pomace silage with the application of inoculant. PC fraction of crude protein is completely inaccessible crude protein which represents ADICP or CP that remains undegraded after treatment of nutrients in acid detergent. It is interesting that the highest value (360.25 g kg^{-1} CP) was established in silages without additives, not treated with inoculant either. It is supposed that the lactic acid bacteria and their enzymes have contributed to greater degradation of CP and PC fraction values were lower when applying inoculants. The minimum value of the PC fraction (123.23 g kg^{-1}CP), almost three times lower than in the

control silage, was found in silage supplemented with protein feed (sunflower meal). Statistically significant difference between all silages was established, in silage treatment factor A, as well as silage treatment factor B. Application of inoculant provided a lower value of PC fraction by nearly 25 g kg^{-1}CP (tab. 3), i.e. increased digestibility and degradability of CP and created the possibility for increased production of milk and meat.

The biochemical changes in silages

The dry matter content was in the range of 172.5 g kg^{-1} in A_1 silage without added dry feeds to 233.3 g kg^{-1} at the level of factor A_3 (tab. 4). DM levels in silage below 300 g kg^{-1} is considered to be unfavourable for lactic acid fermentation process, due to losses in the form of juice, which appears during ensiling process, and due to prevention of activities of spoilage microorganisms (Зафрен, 1977). A highly significant statistical difference was established between the silages without and with added dry feeds.

Table 4. Results of chemical analysis of the lactic acid fermentation process

The degree of acidity of silage is the first indicator of the quality of silage. The highest acidity (pH = 3.40) was found in the silage without added dry feed, and the lowest in silage with sunflower meal (pH = 3.77) (tab. 4). The differences were statistically significant only between silage A_1 on the one hand and other silage treatments. Although the differences were significant in the context of factors in all treatments, methods for evaluating the quality of silage consider as a significant value only difference of above pH 0.20 units. In this study, a significant difference would be between the A_1 and A_3 silages and border significance between the silages A_1 and A_4.

The amount of ammonia nitrogen (NH_3-N/ΣN) is a basic indicator of complete protein degradation. The amount of soluble nitrogen in the silage (H_2O-N/ΣN) also represents a parameter indicating the process of degradation of protein in the silage. Both indicators are expressed in absolute values gkg^{-1}DM and as a % of ammonia nitrogen relative to the total nitrogen. The values in these studies for NH_3-N/ΣN are extremely low, ranging from 2.03% in the silages A_2 to 5.69% in silages A_4. The highest value was expected in silages A_4 since they were supplemented with NPN substance. Differences in these parameters were statistically

significant, but if the silage is evaluated only on the basis of NH_3-N/ΣN, maximum points (great scores) by the method of Zelter (Đorđević and Dinić, 2003) and Weissbach and Hoing (1997) are obtained when the content of NH_3-N/ΣN is up to 10%. Slightly more stringent criterion has the method by Dulphy and Demarqilly (1978), where the content of NH_3-N/ΣN of alfalfa silage to 8.00%, and of other silages to 7.00% of NH_3-N/ΣN receives the maximum points, or excellent score for that parameter.

The values of soluble nitrogen in these studies were slow, and only in one case exceeded 50% H_2O/ΣN in the silages with added NPN substances (tab. 4). The concentration of soluble nitrogen compared to the total is scored the highest if the percentage is 50% or less, which is almost in all treatments except silages with added NPN substances.

Conclusion

Based on the performed research of ensiling apple pomace with the addition of dried beet pulp, sunflower meal and NPN substances, the following can be concluded:

Apple pomace is extremely suitable for silage, has a very favourable WSC/BC ratio and can be used as a supplement for biomass that are difficult to ensile;

Addition of dry feeds (dry sugar beet pulp and sunflower meal) in the amount of 15% increases the content of DM and creates favourable conditions for the process of ensiling;

Sunflower meal in the amount of 15% provided the highest value of CP (227.5 g kg^{-1}DM) and PB_2 fraction in silage, while adding NPN substances (Benural S) in the amount of 1% provided the highest value of PA fraction (525.9 g kg^{-1}CP).

Use of inoculants contributed to reducing the fraction PC (214.64 : 239.47 g kg^{-1}CP), i.e. contributed to the increase of digestibility or nutritive value of silage.

High WSC/BC ratio provided a slightly higher acidity (pH value 3.40 in control silage, to 3.77 apple pomace silage + sunflower meal).

The process of protein degradation in the silage expressed by ammonia and soluble nitrogen relative to total nitrogen in silage was low, resulting in maximum points, i.e. an excellent score for all silage treatments by methods of Zelter and Weissbach and Hoing

Acknowledgment

THE EFFECT OF PRO-MIXTURE ON THE QUALITY OF CHICKEN EGGS FOR CONSUMPTION

Dragana GRČAK*

University of Priština Faculty of Agiculture, Kosovska Mitrovica-Lešak, Serbia
*Corresponding author: dragana.grcak@pr.ac.rs

Abstract

Pre-mixture Panto L 5/25 is imported component Hl Hamburg – Germany. The experiment was carried on ISA Brown hybrid laying hens, on mini farm. The experiment lasted for 150 days. There were 750 hens in one control group (C) and 740 in the experimental group (E) ,,Agro-PLUS''1% (AK) 1% of pre-mixture was added to fodder in the control group and 5% of the same pre-mixture Panto L 5/25 was added in the experimental group.

It has been confirmed that the quality of eggs is determined by physical and chemical characteristics. To evaluate the quality of eggs in technical way, there are many parameters that have to be considered such as weight of egg, egg length, widths of egg, shape index, shell color, shell cleanliness, yolk color, yolk height, albumen height, yolk weight, white of egg's attitude, Haugh units, shell thickness, shell hardness, egg grade etc.

Many genetic factors influence on the value of the above-mentioned parameters, while para-genetic factors influence on other parameters.

The goal of this research is to obtain scientific data on the impact of premix Panto L 5/25, added to complete fodder mixture for laying hens, on the quality of table eggs.

Keywords: *egg-laying hens, pro-mixture, evaluate the quality of eggs.*

Introduction

The premix is a feed mixture that contains vitamins, minerals, colors, methionine, proteins, lysine, fats and oil, phytases… Antioxidants that inhibit the formation of peroxides, i.e. fat rancidity, stabilizers, binding agents, and agents against congelation, and preservatives, have been added to the premix.

Premixes have a favorable influence on better utilization of the genetic potential of livestock, with the aim to achieve a higher and more cost-effective production. Koljajić et al., (1996), Pavlovski et al., (1996) followed the influence of premixes on the eggshell quality, which would reduce losses during transportation. Researchers Kermanchoi and Golion, (1991) believe that, apart from proteins, mineral substances should also be added, in order to regulate the shell quality. The ratio of mineral substances have been examined by Guinate and Nys 1991), through different particle size, where large particles stayed longer in the gizzard and served as a reserve of some elements that hens used when they did not eat.

Vitamin E relieves stress in laying hens and broilers. Woolford (1994) has found that increased levels of calcium in feed act in a depressive way on feed consumption, while an increased concentration of magnesium acts adversely to the adoption of calcium. The level of calcium of 3.5 - 4% in feed daily is required for the shell formation.

Oviposition, and the time of adding marble (Pavlovski et al., 2005) influence the quality of eggs for consumption.

The manner of keeping hens (floor system or in cages) has influenced the quality of eggs (Pavlovski et al., 1982, Torges et al., 1976).

The knowledge of a range of factors that affect the quality of the eggshell, and the internal egg quality, is essential for the production of high quality eggs (Roberts 2004).

The aim of this work is to obtain scientific data on the influence of Panto L 5/25 premix, added to complete feed mixtures.

Material and methods

The experiment was conducted on a mini farm, in laying hens of Isa Brown hybrid (crossbreed of Leghorn and Rhode Island). The experiment lasted 150 days. The number of hens was 754 in the control group (C) and 740 in the experimental group (E). One percent of premix of our own production (AK) was added to the feed mixture for the control group, and Panto L 5/25, 5% was added to the experimental group. The hens were kept in a cage system, with 4-5 hens per cage. Since the experiment lasted 150 days, the samples were taken at the beginning of the experiment, examination I, in the middle of it, examination II, and at the end of it, examination III.

The following parameters were evaluated:

the weight of fresh eggs, determined by measuring on an electronic scale

egg length and width, measured by a calculator with the accuracy of 1 mm

shape index, length to width ratio, obtained by computation. It is the egg shape, which is calculated by dividing the egg width by egg length, and multiplying by 100. The normal egg shape has the shape index of around 73. The normal index is from 61 to 86.

shell color can be determined visually or by using a refractometer. It is evaluated by points from 1 (light) to 5 (dark). Although the shell color is not an indicator of quality, it is often very important for consumers.

the shell purity, visually determined

USDA class, an American standard

egg yolk color, La Roche range (Vuilleumier, 1969).

egg yolk height (index), the yolk diameter was determined by a micrometer

egg white (albumen) height, determined in the same way as the egg yolk height

Haugh unit (HU), calculated with a calculator, according to Haugh's method (Haugh, 1937), based on the height of thick egg white (H, mm) and the egg mass (W, g)

shell thickness, measured with a micrometer on a piece of shell without the membrane.

Results and discussion

According to the technological classification, this premix (a combination of vitamins and minerals) is very good for feeding laying hens. It is intended for meals containing a higher concentration of proteins (25%) and fats (8%), is kept at a temperature up to 25°C, and is resistant to pelleting.

Evaluations of the quality of the eggs for consumption are in Table 1.

Table 1. Evaluations of the quality of the eggs for consumption from Isa Brown hens

Parametric egg quality characteristics	Average for the full view					
	control (C) group			experimental (E) group		
	n	x	Sd	n	x	Sd
Egg weight (g)	45	68,58	4,03	45	69,54	4,29
Egg width (mm)	45	46,54	0,40	45	46,32	0,54
Length eggs (mm)	45	57,59	0,71	45	57,85	1,01
Shape index (%)	45	75,07	2,06	45	75,38	1,96
Yolk colour (1-15, Roche)	45	11,05	0,89	45	11,18	0,82
Yolk height (mm)	45	18,62	0,88	45	18,98	0,82
Yolk weight (g)	45	16,72	2,24	45	16,72	2,03
Albumen height (mm)	45	8,11	0,93	45	8,35	0,79
Haugh Units (score)	45	85,91	5,60	45	*87,58	4,95
Egg shell thickness (μm)	45	356,87	32,64	45	357,78	37,59

n=number of samples, x=average (mean), Sd= standard deviation,*= exponents are statistically different (P<0.05).

The egg weight during the experiment ranged from 67.51 g - 70.12 g. A statistical significance has been found in the egg mass at the end of examinations II and III, in favor of E group compared to the C group.

The egg class; in the control group, the largest number of eggs was of class B, then class A, and lastly class C. The laying hens of the experimental group had eggs of class AA, then class A, less of class B and the least of class C. Each country has its own rulebook on classifying eggs, and it is mainly based on the measured weight of eggs (Pravilnik o kvalitetu jaja i proizvoda od jaja, 2003 i 2004., eng. Regulation…, 2003 and 2004). According to the quality based on the USDA classification (USDA, 2000), it is necessary to break the egg and observe how much it is spilled on the surface. When the broken egg covers a smaller surface, and when the egg white is firm (min 72 Haugh units), the egg class is better.

The egg width; this feature is inherent, and therefore it is less affected by feed. Larger breeds produce larger eggs. The egg size increases from the time hens begin laying to the 6^{th} month of laying. Averagely for the entire experiment, the egg width for C group was 46.54 mm and 46.32 mm for the E group. A statistical significance has not been found here.

The egg length, as well as the width and size, depend on genetic factors. During the entire experiment, the index value for the egg length was higher in E group by 0.45%.

The egg shape index; this is also a parameter linked to genetic factors, heritability (Supić et al., 2000), and in examination I, a statistical significance between the control and experimental group was found. During the entire experiment, a difference of 0.41% in E group compared to the C group was found.

The yolk color; a statistical significance was not found in this evaluation, but the average for the entire experiment was higher by 1.18% in E group compared to C group. Serbian market values the eggs with more intensive yolk color (10-12 Roche). The yolk color is determined visually by comparing it with the color palette that is in the range. The span of the range is 1-15.

The egg yolk height (index); no statistical significance was found in the evaluation of this parameter, but the average value for E group throughout the entire experiment had a lower level by 1.93% compared to C group. This parameter is determined by the ratio of yolk height and yolk width, and the obtained number is multiplied by 100. Normal values are 32-58%.

The yolk weight; throughout the entire experiment, the indices in both groups were unvarying.

The height of egg whites has an influence on Haugh units. The difference of average egg white height between the examined groups was significant in the third examination.

Averagely for the entire experiment, the relative indicator was 2.96% higher in E group compared to the C group. The high value of Haugh units indicates a high value of egg white quality.

The number of Haugh units in eggs is calculated according to the formula for the height of hard egg white and egg weight. There was a statistically significant difference in the average number of Haugh units of eggs from laying hens in examination I and during the entire experiment between E and C groups (higher in E group by 1.94%).

The thickness of egg shell; a statistical difference was found in the third examination in E group by 0.25% compared to C group, and this characteristic is influenced by genotype.

The egg quality depends on the hen age, genetic traits and meal balance.

The role of evaluating the height of egg whites is very important, and with it, a direct role and the importance of Haugh units. Studies have not achieved results in some relations of the external quality such as the shell thickness. For this reason, according to some authors, some individual elements and vitamins have to be added. Eggs have a certain number of Haugh units, which means that they are of high quality.

Conclusions

From what has been said, we can conclude that, when preparing meals and balancing the composition of the mineral-vitamin and antibiotic supplements, everything has to be carefully done, so that they would be appropriate. Genetic characteristics and technological requirements of provenances for chicken eggs for consumption have to be taken into account. Based on our results, Panto L 5/25 premix has shown economic justification and is recommended for the production of feed mixtures for laying hens. The research has found that there were eggs of AA class in the experimental group, while there were no eggs of this class in the control group.

Abstract

Morphometric characteristics of honey bees are used in the taxonomy of honey bees because of that they genetically depend on the race. Chitin nervature of honey bee wings has become a subject of interest to researchers worldwide and in our country. It was observed that these parameters show variability similar to other biometric characteristics. The aim of this paper was to determine the variability of angles of wing nervature of honey bee from the area of Rasina District. The experiment included three sites that are located in the immediate vicinity of Kruševac (Mačkovac, Makrešane and Majdevo). After measurements of selected characteristics, their variability was determined. Eleven angles on the chitinous nervature of front right wing were measured. The highest average values for angles A4 (33.1º), J10 (56.1 º), K19 (7.5 º), L13 (17.2 º) and O26 (41.6 º) were determined on samples from the site Majdevo. In samples from the site Makrešane the highest average values were for the B4 (111.1 º), D7 (99.0 º), E9 (22.4 º), G18 (92.3 º) and J16 (98.1º). The bees from the site Mačkovac had te highest average value for the angle N23 which was 97.6 °. Statistical analysis of data by localities was done and coefficients of variability were determined. The highest variability of angles A4 (7.62), B4 (31.22), D7 (3.40), E9 (7.85), J16 (13.24), K19 (4.02) and N23 (5.40) were found in bees from the site Mačkovac. Honey bees from the site Majdevo showed the greatest variability for angles J10 (8.83) and O26 (6.27).

Keywords: *honey bee, wing nervature, Rasina district*

Introduction

In various areas of the world, different honey bee races evolved under the influence of different environmental factors. These races have their specific biometric features and characteristics that are used in their identification and classification. *Apis mellifera carnica* Pol., also known as domestic carnica or the carniolan grey bee populates the Balkan Peninsula and the valley of the Danube. Area of its distribution is bordered by the Adriatic Sea, the Julian Alps, the Carpathians and the Black Sea. Biometrics is a method that can detect differences within taxa. The first biometric researches studied a few observable and measurable traits (like size and color), but today it is considered that good biometric study should include a greater number of different morphological parameters.

In recent decades, both in the world and in our country, all researches focus on the potential of honey bees from the point of morphometric parameters with the aim of more efficient exploitation of honey bee and its introduction into the selection programs. Considering carniolan honey bee, Ruttner (1988) was among the first scientist to note that different ecotypes can be determined within the race through precise morphometric studies. Elements of external morphology of carnica from Serbia were studied by Krunić (1967), Stojanović (1992), Plužnjikov (1995), Georgijev (2001), Stevanović (2002), Jevtić (2007) and others.

All above mentioned researchers found that there was considerable variation in almost all of observed morphometric traits of honey bees from this area. Variation of some traits is so high

that it differentiates certain populations (local population) in relation to other colonies from neighboring areas. These differences are primarily conditioned by the specificity of relief and eco-climatic conditions on the territory of Serbia. Alpatov (1929) and many authors after him showed that the environment can have a major impact on the morphological traits of honey bee.

The aim of this study was to determine the variability of angles of wing nervature in the honey bees from very narrow geographical area which is one part of Rasina region (an area of (from Kruševac to Stalać).

Material and methods

In this paper, the honey bees from local honey bee populations from areas of central Serbia were analyzed. The study was conducted in 2012. Colonies were taken from the apiaries from three different sites near Mačkovac, Makrešane and Majdevo. Five colonies were selected from each site, and from each colony 30 bees were sampled. Samples of bees were an indigenous source material.

After the sampling, the bees were kept in 96% ethyl alcohol and stored in a refrigerator at a temperature of from -4°C until measurement. The eleven angles of chitinous nervature of front right wing were measured: A4, B4, D7, E9, G18, J10, J16, K19, L13, N23 and O26. Morphometric measurements of angles were performed by standard method by Ruttner et al. (1978).

Temporary anatomical preparations of the wings were made, scanned in high resolution of 9600 dpi and then processed by computer software Motic Images Plus 2.0.

After measuring, descriptive statistics was performed for all parameters and standard deviation and coefficients of variation were calculated.

Results and discussion

Angle A4 had the average value of 31.43° and the highest value was in bees from the site Majdevo, while the lowest was in bees from Mačkovac (Table 1). The highest variability within the same site was found in bees from Mačkovac (CV=7.63). By the analysis of variance, it was found that the site had a statistically significant effect on the expression of this trait (level of significance P=0.05).

The average value of the angle B4 was 103.63°, the highest value was measured in Makrešane (111.1°) and the lowest in Mačkovac (93.9°). Analysis of variance, as a single factor experiment, showed that location had very significant impact on the expression of this trait on the level of probability P=0.01. Testing the difference (LSD test) showed that the honey bees from all three sites differed very significant in the size of the angle B4. Obtained results for the honey bees from the site Makršane are similar to the results of Maul and Hähnle (1994) and Stojanović (2002), but the other two sites differ considerably from those data.

Angle D7 in the analyzed samples of honey bees had a value of 98.33°, and very little variation considering the sites. This angle had the lowest coefficient of variation in total and by sites. The differences in the mean values were not statistically significant. The results are consistent with the results Maul and Hähnle (1994), but are slightly higher than in the research Stojanović (2002) and Nedic et al., (2011), and slightly lower compared to the results obtained in research Mladenovic and Simeonova (2010).

Angle E9 had an average value of 22.13°, and in comparison to the previous angle had a slightly higher coefficient of variation (CV=7.14). The resulting differences in the mean values between different sites were not significant. In studies of Stojanović (2002), this angle had lower average value (19.50), lower extremes (18.4 and 20.59) and a lower CV (3.83).

Angles G18 (91.67), J10 (54.53) and J16 (96.83) had very similar values in all three locations from which the bees were sampled. Except J10 (7.05), all had low coefficients of variation, and analysis of variance showed that the differences between sites were not statistically significant. The results for the angles G18 and J10 are consistent with the values obtained in the research by Nedić et al. (2011), while the results for angle J16 (91.44) differ from those.

Angle K19 had a mean value of 76.77°, with a coefficient of variation of 3.09. The analysis of variance revealed that the location had a very significant impact on the values for this angle. Values for this angle in honey bees from site Majdevo (79.5°) were statistically significantly different from the values obtained in bees from the site Mačkovac (76°), and very significantly different from the site Makrešane (74.8°).

Angle L13 (15.4), after the angle B4, showed the largest variation between sites (CV=10.84). Particularly high coefficient of variation was found in honey bees from Makrešane (12.71°) and Majdevo (13.92°), while in Mačkovac the value for this angle was significantly lower (5.88). The analysis of variance showed that the location had a very significant effect on the expression of these traits. Values obtained in the sites Makrešane and Mačkovac did not differ significantly while the values obtained in Majdevo were very significantly different in relation to the others.

Angle N23 (96°) had a very small differences between sites and, therefore, had lower CV (4.22). Location did not significantly affect the value of this angle, and the differences between sites were not statistically significant. Angle O26 (40.33°) had a slightly higher CV

compared to the previous (9.2°), but a lower standard deviation. Analysis of variance showed that the differences between localities were not statistically significant. The values obtained for the angles N23 and O26 were for 3-40 degrees higher compared to the results obtained in research of Nedić et al. (2011).

Conclusion

Based on measurements of 11 angles on the front wing of honey bees from three different sites in the wider area of Kruševac in central Serbia, it can be concluded:

- The samples from the site Makrešane had the highest average values for angles B4, D7, E9, G18 and J16. Honey bees from the site Mačkovac had the highest average value for the angle N23. The highest average values for the angles A4, J10, K19, L13 and O26 were determined in honey bees from the site Majdevo.
- The highest variability for angles A4, D7, E9, J16, K19 and N23 was found in bees from the site Mačkovac. Honey bees from the site Majdevo showed the highest variability for the angles G18, J10, L 23 and O26, and bees from the site Makrešane showed the greatest variability for the angle B4.

The analysis of variance showed that the site has a significant impact on the size of the angle A4, and a very significant impact on the size of the angles B4, K19 and L13.

Abstract

The present study aimed to investigate the silage quality, derived from whole plant biomass, of six experimental inbred lines derived from local maize populations. Chemical composition of the silage inoculants and control without the use of inoculants (content of free and total acids) and nutrient content (crude ash, crude fiber crude protein, crude fat, NFE, NDF, ADF), were investigated.

The results indicate that the silage of the whole plant of maize inbred lines can have a good quality.

Content of ash had numerically lower values in DM of silages with inoculant than maize silages without inoculant. Crude protein content was higher in LC4 (72,60% vithout inoculant; and 77.10% in treatment with inoculant). Line LC3 had the lowest content of crude fiber (299.7% without inoculant, and 288.8% with inoculant). The content of NFE was higher in the silages with inoculant ($P< 0.01$) than in silages without inoculant. The neutral detergent fiber (NDF) was significantly (inbred lines LC1, 2, LC3 and LC5) or numerically (inbred line LC6) lower in inoculated silages, than in silages without inoculant. The content of ADF were also significantly lower in the silages with inoculant compared to treatment with inoculant.

The amount of dry matter was highest in line LC6 (280,0 g kg^{-1} DM in variant without inoculant), and in line LC4 (301,3 g kg^{-1} DM in variant with inoculant). The pH of all silages tended to be under 3.55, which is considered to be acceptable for maize silages. Crude protein content in all maize silages were numerically higher in inoculated silages compared to silages without inoculant. The lowest content of lactic acid was detected in DM of inbred line LC4 (61.03 g kg^{-1} DM without inoculant, and 95.07 g kg^{-1} DM with inoculant). In our investigation, addition of inoculant slightly decreased lactic acid to acetic acid ratio, except in inbred line LC6 where addition of inoculant increased lactic acid to acetic acid ratio.

Maize silages treated with inoculants were more stable, because inoculant successfully stimulated the production of lactic and acetic acid which is antimycotic and enhanced aerobic stability.

Keywords: *inbred lines, genetic diversity, silage, nutrient content*

Introduction

A large number of maize hybrids with different genetic origin and purpose are present in agricultural Serbian market. Domestic hybrids are showed great competitiveness in such conditions.

Pollak et al. (2003), asserted that old maize varietes could be a significant source of quality features. In the process of obtaining and developing hybrids, comprehensive examination of starting material is very important (Bertoia et al., 2002).

In some rural areas of Serbia, we can still find old varieties of maize which, for many years of cultivation, became the native population of that area. In order to preserve genetic diversity, it is important to collect this material. During the period 1997-2000, such of this populations

were collected (in the willages of Stara Planina mountain) and begin the process of obtaining inbred lines. Extensive studies in the laboratory and in experimental plots were conducted (Milenkovic et al., 2012, 2014a, 2014b, 2015), and the results indicate the high quality of grain and biomass of this inbred lines.

Due to the high biomass production in just one growing season, maize is very widespread culture for silage production. In the area of Kruševac, production of maize for silage are represented to a greater extent, due to the favorable conditions of climate and soil. There is a large number of mini farms in this region (Milenkovic et al., 2015).

After the testing of suitability from silage, from whole plant of maize inbred lines originating from local populations (Milenkovic et al., 2015), the aim of this study was to investigate silage quality from the same material.

The ensiling process allows preservation of forage in long period. Silages are preserved through a fermentation process that produces acids to inhibit spoilage.

Using biological additives (inoculants) in silage is a good way to improve the qualitative characteristics of silage, due to the intensification of lactic acid fermentation in materials with different amounts of soluble sugars (Djordjevic et al, 2004).

Maize silage quality is determined by energy content and content of protein and minerals. Evaluating silage quality include chemical, biological and instrumental methods. In this research we use chemical methods to determine silage quality.

Material and methods

Inbred lines are planted in a growing season 2012, according to a randomized block design with two replications. At the stage of milk ripeness of grain, a representative sample of plant biomass from maize was taken. For the preparation of silage 10 plants of each genotype was taken. Whole plants are chopped (mixed and equable for the standardizing), then the sample was taken for silage.

Ensiling biomass was carried out in experimental containers holding 60 dm^3. For each genotype were used by 4 courts (two replications and two treatments: without inoculant-A_0 and with inoculant-A_1). In one treatment is added 1 g per 100 kg of green mass of inoculant Sill-All (Alltech). The inoculum was previously dissolved in distilled water and uniformly distributed in the powdered mass. In order to achieve uniform moisture both treatments, without inoculant is sprinkled with the same amount of distilled water.

The trial was set up according to the model a factorial experiment (with two variants: with and without inoculant), where the factor is genotype. The courts were opened after 90 days and quality parameters and chemical composition were tested (AOAC, 1984). In the lab, they made the following chemical analysis: Dry Matter (DM is percentage of the biomass without water); Crude Protein (CP) is the total amount of nitrogen (N percent multiplied by 6.25 equals CP); Crude Fat (CF), and Crude Ash.

We examined the content of the following nutrients in the silage: Neutral Detergent Fiber (NDF is the percent of cell wall material in a forage); Acid Detergent Diber (ADF is a highly indegestible percent of plant material); Lactic Acid is colorless, liquid organic acid resulting from fermentation; Acetic Acid is corosiv, colorless organic acid with pungent odor; Butyric Acid is viscous, foul-smelling, liquid carboxylic acid. In our material there was no content of butyric acid.

The results were statistically analyzed using the program Minitab. For comparison the middle of treatment was used Tukey test (Snedecor and Cochran, 1982).

Results and discussion

Crude protein content (CP), in all silages from maize, was numerically higher in inoculated silages compared to silages without inoculant (Table 1). Koc et al. (2008) found a decrease

(P< 0.01) in CP content in inoculated silages. Baytok et al. (2005) found that higher concentration of the same inoculant did not affect CP concentration in maize silage. Despite the crude protein, concentration of crude fiber decreased in silages with inoculant, except in DM of inbred line LC5, where content of crude fiber increased in silage with inoculant.
Content of ash had numerically lower values in DM of silages with inoculant than maize silages without inoculant. The highest content of crude fat was in silage with inoculant in DM of inbred line LC6 (40.03 g kg^{-1} DM) and the lowest content in silage without inoculant made from inbred line LC2 (21.77 g kg^{-1} DM). The content of NFE was also higher in the silages with inoculant (P< 0.01) than silages without inoculant (Table 1).
The neutral detergent fiber (NDF) was significantly (inbred lines LC1, LC2, LC3 and LC5) or numerically (inbred line LC6) lower in inoculated silages, than in silages without inoculant. In silage made from inbred line LC4 content of NDF was higher in treatment with inoculant (751.9 g kg^{-1} DM) than in treatment without inoculant (728.9 g kg^{-1} DM). High NDF may be the result of stress during the maize growing season, because 2012 was very dry, with high temperatures. The content of ADF were significantly lower in the silages with inoculant inclusion (silages from inbred lines LC1, LC3 and LC5) compared to those silages from inbred lines LC2, LC4 and LC6 where treatment with inoculant had higher content of ADF.

Table 1. Content of nutrients in maize silage g kg^{-1} DM

The fermentation characteristics of investigated maize silages are given in Table 2. Dry matter silages were higher in treatments with inoculant, with exception for inbred line LC1 where DM was lower in treatment with inoculant than in treatment without inoculant, and for inbred line LC6 where DM was equal in both treatments, with and without inoculant. Similar results

were presented by Jolč et al. (2010) and Koc et al. (2008) where the mixture of inoculants and enzyme were used in maize silages.
The pH values of silage with inoculant decreased, and all treated silages had lower pH than untreated silage. The pH of all investigated silages tended to be under 3.55, which is considered to be acceptable for maize silages (Kung and Shaver, 2001). The ammonia-nitrogen content was highest in silage from inbred line LC2 without inoculant, and the lowest in the same silage with inoculant.

Tukey test; P=0.01

Inoculant-treated silages were more stable, because inoculant successfully stimulated the production of lactic and acetic acid which is antimycotic and enhanced aerobic stability. The concentration of butyric acid was not detectable.
Lactic acid should be at least 65-70% of the total silage acids in well fermented silage (Shaver, 2003). Our results are in consistant with the results obtained by Shaver (2003), who indicated that lactic acid could have higher values. The lowest content of lactic acid was detected in DM of inbred line LC4 (61.03 g kg^{-1} DM without inoculant and 95.07 g kg^{-1} DM with inoculant). The ratio of lactic acid to acetic acid is a good indicator of the efficiency of the silage fermentation. Ideally, the ratio of lactic acid to acetic acid should not be less than 3:1, and a higher one is beter (Kung and Shaver, 2001). In our investigation, addition of inoculant slightly decreased lactic acid to acetic acid ratio, with exception for inbred line LC6 where addition of inoculant increased lactic acid to acetic acid ratio.

Conclusion

This study showed that ensiling maize maintains good silage quality. All the silages were well preserved as indicated by low pH, low ammonia and no butyric acid. The low pH, together with elevated levels of lactic acid showed that the herbage contained sufficient amounts of soluble carbohydrates to effectively preserve the silage.

Inoculant affect the intensification of lactic acid fermentation and increase the amount of lactic acid, reducing the pH, and complete absence of butyric acid.

The results of silage quality indicate that the investigated maize inbred lines can be used in the further process of getting a quality silage hybrids.

Abstract

Improving the efficiency of use of feed nitrogen (N) has become a central component of the ration formulation process primarily to reduce feed costs and also for the desire to be more environmentally friendly. New data are available that better describe the characterization of feed fractionation and these data along with changes in available models suggest that more protein has been available to lactating cattle than previously considered. Evaluation of the current data are suggesting that how we currently characterize feed protein fractions and their associated degradation and passage rates might cause us to over-feed protein. This study was conducted to assess effects of cultivar and cut on protein fraction content using a factorial experiment with a randomized complete block design. Samples of red clover *cv* K-32 (tetraploid cultivar) and *cv* K-39 (diploid cultivar) was taken at mid-bloom stage on May the 21st in the first cut, on June the 18th in the second cut and on July the 9th in the third cut, at the same stage of growth. Crude protein content increased from the first to the third cut in both investigated cultivars of red clover, but *cv* K-32 had higher content of crude protein than *cv* K-39 ($P< 0.05$). The neutral detergent insoluble protein was lower in dry matter of tetraploid cultivar of red clover, while, the acid detergent insoluble protein values were low in both cultivars, indicating that forages had not been subjected to heat damage. Cultivar differences in soluble protein, true protein and non-protein nitrogen were significant, and the highest content of insoluble protein and true protein were detected in the third cut. Our results confirm that there is significant variability in protein fractions and degradability among red clover cultivars. The foregoing discussion leads to consideration of ways that legume forages might be altered to improve the nutritional value of their proteins for productive ruminants.

Keywords: *protein fractions, nitrogen utilization, red clover*

Introduction

Red clover (*Trifolium pratense* L.) is commonly grown throughout the world. It is an important perennial forage legume because it is used as hay or as pasture in crop rotations (Fornham and George, 1993) and has high productivity and protein content (Murray et al., 2007). It is especially suitable for cattle breeding, because it has quality and nutritive hay (Acikgoz, 2001).

The main storage components accumulated by red clover are total protein, which can make up as much as 21% of the dry matter. Both di- and tetraploid forms of red clover are grown commercially. The two forms have different morphological traits and agricultural characteristics. Zuk-Golaszewska et al. (2006), who analysed yields of di- and tetraploid cultivars of red clover demonstrated that red clover tetraploid forms were superior in production of total protein yields.

At present, the quality-orientated breeding of clover focuses on improving the content and quality of proteins (the amino acid composition, sensitivity to proteolysis, polyphenol oxidase activity) delaying the lignification process as plants mature or increasing the share of carotens and decreasing the concentration of anti-nutritional compounds, e. g. isoflavones

(Lee et al., 2004). Under these economic and environmental constraints, improving the efficiency of N utilization and reducing N excreted are very important to maintain the sustainability of dairy farms, and nutrition models have become an effective farm management tool to accomplish these tasks (Lanzas et al., 2007). Milk production will be reduced when protein supplied by the diet is below energy allowable milk production, which is affected by protein degradation rates (Fox et al., 2004). Feed protein fractionation systems have been integrated into nutrition models to account for differences in protein availability and utilization. The *in situ* techniques and schemes based on solubility in buffers and detergent solutions have been adapted by the NRC (2001) and the Cornell Net Carbohydrate and Protein System (CNCPS, Fox et al., 2004) to measure protein fractions in feeds.

The objective of this study was to investigate the effect of variety of red clover grown in Serbia in different cuts on crude protein content and to determine the component of CNCPS model containing NPN (Non protein Nitrogen), SolP (Soluble Protein), NDICP (neutral Detergent Insoluble Crude Protein), ADICP (Acid Detergent Insoluble Crude Protein), TP (True Protein) and IP (Insoluble Protein).

Materials and methods

This experiment was carried out in the experimental field of Institute for forage crops in Kruševac (43^{o}34`58``N, 21$^o$19`35``E) from May to July in 2012. The study area was situated at altitude of 166 m above sea level in Central Serbia. The mean annual temperature and the total precipitation for the region are 12.6º C and 653.2 mm, respectively. Climatic dates of research peroid and long terms averages are reported in Table 1.

2011	29	44	48	19	47	66	104	0	8	33	0	42	440
2012	118	62.1	20	69.1	150	29.3	33.3	0.0	15.2	55.4	12.2	88.6	653.2

The experiment was designed as a factorial trial, by randomized block system in three replicates. Samples of red clover, *cv* K 32 – tetraploid (4n) *cv* and K 39 – diploid (2n) *cv* were taken at mid-bloom stage on May the 21st in the first cut, on June the 18th in the second cut and on July the 9th in the third cut, at the same stage of growth. Dry matter was determined by drying out samples at 65º C and grinding and sieving them to 1 mm particle size. The samples were dried in an oven of 105º C for 6 h for dry matter determination.

The CP (Crude Protein) of the samples was determined using Kjeldahl method. The CP in the forage samples were partitioned as proposed by Cornell Net Carbohydrate and Protein System, CNCPS (Licitra et al., 1996). Soluble CP (SolP) was determined using the borate-phosphate buffer. Non-protein N (NPN) was calculated as the difference between the total CP and True protein (TP) precipitated with threechloracetic acid. Neutral Detergent

Insoluble Crude Protein (NDICP) was determined after NDF determination and Acid Detergent Insoluble Crude Protein (ADICP) was determined after ADF determination.
Data were processed by the analysis of variance in a randomized block design. Effects were considered different based on significant (P< 0.05) F ratio.

Results and discussion

In 2012, precipitation and temperatures during active forage growth were near long terms norms in April and May, while June and July was hot and dry. Except for a dry June and July, precipitation in 2012 greatly exceed long-term norms from the beginning of the year (except March), whereas temperatures were relatively high in June and July, but near normal from March to May (Table 1).

Following the mean values of crude protein content for cultivars and cuts, tetraploid *cv* featured higher CP content (P< 0.05) and the highest value of CP was in the third cut (Table 2). Previous work with three-cut harvest systems indicated bud-stage red clover from spring growth was lower in CP than subsequent summer cuttings taken at comparable maturity (Wiersma et al., 1998). Therefore, earlier cutting of spring growth may improve CP concentrations and their uniformity across harvest.

Different letters denote significantly different means (P< 0.05)

Comparing different red clover cultivars means, tetraploid cultivar was higher (P< 0.05) in SolP and NPN, but lower (P< 0.05) in NDICP and TP, indicating large and potential differences in rumen CP degradation characteristics between tetraploid and diploid cultivars of red clover. The cut was an important source of variability for all investigated protein

fractions. The results indicate that red clover had the highest content of NDICP, IP and NPN in the first cut. The contents of IP were similar in the first and the third cut of red clover, but the lowest value ($P< 0.05$) was observed in the second cut. Therefore, content of ADICP and SolP were the highest in the second cut, and TP content was the highest in the third cut (Table 2).

Soluble crude protein is a simplastic concept that evolved out of the observation that most soluble nitrogen components were rapidly degraded in the rumen and therefore, reduced protein that could be passed to the lower tract. Protein solubility was significantly different among investigated cultivars of red clover ($P< 0.05$). Somewhat higher values were obtained in the second and third cut (Table 2). There was no statistical difference between the cultivars of red clover obtained in the third cut. In models designed to assess utilization of dietary protein by ruminants, it is assumed that most of the soluble protein is completely degraded in the rumen and varying proportions of the insoluble fractions escape ruminal degradation depending on the interactive effects of digestion and passage (Sniffen et al., 1992). Because various protein fractions differ in rate and extent of ruminal degradation, the proportions of these different protein fractions in feedstuffs are believed to influence the amount of ruminally degraded and escape protein consumed by animals (Elizalde et al., 1999).

The differences in the content of protein fractions were relatively small, but diploid cultivar of red clover had much more NDICP ($P< 0.05$) in the first cut, and much lower SolP ($P< 0.05$) than tetraploid cultivar of red clover. The highest content nof NDICP was found in the first cut (37.2 g kg^{-1} DM or 23.6% of CP). Comparing the two varieties of red clover there were no differences ($P> 0.05$) in ADICP in the first and the third cut and in IP in the third cut. Diploid cultivar of red clover, K 39, was higher in TP, but lower in NPN ($P< 0.05$) than tetraploid cultivar of rd clover–K 32, indicating potential differences in rumen CP degradation characteristics between investigated red clover varieties. The weather conditions during the growth of plants and the form of red clover differentiated the concentration of protein fractions in DM of red clover. Harvest schedule had cut specific effects on all buffer-soluble CP fractions and on most detergent fractions. Grabber (2009) indicated that the early harvest schedule increased the proportion of readily degraded buffer-soluble CP and reduced the proportion of slowly degraded NDICP in the first cutting of red clover.

The nitrogen associated with NDF is normally cell wall-bound protein which also includes the indigestible nitrogen found in the acid detergent residue. The protein insoluble in the neutral detergent solution, but soluble in acid detergent solution is digestible, but slowly degradable. Generally, the cell wall-associated protein is extension covalently linked to hemicellulosic carbohydrate (glycoproteins) that are involved in cross linking carbohydrate chains in plant cell walls (Licitra et al., 1996).

The CNCPS model was only sensitive to NDICP measurements for feeds that contain high proportions of protein as NDICP (Lanzas et al., 2007). Reported values for NDICP degradation rates might be similar or slightly greater than NDF degradation rates (Lanzas et al., 2008). This fact has led to the question of the appropriateness of using the N isolated in detergent solution as an indicator of the slowly protein degradation factor. When protein degradation is very rapid, ruminal microbes can not utilize all of the amino acids and ammonia released and more protein will be degraded than is synthesized. Protein entering the rumen has at least three fates: it is degraded to ammonia and is used for bacterial protein synthesis, leaves the rumen as ammonia and converted to urea in the liver, or escapes microbial action becomes metabolizable protein directly.

The two most important considerations of feed CP chemistry are: the proportional concentrations of NPN and the true protein and the physical and chemical characteristics of the proteins that comprise the true protein fraction of the feedstuff (NRC, 2001). Differences in 3-dimensional structure and chemical bonding (i. e., cross-links) that occur both within and

between protein molecules and between proteins and carbohydrates are functions of source as well as processing. These aspects of structure affect microbial access to the proteins, which apparently is the most important factor affecting the rate and extent of degradation of proteins in the rumen (NRC, 2001).

Conclusions

Overall, the present study gives a deeper insight into CP fractions in the spring growth and summer regrowth period of different varieties of red clover. The CP fractions seem to provide common parameters for grassland scientists, who focus on plant breeding targeting the nutritive value linked to physiological processes in plants, and for animal nutritionists, who wish to improve protein quality in forage-based diets using CP fractions at specified harvest dates. Although, from the point of view of ruminant nutrition, red clover showed advantages for the NPN and ADICP fractions of CP. In general, the chemical CP fractionation provides, in addition to the classical characteristics such as energy or fibre content, further information to achieve a better evaluation of the quality of forage legume species. Moreover, the present study provides valuable data for the modelling of the CP fractions, which should be the aim of continuing investigations.

Abstract

Determination of milk urea (MU) is a relatively new test developed to assess dietary needs of lactating dairy cows. Concentrations of MU are variable from herd to herd and between cows in the same herd. Higher values of MU indicate an imbalance of protein and energy, but MU concentration is influenced by a whole range of factors too (feeding, breed, stage and number of lactations, body weight, daily production and chemical composition of milk, somatic cell count, season and milking).

The aim of this study was to determine MU concentration in cow milk from dairy farms in Vojvodina.

The determination was based on representative samples from four farms in Vojvodina, handled according to Dairy Herd Improvement (DHI), during for the period of one year. A total of 17774 collected samples, of Holstein cows, were shown milk urea content from 7.0 to 82 mg/dl, with the next average value of the farms (F): F1 23.84mg/dl, F2 29.47 mg/dl, F3 21.79 mg/dl and F4 20.45 mg/dl. Statistical analysis showed significant differences between farms on MU concentration.

Coefficient of variation for MU was higher (32.68 – 43.58%) compared with other milk production traits: fat percentage (17.69 – 24.97%) and protein percentage (12.3-13.93%).

In this research a negative correlation coefficient was determined between protein content and urea concentration in milk, on farms F2, F3 and F4, while only on farm F1 a positive correlation coefficient was determined. Variations of urea content were observed, affected by seasonal change.

Keywords: *dairy farm, milk urea, protein, season*

Introduction

Testing for milk urea (MU) is a relatively new test developed to assess dietary needs of lactating dairy cows. Urea is considered a normal component of milk and is part of the non-protein nitrogen (NPN) found in milk (Ferguson, 1999). Milk urea nitrogen (MUN) is primarily derived from blood urea nitrogen (BUN) because urea equilibrates with water in the body. This equilibrium explains the high correlation between MUN and BUN concentrations (Sosa et al., 2010). BUN derives from the liver detoxification of ammonia diffused from the rumen in the liver (DePeters and Ferguson, 1992). The normal/target values of MUN are considered to be within the range from 10 to 15 mg/dl (Carlsson and Peherson, 1994; Moore and Varga, 1996). High values of MU indicate an imbalance of protein and energy (Wood et al, 2003). The benefits of using MU as a monitoring also help to optimize the efficiency of dietary protein utilization which include improved efficiency and reduce cost of production and nitrogen excretion into the environment (Kohn et al., 2005, Stoop et al., 2007). Animal husbandry has been identified as a major contributor of N pollution to water resources. MUN is highly correlated with urinary N exertion (Jonker et al., 1998; Kauffman and St-Pierre, 2001) and is good indicator of NH_3 emission from dairy manure (Burgos et al., 2007).

MU is varied from herd-to-herd and between cows in the same herd (Arunvipas et al, 2003). Concentrations of MUN may also differ even if cows consuming the same diet, due to genetic differences in the ability to metabolize protein (Wood et al, 2003). Aguilar et al. (2012)

considered that genetic diversity also exists among cows. MU might be used as a selection tool, and therefore, information on factors affecting it is needed (Stoop et al, 2007).
The aim of this study was to determine MU concentration in cow milk from dairy farms in Vojvodina.

Materials and methods

Raw milk samples were obtained from four farms in Vojvodina (Bačka), by the ICAR (2012) AT_4 method. All samples in this study were taken during milking time, once a day. Herd sizes ranged from 300 to 700 cows. Cows on Farms 1, 2 and 3 were housed in tie stall barns, and on Farm 4 were housed in free stall barn. The averages of 305 days milk production were on F1 8,586 kg/cow, F2 7,359 kg/cow, F3 8,045 kg/cow and F4 8,045 kg/cow. It was analyzed 17774 milk samples in total. The majority of the cows belong to Holstein breed (black and red). In generally, the feeding of dairy cows was using total mix ration with the most common management practice on the dairy farms in Vojvodina. Samples were collected in 40 ml bottles, containing potassium dichromate ($K_2Cr_2O_7$) as preservative and kept on temperature 1-4°C. Individual test-day milk samples were analyzed in the Laboratory of milk quality, at the Faculty of Agriculture in Novi Sad. Analysis of milk samples were performed on Foss's instrument MilkoScan^{TM}FT. To convert MU (milk urea) to MUN (milk urea nitrogen), the following conversion formula can be used:

MU (mg/dl) x 0.467 = MUN (mg/dl), Oudah (2009).

Extreme values of particular parameters were not analyzed in the following cases:
Milk urea content less than 7 and more than 90 mg/dl was excluded.
Milk fat percentage less than 2 and more than 6 was excluded.
Milk protein percentage less than 2 and more than 5 was excluded.
Milk urea was grouped into seven categories by increments of 5 mg/dl, started with those less than 10 mg/dl and finishing with concentration greater than 35 mg/dl.
Statistical data analysis was carried out using program STATISTICA 12. Statistical analyses included means values, standard deviation for individual parameters, coefficient of variation and correlation coefficient between protein and MU content in milk.
Using method of analysis of variance it was tested the difference in milk fat, protein and urea content between farms. Using the t –test the average milk fat, protein and urea content values between farms were compared.

Results and discussion

The mean value of MU for all the farms, during the one year, was 23.06 mg/dl. Results for MU for four farms were F1 23.83 mg/dl (MUN 11.13mg/dl); F2 29.47 mg/dl (MUN 13.76mg/dl); F3 21.79 mg/dl (MUN 10.17mg/dl) and F4 20.45 mg/dl (MUN 9.55mg/dl) (Table 1).
Our results are similar to the values for MU obtained by Hof et al. (1997), Kauffman and St-Pierre (2001), Bastin et al. (2009) and Bandelja et al. (2011) for Holstein breed.
The higher values of MUN reported Broderic and Clayton (1997), Jonker et al. (1998), Johnson and Young (2003), Wood et al. (2003) and Oudah (2009).
Coefficient of variation for MU was high (32.68 – 43.58%) compared with other milk production traits: fat percentage (17.69 – 24.97%) and protein percentage (12.30-13.93%). Bastin et al. (2009) and Bandelja et al. (2011) also found a high coefficient of variations for MU (42% and 36.16%). Oudah (2009) found les CV for MUN (31.5%).

Table1. Farm results for milk fat, protein and milk urea content

Farm	N	%						mg/dl			
		Milk fat			Protein			MU			MUN
		Average	SD	CV	Average	SD	CV	Average	SD	CV	Average
F1	3097	3.5	0.91	2497	3.24	0,45	13,93	23,83	10,38	43,58	11,13
F2	3215	4.19	0.88	20.99	3.20	0.41	12.91	29.47	9.63	32.68	13.76
F3	5034	4.08	0.72	17.69	3.24	0.39	12.30	21.79	7.57	34.76	10.17
F4	6428	3.75	0.79	21.09	3.31	0.41	12.42	20.45	7.51	36.75	9.55
Total	**17774**	**3.91**	**0.84**	**21.47**	**3.26**	**0.42**	**12.82**	**23.06**	**9.10**	**39.46**	**10.77**

*N = number of milk samples

Wood et al. (2003) indicated that concentrations of MUN may also differ if cows are consuming the same diet. Aguilar et al. (2012) pointed on the significant effect of cow in their research and field trials is clear evidence of phenotypic differences in MUN concentrations among cows that are not explained by N intake, milk yield, body weight, or other production – related factors.

The results of F-test showed significant differences between the farms concerning milk fat, protein and milk urea content. Using t-test it was found statistically significant differences between averages of milk fat, protein and milk urea content on four farms ($p<0,01$ and $p<0,05$). Only the difference between the mean protein content between farms F1 and F3 was not statistically significant, Table 2.

Table 2. The values of t test between farms

Farms	F2			F3			F4		
	%		mg/dl	%		(mg/dl	%		mg/dl
	Milk fat	Protein	MU	Milk fat	Protein	MU	Milk fat	Protein	MU
F1	24.35**	3.27**	22.0**	22.98**	0.47	10.22**	5.61**	7.87**	18.06**
F2	-	-	-	6.64**	3.34**	40.35**	25.18**	12.21**	50.44**
F3	-	-	-	-	-	-	22.20**	9.94**	9.42**

$t_{0,05}$=1,96, $t_{0,01}$=2,58

On Figure 1 it can be seen that at the farms F3 and F4 with the highest percentage of milk samples had MU content in the range from 15 to 30 mg / dl (7.01 MUN – 14.01mg / dl), which is considered to be the normal physiological values of milk urea in cow's milk (Abdoul et al, 2008).

At farms F1 and F2, that percentage are was slightly lower. At farm F2 with increasing MU content the percentage of milk samples increasing too.

As can be seen in Figure 2, milk urea was higher during the spring and summer months. For all farms the highest mean value is was in May (32.54 mg/dl) and the lowest in October (18.14 mg/dl). Similar results have been reported by other authors (Carlsson et al., 1995; Godden et al., 2001, Abdouli et al. (2008), Čobanović and Perišić, 2014). Rajala-Schultz and Saville (2003) were observed that in the low producing herds MUN concentrations were the highest during summer and significantly lower in winter, spring and fall. In the high producing herds, the differences among seasons were much smaller, but MUN concentrations were lowest during summer. Hojman et al. (2004) reported higher concentration MUN in the spring and the highest in the beginning of the summer, in June (18.1mg/dl). Bastin et al. (2009) found the highest MU during summer months, especially in August, and the lowest during the month of February. This fluctuation could reflect the grazing period and the access of cows to fresh pasture, which typically contains highly degradable protein and has a high protein-to-energy ratio (Soriano et al., 2001).

In this research a negative coefficient of correlation was determined between MU and protein content, on farms F2, F3 and F4. Only on farm F1 a positive correlation coefficient was determined. In Figure 3, the protein content, for different MU (mg/dl) groups is displayed.
In majority of the researches a negative correlation coefficient between protein content and urea concentration in milk was determined (Godden et al (2001), Johnson and Young (2003), Rajala-Schultz and Saville (2003), Hojman et al (2004), Abdouli et al (2008).
Abdouli et al. (2008) suggested that when herd - level mean milk protein was 3.0 to 3.2% and MUN concentration was 12 to 16 mg/dl, protein degradability fractions and net energy were most likely balanced.
Oudah (2009) found that the lowest MU (<15 mg/dl) had the lowest protein percentage (3.38%), and meanwhile the highest MU category (>55 mg/dl) had the highest protein percentage (3.46%).

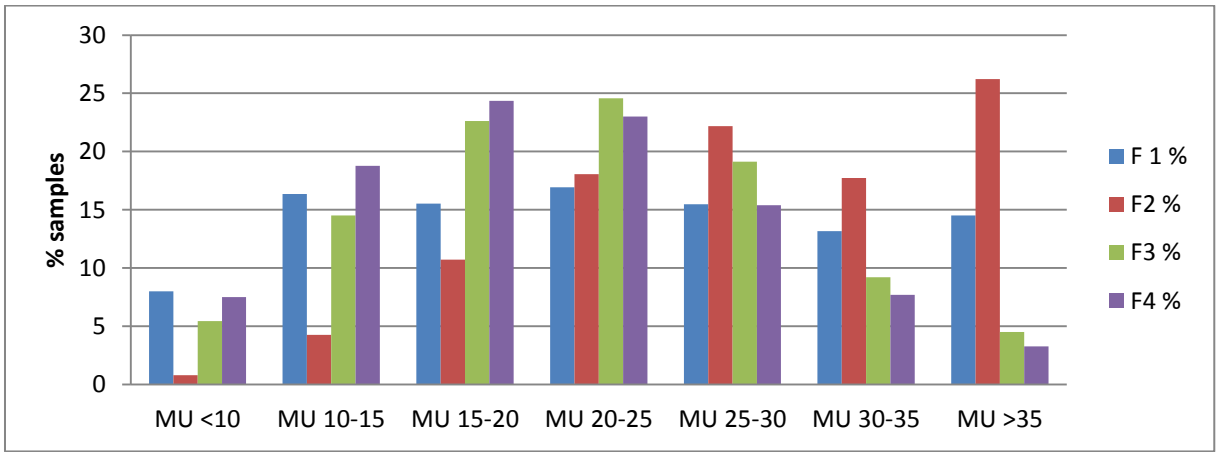

Figure 1. The distribution of milk samples per MU (mg/dl) groups

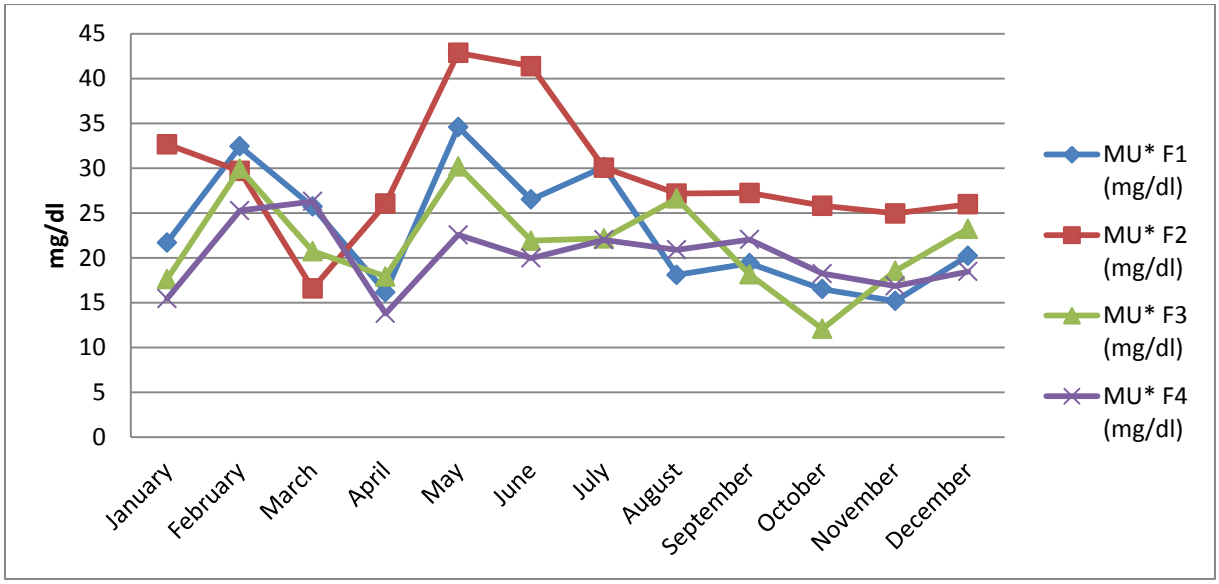

Figure 2. Content of MU (mg/dl) for farms by month of recording

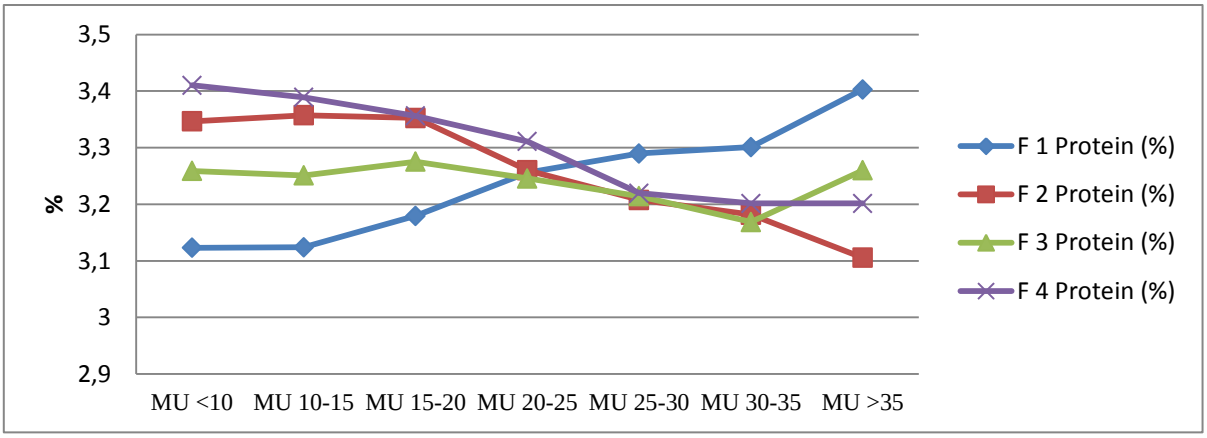

Figure 3. Protein content by MU (mg/dl) groups

Conclusion

The mean value of MU for all the farms, during the period of one year, was 23.06 mg/dl.
MU values for farms were 23.83 mg/dl (MUN 11.13mg/dl); 29.47 mg/dl (MUN 13.77mg/dl); 21.79 mg/dl (MUN 10.18mg/dl) and 20.45 mg/dl (MUN 9.55mg/dl) respectively.
Management at farms plays a great role as a source of variability in MU levels.
Compared with other milk production traits, fat percentage (17.69 – 24.97%) and protein percentage (12.3-13.93%), coefficient of variation for MU was higher (32.68 – 43.58%).
In this research a negative correlation coefficient between protein content and urea concentration in milk was determined, on farms F2, F3 and F4. Only on farm F1 was determined positive correlation coefficient. MU content varied according to season.
Using MU to monitor and adjust ration energy-protein balance might provide an opportunity to reduce feed costs and to improve profitability of the herd.

IMPLEMENTATION OF THE „BREEDING PROGRAM” IN PIG PRODUCTION IN VOJVODINA PROVINCE (SERBIA)

Ivan RADOVIC, Mile MIRKOV*, Slobodan KONJEVIC, Ivan ZARKOVIC, Velibor VASILJEVIC

Faculty of Agriculture, University of Novi Sad, Trg Dositeja Obradovića 8, 21000 Novi Sad, Serbia
*Corresponding author: mile.mirkov@stocarstvo.edu.rs

Abstract

The „Breeding program“(B.p.) is a set of breeding and selection methods and procedures which provide genetic improvement of pigs in Vojvodina province (Serbia). The application of appropriate breeding and selection methods according to the set goals represents the basis for pig production, while it maintains or improves vitality, increases efficiency, improves product quality and preserves genetic diversity.

The legal basis for the B.p is given in the Act of Livestock from 2009. First B.p came in 2010, and was enforcing by the end of 2014.The new B.p. which is a continuation of the previous one, with more strict evaluation criteria when selecting animals for breeding, was adopted in 2014 and entered into force in early 2015.

One of the selection methods which is prescribed by the B.p. is the selection and evaluation of the animals on the basis of data on individual abilities, or performance test. The aim of the performance test is to be used for breeding of superior animals in terms of their own phenotypes for a particular trait, where examined animals are the candidates for further selection.

Main breeding organization collects, processes and analyzes data related to recorded population at the territory of Vojvodina. Data were collected from primary and regional breeding organizations, through quarterly reporting documentation.

Based on the data of the main breeding organizations for the period from 2010 to 2014, the number of gilts in performance test increased by 24.54%, while the number of boars in performance test was reduced by 23.72%.Meat yield was increased to 56.35% in boars, and 57.9% in gilts, while the depth of MLD increased to 76.69mm and 77.6mm in boars and gilts respectively.

Application of B.p.in the previous period and the increase of breeding goals for the upcoming period will give a positive effect on important production traits that directly affect the cost of pig production in Vojvodina affecting that production will be more economical and cost effective. According to the mentioned above, it is concluded that the implementation of B. p. provides positive effects on pig production in Vojvodina.

Introduction

The implementation of breeding programs in animal husbandry is the primary activity of the Centre for the breeding of domestic animals at the Department of Animal Science, at the Faculty of Agriculture in Novi Sad. One of the most important segments of the breeding value is the genetic improvement - selection of domestic animals. Work on the selection of animals in Vojvodina, institutionally started by establishing the Regional Institute of Animal Science in 1950. Over the years, the structure of organizational functioning was repeatedly changed.

When the Law on Animal Husbandry entered into force (“Sl. glasnik” RS41/09), Department of Animal Science, at the Faculty of Agriculture, University of Novi Sad in 2010 received the "Decision on registration breeding organization of the Ministry of Agriculture, Forestry and

Water Management" as the Main breeding organizations in Vojvodina and in the same year it started the implementation of a major breeding program for pig farming. (Trivunovic et al., 2014).

Subjects in the implementation of Main breeding programs of pig farming in Vojvodina are: Farmers, Basics breeding organizations, Regional breeding organizations, Main breeding organization, Organizations with special authorization, Provincial Secretariat for Agriculture, Water Management and Forestry, Ministry of Agriculture and Environmental Protection.

The Main breeding program for pig farming in Vojvodina deals with a various number of different but also interrelated parts for the further development of pig production such as: the state of the pig, the conservation of genetic resources, animal welfare, genetic improvement (breeding), selection and testing of breeding animals, assessment of conformation breeding pigs and fattening pigs as well as issues related to the modernization of pig production in order to comply with European Union standards. The Main breeding goals are: increasing productivity of farm animals, changing and improving the racial composition and preventing decreasing in number of animals (Main breeding program, 2014).

Breeding programs can be considered as an investment in the context of long-term development programs that should be implemented in accordance with the national strategy for agricultural development while respecting existing limitations (finance, etc.). Breeding programs should be simple, direct and clear, unlike some other breeding programs for which program measures would not be guaranteed in time and experience (Kosgei et al., 2011). Above all is the implementation of the components of the breeding program, where it is necessary to monitor program results.

Programs for improving production characteristics which are applied today in pig breeding mainly consist of selecting the best breeding race, recommending of appropriate combination of race with the crossing and continuous improvement of production characteristics of pure breeds and the use of breeding animals which have a high breeding value. There is no doubt that there is a difference in breeding programs between certain countries and manufacturers (Merckx and De Vries, 2002).

Today the breeding program is based on the inter section of paternal and maternal lines and race, as well as performance testing and application of BLUP animal model, using PEST and PIGBLU software packages. For more precise estimation of the breeding values for the tested animals, it is necessary to use those models to include different factors affecting the variation characteristics (Mijatovicet et al., 2006; Trivunović, 1996). In Vojvodina province (Serbia), as a basic method to improve production performance is to use pig crossing. To produce commercial F1gilts, Landrace and Large White are used, while for the production of three-breed crossbred, F1 commercial gilts are intersect with terminal boars race (Trivunovic et al., 2014).

The breeding goal in swine production is focused on the repair of all economically important traits (life gain, back fat thickness, depth of MLD) so that total production could be bigger and more profitable (Radovic, 2011).

The most important goals of the pig breeding program in Vojvodina are the production of 21 fattening pigs per hybrid sow with 80% of yields of frozen carcass and 55-58% of meat in carcass, 880-928 kg of quality muscle tissue per year per sow, the necessary amount of food per piglet born alive of 60 kg, number of farrowing 2, 3 per sow per year, the number of piglets born alive per litter > 10.5, the total number of piglets per sow per year 24, the number of raised piglets per sow 22 (Main breeding program in Vojvodina province, 2014).

Materials and methods

The Main breeding organizations collect process and analyze data relating to the population of pigs in the territory of Vojvodina. Data are collected from Basic breeding organizations, through the Regional breeding organization by submitting quarterly reporting documentation. One of the selection methods prescribed by breeding programs is the selection and evaluation of the animals on the basis of data on individual abilities, i.e. performance test. Performance test represents a selection measure, performed by the Main organization of the breeding farms with an apparatus for ultrasonic measurement "Krautkramer", where the tested pigs are the candidates for further selection gilts and boars of pure race, as well as the F1 generation that are prescribed by Main breeding program. The very purpose of performance testing is to improve the performances of herd by increasing the frequency of desired genes, selecting the best rated animals, based on the results of performance test. The results of the Performance tests are processed in the General breeding organization using the software packages scheduled for making the selection index. The results of the test are sent to farms and on its basis the animals with positive results continue to be engaged in breeding, as the nucleus of the herd.

Results and discussion

Trivunović et al. (2014) recorded a decrease in number of tested boars, where it was observed a constant decrease which was particularly visible in 2011. (compared to 2005 by 43.6%). In 2013, this trend continued to declines lightly compared to the previous year. During the 2014, in the Autonomous Province of Vojvodina performance test was conducted on 987 boar which is an increase of tested boars for 12.92%, more than in 2013.

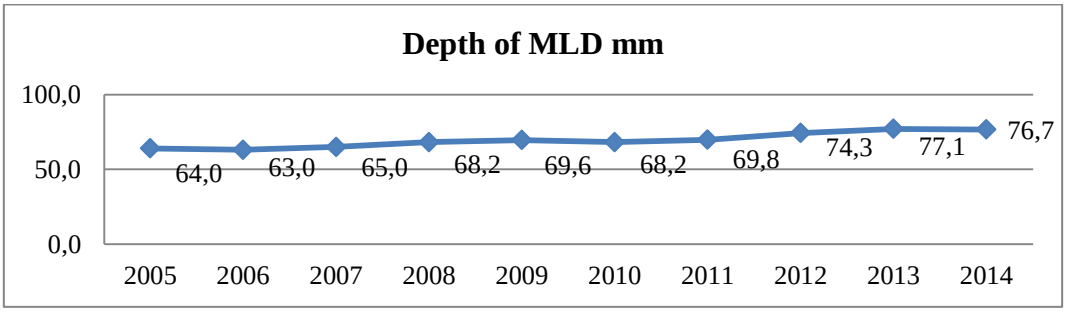

Chart 1. Depth of MLD in boars in the test from 2005-2014.

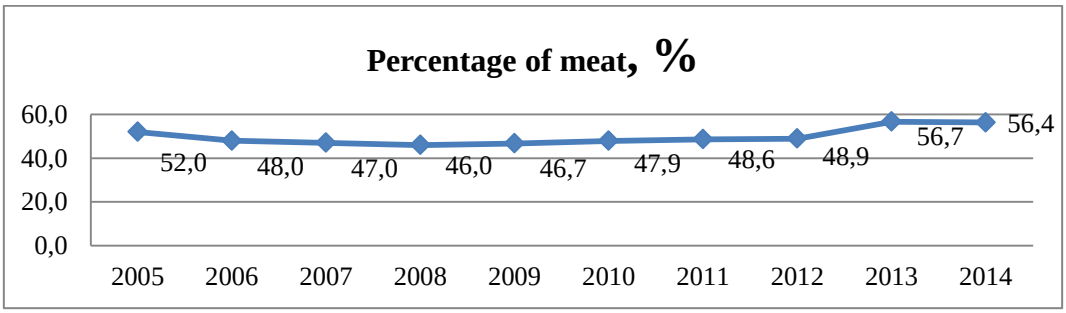

Chart 2. Percentage of meat in boars in the test from 2005-2014.

It appears from the chart (1 and 2) when it comes to the depth of MLD in boars, there had been a constant increase from 2006, while a slight drop was recorded in 2014. (76.7mm), an increase of MLD was recorded by Radovic (2010) for the period 2005-2009 and the increase was from 64 mm to 69.6 mm. When it comes to the percent of meat in boars, it was observed the increase of conformation of the meat in 2009 (46.70%), while the average leanness of

meat in 2014 was 56.4% (Chart 2). Radovic (2010) found that the average leanness of the meat in 2009 amounted to 46.7%. The trend of increasing has continued which leads to a more strict system of more stringent selection. Due to the high degree of heritability, genetic improvement can be achieved by using the performance test results. Based on the data of the test results (weight gain, feed conversion, back fat thickness, % of meat in carcasses, number of tits, constitution, size and number of litter from which originates),the best boars should be selected (Yoo and Lee, 2011).

What constitutes a significant improvement compared to the previous year is a performance test on gilts which was conducted at 27.747 gilts (23.208 in 2013). The increased number of tested gilts was recorded by Trivunovic et al. (2014), where they recorded a number of tested gilts in the last seven years, despite the fact that in 2011 the number of tested gilts fell by 3.3% in comparison to 2010. The positive growth trend continued in the following year by 6.6%.

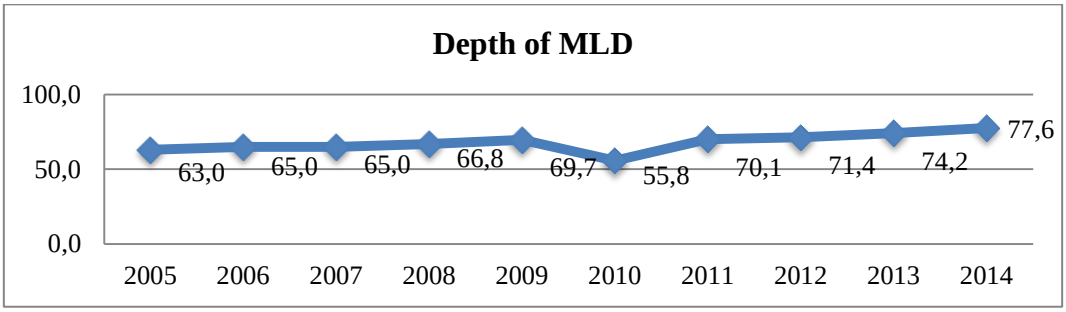

Chart 3. Depth of MLD in gilts in the test from 2005-2014.

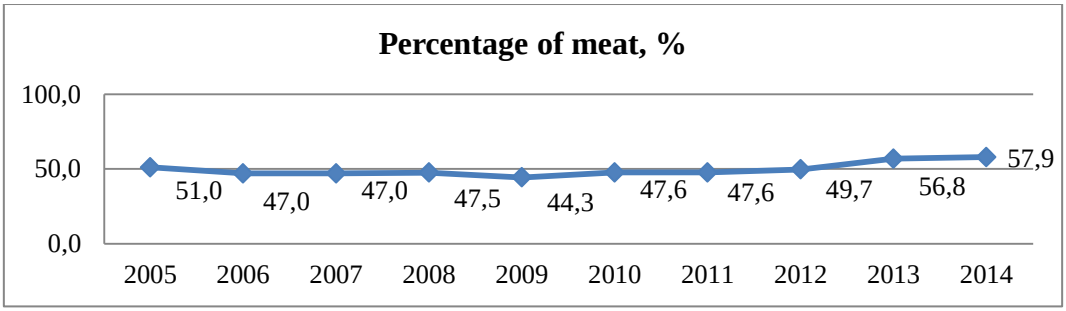

Chart 4. Percentage of meat in gilts in the test from 2005-2014.

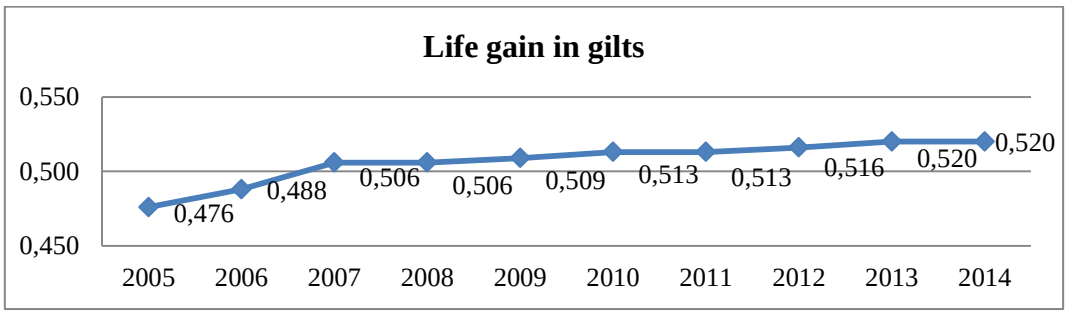

Chart 5. Life gain in tested gilts from 2005-2014.

By reviewing the results of the test it was determined an increase in the depth of MLD to 77.6 mm compared to the previous year (chart 3), which represented an increase of MLD compared to 2009, when the thickness of MLD was 69.7 mm (Radovic, 2010). The percentage of meat in 2014 was 57.9% (Chart 4), which represented an increase compared to

the percentage of meat in previous years. The reduction of the percentage of meat in the period from 2005-2009 was recorded by Radovic (2010) from 51% to 44.3%.
It was also an increase of live gain in tested gilts, which in 2005 amounted to 476 g and in 2008 506 g (Radovic, 2010). Increasing life gain in tested gilts was continued and in 2009 when the average life gain was 509 g, while in 2014 it amounted to 520g.

Conclusion

Swine production is an important part of agriculture in the overall economy of Vojvodina. On this basis, it is of great importance to increase the number of high-quality breeding animals and to improve the racial composition.
By specialized production on the national level, areas, with in a company (association) or large farms and by using modern methods of testing, selecting and crossing it is possible to improve the genetic basis of pigs in a relatively short period of time.
One example of the specialized production represents the organizational structure of breeding organizations in the Scandinavian countries, the hierarchical organization of the nucleus farm, production farms and commercial farms. Performance testing is done on gilts nucleus farms in Finland and production farms.
Reducing the number of tested boars is the result of strict selection, which is conducted in the choice of dam of boars, where strictly ensures that boars to be used for breeding improve the economic characteristics. Increasing the number of gilts at the end of the test is reflected in the possibility to perform ultrasonic measurement of the thickness of the back fat in a large number of gilts, with modern appliances by the Main breeding organizations. In order to done the appropriate selection of expectant mothers, and to increase the intensity of selection, it is included a larger number of gilts in the control.
Based on the results achieved in Vojvodina, leads to the conclusion that the implementation of Main breeding program by the Main breeding organizations produced a positive effect on the development of pig breeding in Vojvodina.
The objectives of the new breeding program has been expanded, so that they include new features (production, functionality, conformation), which are in accordance with professional standards, with optimal management (nutrition, medical care program and breeding animals), which will increase in the future and expand the positive effect implementation of breeding programs in pig production.

Abstract

The objective of the present study was to investigate nutritional and metabolic status in Simmental cows during early and mid lactation. Fifteen early lactation cows and 15 mid lactation cows were chosen for the analysis. Blood samples were collected to measure beta-hydroxybutyrate (BHB), non-esterified fatty acids (NEFA), triglycerides (TG), glucose and the activity of aspartate transaminase (AST). Blood metabolites, milk yield (MY), dry matter intake (DMI) and energy balance (EB) were recorded. Correlation analysis showed that DMI was significantly ($p<0.05$) negatively correlated with NEFA, BHB and AST, and positively ($p<0.05$) with glucose and TG. EB was significantly ($p<0.05$) negatively correlated with NEFA, BHB and AST, and positively ($p<0.05$) with glucose. Early lactation as compared to mid lactation cows were found to have significantly ($p<0.05$) higher blood serum concentrations of NEFA, BHB and AST activities and lower blood serum concentrations of glucose and TG, but not significant ($p>0.05$). These metabolic changes were in correlation ($p<0.05$) with DMI and EB, but not with MY($p>0.05$). Suggest that they can serve as useful indicators of the nutritional and metabolic status of dairy cows during lactation.

Keywords: *blood metabolites, dry matter intake, energy balance, dairy cows*

Introduction

Production diseases i.e. diseases associated with improper nutrition or management are common in dairy cows. Dairy cows suffer from negative energy balance (NEB) during the first weeks of lactation due to energy expenditure associated with milk production and limited feed intake, resulting high mobilization of lipids from body fat reserves, and hypoglycaemia (Veenhuizen et al., 1991; Drackley 1999, Oetzel, 2004; Djokovic et al., 2007,2011). Nutrition, age, heredity, body condition score (BCS), management and energy imbalance as various risk factors are possible causes of NEB, periparturient fatty liver and ketosis (Pechova et al., 1990; Drackley 1999). Clinical ketosis in dairy cows usually occurs between the second and seventh week of lactation. Nevertheless, most of cows in this stage of lactation may suffer a subclinical form of ketosis defined as increased blood ketone bodies without any other symptoms but accompanied by considerable decrease in milk yield and susceptibility other diseases (Duffield et al. 2000, Oetzel, 2004). The degree of NEB in early lactation and the recovery rate from are critical for health status and productivity. Various metabolic and endocrine blood and milk traits have been shown to relate to EB (Reist et al., 2002). Consequently, stressors and poor nutritional management causing reduction in voluntary DMI will result in large increases in NEFA around calving (Drackley, 1999). The main blood indicators of lipomobilization in ruminants are BHB, the most important and abundant ketone

body, and NEFA (Duffield et al. 2000, Oetzel 2004, González et al. 2011). NEFA are preferentially and greatly accumulated as TG in the liver, primarily because of a decrease in the very low density lipoproteins (VLDL) synthesis by hepatocytes (Sevinc et al. 2003). However, when steatosis occurs, endogenous liver synthesis decreases, leading to a reduction in blood glucose, total proteins, albumins and globulins, cholesterol, TG and urea. (Veenhuizen et al. 1991, Sevinc et al. 2003, Oetzel 2004, Djokovic et al. 2007, 2011). Fatty liver infiltration and hepatocyte degeneration involve cell membrane damage and hepatocyte destruction coupled with the release of cytoplasm enzymes (AST, GGT, LDH) and marked increases in the circulating activities (Pechova et al. 1990, Drackley, 1999). The objective of the present study was to investigate nutritional and metabolic status in Simmental cows during early and mid lactation on the basis the correlations between blood biochemical metabolites, MY, DMI and EB**.**

Material and methods

Animals, diets and protocol design

This experiment was carried out in a dairy herd (166 Simmental cows) suffering from several metabolic and reproductive disorders. Two groups (n=15 cows) of clinically healthy cows were chosen from the herd. The cows were mid-yielding with a preceding lactation of about 6500 l and MY=25±5 l/day (early lactation cows: 6488±980, and MY=23±4 l/day); mid lactation cows cows: 6677±1088 and MY=28±6 l/day). Group 1 consisted of early lactation cows, in the first month of lactation (16 ± 9 days), and Group 2 included mid lactation cows between 3 to 5 months of lactation (114 ± 28 days). The experimental cows were kept in tie-stall barns. Diet and the housing facilities were adapted to research purposes, with diet suited to the energy requirement of early and mid lactation cows. Early lactation cows were fed a diet consisting of 7 kg lucerne hay, 20 kg maize silage (30% Dry Matter, DM), 5 kg concentrate (18% crude proteins, CP). Mid lactation cows received a diet consisting of 5 kg hay, 7 kg lucerne hay, 30 kg maize silage (30% DM), 8 kg concentrate (18% CP) Dietary nutrient contents for dairy cows in early and mid lactation are given in Table 1. The chemical analysis of the feed was performed by Weende methodology. EB was calculated by NRC recommendation (17).

Table 1: Nutrient contents in daily ration for early lactation and mid lactation dairy cows.

	Early lactation cows	Mid lactation cows
Dry matter intake (DMI) (kg)	16.05	24.82
Net Eanergy of Lactation (NEL) (MJ)	87.15	130.23
Crude Protein (CP) (% of DM)	13.58	13.38
Rumen undergradable protein (RUP) (% of CP)	35.91	28.33
Fat (% of DM)	3.09	3.14
Fiber (% of DM)	23.26	24.33
EB (MJ/day/cow) mean ± SD	-15,21 ±20.37	3.49 ±8.16

Biochemical analysis

Blood samples were collected at 10:00 h or 4 to 6 hours after milking and feeding, by puncture of the jugular vein into sterile disposable test tubes, without anticoagulant. After clotting for 3 hours at 4°C and centrifugation (1500g, 10 minutes, 4°C), sera were carefully harvested and stored at -20°C until analysis. Blood samples collected on fluoride were immediately centrifuged in the same manner and plasmas were assessed for glucose concentrations. The following biochemical blood components were measured at Biochemical Laboratory by different colorimetric techniques using spectrophotometers (Cobas Mira and

Gilford Stasar): BHB and NEFA levels were measured by Randox (United Kingdom) kit, AST and glucose by Human (Germany) kit, and TG by Elitech (France) kit.

Statistical analysis

Data were subjected to statistical analysis using the GLM model and t-test (Statgraphic Centurion, Statpoint Technologies Inc.Warrenton, Va, Virginia, USA). The model included lactation period and metabolite values. Pearson's test was performed to evaluate significant correlations between MY, DMI, EB and biochemical metabolites separately. The intensity of change in metabolic profile during negative energy balance in early and mid lactation stages was analyzed by comparison of b parameters in linear equations (t-test). Finally, correlation between metabolic parameters was evaluated. Differences were considered significant at p values below 0.05 or 0.01.

Results and Disscusion

Blood biochemical metabolites MY, DMI and EB in early lactation and mid lactation cows were compared in this study. Homeorhesis induces intense lipid mobilization and ketogenesis, and the liver is adapted to metabolic changes in dairy cows. Intensive postpartal lipid mobilization and ketogenesis are sufficient for a series of compensatory metabolic processes with changes in blood metabolic profile during early lactation in healthy cows (Drackley 1999). Results on blood biochemical metabolites for both groups of cows are shown in Table 2.

Table 2.Blood metabolites in early and mid lactation dairy cows (n=15 in each group). Results are expressed as mean ± standard deviation (SD).NS: non-significant

	Early lactation cows	Mid lactation cows	p
Glucose (mmol/l)	2.29±0.48	2.76±0.43	< 0.05
BHB (mmol/l)	1.59±0.25	0.91±0.16	< 0.05
NEFA (mmol/l)	0.38±0.29	0.13±0.04	< 0.05
TG (mmol/l)	0.12±0.02	0.15±0.04	NS
AST (U/l)	69.46±27.54	39.31±18.90	< 0.05

The metabolic levels significant correlated with DMI and EB and did not significant correlated with MY (Table 3).

Table 3. Correlation coefficients between metabolites and milk production, DMI and EB. Significant correlations ($p<0.05$) are marked with asterix (*).

Metabolites	MY(l/day)	DMI (kg/day)	EB (MJ/day)
Glucose	r= 0.18	r= 0.43*	r= 0.45*
NEFA	r=-0.21	r=-0.50*	r=-0.49*
BHB	r=-0.25	r=-0.38*	r=-0.53*
TG	r=-0.11	r= 0.42*	r= 0.18
AST	r= 0.07	r=-0.49*	r=-0.41*

Change of metabolites as a function of EB in early and mid lactation is shown in Table 3. The values changed much more intensely in early lactation than in mid lactation. The decrease in energy balance led to increased NEFA, BHB and AST and decreased glucose levels for every unit change much more intensely in early lactation than in mid lactation.

Table 4. Change of metabolites as a function of EB in early and mid lactation (comparison of b parameters from linear equation). NS: non-significant

	b parameters	(relation EB to metabolite)	
Metabolites	Early lactation	Mid lactation	p
Glucose	0.08	0.05	<0.05
NEFA	-0.07	-0.03	<0.01
BHB	-0.09	-0.05	<0.01
TG	0.002	0.003	NS
AST	-4.35	-2.28	<0.01

The correlation coefficients among the biochemical parameters calculated for all cows in this experiment are summarized in Table 5.

Table 5**.** Correlation coefficients for the biochemical metabolites calculated for all cows in the present study. Significant correlations ($p<0.05$) are marked with asterix (*).

	NEFA	BHB	TG	AST
Glucose	r= -0.35*	r=-0.47*	r=0.65*	r=-0.23
NEFA		r=0.39*	r=-0.21	r= 0.34*
BHB			r=-0.36*	r=0.15
TG				r=-0.04

In early lactation cows, NEFA and BHB values were significantly higher than in mid lactation cows. NEFA concentrations > 0.40 mmol/l indicate problems with energy balance and subsequent intensive lipomobilization (Oetzel, 2004). According to this report, in early lactating cows, NEFA values in blood were 0.38 ± 0.29 mmol/l, showing evidence of high lipomobilization in the present study. These are result the some early lactating cows in the present study had NEFA concentrations above the value indicative of subclinical ketosis. Subclinical ketosis also may be diagnosed when serum BHB concentrations are above 1.2 mmol/l, while clinical ketosis is associated with BHB concentrations above 2.6 mmol/l (Duffield 2000, Oetzel, 2004). These are result early lactating cows in the present study had BHB concentrations above the value indicative of subclinical ketosis (1.59±0.25 mmol/l). The data presented show that serum NEFA may be used for detecting high lipomobilization, but not subclinical ketosis. This is in agreement with Duffield (2000), who stated that the use of NEFA is a better indicator of energy imbalance in prepartum animals than BHB, but BHB is more useful postpartum. In the present study, a significant positive correlation was established between NEFA and BHB in the sera, suggesting that both parameters are helpful indicators of energy balance during lactation. Blood NEFA and BHB concentrations were not in correlation with the intensity of milk production during lactation, but a significant correlation was observed with DMI and EB. Reist et al. (2001) reported a strong correlation among blood NEFA and BHB concentrations and EB in early lactation dairy cows. BHB is negatively correlated with food level and it therefore increases in cows fed a good diet in dry and lower quality in post partum (Stockdale, 2008). Blood glucose values in mid lactation cows were within the physiological range 2.5 - 4.2 mmol/l (Oetzel 2004), whereas hypoglycemia (2.29 ± 0.48 mmol/l) was detected in early lactation cows. Taking this criterion into account, early lactation cows had indicative values, but did not display any clinical signs, suggesting that they had a typical subclinical condition. Blood glucose concentrations in early lactation cows were significantly correlated with DMI and EB. In fact, a significant correlation was observed between NEFA values and glucose and BHB and glucose. Similar correlations were observed by other authors (Reist et al. 2002, Laszlo et al. 2009). Cows in NEB have low rates of glucose and high levels of BHB (González et al. 2011). Fat infiltration into the liver may also affect the concentration of some blood components. Serum level of TG, is indicator of hepatic

functionality, and decreases in their concentration may suggest fat infiltration in the liver (Sevinc et al. 2003, Djokovic et al. 2007, 2011). The concentration of serum TG was significantly lower in ketotic cows compared to healthy cows (Djokovic et al. 2007). These results are showed that TG accumulate in the liver cells of ketotic cows and cause their blood values to decrease. In the present study, TG in the blood was low (0.12 ± 0.02 mmol/l vs 0.15 ± 0.04 mmol/l) in both groups of cows, but without significant difference. This study was showed a posibility of the development a fat infiltration of the liver in early lactation cows and was confirmed a significant correlation between TG and glucose, TG and DMI and TG and BHB. When fat infiltrates the liver, a lesion appears in hepatic tissues, and the levels of enzymes that indicate liver injury (AST, GGT, and LDH) are generally augmented (Pechova et al. 1990). AST values in the present study were statistically higher ($P<0.05$) in early lactation cows than in mid lactation cows. If AST activity higher than 100 U/l is indicative of hepatic lesions (González et al.2011). These are result early lactation cows in our study suffered from some degree of hepatic lesions, probably due to fat infiltration. Also, a positive correlation was observed between AST activity and NEFA values. In the present study, all data concerning serum AST activities suggested that the process of lipomobilization was sufficient to cause liver lesions in of the early lactating cows. These metabolic changes were not in correlation with the MY during lactation, but a significant correlation was observed between metabolite values and DMI and EB. According to Wathes et al. (2007), milk yield was independent to nutritional and biochemical parameters during only the first two weeks post-calving but it was significantly higher in cows expressing high levels of BHB and urea at the 4th week. Lower DMI could explain lower concentrations of glucose and TG, and higher concentrations of NEFA, BHB and AST. Negative energy balance could explain lower glucose concentrations and higher NEFA, BHB and AST levels. Insufficient DMI in early lactation is known to lead to NEB with the above mentioned changes occurring in the metabolic profile. Metabolic changes during early lactation were more intensive as a function of EB, compared to mid lactation. These changes are due to both lipolysis and ketogenesis occurring during homeorhetic processes and metabolic adaptation in the liver during early lactation. Several authors reported these changes but with different intensities (Reist et al. 2002, Laszlo et al 2009).

Conclusion

On the basis of changes of blood biochemical metabolites, this study suggests that early lactation cows had metabolic disturbances, which were associated with ketosis, and some degree of hepatic lesions, probably due to fat infiltration. These metabolic changes were correlated with DMI and EB, but not with MY, and they can serve as useful indicators of the nutritional and metabolic status of dairy cows during lactation.

Abstract

Thirty (30), twenty – three weeks old Isa brown pullets were used to investigate the egg weight and shell quality characteristics of laying hens fed with different levels of cocoa bean shell. The cocoa bean shell was used to replace maize at 0%, 25%, 50%, 75%, and 100% levels of inclusion. The replacement levels of 0% represent the control treatment (treatment 1). Each diet was fed to the birds for 56 days (8 weeks) and the investigation was on fed intake and egg components which are shell weight, egg weight and shell thickness.

The increase in the inclusion of cocoa bean shell in the diet has no significant effect ($P>0.05$) on the shell weight and shell thickness. However, feed intake decreased with increase in the inclusion level of CBS, and this contributes to the lower body weight of the birds with dietary treatment above 25% CBS meal. At 25% CBS inclusion, the egg weight and the feed intake of the birds are still the same or close to the control treatment. The egg weight of the birds fed with dietary treatment above 25% CBS meal decreases which shows that bird fed with CBS at 25% inclusion level can still have a desirable egg weight.

This investigation shows that CBS meal could partially replace maize up to 25% in layers' diet without negatively affecting the egg weight and shell quality characteristics of the eggs.

Introduction

Monogastrics, particularly poultry compete well with man for conventional feed stuff such as cereal, grains and legumes. This competition between man and livestock has led to scarcity and high cost of feed ingredients and this has resulted in high cost finished foods of animals products which are beyond the reach of average consumers. In Nigeria in recent years, the once prosperous poultry industry has virtually collapsed due to shortage and high cost of feed ingredients particularly maize. Since commercial feed in the country contain an average of 50% maize and 90% of the feeds are consumed by poultry (Olayemi, 1989). However this problem is being aggravated by the ever-increasing demand for maize as both staple food for man and an industrial raw materials, as the country has no recourse to cheap imports or increased supply of maize, the option has been to source locally for available alternative plant materials which are not components of man's food. The high cost of maize grains necessitates the search or locally available materials like agro-industrial by products and wastes, with a view of finding those that could supplement the ration at different levels which would lower feed cost without sacrificing efficiency of livestock production.

However, Egbunike and Ikpi, (1988) highlighted the tremendous potential of agro-industrial by-products which were at least 738,271.6 tonnes and crop residues of at least 52 million tones in Nigeria. Ogbonna (1991) confirmed that production of agro-industrial waste is at least one million tonnes per annum in the same country. The potential valve of agro-industrial by-products and the maximum inclusion rates in livestock diets depend on their nutritional characteristics, their safety for animal health (Boucque and fiems, 1988). Some examples of these agro-industrial by-products are palm kernel, cocoa pod husk, cocoa bean shell, cocoa dust, cocoa bean cake, brewery dry grains (BDG), Wheat bran, e.tc. and these have been

proven to be useful in alleviating the high cost of conventional feed ingredients especially maize. On the other hand, cocoa by-products such as cocoa bean cake, cocoa pod-dusk, cocoa bean shell cocoa butter, discarded cocoa beans etc. all have a theobromine content which has contributed to their limited use in farm animal feed. Theobromine, when taken in moderate quantities acts as a stimulant like caffeine but intake of more the 0.0279kg-1 body weight is injurious to animals. (M.A Menon 1982; Gohl 1981). Cocoa by-products are also high in nutritive value for livestock feed. (M.A. Menon 1982; Gohl 1981).

Cocoa bean shell, (CBS) constitutes nearly 10% of cocoa bean (Menon, 1982). It contains 17.5% crude protein, 13%fibre, 8.1% ash and an anti-nutritional component, theobromine, which is of the proportion 1.3 – 2.0% (Menon, 1982. Yeong*et al.*, 1989; Abiola and Tewe, 1991). It is a by-product of industries processing low grade cocoa beans. It is an unconventional feed ingredients that could be utilized by poultry and is not consumable by man. Gohl (1981) reported that CBS is high in nutritive value but it is of limited use in animal feeds (livestock) because of its theobromine content (anti-nutrient). However there are simple, cheap and effective means of reducing and removing the theobromine content in CBC. Theobromine, when taken in moderate qualities acts as a stimulant like caffeine, but intake of more than $0.0279kg^{-1}$ body weight is injurious to animals (Menon, 1982).

The aim of this paper is to determine the egg weight and shell quality characteristics of layer birds fed with different inclusion level of cocoa bean shell, substitute with maize in the layers mash.

Material and methods

Experimental site

The experiment was carried out at kings farm at Apata, Ibadan, Oyo State Nigeria during 2002. The cages were properly cleaned, Water troughs and the feeding troughs were washed and disinfected a week before the arrival of the birds.

Experimental diet

The cocoa bean shell used for this research was collected from Stanmark Cocoa Processing Company Limited km5 Ondo-Akure roads, Ondo State, Nigeria.

The cocoa bean shell was used to replace maize at 0%, 25%, 50%, 75%, 100% levels of inclusion. The percentage composition of the experimental diets are presented in a table 2.1

Table1. Gross composition of experimental diets

Ingredients (%)	**T1**	**T2**	**T3**	**T4**	**T5**

Experimental bird and management

Thirty (30), Twenty-three weeks old Isa brown pullets were randomly allotted to 5 dietary treatment with two replicated per treatment. Six birds were allocated to each treatment with three (3) birds per replicate. Eight (8) weeks feeding trial was conducted to determine the optimal substitution level of cocoa bean shell for maize in laying hens.The cages we properly cleaned, water troughs and the feeding troughs were washed and disinfected a week before the arrival of the birds. Fresh feed and water were provided ad-libitum. The feed remnants (left over) were removed and the troughs cleaned before serving another feed.

Statistical analysis

The data collected were subjected to analysis of variance (ANOVA) Procedure (steel & torrie, 1980) while treatment means were separated by Duncan Multiple Range Test (Gomes and Gomes, 1985).

Results and discussion

SEM – Standard Error of Means

Row means with different superscript are significantly different [P<0.05]

Feed intake: The feed intake result presented in table 3.1 shows that’s there is significant difference in feed consumption of hens fed different levels of CBS meals (P<0.05). Feed intake of the birds reduced as the level of CBS increases. This decrease in feed intake is as a result of theobromine content (1.3%) in the CBS, which is toxic to the animal. And this is in agreement with Menon (1982) that intake of more than 0.027g/kg is injurious to animal. This can lead to depressed feed intake and consequently reduce performance (Olubamiwa, *et al.,* 2000; Odunsi, *et al.,*1999 and Yeonge*t al.,* 1989). The reduction in the feed intakeleads to lower body weight.

Egg weight: table 3.1 shows that there significant difference in egg weight of laying hens fed different levels of CBS meal ($P<0.05$). It can also be deduced that there is no significant difference between the control treatment (0%CBS inclusion) and treatment 2 (25%CBS inclusion). The result shows that there is a significant difference between treatment 2,3,4 and 5. At 50% inclusion of CBS the egg weight decreased significantly ($P<0.05$) which shows that bird fed with CBS at 25% has a desirable egg weight that those fed with dietary treatment.The decrease in egg weight of birds fee CBS correlate with the report of Gohl (1981) and Hutagalung and Chang (1978) who reported that low level of dietary CBS enhance egg quality but high level limits egg quality due to its theobromine content (anti-nutrient factor)

Egg weight (g)

Shell weight: The shell weight results presented in table 3.1 shows that there is no significant difference between the shell weight of eggs layers fed different levels of CBS meals ($P<0.05$). This indicates that increase in the inclusion of CBS meal in diet of layers has no effects on the shell weight.

Conclusion

The result obtained from the experiment indicate that birds fed with dietary treatment 2 (25% CBS inclusion) showed no significant difference ($P<0.05$) with the control (0% CBS inclusion) with respect to feed intake, egg weight, hell weight and shell thickness.

The increase in the inclusion level of CBS meal also has no significant effect on the shell weight and shell thickness across the treatment.

However treatment 1 and treatment 2 results are significantly higher than other treatments with respect to feed intake, egg weight, shell thickness and shell weigh. It is therefore concluded that laying hens can tolerate 25% replacement of maize with CBS meal and

produce eggs with desirable weight and shell qualities economically, so also with a good body weight.

Based on the results of this experiment, 25% cocoa bean shell meal is recommended for replacement of maize in the feed of laying birds.

EFFECTS OF SUBSTITUTION OF SOYBEAN MEAL BY FABA BEAN ON FATTENED HOLSTEIN BULLS PERFORMANCES IN FINISHING PHASE

Chokri BEN MUSTAPHA*, Nizar MOUJAHED, Cyrine DAREJ

Tunisian National Institute of Agronomy; Genetic, Animal and Feed Resources Laboratory
*Corresponding author: cbenmustapha@yahoo.fr

Abstract

The current research aimed to study the effect of substituting soybean meal by faba bean on performances of fattened Holstein bulls in finishing phase. This substitution concerns 50% and 100% of the nitrogen (N) content in a conventional concentrate provided by soybean meal, with another source of N as faba bean. Authors used 33 Holstein bulls divided into 3 homogenous groups (live-weight and age averaged 346.5 kg and 13.5 months, respectively). The basal diet was composed of oat hay and oat silage, supplemented with 3 types of isoenergetic and isonitrogenous concentrates containing 0% $N_{faba\ bean}$ (D1), 50% $N_{faba\ bean}$ (D2); 100% $N_{faba\ bean}$ (D3) as substitute of N provided by soybean meal. The trial lasted 3 months, and animals were weighted every 2 weeks, and intake measurements were carried out during 3 successive days, in the middle of the period between each 2 weighing times. The results showed that total conversion ratio was significantly ($P< 0.001$) higher for animals receiving concentrates with partially or totally (D2 and D3: averaged 10.27) substituted N than the conventional one (D1: 10.92). No differences were noted in total dry matter intake between the 3 groups (averaged 12.26 kg DM/day). Furthermore, the average daily gain (ADG) resulting from the total substitution of N (D3), was significantly ($P< 0.05$) higher (1.24 g/day) comparatively to the other diets. The including of faba bean did not result in any changes in the final live-weight of animals. Also, the study showed that the substitution of soybean meal by faba bean, particularly once produced by farmers, leaded to a decrease in the feeding cost of the kg of gain (1.46 USD, 1.42 USD, 1.07 USD, respectively in D1, D2 and D3). It was concluded that in the current experiment conditions, substituting soybean meal with faba bean on the base of N supply resulted in higher performances and lower cost for meat production.

Keywords: *Faba bean minor, soybean, Bulls, Fattening*.

Introduction

Bovine meat production holds a great importance in Tunisian animal production. It represents 47% of total meat production (Mehiri, 2010). However, this activity is suffering from several technical and economical constraints resulting in low or moderate performances and high costs. In livestock production, feeding costs represent 60-80% of total charges (Rejeb Gharbi et al., 2007) ;moreover, unpublished investigations carried out in our laboratory showed that concentrate represents about 70% of feeding charges, corresponding to 60% of the total cost of meat. This situation is more and more accentuated by the growing of raw material international prices, mainly soybean and corn grain. Also, this is associated with the use of low quality basal diets overall made of straw and oat hay. Consequently, in order to limit this dependence on imported products, farmers have tested several alternatives to expensive proteic and energetic sources. So they substitute soybean meal (SBM) by some local proteaginous crops as faba bean (*Vicia faba*). In some Tunisian regions, Faba bean grains are traditionally used for bulls fattening especially during the finishing phase. The current work aimed to study the effect of partial or total substitution of soybean meal by faba bean on bulls' intake and performances.

Materials and methods

Animals

The trial was carried out from Mars to June 2009, in the farm of Loubira (North West of Tunisia, sub humid zone). We used 33 Holstein bulls in finishing stage of fattening (average age and initial live weight 13.5 months and 346.5 kg respectively). They were divided into 3 homogenous groups and housed in blocked stalling equipped with linear mangers and troughs. The nutritional requirements of animals were calculated to reach an average daily gain (ADG) equal to 1200 g/day (INRA, 1981).

Feed and diets

All animals received common basal diet (3 kg oat hay and oat silage *ad libitum*), and supplemented with 3 types of fattening concentrate iso-energetic and iso-nitrogen: C0: 0% faba bean (D1), and 2 others concentrate in which the substitution of soybean meal is partial C50 (50% of crude protein (CP) are brought by faba bean: D2) or total C100 (100% of CP are brought by faba bean: D3).

The basal diet was distributed twice /day and the concentrate is distributed 3 times/day at 8 a.m, 12 a.m and 4 p.m. The quantity of concentrate was about 2% of live weight, and is adjusted every 2 weeks after the weighing of bulls.

The raw materials used for the formulation of concentrated food were soybean meal, corn, barley, sound of wheat and the faba bean minor. The centesimal composition and the feeding value of three tested concentrated food are detailed in table 1.

Table 1. Centesimal Composition of the three experimental concentrate.

	faba Bean	soybean 46	corn	barley	Sound wheat	CaCo3	Ph bCa	salt	premix
C0	-	15	10	40	30	1.75	2	0.75	0.5
C50	14.5	7.5	10	43	20	1.75	2	0.75	0.5
C100	28	-	18	20	30	1.5	1.5	0.5	0.5

Measurements and calculation

This essay lasted 3 months. It starts with a period of adaptation of 10 days. Bulls are weighed every 15 days, to adjust the quantities of concentrate and began a period of measure of the ingestion for 3 successive days.

Along the study some samples of concentrate were collected and tow samples of roughage feed were collected for analysis of dry matter (DM), ash, CP, crude fiber (CF) according to AOAC (1990). Neutral detergent fiber (NDF), acid detergent fiber (ADF) and acid detergent lignin (ADL) were analyzed as described by Goering and van Soest (1970).

Dry matter intake of every feed, and of total dry matter intake, were calculated, as well as the ADG and the index of consumption, for various period of measure and global for all the phase of fattening.

Statistics

These measures were subjected to the statistical analysis by the procedure ANOVA of the system SAS (1988). The effect of the type of concentrate was studied through the effect of the experimental diet (D) on the various zootechnic performances measured, according to the following model: $Y = \mu + Di + Pj + D * P + Eij$

With, D: diet effect; P: period effect; D*P: interaction between effects of diet and period; E: error.

Results and discussions

Chemical composition of feeds

The real chemical composition of raw materials used in the manufacturing of the experimental concentrate food is given in table 2. And the real chemical composition of the roughage constituting the basic ration and experimental concentrate is given in the table 3.

The used oat hay is weak in CP and ash (respectively, 4.1 % DM and 6.8 % DM), corresponding to the hay used generally in Tunisia (Kraeim et al., 1997; Moujahed et al., 2011); but the content in CP of the oat silage is low (5.5 % DM) with regards to the bibliography (Mc Cartney et Vaage, 1993; Moujahed et al., 2009). For the NDF and the ADF content are similar to those found by (Mc Cartney et Vaage, 1993). For the concentrate, particularly the content in CP is relatively similar between the various types of concentrate.

Table 2. Chemical composition of raw materials (%DM).

	%DM	ash	CP	CF	NDF	ADF	ADL
Corn	86.5	1.3	7.8	1.54	82.6	2.8	0.5
Faba bean	89.5	3.6	26.1	10.44	37.4	12.3	0.2
Soybean meal 46	87.8	6.8	37.35	6.39	8.7	5.6	0.8
barley	89.8	2.9	9.8	6.0	43.4	9.0	1.0
Sound of wheat	86.2	5.2	14.37	7.67	39.1	12.4	3.0

Table 3. Chemical composition of roughage feeds and experimental concentrate (% DM).

	%DM	ash	CP	CF	NDF	ADF	ADL
Oat silage	22.5	14.6	5.5	-	58.5	36.5	4.1
Oat hay	85.7	6.8	4.1	-	70.7	43.6	5.4
Conc. C0		8.4	17.7	5.4	34.4	7.2	1.1

Intake Parameters

Table 4. Intake parameters for different experimental regimes.

	D1	D2	D3
DMI o. Silage *	4.11 a	4.18 b	4.34 b
DMI o. Hay *	1.81 a	1.69 b	1.67 b
DMI conc	6.34	6.30	6.35
Tot DMI	12.26	12.17	12.36
DMI/kg $P^{0,75}$	0.134	0.135	0.135
IC	10.73	10.49	9.8
Global-IC ***	10.92 A	10.42 B	10.13 B

*: (P<0.05); ***: P<0.001

Intake parameters presented in table 4, show that the quantity of DMI of oat silage is relatively higher (P < 0.05) for D2 group and D3 group (average 4.26 kg DM) than the D1 one (4.11 kg DM). On the other hand, the DMI of oat hay is a little bit lower (P< 0.05) for the groups D2 and D3 than the group D1. It seems that the incorporation of faba bean contributes to a light decrease of the most cumbersome feed, of made of that the faba bean is richer in

walls than the barley and that his proteic /bulk report is more raised than the meals (RAD, 2006).
Besides, there is no significant difference between groups for the intake of the total dry matter, and that of the intake of the dry matter of concentrate. Moreover, the global ratio of consumption is relatively higher (P< 0.001) for D1 group (10.92) with regards to the D2 and D3 groups (respectively 10.42 and 10.13). Our results are in accordance with several works, such as of Haurez (2002) by substituting totally the soybean meal by the faba bean for the fattening of the Frisian bull-calfs with the corn silage. Also, for a regime with oat hay in the works of Ben Salem and al. (2006) by total substitution of soybean meal by the faba bean, and Moujahed and al. (2008) by substituting partially the soybean meal (16 %, 23 % of faba bean). These authors did not find significant differences for dry matter intake and the ratio of consumption between the soybean meal and the faba bean.
So authors conclude that the partial or total substitution of soybean meal by the faba bean in the fattening of bull-calfs in finishing phase, reduce relatively the consumption of hay of whose the UF is more expensive and increases the intake of silage which is more economic. While considering that the intake of concentrate is the same. On the other hand, the concentrate with faba bean diminish relatively the index of consumption (IC) showing that the introduction of faba bean enable to enhance the value of the daily feed ration by animals. Furthermore, economically the substitution of soybean meal by faba bean, particularly once produced by farmers, leads to a decrease in the feeding cost of the kg of gain (1.46 USD, 1.42 USD, 1.07 USD, respectively in D1, D2 and D3.

Growth’s performances of animals

The effect of feeding regime on performances of bulls as change of live weight LW (kg) and ADG are presented in table 5.

Table 5. Growth’s parameters of fattened bulls depending on different regimes.

	D1	D2	D3
initial LW (Kg)	370.9	365.4	368.4
Final LW (Kg)	482.45	477.3	488.6
LW gain	111.54	111.94	120.28
P-ADG	1.150 b	1.170 b	1.240 a

*: P< 0.05; P-ADG: pondered ADG.

In the term of this essay, we found that the total substitution the soybean meal by the faba bean in the D3, relatively engendered a better performance of growth to the bull-calves of the D3 group (table 5, figure 1). Indeed, their P-ADG = 1.24 kg, is slightly more raised (P < 0.05) than the P-AGD engendered by the other regimes D1 and D2, respectively (1.15 kg and 1.17 kg) and which are not significantly different from each others.

But, for other growth parameters (initial weight (IW), final weight (FW), LW gain there is no significant difference between the various diets. The improvement of weight gain is about 90 g, in favour of diet with Faba bean. While, the partial substitution (Moujahed et al., 2008) or the total substitution (Ben Salem and Fraj, 2006) of the soybean meal by the faba bean did not engender a significant variation of the AGD, it is probably due to their diet based on oat hay. Indeed, the energetic density of the silage is better allowing an improvement of the gain of the animals’ weight (Sansoucy et al., 1984; Micol et al., 2003), relatively rich in proteins especially after a phase of feed restriction (Micol et al., 2003). Moreover, the nitrogenous retention is better for the silage than the hay (Smeti et al., 2012), even if, the silage used in this trial is low in nitrogen. Other part, the faba bean is especially rich in non-protein nitrogen

fraction which is very soluble and easily degradable and represents 12 % of CP, according to Bovera et al. (2001), as well as in energy by its wealth in starch (Crepon et al., 2010), 50-60 % (Larralde and Martinez, 1991); 42.3 % DM (Saving and al., 2004); 41.1 and 47.5 % DM (Hood-Neifer, 2012). This involves at least a stabilization of the performances, even if not an improvement.

The evolution curve of the ADG during the finishing phase of fattening (figure 1), reveals three periods which are almost equal in time, and the curve of the ADG follows the same allure for the various diets. The first period shows ADG in the ascending phase, and then they show certain stability in the second period. These two periods are the result of returning on to a high feeding level brought up after a certain period of feeding limitation. So this situation allows an improvement of the ADG due to the compensatory growth (Hoch et al., 2003). Moreover, certain bull-calves achieved more than 1.3 kg / day. During the third period (downward phase) the ADG decreases and reaches values even lower than the ADG of departure, showing that animals achieved their terminal phase of fattening and their growth is slows down.

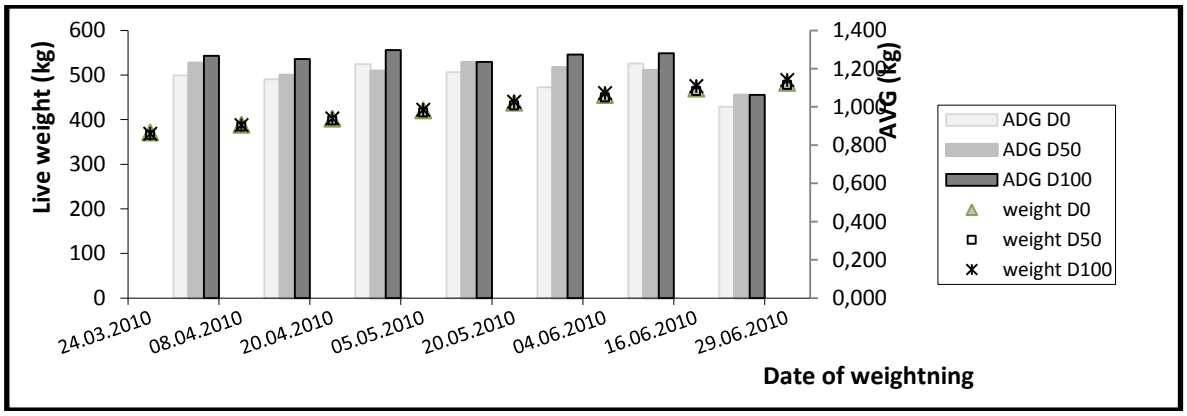

Figure 1: Evolution of live Weight (kg) and ADG (kg) depending on type of diets.

Conclusion

This trial shows that partial or total substitution of soybean by faba bean, doesn't affect the performance of bulls, even it leads to significant better performances marked specifically by a slight decrease in the consumption index and the elevation of Average Daily Gain. These parameters have a good economical interest for bulls' fattener, by reducing the feeding cost and then the cost of 1 kg of meat. Furthermore, the use of faba bean has reduced the feeding cost, particularly when the faba bean is autocultivated by fatteners and not bought from market. Even if the faba bean is bought from market, it leads to producing a concentrate cheaper than the ordinary one composed only of soybean meal.

Abstract

Nine 3-year-old male West Fine-tailedlocal sheep were used to evaluate the effects of the level of the extract as well as the substitution of the barley by the oat on performances of reproduction of Ram. Each animal received, during a first period of the experience, 1.5 kg of oat hay and 400 g of concentrate (A) to basis of barley (80%), of the soybean meal (17.5%) and of mineral and vitamin supplement (2%). Then, animals were divided in two homogeneous groups according to age, the live body weight and the volume of ejaculation. Rams of the two groups continued to receive the same ration of basis complemented with 700 g of the same concentrate to basis of barley (B) and 700 g of the concentrate in which the oat replaced the barley (C). The live body weight of animals increases with the level of the extract and the substitution (61.5; 61.8et 60 kg respectively for C, B and A groups) without any difference among treatments. Testicular size was greater ($P < 0.05$) for C than for B all two superior to A groups. The two applied food treatments, an improvement of ejaculate volume (0.5; 0.7 and 0.9 ml respectively for A, B and C), of the number of spermatozoa ($0.6*10^9 \pm 0.3$; $0.9*10^9 \pm 0.2$ and $1.1*10^9 \pm 0.4$spz respectively for A, B and C) but not of the concentration. The increase of the level of the extract and the utilization of the oat improve as meaningfully ($P = 0.0001$) mass motility (4±0.5; 4.2±0.4 and 4.6±0.2 respectively for A, B, C) and individual (3.6±0.5; 3.84±0.4 and 4.43±0.3 respectively for A, B, C). The diet doesn't affect the dead spermatozoa and the total anomalies.

Keywords: *Rams, food Level, Oat, substitution, Reproduction.*

Introduction

Sheep rearing plays an important role for the sustainability of environmental and farming systems in Tunisia. Sheep meat is very important in various regions of the country. It covers subsistence farming but also supplies the market with diverse reasons such as demographic, religious and socio-economic factors. Sheep meat production has increased considerably, from 45,200 to 50 000 tons between 2004 and 2011 (Givlait, 2011) West Fine-tailed Sheep specialized in meat production represents 35% of Tunisian sheep flock, adapted to extensive and semi-intensive livestock system. Coverage of the demand in sheep meat requires the intensification of production this can be done by increasing the weight of lambs and the decrease in age at slaughter or /and increase the number of products lambs. Accelerating the pace lambing (3 lambing / 2 years) to increase the number of products lams,this requires optimal sexual activity for both sexes. However, there are many studies on sheep reproduction but there are a few researches regarding the effect of diet on semen of ram. The purpose of this present study was to focus on the effects of the level of the extract and of the substitution of the barley by the oat on performances of reproduction of ram.

Materials and methods

The experiment was carried out in Tunisia at the experimental station of the Higher School of Agriculture of Kef, Tunisia (ESAK). The station has a semi-arid climate and is located 8 km south of the town of Kef 35°7 ’ N latitude. Nine adultQueue Fine de l’Ouest rams with an average initial body weight of 59.1±10.89 kg.The rams were housed in individual pens where fresh water was freely available.Experiment was conducted between February and June 2008. During the first trial period(February to April) each animal of group A received 1.5 kg of oat hay/ram/day and daily supplemented with 0.400 kg of concentrate containing 80% barley, 17.5% soybean and 2.5% a mineral and vitamin supplement. After in the second period, rams were allocated to two groups balanced for age, live weight and ejaculate volume. Rams in B group received the same diet as group A but the concentrate was increased to 0.700 Kg. Rams in C group were fed a diet composed of 1.5 kg of oat hay/ram/day and 0.700 Kg of concentrate containing 80% oat, 17.5% soy bean and 2.5% a mineral and vitamin supplement. Measurements of live weight and testicular size were performed every week, however volumes of sperm and semen traits were performed 4 times per week (Tuesday: 2 ejaculates, Friday 2 ejaculates) using an artificial vagina. All semen parameters were measured by the same person throughout the study. Immediately, concentration and sperm motility (0-5) were assessed subjectively using a phase-contrast microscope on a warm water bath (37°C)(Soyluet al., 2007).For the sperm morphology assessment, the percentage of abnormal sperm (detached heads, abnormal mid-pieces, or tail defects) was recorded by counting a total of 150 spermatozoa under phase contrast microscopy (×1000)

Results and discussion

Composition of diets

The chemical composition of different diets is documented in Table 1

Table 1. Chemical composition (%, DM basis)

Nutrient	**Concentrate**		**hay**
	berly	**Oat**	
Dry matter	87.7	88.1	87.1
Organicmatter	96.5	96.8	91.2
Crude fibre	8.9	12.4	45.3
Crudeprotein	12.6	14.3	4.5

The results of this analysis show that the hay is low in CP (4.5%) and rich in crude fibre (45.3%) confirming the results reported by several studies (Mahouachi and Khaldi, 1987).The CP and crude fibre concentrations in the diets containing oat were greater than diet containing berly.

Body weight

Fig.1 shows that the body weight of animals increased slightly in the first period from 59.1 ± 10.2 kg (W1) to 60.84 ± 9.9kg (W9). During the second period of the experiment, the body weight was increased. Three weeks after the change of diet, the live weight of rams is 61.82 ± 9.6 kg and 62.2 ± 9.9 kg for respectively B and C. At the 14th week the body weight decreased is probably due to shearing rams.

Fig1. Effect of the level and nature of the energy source in the concentrate on body weight changes.

As shown in Table 2, there was a tendency for BW to increase in C group in comparison to B group. However, this difference was not statistically significant between this to groups. But a statistical difference was observed between the group A and the two groups. So the level of energy in the diet affects the BW. However,BW was not affected by the nature of the energy in diet.

Table2. Effect of diets on body weight (BW), Mean (± SEM)

Group	BW
A	$60 \pm 10{,}2^{b}$
B	$61{,}8 \pm 10^{a}$
C	$61{,}5 \pm 9{,}9^{a}$

Means with different superscripts (a, b) within each column are significantly different (P<0.05).

Quantitative semen parameters

Two types of examination were performed: macroscopical and microscopical examination. The macroscopical examination included the measurement of the ejaculate volume, the color and smell of semen were assessed. (Table 3)

Table 3. Macroscopic examination of semen

	Semen volume (ml)	**Color**	**Consistency**	**Density**	**Smell**
A	0,5	White	creamy	dense	normal
B	0,7	White	creamy	dense	normal
C	0,9	White	creamy	dense	normal

As shown in Table 4, the testicular size increased for the group C (TSL: 4.8 ± 1.12 cm and TSR: 4.6±1.1 cm)compared with the group B (TSL: 4.1 ±0.47 cm and TSR: 3.9±0.52cm). There was a tendency for ejaculate volume to increase in C group in comparison to A and B groups (0.5±0.1; 0.7±0.2; 0.9±0.4 ml for respectively A, B and C rams).There were significant (P<0.05) differences between diets in both testicular size, ejaculate volume, sperm concentration and spermatozoa number (Mahouachi et al., 2011). These findings agree with those reported by Fernàndez et al. (2004). Although these results are inconsistent with those obtained byLassoued et al.(2013), Bielli et al. (1999) and Lindsay et al. (1984), who found no significant effect between improved pasture or high dietary protein on quantitative semen parameters.The nature of the energy in diet affects the testicular size but not the body weight. These results led to the conclusion that testicular size is more sensitive to changes in diet than body weight indicating a preferential allocation of nutrients to the reproductive system.

Table 4. Effect of regimes on testicular size (TS), ejaculate volume (EV), sperm concentration (SC) and spermatozoa number, mean (± SEM)

Experimental diets	TS (cm)		EV (ml)	SC($\times 10^9$/ml)	Spermatozoa Number
	Left	Right			
A	3.8 ± 0.86^a	3.5 ± 0.81^a	0.5 ± 0.1^a	$1.2\ 10^9\pm0.1^a$	$0.6*10^9\pm0.3^c$
B	4.1 ± 0.47^b	3.9 ± 0.52^b	0.7 ± 0.2^b	$1.2\ 10^9\pm0.08^a$	$0,9*10^9\pm0.2^b$
C	4.8 ± 1.12^c	4.6 ± 1.1^c	0.9 ± 0.4^c	$1.3\ 10^9\pm0.1^a$	$1.1*10^9\pm0.4^a$

Means with different superscripts (a, b, c) within each column are significantly different (P<0.05).

Qualitative semen parameters

Rams that received oat had the highest mass motility (4.6±0.2 for C, 4.2±0.4 for B and 4±0.5 for A) during the experiment (P < 0.05).Diet with oat affects more the mass motility as diet with barley. The highest effect on ram sperm individual motility was observed with the diet of oat(3.6±0.5; 3.84±0.4; 4.43±0.3 for respectively A, B and C rams). However, the results (Table 5) indicated that the diet significantly affected the individual motility (P<0.01).Results of our work confirm that oat affects sperm motility parameters. Oat is more energetic than barley. Mahouachi et al. (2011)reported similar findings.

Table 5. Effect of regimes on Mass Motility (MM) and Individual Motility (IM), Mean (± SEM)

Experimentaldiets	MM	MI
A	$4\pm0,5^a$	3.6 ± 0.5^a
B	4.2 ± 0.4^b	3.84 ± 0.4^b
C	4.6 ± 0.2^c	4.43 ± 0.3^c

Means with different superscripts (a, b, c) within each column are significantly different (P<0.05).

The data on dead spermatozoa and abnormal spermatozoa are presented in Table 6.Dead sperm was higher in A (15.25%) compared with B (13.59%) and C (9.32%).The percentage of abnormal spermatozoa decreased with the level of the extract and of the substitution of the barley by the oat. These data indicated that, the dead spermatozoa and the abnormal spermatozoa were not significantly affected (p<0.01) with the diet.Martin andWalkden-Brown (1995) and Zahid et al. (2003) observed that diet did not affect the semen quality.

Table 6. The percentage of dead sperm and total abnormality of ram spermatozoa

	% Dead spermatozoa	Tails		% abnormalhead	% detached head
		bent	coiled		
A	15.25	16.36	14.51	0.51	2.21
B	13.59	15.99	11.79	0.99	2.39
C	9.32	12.16	12.91	0.16	2.58

Conclusion

increase of feeding level and of the substitution of the barley by the oat improves the quantitative and qualitative characteristics of sperm of the ram of local breed.

In conclusion, these results suggest that the increase of feeding level and of the substitution of the barley by the oat improves the quantitative and qualitative characteristics of sperm of the ram of local breed. Nevertheless, the diet doesn't affect the dead spermatozoa and the total anomalies.

Abstract

Production and emissions of ammonia (NH_3), carbon dioxide (CO_2), methane (CH_4) and nitrous oxide (N_2O) gases and particle matter (PM) are a result of animal husbandry processes. These pollutants can have harmful effects on growth performance of animals and create uncomfortable conditions for people working in the production facilities. In addition, some of the gases from these facilities can impact the atmospheric environment due to their greenhouse effects. Consequently, determination and mitigation of harmful gases and PM emissions are of importance to both protecting the environment and animal and human health. Although a number of approaches are available to quantify these gases and PM, mobile lab system offers many unique advantages. In this paper, we describe the working principles and measurement system components of a Mobile Lab. Examples of monitoring the gases and PM in commercial animal production facilities with the system are also provided.

Keywords: *Mobile Lab, Greenhouse gases, Gas measuring system*

Introduction

Harmful gases and particle matter in animal feeding operations create uncomfortable situation affecting animals and people working in the facility. Moreover the gases in the barn have been one of the major environmental concerns because they are related to global climate change (Ni et al., 2008). These harmful gases that affect air quality are ammonia, carbon dioxide, methane, and nitrous oxide. Most certainly livestock production is blamed to bear the bulk of gaseous emissions in farming that impacts the environment (Schiefler, 2013). Both quantification and mitigation of aerial emissions from animal feeding operations continue to draw attention in animal industry, academia, and environmental regulatory agencies (Xin et al., 2009).

Mobile air emissions monitoring units (MAEMUs) are capable of precise and real-time measurements of concentrations and emissions and are being used typically for continuous and intensive monitoring of emissions from mechanically ventilated animal facilities (Ricardo et al., 2009). The Mobile Laboratory (Mobile Lab) Measurement System that uses photoacoustic multi-gas analyzers can be moved to any desired location and used on a multiple-site basis. Both longevity and availability of Mobile Lab for different agricultural structure types make this system very attractive. Photoacoustic multi-gas analyzers have been widely used by European scientists and U.S. scientists in air emission studies (Fergusun et al., 1998ab; Fenyvesi, et al., 2001; Nicks et al., 2003; Guarino et al., 2003; Li, 2006).

The objectives of this study were to: a) introduce an MAEMU for measuring harmful gases and PM of animal barns that was designed and developed at Iowa State University (ISU); and b) provide examples of the MAEMU application.

Materials and methods

Technical information about of MAEMU

The ISU MAEMU consists of the following components: 1) gas sampling system (GSS); 2) gas analyzer; 3) environmental sensors; 4) hosting computer; 5) data acquisition system; and 6) other peripheral devices and equipment. The measurements of gaseous and PM concentrations and emissions carried out by the system allow for periodic and simultaneous monitoring of a number of buildings. The gaseous concentrations are measured using the instrument called photoacoustic multi-gas analyzer (INNOVA Model 1412, Ballerup, Denmark), and PM concentrations are measured with tapered element oscillating microbalance (TEOM, Model 1400a) (Moody et al., 2008; Stinn, et al., 2013)

General information about the INNOVA-1412 photoacoustic multi-gas monitor

There are several areas of application for the INNOVA-1412 photoacoustic multi-gas monitor: 1) monitoring of greenhouse gases (GHGs) emissions that result from agricultural production processes; 2) measurements of indoor air quality; and 3) determination of building ventilation rate using a tracer gas. The photoacoustic multi-gas monitoring system INNOVA-1412 has proven to be both reliable and stable gas-monitoring system, providing highly accurate measurements (Figure 3). The INNOVA-1412 engages the photoacoustic infrared detection method for its measurement system. It has a capability of providing measurements for various levels of almost any gas that can absorb the infrared light. The optical filters are used to provide for gas selectivity where the INNOVA-1412 has up to five of these filters installed (Moody et al., 2008; Anonymous, 2014a). Figure 1 describes both the internal structure and the interconnection of the device. The interior pump designed to draw the air from the sampling point into the air filter, so it can flush out the "old" air in the measurement system, replaces it with the "new" air sample. The closure of both inlet and outlet valves allow for the "new" air sample to get tightly sealed in the analysis cell. The infrared light source emanates the light which reverberates from the mirror thereafter passing through the mechanical chopper. The chopper forces the light to pulsate and to go through one of the optical filters fixed on the filter wheel (Moody et al., 2008; Anonymous, 2014a).

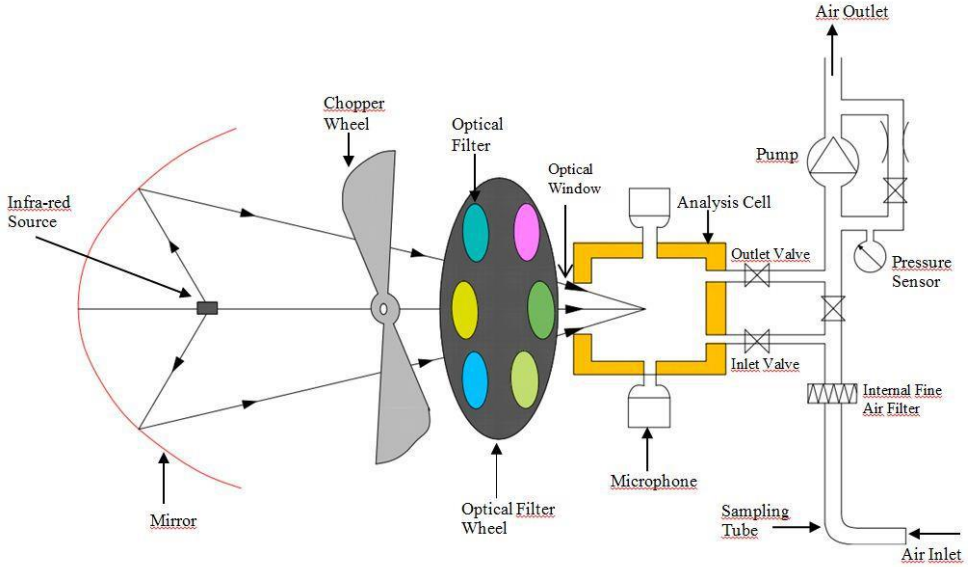

Figure 1. The schematic diagram and the internal structure of INNOVA-1412

General information on the “1400a” series monitor

Air pollution monitoring networks have widely adopted the ambient particulate monitor TEOM (series “1400a”) to be their first choice as it comes to continuous measuring of particulate mass concentrations. The “1400a” series monitor consists of two basic parts: 1) the sensor unit which has the sample inlet and the mass transducer, and 2) the control unit which

has the operator terminal and the box of control electronics. The two parts are connected together using the cable assembly. The “1400a” monitor is the instrument designed on the true gravimetry principle. The ambient air is drawn through the filter with a constant flow rate while the filter itself is being continuously weighed. The mass concentrations are calculated on a near real-time basis (Moody et al., 2008, Anonymous, 2014b).

The gas sampling system

Measurements of air emissions from the animal barn are carried out by the positive pressure gas sampling system that is a part of the MAEMU. The system uses individual pumps to draw sample air continuously from all the locations. If the sample air is not analyzed, it is being bypassed. A four-point gas sampling system is illustrated in Figure 2. The air delivered from the sampling locations via the solenoid valves and into the manifold M1 with the assistance of vacuum pumps P1-P4, then transported to another manifold M2 that is connected to the INNOVA-1412. All wetted parts of the sampling system use either Teflon or Teflon-coating (including the pumps, the solenoid valves, the manifold, and the air tubing). In order to allow measurements of the gas concentrations when automatic gas sampling system is used in each location, both data acquisition system (DAQ) and control unit are used to control the four pairs of the two-way solenoid valves S1-S8 as the process takes place. In order to draw air continuously from each of the sampling locations and avoid potential cross-contamination among the sample locations, individual supply pumps with 16 L/min delivering capacities are used (Moody et al., 2008; Burns et al., 2009).

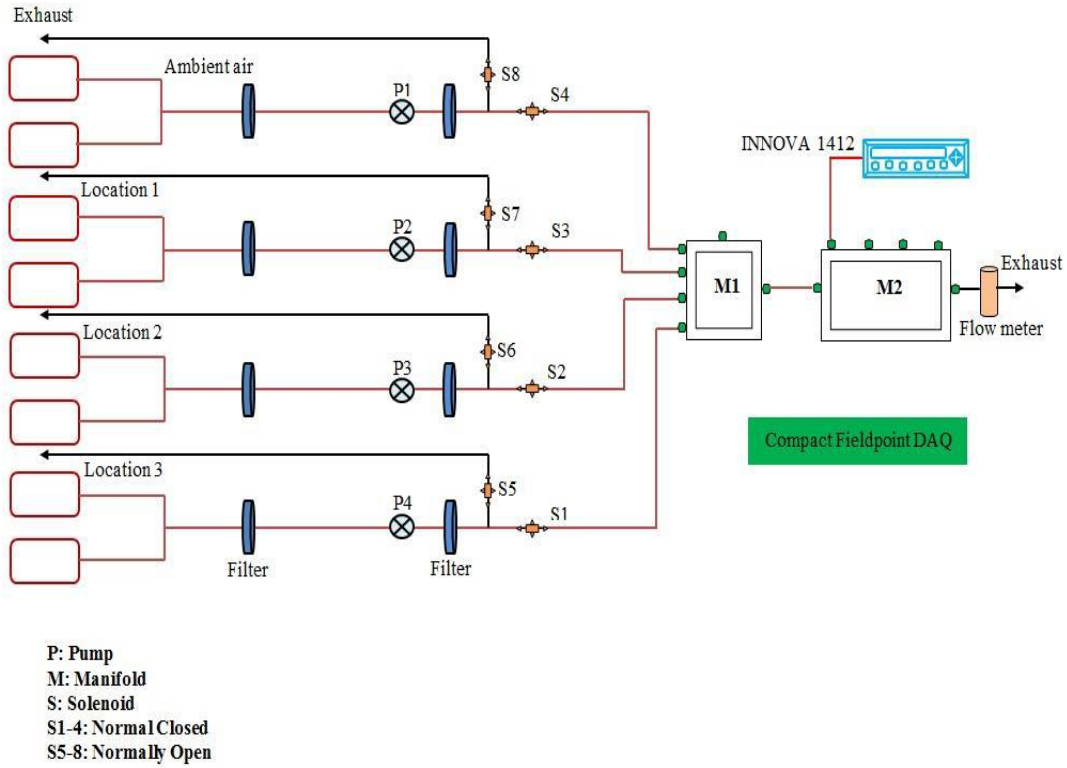

Figure 2. Schematic representation of the positive-pressure gas sampling system used in the MAEMU for measurement of animal barn air emissions.

Sampling of environment conditions

Indoor and ambient relative humidity (RH) is monitored with the electronic RH transmitters, while air temperatures at the air sampling locations and outdoors are monitored with the type T thermocouples. The Temperature and RH sensors are connected to the Compact Field Point modules (National Instruments, Austin, TX) and the PC-based DAQ that is run by LabVIEW 7 program. The program developed by the ISU research team allows for automated sampling location control and display of the real-time data (Moody et al., 2008; Burns et al., 2009).

Results and discussion

The MAEMUs have been successfully used for AFO air emissions research at Iowa State University. Gaseous concentrations (NH_3, CO_2, and CH_4) were quasi-continuously monitored using the fast-response stable H_2O-compensated photoacoustic multi-gas analyzer (INNOVA Model 1412, Ballerup, Denmark). PM_{10} and $PM_{2.5}$ concentrations were measured with the TEOM 1400a units. Specifically the following field studies have been conducted using the MAEMU system.

Li et al, (2011a) carried out a study to determine particulate matter concentration and emissions at a high-rise layer house in Iowa. Two TEOM PM monitors were used in this study to evaluate particular matter concentration. One TEOM monitor measured PM10 concentration, while the other measured PM 2.5 concentration. They determined particular matter concentration ranged from 90 to 1387 μg m^{-3} and from 11 to 168 mg m^{-3} for PM10 and PM2.5 respectively.

Li et al (2011b) have been continuously monitored NH3, PM10, and PM2.5 emissions in turkey barn by using the state-of-the-art mobile air emissions monitoring units (MAEMUs). Average daily NH3, PM10, and PM2.5 concentrations in the tom turkey barn were 8.6 ppm, 1104 g m^{-3}, and 143 g m^{-3}, respectively.

Li et al (2012) have applied three different diets to laying-hen (EcoCall, DGGS and Control diet) to reduce ammonia levels. Also, The MAEMU used to continuously collect data on NH_3,-H_2S, and carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O) emissions from the three laying-hen houses. The EcoCal and DDGS diets led to an overall NH_3 emissions reduction of 39.2% and 14.3%, respectively, relative to the control diet.

Hayes et al (2013) were determined daily concentrations and emission rates of ammonia; the greenhouse gases and particulate matter in aviary houses. They found daily indoor NH_3, CO_2, CH_4, PM10, and PM2.5 concentrations as 8.7 ppm, 1,636 ppm, 10.0 ppm, 2.3 mg m^{-3}, and 0.25 mg m^{-3}, respectively. A fast-response, high-precision infrared (IR) photoacoustic multigas analyzer and real-time tapered element oscillating microbalances (TEOM) equipped were used on determining daily concentration and emission of gases and particular matter respectively.

Stinn et al (2013) used the MAEMU to continuously collect data on gaseous concentrations, thermal conditions, and operational status of the ventilation fans from the barns and farrowing rooms. The NH_3, CO_2, CH_4, and N_2O concentrations of the breeding/gestation barns found 9.7 ppm, 1536 ppm, 78.3 ppm, and 0.30 ppm respectively. Also, farm-level emission rates of NH_3, CO_2, CH_4, and N_2O gases found 38.5, 8731, 301 and 0.24 g AU^{-1} d^{-1}, respectively.

Zhao et al (2015) used the MAEMU to determine the concentrations of NH_3, CO_2, CH_4, N_2O, and dew-point temperature in three commercial laying hen houses (CC, EC and AV). The highest level of ammonia concentration was found in the AV house.

Shepperd et al (2015) monitored gaseous and particulate matter emissions from three commercial laying hen houses (CC, EC, and AV) and their respective manure storage data of gaseous concentrations. The gas concentrations of NH_3, CO_2, CH_4, NO_2, and dew-point temperature (DP) were measured with a photoacoustic multigas analyzer, for particulate matter concentrations tapered element oscillating microbalances was used. . The highest ammonia and particular matter emission were found in the AV laying hen house.

Acevedo et al. (2009) reported that the MAEMUs are capable of real-time measurements of emissions precisely and they are being used typically for continuous monitoring of emissions from mechanically ventilated animal facilities. Xin et al. (2009) measured GHG and PM emissions using MAEMU from two commercial broiler houses in western Kentucky, USA. Schiefler (2013) used the Innova model 1412 multi-gas analyzer to measure GHG and ammonia emissions from dairy barns.

Accurate ventilation rate data are essential to calculate gas emission measurements from any animal barn. To be able to calculate reliable and real emission values, fans should be controlled when they in service as well as performance values should be considered. Because, emission rates are obtained as the product of two measurements: gas concentration difference between discharge air and ambient air, and ventilation rate (Gates et al., 2004; Li et al; 2009).

Conclusions

Mobile Lab measurement system can be used in different agricultural structures and multiple barns to evaluate gas emissions simultaneously. Although the initial investment costs are rather high, considering environmental impacts as well as employees' health, these systems offer numerous advantages. Moreover, the Mobile Lab Measurement System can be moved to any desired location and used on a recurring basis. Both exploitation period and adaptability of Mobile Lab for different types of agricultural structures make that system quite attractive for studies of gas emissions.

Abstract

Greenhouse cultivation is carried out in two periods during spring and autumn at the Adana region for the tomato plant. At the end of these two periods; the number of heating days was determined to be greater for autumn cultivation, whereas the number of cooling days was determined to be greater for spring cultivation. It is possible to gain some knowledge beforehand regarding the energy consumption of the agricultural structure to be built in the region via the heating and cooling degree days method. When the number of ideal days acquired using the long term meteorological data of the study area is examined, it was determined that the ideal temperature values were obtained for only one day during harvesting period in spring cultivation and for only one day during ripening in autumn cultivation. It was concluded as a result of the study that heating or cooling system will be needed in the greenhouse environment for spring and autumn cultivation of tomato plant.

Keywords: *Adana, Cooling degree day, Heating degree day, Greenhouses, Tomato plant*

Introduction

Greenhouses in which cultivation is carried out by keeping the atmospheric conditions under control are agricultural structures in which plant cultivation can be carried out all year round. The objective in greenhouse cultivation is to attain the highest economic efficiency for cases when the optimum environmental conditions and cultivation environment required for the growth and development of the plants are provided in case external environmental conditions are not suited for cultivation. In other words; greenhouses are controlled cultivation environments which provide the proper climate conditions at an optimum level during the growth period of the plants. It is possible to provide the temperature values suited for the plants during cold days and nights by heating the greenhouses and similarly by cooling the greenhouses during hot days and nights (Yuksel and Yuksel, 2012).

The number of businesses that carry out greenhouse cultivation at the city of Adana and its districts is lower in comparison with Mersin and Antalya. Farm cultivation is carried out more at Adana where cultivation in low tunnels is also carried out. Greenhouses with glass and plastic covers can be found more at the coastal areas of Karatas and Yumurtalik districts. In our country, the city of Adana ranks second after Antalya in terms of greenhouse (low tunnel) area size (TUIK, 2015).

The hardness of a climate can be examined sensitively in units of degree-day. Different climate conditions in different regions may have significant effects on heating or cooling energy demand. Degree-day numbers are used all over the world especially for heating, cooling and cultivation to determine degree-day regions that are different than geographical regions (Lstiburek, 2001; Sahal, 2006; Bulut et al., 2007).

The objective of this study was to determine the number of heating and cooling days using the degree-day method and long term meteorological data for the Adana region where spring and autumn cultivation is carried out for tomato plant.

Materials and Methods

The daily temperature data spanning a period of 55 years for the city of Adana was selected as material for this study. Greenhouse cultivation is carried out in two seasons in the city of Adana: spring and autumn. Therefore, long term temperature data were handled separately for periods when spring and autumn cultivation is carried out. The temperature values suggested for the tomato plant during the cultivation period were evaluated according to Seniz (1992).

Degree-Day (DD) Method**:** In general, a degree-day value is stated as a temperature that is added to the ambient temperature. These values are determined based on the quantity and duration of temperature and according to whether the selected equilibrium temperature is lower or higher than the ambient temperature (Matzarakis and Balafoutis, 2004).

Heating Degree-Day (HDD) Method**:** The temperature difference when daily average external temperature decreases below the equilibrium temperature selected for the greenhouse is expressed as a Heating Degree-Day (HDD) (Satman and Yalcinkaya, 1999).

$$\text{For } (T_O < T_b),\ HDD = \sum_{i=1}^{n} (T_b - T_O) \quad (1)$$

Here; HDD is the cumulative sum of the heating degree-days for n days, n is the total number of days in the period, T_b is the greenhouse equilibrium temperature suggested for the tomato plant and T_o is the average external temperature (Gultekin, 1995; Yucel et al., 2014).

Cooling Degree-Day (CDD) Method**:** Cooling degree-day (CDD) values are mathematically defined as the difference between the external temperature value and the equilibrium valueand are defined as the equilibrium temperatures above the external temperature values (Krese et al., 2012; Yucel et al., 2014).

$$\text{For } (T_O > T_b),\ CDD = \sum_{I}^{n} (T_O - T_b) \quad (2)$$

Here; CDD is the cumulative sum of the cooling degree-days for n days, n is the total number of days in the period, T_b is the greenhouse equilibrium temperature suggested for the tomato plant according to Seniz (1992) and T_o is the average external temperature.

Heating Degree-Day Value (HDDV) Method: Heating degree-day values are defined as the difference between the equilibrium temperature and air temperature for each day. Many methods and approaches have been given in literature for the calculation of degree day values (Baskerville and Emin, 1969; Floyd and Braddock, 1984; Yang et al., 1995; McMaster and Wilhelm, 1997; Martinaitis, 1998, Matzarakis and Balafoutis, 2004). HDDVs have been calculated using the equation 3 given below (Buyukalaca et al., 2001; Yucel et al., 2014).

$$HDDV = \sum_{i=1}^{n} HDD \quad (3)$$

Here; n is the total number of days which were HDD during the selected period

Cooling Degree-Day Value (CDDV) Method**:** In this method developed similar to HDDV values, the number of days during the cultivation period in which the average external temperature values for the Cooling Degree-Days were higher than the equilibrium temperature values suggested for the examined tomato plants have been calculated via equation 4 given below (Buyukalaca et al., 2001; Yucel et al., 2014).

$$CDDV = \sum_{i=1}^{n} CDD \quad (4)$$

Here; n is the total number of days in the selected period which were CDD.

Results and discussion

Daily average temperature values between 01.01.1960 and 31.12.2014 along with the equilibrium temperature values suggested for the tomato plant were used to calculate the

number of heating and cooling days for each cultivation period. The temperature data between the start and end dates for both periods were examined according to the cultivation periods of the tomato plant.

Spring cultivation

Spring cultivation in the region starts in the first week of January and the harvest period continues until the end of June. The plantation period of the seedlings covers a period of one week. When the temperature values on these dates are examined, the number of heating days in the greenhouse for tomato plant was determined as (7 days) for both the suggested temperature values (12-22 ^{o}C) and the average temperature value (17^{o}C) (Table1).

Table 1. Heating and cooling day values during the sowing and plantation period of spring cultivation

Numbers of flowering, pollination and fertilization period heating and cooling days were given in Table 2. It was determined that this is a period of two weeks and all of the examined days were determined as number of heating days.

Table 2. Heating and cooling day values during the flowering and pollination period of spring cultivation

Mean	18	14	0	0	14
	19	14	0	0	14
	20	14	0	0	14

When the next stage of spring cultivation which is the fruit set period is examined, it was observed that this period covers a period of one month (Table 3). It was determined that the number of cooling days increased with increasing ambient temperature values during this period. Still, it was determined that the number of heating days increased for values above 19 ^{o}C during this period when the temperature demand is high.

When the data for the final period of spring cultivation, harvesting period are examined, it was observed that the period covers a period of 2 months (Table 4). It was determined that the number of cooling days during this time period increased along with the increase of the temperature demand of tomato plant. It was determined that the number of cooling days was 6 at the average temperature value.

Autumn Cultivation

Autumn cultivation starts on the third week of August and continues until the 3rd week of January. When the temperature values during this period are examined, it was observed that the number of cooling days was 7 for the 1 week period at both the suggested temperature values (12-22 ^{o}C) and the average temperature value (17 ^{o}C) during the plantation period (Table5).

Table 5. Heating and cooling day values during the sowing and plantation period of autumn cultivation

It was determined at the end of the study that the numbers of heating and cooling days for tomato plant cultivation periods met the ideal temperature values for 1 day during the harvest period in spring cultivation and for one day during the fruit set period in autumn cultivation.
The cultivation dates suggested for the tomato plant during the Spring and Autumn period were evaluated according to Anonymous (2002).

Conclusion

Greenhouse cultivation is carried out in two seasons, spring and autumn, for tomato plant in the Adana region. At the end of these two cultivation periods; it was determined that the number of heating days were greater for autumn cultivation, whereas the number of cooling days were greater for spring cultivation. Knowing the sum of the numbers of heating or cooling days is important for calculating the energy requirement (Ulupınar et al., 2012; Yucel et al., 2014). It was determined as a result of this study that energy requirement related with cooling is greater for spring cultivation and that the energy requirement related with heating is greater for autumn cultivation periods.

Abstract

Manure that is not properly managed and is stored in open stacks outside causes odor pollution, visual pollution and water pollution. Problems caused by animal manure from livestock building were determined and necessary explanations were made about utilization of animal manure. Manure should be either stored under proper conditions or properly managed in order to prevent such problems.

The study material was selected as livestock enterprises with ongoing production close to the coastal regions of Seyhan and Ceyhan Rivers. About 20000 cattle are bred in the cattle breeding enterprises in the region. However, 8046 are bred for commercial purposes. The management of animal manure from livestock depending on the capacity of current animal breeding enterprises was made. It was concluded that animal manure which is the output of animal breeding enterprises will result in environmental pollution, water resource pollution as well as posing a threat to life in general by mixing with water resources such as underground water, rivers etc. In addition, the needed precautions for the purpose waste materials not causing environmental pollution.

Key words: *Livestock, Manure management, Seyhan and Ceyhan River*

Introduction

The characteristics of manures obtained from barns differ significantly among farms. The age of the animal, its gender, species, ration, production method and other factors might be shown as factors that affect the characteristics of manure (Anonymous, 2003). Animal based can act as a good plant nutrient if it is managed properly and is applied in a responsible manner (Harris et.al., 2001; Cayley et.al., 2004). However, excessive use of commercial and animal based manure creates serious pollution in addition to potential sources of pollution (Atilgan et al., 2006).

Animal based manure produced in stock breeding enterprises cannot be used very efficiently due to improper storage conditions. Producers that use animal manure do not know how to use it properly and spread the manure on the field in a random manner. The reasons why the necessary importance is not given to animal based manure are that commercial manure is much easier to use and to find. Turkey has an important place among the countries of the region with regard to agriculture and stock breeding. Since the geography and climate conditions of the country are suited to produce agricultural products, it is one of the few countries that meet their own food product demand via agricultural production (Cayir et al., 2012)

The use of farm manure in a benighted manner that does not comply with the relevant technical methods decreases the effectiveness of farm manure in agricultural production. Significant amount of nutrients are lost because insufficient amount of farm manure is left to wait under inconvenient conditions or due to improper application of manure thus resulting in inefficient usage of farm manure in terms of soil efficiency and agricultural productivity

(Boyaci et al., 2011). Pollution sources at stock breeding enterprises are not point source pollution sources such as industrial and urban pollution sources. The fact that they are spread over wider areas makes it more difficult to know the dimensions of water pollution caused by these sources. Manures and animal based wastes that are identified as non-point pollution sources reach surface waters or ground waters thus disrupting the quality of water resources and rendering them unusable (Ozek, 1994; Ongley, 1996; Cayir et al., 2012).
The objective of this study was to determine the probable negative effects of animal manure at stockbreeding animal barns along the Ceyhan and Seyhan Rivers that continue their agricultural activities on the environment and especially on water resources thus attracting attention to this issue.

Materials and Methods

The study was carried out in 2015 t at the region encompassing the area where the Seyhan and Ceyhan rivers flowing to the Mediterranean are located in. This area is known in short as the Seyhan or Ceyhan Basin. Seyhan River is one of the rivers in Turkey that flows to the Mediterranean. It has a length of 560 km and a basin area of 20.600 km². The Ceyhan river is 509 km long with a basin area of 21.222 km^2 (Anonymous, 2015). Even though stockbreeding activities are carried out extensively around the study area, the livestock establishments in the villages of the region closest to the river were taken into account since it was thought that their environmental effects would be greatest. To this end, 3 cities (Adana, Osmaniye and K.Maras) and 64 villages were selected for the Ceyhan River. Whereas 37 village centers located in the city of Adana were selected for the Seyhan River. According to the information acquired from the Adana Provincial Directorate of Agriculture; the number of cattle reared at agricultural establishments along the Seyhan River is 3550, the number of cattle reared at agricultural establishments along the Ceyhan River is 4496 for a total number of 8046 commercially reared cattle. The locations of the establishments were determined via Google satellite map and relevant marking was made.

Results and Discussion

The manure that is generated at animal establishments can be an additional source of income for the establishment if it is evaluated in a suitable and controlled manner. On the contrary, manure that is not stored properly and that is left out in the open may suddenly become harmful for the environment. The manure at animal establishments has to be stored properly so that such negativities do not occur.
Animal rearing is still a popular agricultural sector at the study area. Some of the wastes that occur as a result of animal rearing activities is used as natural manure in agriculture; whereas the remaining is stored improperly at open warehouses and/or is dumped to the nearest farmland. Thus, total nitrate and total phosphor loads are generated due to animal manure which is evaluated as animal based waste; which means in other words that they become significant pollutants for the Seyhan and Ceyhan rivers.
The nitrogen and phosphor loads that are diffused to the environment when animal based wastes are used as natural manure vary significantly with regard to animal category, type, feeding habits, weights and fertilizing properties. Thus, it is very difficult to determine the unit loads. However, controlled agriculture activities should be carried out first at the villages around the rivers and the settlement areas which are affected from the creeks that feed the rivers in order to minimize the environmental effects due to manure at the Seyhan and Basins. In addition, manure and agricultural pests used in agricultural activities, all kinds of uncontrolled animal rearing activities, leakage waters that occur as a result of uncontrolled storage of manure are factors that should be taken into account seriously in order to determine the future of the basin.

The satellite images of cattle rearing establishments that continue their activities around the Seyhan River are shown in Figure 1.

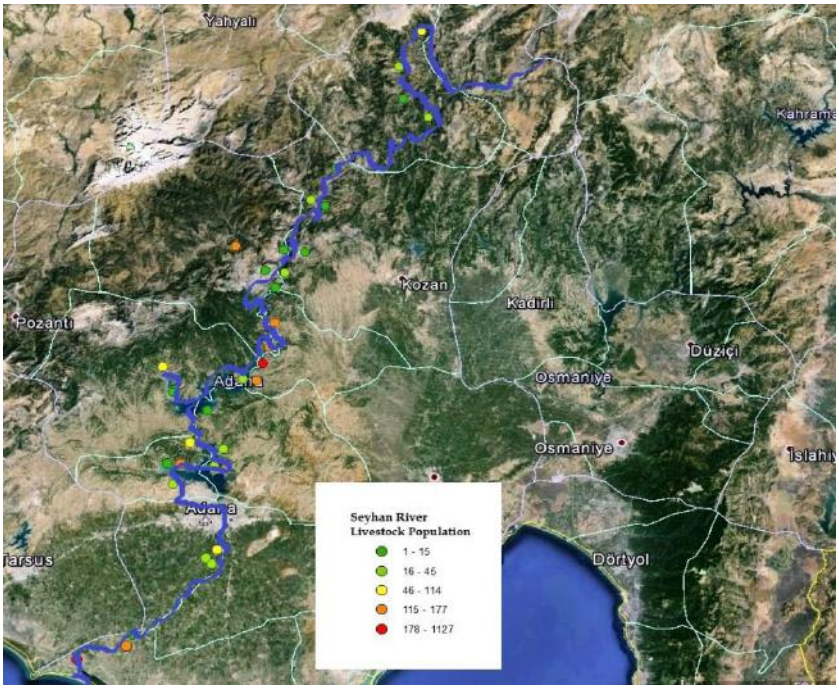

Figure 1. Distribution of animal establishments around the Seyhan River region

When the distribution of the cattle rearing establishments in the region is examined, it was observed that an intensive animal rearing activity is carried out along the river. It is understood from the satellite images of various animal establishments in the region that their locations are close to water sources and that the animal manure that is formed requires a process that is suited to water resources. When the animal manure in these establishments are accumulated in random piles, they create environmental pollution, visual pollution as well as odor pollution while creating potential pollution sources for water sources as well. Because researchers have put forth that the manure piles that are accumulated in the open should be at least 100 meters away from the nearest river, creek and drainage channels. (Mutlu, 1999; Cayley et al., 2004). Care should also be shown for the storage of manure in animal establishments as well as for mixing it with the soil for use in plant cultivation. It should not be forgotten that if the required care is not shown, ground and surface water sources might be polluted in addition to odor and visual pollution, that greenhouse effect might occur due to the gases that are discharged to the atmosphere and that the inorganic nutrient substances in plants (N, P, K) will be washed away with the rains and mix with the lower layers of the soil (Erkan, 2005).

A total of 4496 cattle are reared in the establishments that are currently active around the Ceyhan River. The satellite image of these establishments is shown in Figure 2.

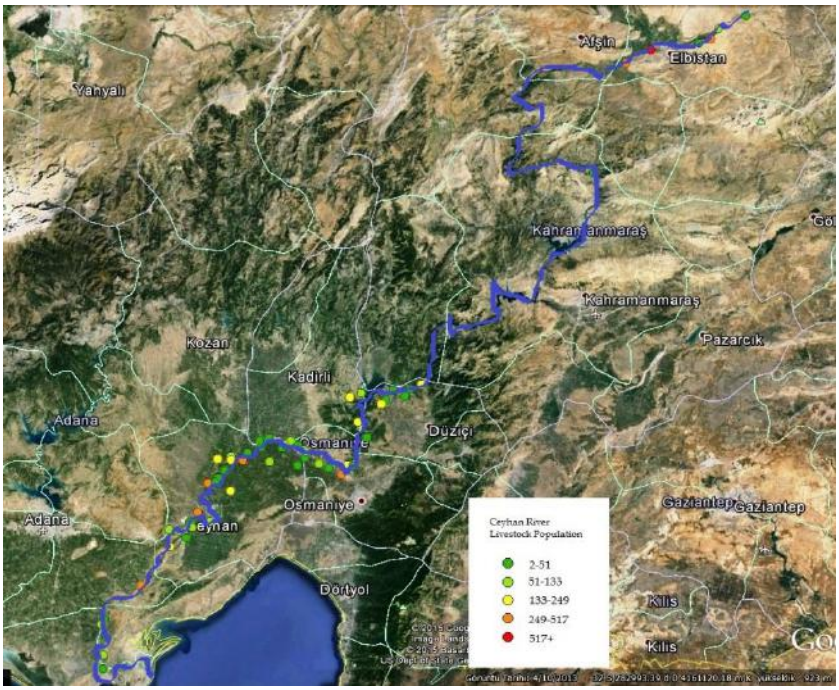

Figure 2. Distribution of the animal rearing establishments in the Ceyhan River region

The mixing of animal wastes to water sources during manure management decreases water quality thus resulting in the death of aquatic living things. The ammonia, pathogens as well as other organic substances with high biological oxygen value result in the contamination of water. The pollution of water might be due to various reasons. The discharge of manure directly to a river, leakage from storage tank or manure storehouses as well as the drainage of wastes to the soil play important parts in the contamination of ground and surface waters (Olgun, 2011).

The main source of river pollution is leakage from sewage as well as from food residues and manure from agricultural areas. The manure and pesticides used in agricultural areas as well as liquid animal manure, other animal residue and wastes cause significant increase in nitrogen and phosphor concentration when mixed with rivers (Gokmen, 2007).

The most important factor that has negative effects on the oxygen balance in the rivers is the consumption of oxygen during the biochemical decomposition of organic substances and nitrous compounds. Even though soluble oxygen is widely found in rivers, a slight decrease in its level may have harmful effects on the living things in rivers. The color and odor of the water changes as a result of river pollution, the plants and animals that live in the water die, microorganisms reproduce, people and animals that make use of these waters get sick or they might be affected dramatically (Gökmen, 2007). We should consume and protect our natural sources in a conscious manner since it takes many years for them to form.

Conclusions

Previous studies put forth that manure storage habits are limited with random storage. This and other similar studies indicate that improperly stored animal manure creates potential pollution sources for our water sources and results in factors that threaten the lives of living things in the environment. However, the precautions that need to be taken have been clearly specified in the relevant literature. It is difficult to state that animal establishments take into account these warnings. Similar results have been obtained from similar studies. It is clear that these studies carried out to protect our environment or to ensure that the manure is properly managed should not be limited only to scientific environments. The precautions to be

taken should be frequently mentioned in the printed press thus becoming accessible for our manufacturers. It was observed that only in this way the results can be effective and that otherwise these efforts will not mean much for the protection of the environment and the water sources.

EFFECTS OF COLD AND HEAT STRESS ON EGG QUALITY TRAITS OF A NEWLY IMPROVED HYBRID LAYER

İsmail DURMUS[1], Serdar KAMANLI[2]

[1]Ordu University Faculty of Agriculture Department of Animal Science-52000/ORDU, Turkey
[2]Poultry Research Station-06172 Yenimahalle- Ankara/TURKEY

Abstract

ATAK-S is a newly developed hybrid layer. Although the laying performance of this hybrid has been studied and determined, the performance response of the hybrid to different environmental temperature conditions is not known. This study was therefore undertaken to determine the effects of cold and heat stress on egg quality traits. Three hundred and sixty hens were divided into three temperature groups; control (20 ^{0}C), low (12 ^{0}C) and high (32 ^{0}C) in the study. All the hens were held in three tier battery cages in an environmentally controlled research poultry house. The study lasted for 3 weeks. No differences were found between different groups in terms of shape index, albumen height and Haugh unit of the egg quality traits ($P>0.05$). Egg shell breaking strength, egg weight, shell thickness and yolk colour differed significantly between the temperature groups ($P<0.05$) and, the values of these traits decreased under the heat stress conditions, whereas were not affected from the cold stress.

Keywords: *Layer, cold stress, heat stress, egg quality*

Introduction

Since mammals and bird species are warm-blooded animals, they have the ability to sustain their body temperature through heat loss or generation. Normally, the body temperature of hens is around 39.4-40 ^{0}C. They will not be able to continue their normal performance during periods when body temperature is elevated. The thermoneutral zone, which is around 18-23.9 ^{0}C for adult laying hens and 26-27 ^{0}C for adult broilers, is crucial for metabolic and productive activity in hens. Energy is efficiently used for growth, immune system and reproductive activities within thermoneutral zone. On the other hand, hens use a large part of their energy for heat production or loss to control body temperature outside thermoneutral zone. In such cases, the efficiency of feed utilisation decreases (Czaricik and Fairchild, 2008).
Heat stress in laying hens has a negative influence on egg efficiency, egg weight and egg quality traits (Ahvar *et al.,* 1982; Daniel and Bolnave, 1979; Deaton, 1983; Feizi *et al*., 2012; Gill and Ganwar, 1984; Moshaly *et al.*, 2004; Rozenboim *et al.,* 2007). It is reported that there is a variation among lines in terms of tolerance to heat stress and that it is necessary to evaluate genetic differences with regard to the response against heat stress (Felver *et al*., 2012).
Many studies have been carried out to decrease the effects of heat stress on production traits. Dai*et al.* (2009) reported that egg production and feed consumption gradually decreased when the drinking water of hens under heat stress was added with NaCl by 0.2 or 0.4% during the study. The egg production rate decreased in the control group with no supplementation. However the production traits returned to normal levels after the stress period. Another study reported that feed efficiency, egg production and Haugh unit values increased by adding vitaminE to the feeds of hens under stress (Ehran and Bolukbasi, 2011). On the other hand, Yardibi and Turkay (2008) pointed out that adding vitamin E in different dosages to the diet had no positive effect on egg production.

The addition of y-aminobutyric acid (Hui*et al*., 2010), aspirin (ZiaoTing and YouMing, 2002) and betain (Ryu*et al.,* 2002) has been reported to increase or improve performance or egg quality traits such as albumen height, Haugh unit, egg production, feed efficiency, shell weight and shell thickness or egg shell breaking strength during heat stress period.

ATAK-S, which is a newly improved commercial layer, has been developed by crossbreeding of Rhode Island Red and Barred Rock (Durmus *et al.,* 2009). Comparative studies have been undertaken to determine the laying performance of this hybrid. Hens of this hybrid have reached to sexual maturity at an age of 138 days with 1.83 kg of weight on average. Total egg production for 72 weeks has been reported as 312.8 with an average egg weight of 64.1 g. ATAK-S have a high viability rate, which is about 95.9 % (Durmus *et al.,* 2009).

On the other hand, the production response of this hybrid under different temperature conditions (heat or cold stress) has not been studied. The aim of this study was to investigate the production response of ATAK-S hybrid to heat or cold stress conditions.

Material and Methods

This study used 360 ATAK-S commercial laying hens, which were located at the Poultry Research Station. Feeds fed to the hens throughout the study are presented with their chemical compositions in Table 1.

Table 1. Compositions of diet

Ingredients	**0-3 weeks**	**4-10 weeks**	**11-16 weeks**	**17-30 weeks**

The study was carried out in three environmentally controlled poultry houses. Each house had a 3-tier battery type cage system with a capacity of 120 hens. The temperature was set automatically to 20±2 ^{0}C in the control group, 12±2 ^{0}C in the low temperature group and 32±2 ^{0}C in the high temperature group. The relative humidity was set at 40% and ventilation was provided as 6.5 m^3 per hour air circulation per kg of live weight. Chicks were transferred

to the poultry house following 16 weeks of rearing in the rearing houses to which a 10 h of environmentally controlled illumination was provided daily. The chicks were randomly distributed to cage tiers. One pullet was placed to each cage (29x43x51 cm in dimension). Illumination period was kept at 10 h per day until the pullet reached 18 weeks of age; afterwards it was increased by an hour a week and fixed at 16 h. Compact fluorescent lamps for illumination were placed with a distance of 120 cm from the cage on the middle tier in the manner to provide 4watt/m^2 of light intensity. Feeds were given *ad libitum* to the animals. Hens were subjected to heat stress for a period of 3 weeks after reaching 27 weeks of age. In the last two days of heat stress, quality traits given below were determined on a total of 540 eggs, with 180 eggs from each group.

-*Egg weight***:** Weight of each egg was weighed by a scale with a sensitivity of 0.01g,
-*Shape Index:* By means of shape index measurement instrument developed by Rauch,
-*Egg Shell Breaking Strength***:** By means of shell breaking strength instrument (Newton/cm^2),
-*Yolk Colour***:** In Roche scale value determined by digital yolk colour measurement instrument,
-*Shell Thickness***:** In mm, by means of micrometre,
-*Albumen Height:* Determined by tripod micrometre,
-*Haugh Unit:* Calculated by the use of egg weight and albumen height,
Haugh Unit = 100 Log (H+7.57 – 1.7 $G^{0.37}$*)*
H: Albumen height (mm)
G: Egg weight (g)
***Statistical Analysis*:** The data obtained from the study were evaluated by using Minitab 16 Package Statistics Program. Analysis of variance was conducted with the intention of determining whether the differences between groups were essential, Tukey multiple comparison method was used to determine the differences between group means.

Results and Discussion

Egg quality traits under cold and heat stress conditions of the present study are presented in Table 2. No differences were found between the temperature groups for shape index, albumen height and Haugh unit of the egg quality traits in the study (P>0.05). However, shell breaking strength, egg weight, shell thickness and yolk colour differed between the temperature groups (P<0.05).

Table 2. Egg quality traits

Egg quality traits	Heat groups		
	Control (20±2 ^{0}C)	Low (12±2 ^{0}C)	High (32±2 ^{0}C)
Shape index	78.244±0.181	77.900±0.214	77.278±0.850
Haugh unit	79.326±0.616	80.852±0.590	80.999±0.735
Albumen height (mm)	6.343±0.081	6.508±0.079	6.446±0.094
Shell breaking strength (N)	43.372±0.596^a	44.856±0.497^a	41.584±0.534^b
Shell thickness (mm)	0.337±0.002^a	0.335±0.002^a	0.323±0.002^b
Egg weight (g)	59.990±0.330^a	59.874±0.307^a	58.226±0.311^b
Yolk colour	11.278±0.050^a	11.400±0.069^a	10.804±0.078^b

Within columns, means followed by different letters are significantly different at $P = 0.05$; n=180; ± expresses the standard error

Egg shape index, Haugh unit and albumen height of the eggs did not change during 3 weeks of heat or cold stress in the present study (Table 2). These findings are not consistent with the results of Ahvar *et al.* (1982), Deaton, (1983), Gill and Gangwar, (1984), who found that

albumen height and Haugh unit decreased when hens were kept under the heat stress conditions. The difference between this study and other studies can be explained by the length of stress period, which might not be long enough to observe the negative effects of temperature stress especially at high temperature (32 ^{0}C).

Shell breaking strength, shell thickness, egg weight and yolk colour did not differ in hens under cold stress but substantially decreased under heat stress. Lack of difference between the hens in the control group and in the cold stress can be explained by the ability of hens to balance their body temperature through obtaining additional feed during cold environmental conditions. This probably did not cause a serious problem for the metabolic and productive activities of birds (Czaricik and Fairchild, 2008). However a limitation in the provision of feed to the hens under cold environments can likely result in effects, which are similar to those observed under heat stress conditions. The findings of hens under heat stress are consistent with those of Ahvar*et al.* (1982), Daniel and Bolnave, (1979), Deaton, (1983), Gill and Ganwar, (1984), Patterson, (2004) and Rozenboim *et al*. (2007), but contradict with the findings of Dai *et al.* (2009), which indicated that heat stress did not influence egg weight, shell thickness, shell breaking strength and yolk colour.

Conclusion

Heat stress decreased egg quality traits in ATAK-S layers, which would have a negative effect on both producers and consumers. In order to prevent such losses, the construction and management of poultry houses for ATAK-S layers, especially in regions with warm climate should carefully be planned and anti-stress measures should be taken.

A STUDY ON THE PRESENT DISEASE SITUATION OF THE CULTURED RAINBOW TROUT (ONCORHYNCHUS MYKISS, W.) IN TURKEY

Jale KORUN

Akdeniz University Faculty of Fisheries Campus Antalya Turkey
*Corresponding author: jalekorun@akdeniz.edu.tr

Abstract

The aim of this study is to inform about the present disease sitiuation of the cultured rainbow trout (*Oncorhynchus mykiss*, W.) in Turkey. Aquaculture around the world has been increased during the last decades, leading to spreading of infectious diseases and economical losses due to fish mortalities and costs of treatments. Rainbow trout was first introduced Turkey in 1970s and then the culture of species has gained in 1980s. Nowadays, it is grown at the farms which are located in the different regions of Turkey. However, disease is one of factors that limits to fish production because of causing problems including morbities and mortalities. Disease outbreaks at the farm conditions can result from the introduction of pathogens or parasites, from physical and chemical alterations of the surrounding water, and from all these factors. Although infections due to Gram-negative bacterial species are commonly observed among the cultured fish species, reports on Gram-positive coccal infections have been increased during the last decade. Among infectious diseases, some of them are known as old diseases such as IPN, RTFS and Yersiniosis. These were reported in the rainbow trout farming in Turkey. Nevertheless, the rainbow trout culture has been increased, new pathogens and diseases are observed by producers and researchers.

Keywords: *Rainbow trout, Oncorhynchus mykiss, diseases, Turkey*

Introduction

Rainbow trout (*Oncorhynchus mykiss*, W.) is one of the economically important fish species. Farming of the species was first started in 1879 in the United States and then, it was introduced to another countries for food, restocking and angling purposes (FAO, 2012). In Turkey, the farming attempts of the rainbow trout began in 1970s; however, the principal developments on its culture were gained in 1980s. Because of the marked demand of it, the annual production of the species has gradually been increased from 38.500 t in 1999 to 111.335 t in 2012 (TUIK, 2012). One of the primary goals in aquaculture systems is to maintain fish in healthy condition. This helps that fish grow rapidly and they show high survival from egg to marketable size (Gatlin, 2002). Fishes are aquatic and poikilothermic animals. In oceans and seas, the conditions of water column are very uniform but ponds, hatchery facilities and aquaria in which fishes are grown have more variable conditions (Wedemeyer *et al*., 1976). If these conditions have advers effects in maintaining health of fish, the fish are under the stress and a result of stress, they become sick. This paper informs the present disease sitiuation, especially major infectious bacterial, viral and parasitic diseases of the cultured rainbow trout (*Oncorhynchus mykiss*, W.) in Turkey.

Bacterial Infections

This group includes diseases which are caused by Gram-negative bacterial pathogens including *Flavobacterium psychrophilum*, *Yersinia ruckeri*, non-motile *Aeromonas* species and Gram-positive bacterial pathogen, *Lactococcus garvieae*. Because of their economical important, these diseases have been studied extensively and informed by different authors in Turkey. *Flavobacterium psychrophilum* was commonly reported from the disease outbreaks in Turkey and it is etiological agent of cold water disease (CWD) and rainbow trout fry

syndrome (RTFS). This pathogen from the affected rainbow trout samples from the different rainbow trout farms which were located in Mediterranean, Black Sea and Aegean regions of Turkey was first reported by Balta in 1997 (Balta, 1997). Then, the outbreaks from rainbow trout rearing facilities at Sapanca, Marmara region in 1997 was informed by Korun (Korun, 1999) and later, the outbreaks were reported by different researchers in the country (Durmaz *et* al., 2012; İspir *et* al., 2004; Diler *et* al., 2003; Korun and Timur, 2001). There is not commercial vaccine against *F. psychrophilum* agent. The treatment is achieved by adding different antibiotics into feed, especially onset of the disease. However, use of antimicrobial agents for the control of the disease, leading to increasing antibiotic resistance to *F. psychrophilum* strains. For example, Boyacıoglu *et al*., (2015) reported the efficacy of oxytetracyline (OXY) dropped between the strains of *F. psychrophilum* and currently, florfenicol (FFC) is favorable drug against the bacterium and until this time, resistance to this drug has slightly informed from Turkey. Yersiniosis or Enteric redmouth disease (ERM) is an important infection of freshwater farmed fish. Etiological agent is *Yersinia ruckeri*. First outbreak was informed from cultured rainbow trout in the Hagerman Valley of Idaho, the United States in 1950s. Then, the disease had a wide geographical distribution and reported in most countries (Austin and Austin, 2012). In Turkey, ERM from commercially produced rainbow trout was first observed in 1991 and afterwards the disease outbreaks in many parts of the country have been reported (Şeker *et al*., 2012; Onuk *et al*., 2011; Altun *et al*., 2010). Although commercial vaccine is available, disease outbreaks are stil observed. Şeker *et al*., (2012) informed that *Y. ruckeri* infection posed a significant threat to the farms in the sample area included Elazığ and Malatya provinces in Turkey and it was necessary precautions. Motile *Aeromonas* septicemia (MAS) is a fatal disease of fish and the infection is caused by different motile *Aeromonas* species (Das *et al*., 2013). *A. hydrophila* and *A. veroni* biotype *sobria* are predominantly responsible for outbreaks in fish. Motile *Aeromonas* septicemia from rainbow trout at a fish production and research station in Çifteler-Sakaryabaşı, Marmara region was first reported by Baran *et al*. (1980) in Turkey. The etiological agent is *A. hydrophila.* Subsequent informations on disease outbreaks due to this bacterium were given by other researchers (Aksoy, 2009; Sağlam *et al*., 2006). *A. sobria* was reported from rainbow trout farms located in the Central and East Anatolia and Mediterranean regions of Turkey (Özer *et al*., 2009; Özkök, 2005). It is understood that *A. hydrophila* and *A. sobria* are among the predominant motile *Aeromonas* species from rainbow trout affected by MAS. Lactococcosis is a serious septisemic problem of freshwater fish species including rainbow trout (Fereidouni *et al*., 2013). *Lactococcus garvieae* is etiological agent and the bacterium was first isolated from rainbow trout in Turkey in 2002 and then, it was reported from rainbow trout which had been affected by natural outbreaks in Turkey (Özer *et al*., 2008; Kav and Erganiş, 2007; Altun *et al*., 2004; Diler *et al*., 2002).

Viral Infections

Viral infections are important because of causing economic losses in fish farms around worldwide. Major salmonid viral infections include Infectious Pancreatic Necrosis (IPN), Infectious Hematopoietic Necrosis (IHN), Viral Haemorrhagic Septicaemia (VHS), Infectious Salmon Anemia (ISA) and Epizootic Hematopoietic Necrosis (EHN) (Collet, 2014). IPN virus (IPNV) infection as a case report was first reported in Turkey in 2002 but epidemiological screening and the following studies after outbreaks of the disease started in Turkey in 2004 (Kalayci *et al*., 2012). To date, the virus has been detected in mature and inmature rainbow trout samples from commercial farms located at the regions of the middle and east Black Sea, east and southeast Anatolia, Mediterranean and Anatolia of Turkey from December, 2006 to March, 2011 (Gürçay *et al*., 2013; Albayrak and Ozan, 2010). According to these authors' studies, IPNV occurs in the ova and milk of the infected fish and also rainbow trout farms so fish transports from one farm to another should be taken strictly

control measurements otherwise the infection will introduce to rainbow trout farms which have IPNV free rainbow trout. VHS was first described in Germany in 1930s but identification of the virus was carried out in 1960s (Faisal *et al*., 2012). VHS virus (VHSV) generally results in an haemorrhagic syndrome with septicaemia with severe bleeding of internal organs (Gadd, 2013). VHSV was first isolated from the diseased rainbow trout fry from a farm located at Bolu province in Marmara region, Turkey in 2006 (Kalayci *et al*., 2012). After one year this outbreak, VHSV was reported from another farm located at the same province. According to the European Union Directive (No: 91/67), the strict control and quarantina measurements were applied and then, the virus was not isolated the fish from these farms (Kalayci *et al*., 2012). IHN is one of the most serious diseases of the salmonid fish. Occurence of IHNV in rainbow trout was investigated in Turkey from 2006 to 2007 but the virus was not isolated (Albayrak and Özan, 2010).

3.Parasitic Diseases

Rainbow trout plays a role as host for more than 23 protozoan and at least 169 metazoan parasites in the worldwide (Buchmann and Bresciani, 1997). From protozoan parasites, White spot disease (Ich) is important for salmonid fish. The disease was reported from rainbow trout which were cultured in the different geographical regions such as Black Sea, Mediterranean and Aegean of Turkey (Özer *et* al., 2010; Kayış *et al.,* 2009; Öğüt *et al*., 2005; Tokşen, 2000). Öğüt *et al*. (2005) reported that *I. multifiliis* was endemic in the eastern Black Sea region and adverse enviromental factors including reuse of the water which was not treated by disinfection methods, improper water circulation, insufficient water supply and tank cleaning could be responsible for this endemic situation.

Conclusion

The above mentioned diseases are widely observed and informed infections except some of them. These are known since the trout culture has been started in Turkey. However, new diseases were reported in Turkey although they have not been known whether they are endemic or not.

Abstract

In Turkey, supply-demand fluctuations and price instability in alternative products, poultry sector has done in the foreground and sector, especially that it has rapidly developed in last years on broiler meat and egg. Turkish poultry sector is accepted industry together with these developments, modern facilities, production methods, thanks to international standards and international markets in close proximity, such as benefits, has advantages and can compete with the whole world. However, there are some problems such as the height of the production costs of the industry, dependence on external inputs such as raw materials in feed and breeders. Fortunately, Turkey is a country that can adapt very quickly to emergencies. Turkish poultry sector is also facing difficult conditions and trying to adapt to new and often succeed. The policies being followed for the elimination of dependence on foreign, measures are taken to reduce costs and the growth of the sector is supported in a stable manner to increase production and consumption. A sector of the problems encountered, so a closer cooperation with all partners in the industry to give serious economic losses to the country and more work. Thus, the Turkish poultry sector healthier, more power, showing rapid increase of the current employment and a planned development, the reduction of unemployment and finding a solution to the immigration problem is expected to become much more useful sector. Thus, the more healthy the Turkish poultry sector, developing fast and planned faster in further increase of current employment power, reduction in unemployment and finding a solution to the immigration problem is expected to become much more useful sectors.

Keywords: *Turkish poultry sector, broiler, egg, productivity.*

Introduction

Poultry industry in the world is contributing an amount increasing the supply of affordable animal protein. Poultry products, which occupies a strategic position in human nutrition, also has a special emphasis on red meat off the unstable nature of the production deficit. Poultry meat production in more than 50 countries around the world because of these features have economic importance (Roenigk, 1999).

"Poultry meat" are classified in five groups as chicken meat, duck meat, geese and guinea fowl meat, turkey meat, pigeon and other birds by Food and Agriculture Organisation of the United Nations (FAO). Due to almost all of the broiler and turkey meat is Turkey’s poultry production and the lack of an industrial production of meat that is considered important outside of these two groups, the review is given to the broiler and turkey meat.

Nowadays in Turkey, 91% of the production of poultry meat, hatching eggs and chicks, and 75% of the production of table eggs are carried out by a small number (respectively 29 and 45) of large capacity integrated firms (Koca, 2015). The majority of these facilities working with contract producing systems are newer and more advanced technology is used compared to developed country. Therefore, the quality of poultry products generated is very high and the quality of products produced on a very large number of developed countries. Determining as one of several sub-sectors of the Turkish poultry sector could compete with the EU in the

food sector and being one of the most well-organized food sub-sector, reveals the importance for the Turkey. In this study, actual developments, problems and solution alternatives on Turkish poultry sector are evaluated.

Developments in Turkish Poultry

Broiler meat production in Turkey generally increased regularly, while turkey meat production began to decline after 2005 began to rise again in recent years. Broiler meat production in Turkey is developing rapidly settled 8th place in the world as of 2013 (Anonymous, 2014a). 3300000 tons of broiler meat production and 95.000 tons of turkey meat are expected to reach in 2023 (Table 1).

Poultry meat consumption in Turkey, depending on developments in the sector level and red meat prices, especially in recent years has increased considerably. The increase in poultry meat consumption is largely due to the increase in consumption of broiler meat (Table 1).

Table 1**.** Development of Turkish Poultry Sector (Anonymous, 2015).

Years	2005	2010	2014	2023 (target)
Production, ton				
Broiler meat	978400	1423000	1894668	3300000
Turkey meat	53530	33000	48663	95000
Consumption, kg/person/year				
Broiler meat	13.6	17.9	21.0	27.0
Poultry meat	15.1	19.0	22.3	28.8
Poultry meat exports				
Ton/year	44974	151339	430544	1086800
Million USD/year	34	230	700	1960

Turkey's poultry meat exports almost all chicken meat exports. According to the data of 2013, Turkey ranks 4th in the world chicken meat trade with 4.1% market share (Anonymous, 2014a) and aims to settle for third place behind the US and Brazil. 2014 poultry meat exports amounted to 431 thousand tons and 700 million US dollars. About 82% of poultry meat exports are 8 countries. Iraq (63.97%), the Turkish Republics (11.52%) and Russia (5.79%) to come is one of the countries with the highest export (Koca, 2015). Between the years 2005-2014 about the product from 5% to 20% share of exports directed to the rising generation, is expected to exceed 30% in 2023 (Table 1).

Turkey's imports of poultry meat, is quite low when compared to exports. Turkey in the last 15 years 1996, 2000 and has been performing ever chicken meat imports in 2004, chicken meat were imported at very low values in other years.

Table 2. Development of Turkish Egg Production (Anonymous, 2014b).

Years	2006	2010	2014
Production, million			
Poultry Egg	8401	12737	17607
Consumption, total/person/year			
Poultry Egg	114	174	226
Egg Exports, million			
Quantity	195	2.143	4.649
Value, million USD	18.927	156.619	404.094

Egg production in Turkey is rapidly developing. Our country ranks 13th in the world in terms of egg production. Due to increased production and consumption, rapidly developing egg exports reached 4.649 million eggs and 347 million USD levels in 2014 (Table 2).
Besides meat and eggs, as well as the main chicken product, slaughter by products is used as feed ingredients in feed mills by processed in rendering plants such as poultry offal and feathers. Recently, chicken feet are exported to the Far East countries constitute a growing economic potential. Obtained manure, slaughterhouse and hatchery by-products during the activities in the sector can also be used in other areas of agriculture

Problems and Solutions in Turkish Poultry

In the world, 2008-2009 followed by a partial recovery of the global financial crisis, although seen, troubles in the euro zone is still continuing. However, the growth of the Turkish poultry sector in 2014 was 3.5% (9.2% increase in broiler meat production (Koca, 2015)) and the success of the sector's production and export growth can not to be disputed. In Turkish livestock sector, poultry sector is the most advanced and competitive sector. This success in the sector, carried out by means of a high amount of production and export and which is making an enormous effort to do this and are trying to overcome a lot of adversity. Although the rapid development in the Turkish poultry sector is also experiencing major problems. Problems in the Turkish poultry sector can be divided into four main sections as production, consumption, sales-marketing and legislative issues.

Production Problems and Alternative Solutions

A set of problems related to raw materials, house and breeding are considered as problems related to production. In particular, high raw material costs and dependence on external inputs, it is observed as the main difficulties preventing the development of the sector. Importing of corn, soy and fish meal which are main raw materials of poultry feed has led to increased dependence on the outside of the industry. In Turkey, especially inadequate in soybean production (need 2 million tons, production 200 thousand tons), while maize production is very expensive (US 1.5 times) due to the fact, come to import the agenda and continues related problems (Koca, 2015). Moreover, feed raw materials such as corn and soybeans, even if taken within the scope of inward processing regime (Inward Processing Authorization Certification/DIIB), is reported to be a major disadvantage of high shipping cost (Akbay et al., 2000 and Turkoglu et. al, 2010). In order to eliminate problems that might prevent the development of industry, primarily reducing feed costs make up a large portion of production cost is required. To do this, increase the amount of domestically produced feed stuffs, especially with the development of policy support in soy and corn may be helpful (Dastan, 2010). Base price application is another factor that increases the costs and the base price an end to the practice, with world prices + the bonus system started to be well worthwhile.
An insufficient number of poultry house is a major obstacle in front of the healthy production. When not enough growing houses, arrest the targeted production is very difficult. In 2014, the Instrument for Pre-Accession Assistance Rural Development Program (IPARD) grants and disbursed through the Ziraat Bankasi reduced interest in the investment and business loans, house investments have taken place and has set an important contribution to the state sector. Such supports the continuation of improved and will provide a reduction in the problems of production-induced house.
Activities related to breeding, is notable as one of the least important part of the poultry industry. One of the reasons is the high research and production cost of breeding. Lack of trained personnel and experts is another important reason. In the Turkey breeder production to eliminate the dependence on foreign, the establishment of public and private sector

organizations institutions to hold the hands of the breeder production and grant these organizations, supported by applications such as low-interest loans and tax exemption aimed to encourage investment (Akbay et al., 1995 and 2000). As a result of improvement works carried out under these objectives, ATABEY, ATAK and ATAK-S is domestic laying lines have been developed. In 2013, the number of breeding domestic laying 25000, while the number of chicks laying sold reached approximately 500000. Even if efficiency levels up to foreign lines, production conditions in some facilities are not adequate for foreign hybrids, have been shown to yield positive results. The work initiated for domestic broiler breeder production is expected to be taken in the shortest time (Anoymous, 2013). To be successful, this project is supported investments are encouraged cooperation between public and private sectors. In addition, a set of environmental conditions inside the organization to take part in genetic improvement in the public sector, are arranged according to today's technology, lack of staff and experts are trying to resolve.

Consumption Problems and Alternative Solutions

Although the consumption of poultry meat increased significantly in recent years in Turkey is lower than the consumption of the major producing countries is another problem that needs to exceed the industry. To increase the Turkey's domestic consumption and export, it is necessary to increase the supply of further processed poultry meat products with different-flavoured, spicy and ensure the supply of different poultry species meat products (Keskin and Demirbas, 2012).

Media-related problems and information pollution are among the most important issues affecting consumption. In the written and visual media, without any scientific basis for the information and explanations which cause pollution in the community, causing serious damage to the sector. Development of the poultry industry, creating facilities that will contribute to companies and providing of public sector-private cooperation, many studies are performed by different organizations. Turkish Poultry Meat Producer and Breeders Association (BESD-BIR), Turkish Egg Producers Association (YUM-BIR) and Turkish Feed Manufacturers Association (TURKIYEM-BIR) are the most important of this organizations.

Social media are monitored and significant improvements are reported in order to reduce media-related problems and information pollutions, improve communication and inform the public and press. Press releases are issued in consultation with subject matter experts and PR activities are carried out. Together with PR work, as opposed to unfair and inaccurate perceptions about the sector's existing knowledge and perception of pollution has been started work to translate. The perception surveys are performed to demonstrate the consumption habits in the industry. The research results are evaluated and policy are determined accordingly. The results of the studies are recorded significant progress in solving the problems related to consumption.

Sales & Marketing Problems and Alternative Solutions

Problems with exports are among important factors limiting the development of the sector. To achieve the export target, it is necessary to develop existing markets and reach new markets. As a result of a variety of political reasons not affect the poultry meat exports, Turkey has suffered in unable to use the potential and enter new markets. Brazil dominate some markets such as the Middle East and Russia makes it difficult for Turkey's entry into this market. Although it is ready for the legal procedures relating to exports, cheap raw materials, labour and energy costs cannot be engaged in the production and compete with Brazil. However, geographical proximity to the Russian market and that Muslim countries in the Middle East market, may be an advantage for Turkey. If it can be used effectively these advantages, Turkey are believed could receive a larger share of the Middle East and Russia market. For

example, Saudi Arabia, with over 800000 tons of chicken meat imports in 2014 are among the countries with the highest import. The region has become very important for Turkey from 2012 (Anonymous, 2015). Russia is an important market for Turkey and a very large part of Turkey's exports to Russia are mechanically deboned poultry meat (MDM). Russia, along with the US and EU to stop food imports, our exports to this country began our revival. To further increase exports to Russia, it is necessary to make some bilateral agreements and increase the quota (Turkoglu et al., 2014 and Koca, 2015).

Exports to China, Japan, and the Philippines is very important for Turkey. Preliminary studies have been completed in these countries, Japan is the breast meat importer such as the EU and China is chicken feet importers, it is important in terms of the increase in unit export prices. In particular, due to the Chinese export made with brokers and high transport costs, the economic loss in 2014 is estimated to be around 13.6 million USD (Koca, 2015). The development of trade with these countries, which will reduce losses and will encourage effortless reach new markets. EU is also a target market for more than 10 years, however, exports to this region with legal permits a kind of incomplete.

Export incentives are among the most important issues affecting the sales and marketing. Export support is available for $ 26 per ton broiler meat and $ 15 per 1000 table eggs. It is believed that in order to attain the target countries should be given special support exports and the sector for export subsidies should be increased (Turkoglu et. al., 2010 and 2014). At the beginning of 2011, was established to increase the export of Poultry Promotion Group (Turkish Poultry) of increasingly more successful activities are also expected to contribute to development.

Legislation Problems and Alternative Solutions

The problems concerned with legislation are very important issues for the sector. Use of mechanically deboned meat (MDM) in some further processed poultry meat products ban, use of animal by-products (rendering products) in poultry feed ban, the difficulties in the importation of GMO-containing feed stuffs, the small number of reference laboratory, health issues such as the presence of Salmonella in poultry products, the lack of R&D projects and related supports are the most important problems related legislation.

Turkey, which is still in force, the use MDM ban in some further processed poultry products like sausages, nor the EU, nor the USA nor in any other region of the world is not prohibited. Therefore, improving the regulations on the use of MDM shall be made as soon as possible for the holders of both country and industry with consumers. The using ban of rendering products will also lead to additional costs and foreign exchange losses. In this regard, it is believed that it was necessary to postpone the application. Also, evaluate and develop waste projects all over the world to make the food, some groups in our country do not want to become waste of food is also considered to be a significant problem. The risk of contamination depends on the GMO feedstuffs, analyse errors and problems due to the difficulty of importing new development sector puts too much trouble. Increasing the number of reference laboratory as soon as possible will reduce the waste of time and money in the sector. Manure subject, for not properly managed, consistently stands out as a problem in front of the Turkish poultry sector. To solve the problem as soon as possible is being done to continue negotiations with relevant ministries.

Conclusion

In the poultry sector, as in all sectors, target, to obtain more products with low cost, high quality and healthy, and markets these products at high prices by ultimately achieve the highest profit possible. Turkish poultry sector has advantages in terms of factors such as modern facilities, international standards and can compete with the whole World, appropriate production methods and the proximity to the international market. But the height of

production cost feed raw materials and foreign dependency in feed stuffs and other outputs is limiting case for the future of the sector. In addition, factors such as infectious disease, can negatively affect industry and can change the market preferences.

Monitoring of policies to eliminate dependence on foreign, of taking measures to reduce costs and to increase the domestic consumption sector are expected to support growth in a stable manner and the positive impact that sector.

Republic of Turkey Ministry of Food Agriculture and Livestock, the objective of the policies implemented in the poultry sector, to increase per capita poultry meat and egg consumption to the European countries level by consumer education and advertising has determined to bringing to work at full capacity established facilities and increasing to exports (Anonymous, 2013. In line with these objectives, studies are carried out in the private sector and government cooperation and with great sacrifice to perform suitable for animals, economic and controlled care and feeding. Thus, both the economic efficiency and more comfortable poultry production with high-quality meat production of poultry will be possible.

Turkey is a country that can adapt very quickly to emergencies. Turkish poultry sector is also facing difficult conditions and trying to adapt to new and often succeed. The problems encountered in the sector and thus causing serious economic losses to the country, it is thought that a closer cooperation with all partners in the sector and further work is required. The problems encountered in the sector, does not cause serious economic loses in our sector and our country, it is thought that more effort is needed.

Turkish poultry sector is healthy, with rapid and planned development, when the obstacle is reduced, a further increase of the current employment force, the reduction of unemployment and finding a solution to the immigration problem will become much more useful one sector.

Abstract

Aim of this paper is to revise dog fighting in Europe. Dog fighting has been illegal in Canada since 1892. Nowadays in USA dog fighting is illegal in all 50 states. Dog fighting is also illegal in most South American countries. In Afghanistan although dog fighting is banned by the Taliban it is still common throughout Afghanistan as a winter weekend pastime. In India dog fighting is not common, but can be found in some rural areas, and is illegal as defined by the Indian law. In Japan dog fighting seemed as legal. Dog fighting was considered a way for the Samurai to retain their aggressive edge during peaceful times. In Pakistan dog fighting and other forms of animal fighting are highly popular in all parts of the country even though it has recently been banned. It is deeply rooted in the rural culture. In Russia dogfighting is prohibited in much of the West. These blood sports were officially eliminated in 1835 as Britain began to introduce animal welfare laws. In Africa the Republic of South Africa is a country where one of the most dog fighting events happens. Dog fighting and the possession of any fighting equipment designed for dog fighting is illegal in Australia. "Restricted Breed Dogs" cannot be imported into Australia.

Keywords: *Canis familiaris, Pit Bull, blood sport, illegal sports, animal fight.*

Introduction

Domestic livestock animals serve humanity by giving plenty of products including meat, milk, egg, honey, floss silk, wool, fur, skin, feather, intestine, work, amusement etc (Ertugrul et al., 1993). Moreover some animals have been and continue to be used for fighting by some mentally abnormal people. In various regions of the world there are popular animal fighting events including fighting of bull, camel, cock, cricket, dog, horse, partridge and ram (Köhne and Ewigleben, 2000; Kalof, & Taylor 2007). For centuries usually dog fighting has been principally enjoyed by men. Unfortunately, the popularity of this activity has increased (Anon, 2014a). There was little initial interference from the law, since it was possible to fight two dogs in any hollow or shed without attracting much attention, for dogs fight with relatively little noise. They can easily be removed after the fight, carried away in sacks if their condition was likely to draw suspicion (Drable, 2014). For example in USA dog attacks and bites are not so common (Hussain, 2005). Although more than 20 fatalities happened each year in USA because of dog biting, there was no report that a man did during dog fight, but the dog. Maybe the 20 fatalities because of dog biting seem as tragic but at least 8.000 humans were killed by other human each year which was 200 times more than dog biting deaths (Lockwood, 1995).

The purpose of this paper is to review dog fighting in European countries.

Dog Fighting in the World

Dog fighting has been illegal in North America and under police surveillance but in South America there are some dog fighting events in some countries (Anon, 2014b). Nowadays in USA dogfighting is illegal in all 50 states (Anon, 2014c, Villavicencio, 2007, Kalof and Taylor, 2007).

In Asia dog fighting is quite common. Although it is one of the poorest countries in the world, animal cruelty arguments don't carry much weight in Afghanistan (Villavicencio, 2007; Anon, 2014a; Motlagh, 2014). In India dog fighting is not common, but can be found in some rural areas. In Japan dog fighting seemed as legal (Villavicencio, 2007; Ensminger, 2010; Anon, 2014d,e,g). In Pakistan dog fighting and other forms of animal fighting are highly popular in all parts of the country. Generally two breeds are raised for the purpose, such as the Bully Kutta and Gull Dong (Longbottom, 2011; Nizami, 2012; Longbottom, 2011). In Russia dogfighting is prohibited in much of the West. Even though animal cruelty laws exist, dog fighting is widely organized in some part of the country (Anon, 2015a). The breeds of Caucasian Shepherd Dog, Georgian Shepherd, Central Asian Shepherd Dog, and Wolfhounds are used for dog fighting (Chivers, 2007; Villavicencio, 2007; Anon, 2014e).
In Africa the Republic of South Africa is a country where one of the most dog fighting events happens (Anon, 2014e, h, i).
Dog fighting in Australia is illegal but dog fighting is often associated with gambling activities and other illegal practices such as drug dealing and firearms (Anon, 2014e, h, j).

Dog Fighting in Europe

These blood sports were officially eliminated in 1835 as Britain began to introduce animal welfare laws. Since dogfights were cheaper to organize and far easier to conceal from the law than bull or bear baits, blood sport proponents turned to pitting their dogs against each other instead. Dog fighting was used as both a blood sport (often involving gambling) and a way to continue to test the quality of their stock. For decades afterward, dog fighting clandestinely took place in pockets of working-class Britain and America. In recent years the inner cities, especially in London have seen a steady rise in the number of convictions for dog fighting, primarily among teenage youths of Pakistani descent (Anon, 2014e). A research study was carried out to discuss financial aspects of illegal dog-fighting in the UK and to reflect upon and discuss the difficulties of researching illegal entrepreneurial activities such as dog-fighting which were operated for criminal profit. According to the study dog fighting activities were conducted by urban criminals often in a rural setting. Those crimes invariably occurred in a closed social environment to which the authorities and the academic researcher cannot legitimately gain access. In the case study the illegal activities can legitimately be regarded as being an entrepreneurial activity as they entail trading in a Kirznerian sense as well as financial implications associated with gambling (Smith, 2011).

Rules

Among animals the dog is well known that dogs are known as very loyal animals. Humans abuse this quality of the dog (Kalof and Iliopoulou 2011). A dog's bond to humans is analogous to child-parent and chimpanzee-human attachment behavior, because the observed behavioral phenomena and the classification are similar to those described in mother-infant interactions (Topal et al. 1998).
Dog fighting is described as “The act of baiting two dogs against one another for entertainment or gain” (Evans et al. 1998). It involves placing two dogs in a pit until one either quits or dies. Dog fighting is almost universally illegal. Generally, two dogs, often of a pit bull breed, are put into an area to fight and sometimes kill each other. Dog fights usually last until one dog is declared a winner, which occurs when one dog fails to attack under the rules of such events, one dog dies, or one dog jumps out of the pit (Iliopoulou 2014). Dog fighting can involve high stakes, and carries with it the same sociological dangers of other gambling, particularly illegal gambling, activities (Anon 2014b). In some organized fights, the fighting dogs are weighed to make sure they are approximately the same weight. Handlers

will often wash and examine the opponent's dog to remove any toxic substances that may have been placed on the fur in an attempt to deter or harm the opposing dog (Anon 2014d).
When the fight begins, the spectators place bets with one another on which dog will win. There are some strict rules for fights. The dogs continue fighting until one of them makes a "turn," which is defined as turning the head and shoulders away from the opponent. When the referee calls the turn, the handlers then handle their dogs when they are out of "holds," which means they are not biting each other. The dog who made the turn must "scratch" to his opponent. Scratching is defined as crossing the scratch line, which is drawn in the center of the pit, and attacking one's opponent within a specified amount of time usually 10 to 30 seconds. If a dog fails to scratch, his opponent is declared the winner. If the scratch is successfully completed, the fight continues. From this point on the dogs are handled only when they are out of holds, and the dogs are required to scratch in turn. If a dog fails to scratch in turn, he is declared the loser. The fight may end in one of four ways: first a dog's failure to scratch; secondly the owner's calling the fight (analogous to the manager of a boxer throwing the towel into the ring, a signal that the fighter has quit); thirdly the death of one or both dogs, or fourthly one of the dogs jumping the pit (Forsyth and Evans 1998, Anon 2014d, Gasimzadeh 2014). Fights can last either just a few minutes or several hours depending on condition of dogs. Both animals may suffer injuries, including puncture wounds, lacerations, blood loss, crushing injuries and broken bones. Although fights are not usually to the death, many dogs succumb to their injuries later (Anon 2014d).
Dog fighting events also help to spread some diseases such as *Canine babesiosis* and *Babesia gibsoni*. *C. babesiosis* and *B. gibsoni* spread during dog fighting because of non-vectored transmission by blood exchange during fighting and biting (Irwin 2009).

The Dogs

Many dog breeds have been bred specifically for the strength, attitude, and physical features that would make them better fighting dogs. Some traits are common among most of fighting breeds that it’s outward appearance, a large, stocky, heavy breed with a powerful build and strongly developed head, and threatening voice (Massey 2012). Drable (2014) reported from Vesey-Fitzgerald that early fighting dogs were of all sorts of shapes, sizes and colors since their breeding was very promiscuous. In 1860s they were two groups, from one of which the English Bull Terrier was developed and from the other the Staffordshire Bull Terrier. The both breeds were initially very game, since nobody would keep a bull terrier which was not, but men soon bred the English variety for show, and looks were "improved" at the expense of courage. The Staffordshire bull terrier continued to be bred for the pit and, though not very standardized even yet there is no living breed so game (Drable 2014).
In USA about 30 percent of all dogs in animal shelters are pit bulls, the breed used for dogfighting. In some areas this figure can climb to 60 percent (Villavicencio 2007). For professional and hobbyist dogfighters, the sale of pups from parents who have won several fights is a major part of their activity. Underground dog fighting publications and websites are commonly used to advertise pups or the availability of breeding stock. Many "street" fighters think they can also make money by breeding and selling dogs, but a great number of these animals are killed or abandoned if they fail to perform (Anon 2014d).
Generally all kinds of dogfighters crop the ears and dock the tails of fighting dogs. There are two main reasons. First it limits the areas of the body that another dog can grab onto in a fight. Secondly it makes it more difficult for other dogs to read the animal's mood and intentions through the normal body language cues dogs use in aggressive encounters. Fighters usually perform this cropping or docking operation themselves using crude and inhumane techniques (Anon 2014d).

Early dogs of the bull terrier type were bred for the working characteristic known as gameness, with the pitting of dogs against bear or bull testing this attribute along with the strength and skill of the dog. These early "proto-staffords" provided the ancestral foundation stock for the Staffordshire Bull Terrier, the Bull Terrier, the American Pit Bull Terrier and American Staffordshire Terrier. This common ancestor was known as the "Bull and Terrier" (Anon 2014j). Generally the breeds of Staffordshire Bull Terriers, American Pit Bull Terriers, American Staffordshire Terriers, and Bull Terriers are called as pit bulls (Massey 2012). In other countries breeds of Bully Kutta, Caucasian Ovtcharka, Central Asian Ovtcharka, Dogo Argentino, Fila Brasileiro, the Presa Canario, the Tosa Inu, and Turkish Kangal (Karabash) Shepherd are used for fighting (Gibson 2005, Ensminger 2010, Anon 2014d, Gasimzadeh 2014, Anon 2015b). Also some breeds are accepted as extinct such as Blue Paul Terrier, Bull and Terrier, Cordoba Fighting Dog, Dogo Cubano, English White Terrier, Molossus, Old English Bulldog dogs (Anon 2014d).

Table 1. Some breeds which are used for dogfighting (Anon 2015b).

Breed	Origin		Breed	Origin
Aryan Molossus	Afghanistan		Gull Terrier	Pakistan
Kuchi	Afghanistan		Dogue de Bordeaux	Portugal
Dogo Argentino	Argentina		Caucasian Ovtcharka	Russia
Armenian Gampr	Armenia		Central Asian Ovtcharka	Russia
Shar Pei	China		Alano Español	Spain
Tibetan Mastiff	China		Perro de Presa Canario	Spain
Georgian Shepherd	Georgia		Perro de Presa Mallorquin	Spain
Guatemalan Dogo	Guatemala		Kangal Dog	Turkey
Glen of Imaal Terrier	Ireland		Bull Terrier	UK
Lottatore Brindisino	Italy		English Mastiff	UK
Neapolitan Mastiff	Italy		Staffordshire Bull Terrier	UK
Akita Inu	Japan		American Pit Bull Terrier	USA
Tosa	Japan		American Staffordshire Terrier	USA
Korean Jindo	Korea		American Bulldog	USA
New Guinea Singing	Papua New Guinea		Boston Terrier	USA
Bully Kutta	Pakistan			

It is often asked whether the Pit Bull is unsuitable as a family pet or not? In the early 1900s pit bulls were considered the epitome of the all American dog. For example Stubby, the first war hero dog and Pete the Pup, from “The Little Rascals” were very good examples of this breed (Hussain 2005). Although bred for fighting other dogs the American Pit Bull terrier has long been a popular family pet, noted for his strength, intelligence and devotion. It is clearly understandable that any dog can behave aggressively, depending on the context, his genetic background, and his upbringing and environment. If a dog is treated well, properly trained and thoroughly socialized during puppyhood and matched with the right kind of owner and household, it is likely to develop into a well-behaved companion and cherished member of the family. However, some Pit Bulls and Pit Bull crossbreds may be more inclined to develop aggression toward other dogs (Anon 2014d).

American Pit Bull Terrier is a wonderful dog breed, but it comes with risks. Being large-jawed, it is more capable than many breeds of doing damage with its bites. As with any dog, pit bulls can be trained, and often are as calm as dogs can be, but people assume they are vicious because they have become popular with gangs and other unpopular members of American society (Ensminger 2012).

Even though German Shepherd Dogs (GSD) do not seem a fighting dog breed, they are actually a biteable dog breed. Lockwood reported from a study realized by Berzon that GSDs made up 45% of the dogs listed in Baltimore bite reports. Lockwood also reported from a study realized by Moore about percentage of the registered population of various breeds that were involved in bites. The highest rankings in that research were pit bulls (12.3%), chow chows (11.4%), GSD (6.5%), Dobermans (4.3%) and Rotweilers (4.1%) (Lockwood 1995). A study claimed that the annual incidence of dog bites was 0.5 percent 1000 children between 0 and 16 years of age. The relative risk for a dog attack by a German shepherd or a Doberman was 5 times higher than that of a Labrador Retriever or cross-breed (Schalamon et al. 2005).

Train

According to fighting dog trainer fighting dogs must be kept isolated from other dogs, so they spend most of their lives on short, heavy chains, often just out of reach of other dogs. They are generally unsocialized to any other dogs and to most people. However, many professional fighters invest much time and money in conditioning their animals. They are frequently given quality nutrition and basic veterinary care. The dogs are exercised under controlled conditions. The maintaining condition of fighting dogs may also make use of a variety of legal and illegal drugs, including anabolic steroids to develop muscle mass and encourage aggressiveness. Narcotic drugs may also be used to increase the dogs' aggression, increase reactivity and mask pain or fear during a fight. Young animals are often trained or tested by allowing them to fight with other dogs in well-controlled rolls. Any dog may be discarded or killed, if the dog shows little inclination to fight. Some fighters will use stolen pets as bait dogs or sparring partners. There are many other common techniques used in the training and testing of dogs, but these methods vary widely among different fighters and may range from systematic to haphazard. In USA the street fighters usually make little investment in conditioning or training their animals. Instead, they rely on cruel methods to encourage their dogs to fight, including starvation, physical abuse, isolation and the use of stimulants or other drugs that excite the dogs (Anon 2014d).

In USA fighting dogs are commonly conditioned from a very early age to develop what dog-fighters refer to as “gameness.” Dog-fighter applies training by depending on his level and experience on dogs. In USA the methods are commonly used to train the dogs:

Treadmill: The fighting dogs are run on the treadmills to develop cardiovascular fitness and endurance.

Catmill or Jenny: This device looks like a carnival horse walker with several beams jetting out from a central rotating pole. The dogs are chained to one beam and another small animal like a cat, small dog, or rabbit, is harnessed to or hung from another beam. The dogs run in circles by chasing the lure. Once the exercise sessions are over, the dogs are usually rewarded with the bait they had been pursuing.

Springpole or Jumppole: It is a tool that a large pole with a spring hanging down to which a rope, tire, or animal hide is affixed that the dogs jump to and dangle from for extended periods of time. This strengthens the jaw muscles and back legs.

Flirtpole: A handheld pole with a lure attached. The dogs chase the lure along the ground.

Chains: Dogs have very heavy chains wrapped around their necks, generally in lieu of collars; they build neck and upper body strength by constantly bearing the immense weight of the chains.

Weights: Weights are often affixed to chains and dangled from the dogs’ necks. This builds neck and upper body strength. Generally, dogs are permanently chained this way. However, sometimes the trainers run them with their weights attached.

Bait: Animals are tied up while the dogs tear them apart or sometimes they are confined in an area to be chased and mauled by the dogs.

Drugs, Vitamins, and Supplements: Dogs are given iron/liver extract; vitamin B-12; Provim; Magnum supplement; hormones of testosterone, Propionate, Repotest, Probolic Oil; weight-gain supplements; creatine monohydrate; speed; steroids of Winstrol V, Dinabol, Equipose; and cocaine. The dogs are trained against one another and against older, more experienced dogs. In the early stages of training, the dogs are incited to lunge at each other without touching and engage in quick, controlled fights called rolls or bumps. Once the dogs appear match ready, they are pitted against stronger dogs to test their gameness or tenacity in the face of exhaustion and impending defeat. If the dogs pass the test, they are deemed ready to fight (Gibson 2005).

Types of Fighters

There are three types of dog fighters including street fighters, hobbyists, and professionals. Hobbyists and professionals often decry the techniques street fighters use to train their dogs. Such techniques include starving, drugging, and physically abusing the dog. Street fighters are frequently associated with gang activities. They fight dogs over insults, turf invasions, or simple taunts like "My dog can kill your dog”. These type of fights are often spontaneous, unorganized, conducted for money, drugs, or bragging rights. Urban street fighters generally have several dogs chained in back-yards, often behind privacy fences, or in basements or garages. The dogs are often found by police and animal control officers either dead or dying after a street fight. Due to the spontaneity of a street fight, they are very difficult to respond to unless reported immediately. The second types of fighters are hobbyists. They fight dogs for supplemental income and entertainment purposes. They typically have one or more dogs participating in several organized fights and operate primarily within a specific geographic network. Hobbyists are also informed with one another and tend to return to predetermined fight venues repeatedly. The last types are professionals. Professionals breed generations of skilled "game dogs" and take a great pride in their dogs' lineage. Those fighters make a tremendous amount of money charging stud fees to breed their champions. They also earn the fees and winnings they collect for fighting them. Professionals also tend to own a large number of dogs which are sometimes 50 dogs or more. In USA professional fighters also use trade journals to discuss recent fights and to advertise the sale of training equipment and puppies such as Your Friend and Mine, Game Dog Times, The American Warrior, and The Pit Bull Chronicle. Some fighters operate on a national or even international level within highly secret networks (Gibson 2005, Ensminger 2010, Boucher 2011, Anon 2014b,d).

Place

Dog fights are organized in places of variety of locations and at any time. In rural areas they may be impromptu events in a barn, outdoor pit, back alley, or carefully planned and staged enterprises in a location specially designed and maintained for the purpose. On the other hand in urban areas, fights may happen in garages, basements, warehouses, abandoned buildings, back alleys, neighborhood playgrounds, or even in the streets (Kalof and Talor 2007, Anon 2014a,d). In USA two dogs are put into a square pit, which measures from 3.5 to 6 meters on each side. The pit is surrounded by walls between 0.6 and 1.2 meters high and usually made of wood, plywood, hay bales, or chain link. There are two handlers and one referee in the pit with the dogs. During dogfight spectators surround the pit, the sides of which are wooden and three to four feet high. The dogfight starts when the referee tells the handlers to pit their dogs, at which time the dogs are released and attack (Forsyth and Evans 1998, Anon 2014d).

Conclusion

It can be said that it is too difficult to understand that some people provide dog fighting events. According to those abnormal people dog fights are necessary and should be carried

out (Gasimzadeh 2014). This kind of people is rare in community but they are always present in the community and always will be. The most important thing to prevent dog fighting is inform related police or gendarme forces. Also penalties should be more increased and dog fighters should be published in TVs.

Abstract

The research was conducted on eggs of Guinea fowl maintained in Department of Animal Science, Faculty of Agriculture, Akdeniz University, Turkey, in 2012. One hundred eggs selected randomly. Egg weigth (g), egg lenght (mm), egg width (mm), shell weight (g), shell thickness (mm) and yolk weight (g) were measured. The egg weight was beter predictable from egg width and egg lenght. Following equation was developed to predict egg weight from egg width and egg lenght. Y=-65.187*egg lenght+2.021*egg width. Folowing equation was developed for predicting shell weight from egg weight. Y=-2.507+0.224*egg weight. Egg shape index was predictable with sufficient accuracy from egg lenght and egg width and, following equation was developed to predict it; Y=0.752-0.015*egg lenght+0.021*egg width. Eggshell thickness was beter predictable from shell weight. So, following equation was developed for predicting shell thickness. Y=0.232+0.048*egg weight. Yolk weight was predictable with sufficient accuracy from egg weight and following equation was developed to it; Y=3.898+0.241*egg weight. Weight of egg albumen could be predicted from the following equation, Y=-30.438+1.374*3gg width. Followig equation was developed for predicting yolk height from egg weight, Y=9.871+0.128*egg weight. Eggshell surface area was predictable with sufficient accuracy from egg weight and following equation was developed to predict it; Y=18.85+0.918*egg weight.

Keywords: *Guinea fowl, egg weight, egg lenght, egg width, shell thickness*

Introductıon

Guinea fowl (*Numida meleagris*) are native to Africa and are believed to have originated in Western, Central and Southern parts of Africa (Ikani and Dafwang, 2004; Fajemilehin 2010; Tebesi *et al.*, 2012, Elhashmi *et al*., 2012). Although Guinea fowl are thought to have originated in Africa, its production has increased rapidlythroughout the entire world. Guinea fowl can be successfully reared under semi-intensive conditions with less effort (Seabo et al., 2011). That is why it has been very important for Third World Countries. With the help of developments in organic farming rechnigues in recent years the Guinea fowl has been given importance as altenative poultry (Yildirim, 2012).

Their meat and eggs are very popular and carcass weights between 0,5 and 1,0 kg at 10 weeks of age making them suitable table birds for the small family. The demand for guinea fowl meat in the market has significantly increased due to flavour making it to be serves extensively in the larger hotels and higher priced restaurants (Feltwell, 1992). Guinea fowl represents a reliable and active contributor to the survival of the rural folk since it has economic, cultural, livelihood and social values in their lives (Tye and Gyawu, 2001). In Zimbabwe today, guinea fowl is now being viewed as a potential vehicle in the reduction of rural poverty, a strategy already operational in Ghana (Ghanadot 2009; Kusina 2012). These fowls have kept their characteristics until today such as being matured, reproduced and resistant to diseases under different ambient temperatures (Kusina, 2012). Other advantages

are their need for less water and pratical semi-intensive breeding in the farms or around villages.

The quality of table or hatching eggs depends on a number of traits which include egg weight, egg lenght, egg width, eggshell weight, eggshell thickness, eggshell ratio, egg shape index, egg surface area, unit surface shell weight, yolk weight, yolk diameter, yolk height, yolk index, yolk ratio, haugh unit, albumen weight and albumen height if other management conditions and health status of the birds are not the limiting factors (Khurshid *et al.,* 2003; Fajemilehin, 2008). Among the traits mentioned above, egg weight, lenght and width are the only parameters which could be determined before breaking the eggs, while information on rest parameters are usually determined after the eggs have been broken.

Regression analysis is indeed the single most important useful measure of association which can be used to explain the amount of change in one variable as a result of a unit change in the value of other variable since we have control over the first variable and can measure it essentially without error (Glover and Mitchell, 2001; Fajemilehin, 2008). Egg weight was esaily predictable from egg lenght and width as positive association among these traits existed (Farooq *et al.,* 2001). This type of information on egg weight along with other egg parameters will poen the domain for trying out various prediction equations in order to predict each of the parameters. Prediction of egg quality traits prior to marketing for table is the prerequisite for economic production of eggs.

The research was carried out to predicting egg weight, shell weight, shell thickness, shell surface area, egg shape index, height of egg yolk, yolk width, yolk weight, albumen length and albumen weight using various egg traits as independent variables.

Materıal and methods

This study was conducted on total 100 egg of Guinea fowl maintained in Department of Animal Science, Faculty of Agriculture, Akdeniz University Turkey, in 2012. During the research, 0.01 g sensitive electronic scale was used for weighing the eggs; a compass sensitive to 0.01 mm was used for measuring the length, width, yolk diameter, albumen length of the eggs; a table with a flat glass on it was used on which the eggs are broken; a 3-legged micrometer sensitive to 0.01mm was used for measuring the height of yolk and albumen and a micrometer sensitive to 0.01 was used for measuring the shell thickness. The collected eggs to be used in this research were numerated at first. Then, they were balanced in order to determine their weights. Later, the width and length of the egg were measured. After this process, the eggs were broken on table with a glass cover in order to measure yolk height, yolk diameter, albumen length and albumen height. The eggshells were washed under slightly flowing water so that albumen remains are removed. The washed eggshells were left to dry in the open air for 24 hours. Then, they were balanced together with the eggshell membrane. Finally, samples taken from sharp, blunt and equatorial parts were measured and the average shell thickness was obtained from the average values of these three parts (Tyler, 1961). The surface area, expressed as centimeters squared (cm^2), of each egg was estimated using the formula of Carter (1975), 3.9782 x W.7056, where W is egg weight in grams.

Shape index = egg width / egg length x 100

Following model was used for prediction of egg weight, using egg length and width as independent variables in different cases;

$Y_{ij} = a + b_iX_i + e_{ij}$

Where, Y_{ij} :egg weight (g), a: the intercept, b_i: the regression coefficients, X_i: egg width and length (mm) and

e_{ij}: The residual term.

A similar model was used for predicting other traits using egg weight, length and width as independent variables.

Results and dıscussıon

Predicting of egg weight from egg lenght and width

In this study, following equation was developed for predicting egg weight from egg length and width.

Y = -65.187 *Egg lenght + 2.021*Egg width

Where; Y = will be predicted egg weight

Predicting of eggshell weight from egg weight, egg length and width

Following equation can be effectively used for predicting eggshell weight from egg egg weight;

Y = -2.507+0.224*egg weight

Where; Y = will be predicted eggshell weight

Predicting of eggshell thickness from egg weight, egg length and width

Following equations were developed for predicting eggshell thickness from eggshell weight and egg weight.

Y = 0.232 + 0.048*eggshell weight

Y=0.196+0.09*egg weight

Where; Y = will be predicted eggshell thickness

Predicting of eggshell surface area from egg weight, egg length and width

Following equation was developed to predict eggshell surface area from egg weight.

Y = 18.85+0.918*egg weight

Where; Y = will be predicted eggshell surface area.

Predicting of egg shape index from egg weight, length and width

Following equation was developed to predict egg shape index from egg length and width.

Y = 0.752 - 0.015*egg lenght + 0.021*egg width

Y = will predicted egg shape index

Predicting height of yolk from egg weight, egg length and width

Following equation was developed to predict height of yolk from egg weight.

Y = 9871.908 + 0.128*egg weight

Y = will predicted height of yolk

Predicting width of yolk from egg weight, egg length and width

Following equation was developed to predict width of yolk from egg width.

Y = 17.0064+ 0.624*egg width

Y = will predicted width of yolk

Predicting weight of yolk from egg weight, egg length and width

Following equation was developed to predict weight of yolk from egg weight.

Y = 3.898+ 0.241*egg weight

Y = will predicted weight of yolk

Predicting weight of albumen from egg weight, egg length and width

Following equation was developed to predict weight of albumen from egg width.

Y = -30.438+ 1.374*egg width

Y = will predicted weight of albumen

Egg weight was predictable with sufficient accuracy from egg width and length as association of both traits with weight of the egg was significant (P<0.01). Regression coefficient of the fitted model was 79.30%. Khurshid *et al.* (2003) reported significant and positive association of egg weight with egg length and width of Japanese quails and regression coefficient was calculated as 31.86%. As reported by Alkan *et al.* (2008) egg lenght and width have significant effect on the egg weight of Japanese quails and the regression coefficient was calculated as 82.60%. Farooq *et al.* (2001) also reported positive association of egg weight with egg width and length of Fayumi eggs. In another research, Fajemilehin (2008) reported significant and positive relationship of egg weight with egg lenght and width of Quinea fowls and regression coefficients were calculated as 21.10% for egg lenght and 16.82% for egg width.

The eggshell weight, shell thickness and eggshell stiffness are important egg traits that can't be exactly predetermined until and unless eggs are broken. However, prediction equations can be developed to get information about these traits without breaking eggs. Some researchers had focused on the studies related to the increasing of the stiffness of the eggshell, because the quality of the eggshell has a vital importance for the laying force, embryo growth and the chick quality (Altan *et al.*, 1998). In this study, eggshell weight was found significantly (P<0.01) and positively associated with egg weight providing a good ground for predicting eggshell weight. In this study, adjusted R^2 of the fitted model was 42.70%. Khurshid *et al.* (2003) reported significant and positive association of eggshell weight with egg length and width of Japanese quails and regression coefficient was calculated as 7.01%. As reported by *Alkan et al*. (2008) egg lenght and width have significant effect on the egg shell weight of Japanese quails and the regression coefficient was calculated as 50.70%. In another research, Fajemilehin (2008) reported significant and positive relationship of egg weight with egg lenght and width of guinea fowls and regression coefficients were calculated as 7.40% for egg lenght and 8.20% for egg width and 8.40% for egg weight. Also, Farooq *et al.* (2001) who reported significant association of shell weight with egg width in Fayoumi eggs.

The eggshell thickness was predictable with sufficient accuracy (P<0.01) from egg eggshell weight and and egg weight. In this study, regression coefficients were 74.90% for eggshell weight and 20.50% for egg weight. But, Farooq *et al.* (2001) and Khurshid *et al.* (2003) also reported significant association of eggshell thickness with egg width. Also, Alkan *et al*. (2008) reported that there was a significant relationship of eggshell thickness with egg lenght of quails. As reported by *Fajemilehin* (2008) eggshell thickness was predicted with sufficient accuracy (P<0.01) from egg lenght, width and weight. Eggshell surface area was predictable with enough accuracy (P<0.01) from egg weight. Regression coefficient of the fitted model was 1.00%. Alkan *et al.(*2008) reported significant association of eggshell area with egg weight of Japanese quails and the regression coefficient was calculated as 99.40%.

Egg shape index was predictable with better accuracy from egg egg width and length. Regression coefficient of the fitted model was 97.90%. Alkan *et al.(*2008) reported significant association of eggs shape index with egg lenght and width of Japanese quails and the regression coefficient was calculated as 98.80%. Height of yolk was predictable with accuracy (P<0.01) from egg weight. Because, egg length and widtht have no significant effect on height of yolk. Regression coefficient of the fitted model was 8.50%. But, Alkan *et al.(*2008) reported significant association of yolk height with egg width of Japanese quails and the regression coefficient was calculated as 46.50%. Yolk width was predictable with enough accuracy (P<0.01) from egg width. Regression coefficient of the fitted model was 10.90%. But, Alkan *et al.(*2008) reported significant association of yolk width with egg weight, lenght and width of Japanese quails and the regression coefficient was calculated as 79.40%.

Weight of yolk was predictable with better accuracy (P<0.01) from egg weight and regression coefficient of the fitted model was 31.60%. Khurshid *et al*.(2003) reported

significant association of yolk weight with egg weight and width of Japanese quails and the regression coefficient was calculated as 60.54%. Fajemilehin (2008) also reported positive association of yolk weight with egg weight of Quinea fowl eggs and the regression coefficient was calculated as 60.00%. Weight of albumen was predictable with better accuracy ($P<0.05$) from egg width and the regression coefficient of the fitted model was 5.10%. Fajemilehin (2008) also reported positive association of albumen weight with egg weight and width of Quinea fowl eggs and, the regression coefficient was calculated as 72.75%.

Conclusıon

As a result, the egg weight was enough predictable when egg lenght and egg width were used as independent variables. However, egg lenght and egg width can be used individually for predicting of egg weight. The eggshell weight was predictable with sufficient accuracy from egg weight. Eggshell thickness was predictable with sufficient accuracy from egg weight. Also, egg shape surface area and yolk weight can be predictable enough from egg weight. Albumen weight was predictable from egg width ($P<0.05$). But, egg weight has no significant effect on the albumen weight. At the same time, yolk width was enough predictable when egg width was used as independent variable. Egg weight, lenght and width have no significant effect on albumen width.

Abstract

This study was conducted to determine the effects of different silage additives on sunflower silage quality.The treatments were as follows: (1) control (C, no additive), (2) 5% molasses (M) (3) inoculation of lactic acid bacteria (LAB; 1.5 g/ton, a mixture of *Lactobacillus plantarum*and *Enterococcus faecium* applied at a rate of 6.00 log10 cfu LAB/g of fresh material),and 4: LAB+enzyme mixture 2 g/ton (LEN, *Lactobacillus plantarum* bacterium (6.00 log10 cfu/g) and cellulose (150000 CMCU/kg) and amylase (200000 SKB/kg) enzymes). Silage additives were mixed and stored in glass jars with 5 replicates for 90 d.There were no significant differences among the groups in terms of pH, ether extract (EE), acid detergent lignin (ADL) and hemicellulose (HEM). The water soluble carbohydrate (WSC) concentration was higher in the M group than those of other groups ($P<0.01$). Lactic and acetic acid concentration were low in the LEN group than others ($P<0.05$). In the LAB group, the dry matter (DM), crude protein (CP), crude ash (CA) and fleig point (FP) were lower than those of other groups ($P<0.01$). In the M group, the neutral detergent fiber (NDF) and acid detergent fiber (ADF) were lower and the total digestibility nutrient (TDN) and non-starch carbohydrate (NFC) were higher than those of other groups ($P<0.01$). The crude cellulose (CC) of M and LEN groups were lower than C and LAB groups. In conclusion, the inoculants (LAB and LEN) and molasses addition to sunflower crop before ensiling may positively affect different silage quality characteristics.

Key words: *sunflower silage, molasses, inoculant, silage quality*

Introduction

In ruminant nutrition, roughagesarecheap and good nutrient sources and essential for goodrumen function. Silage production has some advantages in the dairy farms. However, to provide superior quality silage, appropriate plant, appropriate harvest time, enough in easy water soluble carbohydrates (WSC), thengood ensiling and fermentation are necessary.

Corn silage production is very common in dairy or beef cattle and sheep and goat farms. However, sunflower silage is not common as corn silage in these farms. For corn production, it is necessary better soil properties, high climatic temperature and more irrigation compared to sunflower plant (Gonçalves et al., 1999). As an alternative, sunflower has a good ability for drought tolerance, resistance to cold and heat, adaptability to different climatic conditions high dry matter (DM) yields, and relative independence of latitude, altitude and photoperiod (Tomich, 1999). Sunflower silage has higher concentration of protein and fat compared to corn (Gregoire, 1999) and sorghum (Demirel et al., 2006) silages. However, when it late harvest, due to increase fiber content of sunflower silage, lowersilage quality and digestibility of material in ruminants (Demirelet. al., 2006; Ozduven et al., 2009).

Silage additives commonly have been using in many farms for improve silage fermentation and quality.There are many commercial bacterial inoculants, enzyme and organic acids and their combinations (Meeske and Basson 1998; Sucu and Filya, 2006). However, many

experiments were done in corn silage (Aksu et al., 2004; Baytok et al., 2005; Filya et al., 2006) but lesser experiments done with sunflower (Denek et al., 2004; Ozduven et al., 2009) and other silage materials (Ozduven et al., 2010).

The biological inoculants as silage additive are producing via*Lactobacillus* bacteria (LAB) and stabilized for silage additive and generally they increase lactic acid concentration and reduce pH, acetic acid, butyric acid and ammonia- nitrogen levels in silage (Aksu et.al., 2004). Last decade, there are many effort to produce new strainof homo and hetero fermentative bacterial inoculants by the commercial companies as an alternative to former inoculants and new combinations with enzymes. On the other hand, commercial biologic silage inoculants may be costly to farmers and some conditions may not reliable due to inactivated microbial organisms (Weinberg and Muck 1996). Molasses is a by-product of sugar production factories and it can be used to get water soluble carbohydrate source in silage (Nkosi et al., 2010).

The aim of this study was to evaluate the effect of molasses and biological silage additives on sunflower silage quality traits.

Material and methods

Sunflower plant material was obtained from Erciyes University Agricultural Research Field without any treatment and harvested at the late flower stage of maturity (31.10 ± 0.81% DM) at August17, 2013. The whole plants were chopped about 2 to 4 cm and ensiled in 1 kg capacity glass jars with 5 replications. The chopped fresh materials were filled tightly in order to avoid oxygen. The ensiled jars were stored at room temperature (20°C ± 3°C) for 90 days.The treatment groups were as follows: (1) control (C, no additive), (2) 5% molasses (M) (3) inoculation of lactic acid bacteria (LAB; 1.5 g/ton, a mixture of LAB consisting of *Lactobacillus plantarum*and *Enterococcus faecium* applied at a rate of 6.00 log10 cfu LAB/g of fresh material, Pioneer 1174, USA),and 4: LAB+enzyme mixture 2 g/ton(Inoculant and enzyme mixture (LEN, *Lactobacillus plantarum* bacterium (6.00 log10 cfu/g) and cellulose (150000 CMCU/kg) and amylase (200000 SKB/kg) enzymes, Silaid WS^{TM}, Global Nutritech Co., USA). Themolasses, LAB and LEN were dissolved in 20ml water and sprayed on the chopped sunflowerfresh materials.

Chemical analyses

At the end of the 90 days ensiling period the silages were sampled for chemical and other analyses. pH measurements were taken for 25 g of silage samples taken in a beaker by adding 100 ml of distilled water in a blender for 5 minutes then decomposed with silage pH was measured (Akyildiz, 1986). The DM content of the silages was determined by drying at 60°C for 72 h in an oven. Crude ash of samples was obtained after 4h at 600°C (AOAC, 1990). Crude protein (CP), crude fiber (CF) and ether extract (EE) were determined according to the AOAC (1990) method. Neutral detergent fiber (NDF) and acid detergent fiber (ADF) were analysed using the sodium sulphite addition method with residual ash (Van Soest et al., 1991). The difference between NDF and ADF values provides an estimate of hemicellulose. At the end of the ensiling period the silages were sampled as a liquid extraction for WSC and volatile fatty acid (VFA) analysis. The liquid extractions were prepared with 40 g silage to be put into a beaker and added 360 ml distilled water, than mix with a blander. This liquid was filtered through Whatman 54 filter paper and then centrifuged. Samples were stored at -20 °C until analyzed. WSCs were determined by the phenol-sulphuric acid method (Dubois et al., 1956). Lactic acid (LA) was determined by Lepper's methods (Akyildiz, 1986). VFA (Acetic, Propionic and Butyric acid) analysis were analysed in a gas chromatograph with an capillary column (30 m × 0.25 mm × 0.25 μm, Restek), in a Shimadzu GC-2010+ (Kyoto, Japan) gas chromatograph equipped with FID, over a temperature range of 45–230°C.

The total digestible nutrients (TDN) values were calculated according to the equation proposed by Chandler (1990), where %TDN = 105.2-0.68 x %NDF. The non-fiber carbohydrates (NFC) were calculated by the equation proposed by Weiss et al., (1992): %NFC = 100 - (%NDF + %CP + %EE + %CA). Total carbohydrates (TC) were determined according to Sniffen et al., (1992) by equation TC = 100 - (% CP +% EE +% CA). The metabolic energy (ME) was calculated by the equation proposed by Kirchgesser, (1997): 14.03-(0.01386 x % CF)-(0.1018 x % CA).

Statistical analysis

Data were analyzed using the general linear model procedure of the SPSS program. Differences between reported means were determined using the Duncan's multiple range tests with a 5% level of probability. The results of statistical analysis were shown as mean values and standard error of the means (SEM) in the tables.

Results and discussion

The effect of molasses, lactic acid bacteria inoculant and enzyme supplementation on the sunflower silage pH, dry matter, crude protein, crude cellulose, crude ash and ether extract concentration are showed at Table 1.

$^{a,b,c:}$ Values with different superscript in a line differ significantly; LAB: Lactic acid bacteria inoculant, LEN: enzyme and bacteria inoculant P:probability; *:P<0.05; **:P<0.01; SEM: pooled standard error of means. NS: non significant

There were no statistically differences between the treatment groups in terms of pH, and ether extract values. Similar findings were observed that molasses addition to ryegrass (Islam et al., 2001) and Lab inoculant addition to corn silage (Filya et al., 2004) did not chance silage pH. Addition of 5% molasses caused an increase in DM content compared to LAB and LEN groups. In the LAB group the DM was lower than those of other groups (P<0.01). Islam et al. (2001) and Gul et al. (2008) noted that molasses addition caused an increase in DM content of grass silages. However, Ozduven et al. (2009) reported that LAB inoculant and LEN addition and Polat et al. (2005) LAB inoculant addition to sunflower silage material did not affect DM content of sunflower silage. Similar findings were reported by Meeske and Basson (1998) and Filya and Sucu (2006) in corn silage LAB inoculant addition did not affect DM of corn silage. In the LAB group crude proteinand ash were lower than those of C, M and LEN groups (P<0.01).In the experiment LAB supplementation may be increased lactic acid bacteria and thus, bacteria used some protein and minerals to bacterial growth and improvement. Ozduven et al. (2009) and Koc et al. (2009) reported that LAB and enzyme mixture inoculants did not change crude protein, ash and ether extract of sunflower silages. The crude cellulose content of 5% M and LENgroups were lower than those of C and LAB groups(P<0.05).In the M group, ADF and NDF values were lower than those of other groups (P<0.01).There were no

significant differences among the groups in terms of HEM and ADL values.Islam et al (2001) determined that molasses and bacterial inoculants reduced cellulose components in grass silages. However, Ozduven et al. (2009), Koc et al. (2009) reported that LAB and enzyme mixture inoculants did not change crude protein, ether extract, crude cellulose, ADF, NDF, ADL, HEM contents of sunflower silages. As a biological material, effectiveness of silage additives and silage fermentation characteristic may vary according to ensiled material properties, ensiling techniques, stored conditions and properties inoculants (Kılıç, 1986; Henderson and McDonald, 1984).

The effects of M, LAB and LEN supplementation on the WSC, lactic, acetic, propionic and butyric acid concentration of treatment groups are showed at Table 2.

Table 2. The effects of molasses, lactic acid bacteria (LAB) inoculants and enzyme supplementation on the water soluble carbohydrate (WSC), lactic, acetic, propionic and butyric acid concentration of sunflower silage

	Treatment groups					
Item	Control	Molasses	LAB	LEN	SEM	P

LAB: Lactic acid bacterial inoculant, LEN: enzyme and bacterial inoculant; P: probability; ND: Not detected; *:P<0.05; **:P<0.01; SEM: pooled standard error of means, NS: non significant.

Molasses supplementation was increased WSC concentration compared to other groups. Also, in the LEN group's WSC concentration was higher than those of C and LAB groups (P<0.001). It is reported that WSC content of corn (Ozduven et al., (2010) and sunflower silage (Ozduven et al., 2009) increased by the LAB and enzyme inoculants addition. The lactic acid concentration in the LEN group was lower than those of other groups (P<0.05) andthe acetic acid concentration was lower than M and LAB groups (P<0.05), however there was no statistical difference with C group. There was no difference between the treatment groups in terms of propionic acid concentrations (P>0.05). In silage samples, butyric acid was not determined.It is expected that silage additives such as LAB and LAB+enzyme mixtureinoculants can increase WSC and lactic acid and decrease in pH, acetic, propionic and butyric acid ratio in silages. These additives may support to release fermentable sugars to produce more lactic acid in proportion to other products and lowered pH level (Kung et al., 1991). In the current experiment LA concentration did not change in LAB group and lowered with LEN addition. In contrast to these findings,Islam et al. (2001), Filya et al. (2004), Ozduven et al. (2009, 2010), and Koc et al. (2009) reported LAB and enzyme addition reduced LA concentration in silages.

The effects of M, LAB inoculants and LEN supplementation on the TDN, OM, NFC, TC, ME and FP are given at Table 3. In the M group, TDN and NFC values were significantly higher than those of C, LAB and LENgroups (P<0.01 and P<0.05). The LAB supplementation increased the OM, TC and ME values statistically higher than those of C, M and LEN groups (P<0.01 and P<0.05). However, in the LAB group the FP was lower than those of other groups (P<0.01). No significant effect were determined between the C and LEN groups in terms of TDN, OM, NCF, TC, ME and FP.Molasses and LAB inoculants were increased energy value parameters. Islam et al (2001) reported that molasses and inoculant addition did not affect gross energy of silages. Feed value of ensiled feed is affected by variety of factors such as seed content that varies according to vegetation period, NDF content and digestibility, carbohydrate, fat and protein content of feed (Bal et al., 1997).

Table 3. The effects of molasses, lactic acid bacteria (LAB) inoculants and enzyme supplementation on the total digestibility nutrients (TDN), organic matter (OM), non-starch carbohydrate (NFC), total carbohydrate (TC), metabolizable energy (ME) and fleig point (FP)

	Treatment groups					
Item	Control	Molasses	LAB	LEN	SEM	P
Total digestibility nutrients, g/kg DM	78.26[b]	80.93[a]	76.55[b]	78.13 [b]	0.497	**
Organic matter, g/kg DM	86.37[b]	87.28 [b]	89.95[a]	86.28 [b]	0.458	**
Non-starch carbohydrate, g/kg DM	34.28[b]	39.28[a]	36.12[b]	34.61 [b]	0.659	*
Total carbohydrate, g/kg DM	73.90[b]	74.97 [b]	78.26[a]	74.43 [b]	0.584	*

Fleig point	104.18[a]	107.03[a]	99.28[b]	103.80[a]	0.881	**

[a, b,c:] Values with different superscript in a row differ significantly; P:probability; *:P<0.05; **:P<0.01; SEM: pooled standard error of means. LAB: Lactic acid bacteria inoculant, LEN: enzyme and bacteria inoculants.

Conclusion

In conclusion, addition of molasses increased DM and lowered ADF and NDF level in silage samples. Also, molasses inclusion increased WSC and LA concentration in silages. The LEN group (LAB+enzyme mixture) did not influence positively silage quality traits. The molasses and LAB inoculant addition positively affected silage TDN, OM, NFC, TC and ME levels. According to these results molasses and LAB can be preferred as a sunflower silage inoculant.

Acknowledgements

The authors would like to thank to Erciyes University Agricultural Research and Application Center (Kayseri, Turkey) authorities for supplying sunflower plant material and help to make silage.

Abstract

In this study, it was aimed to install electronic transmitters (radio tags) with surgical operation without resorting to euthanasia and after the incision to Rainbow trout and to heal by using waterproof tape and disinfectant, antibiotic.

Forty eight rainbow trouts about 250-260 g were used in the surgery operations and then were placed in six tanks with 500 lt volume under laboratory condition after the surgery. The tank water was kept in suitable temperature and dissolved oxygen with a well aeration and continuously cooling. Fishes were anaesthetized with 0,4 ml/L 2- phenoxyethanol by bath method after they were starved for a day. The continuous water containing anesthetic 0.2 ml / L 2-phenoxyethanol were given to the mouths of fishes with a hose. Fish anus to about 7 cm, ventral fins 3 cm, pectoral fins 2 cm, operculum 5 cm, so that the incision 3 cm long; puncture of a sterile scalpel sharp on the full abdominal cavity facing and made an incision by followed were opened muscle and layers subcutaneous connective tissue, skin. Electronic transmitter was inserted into the abdominal cavity. Then of the incision was discarded 3 of the operation sewing needle. The purpose of improve the incision fish was used to heal of penicillin, disinfectants, waterproof tape, disinfectant +waterproof tape and pensile the + waterproof tapes. Complete healing of surgical was observed in 20 days in the control group not given anything; 15 days group at penicillin, in disinfectants and disinfectant + waterproof tape; 10th day of the pensile + waterproof tape group.

This research demonstrated that surgery can be done in the future fish, in particular the internal organs of the biopsy has demonstrated to be contribution to a very important.

Key Words: *Rainbow Trout, Oncorhynchus mykiss, Punction, Incision, Surgical Operation, Electronics transmitter*

Introduction

Use of electronic transminatter (radio tag) in the world has been started from the 17th century, especially in recent years, fishes economically important and endemic is used citations various known electronic tag placed inside the body in order to examine the behavior (Thorsteinsson, 2002; Lucas and Bubb, 2005; Enders et al., 2007; Nelson et al., 2007). In recent years, their habitat use and fish migration with the development of electronic brand technology has become more important (Thorsteinsson, 2002).

The objective of the operation applied to live on anesthesia is to ensure that slowing of the metabolic rate live, not suffering from the intervention of living, facilitating the intervention in living, by slowed down to stop the reflex response, destruction or decreased consciousness, lively sense of recruitment (Çetinkaya and Şahin, 2005).

Surgical applications in fish applied removal of tissue for treatment of nonpathological and other pathologic, removal various organs and tumor, various organ biopsy, sperm and egg sampling, branding, implant placement, drug injection, blood, vaccines (Akyol and Ceylan, 2003).

Studies surgical operation made could not determin morphological characteristics of maturity gender and sex in Sturgeon (Akbulut et al., 2005). But trout or other fish in operation has not been observed in studies.

Recent years to examine individual behavior in fish electronic tag placed into the body fish have been used. Radio tags, also known as transmitter tag used to investigate the more fish migration and habitat (Thorsteinsson, 2002; Anonim, 2015b; Hale and Gray, 1998; Ramstad and Woody, 2003; Brennan et al., 2005; Neely et al., 2009).

After the operation the fish disinfectant and antibiotic water-soluble control dose to prevent infection can be applied (Anonim, 2015a).

People, especially evaluation stages and for follow-up the surgical wound can be an important record about the development of the photographing process after receiving the approval of the patient (Yüceyar, 2008). In a study conducted in fish is made assessment depending on whether or redness and inflammation of the incision looking over the eye clinical examination of the surgical wound (Pedersen and Andersen, 1985).

Successful survival of Rainbow trout has been achieved by inserting an electronic brand (radio tag) through a surgical operation and treating the region with antibiotics, disinfectants and waterproof tape after incision without the need of euthanasia. To our knowledge, this study demonstrates the use of antibiotics, disinfectants and water-proof tapes to heal the incision region of fish for the first time. Additionally, with the results generated here, it has been clearly shown that this research can significantly contribute to surgical interventions, especially internal organ biopsies, which may be performed on fish in the future. Lastly, we believe that the results of this study will be beneficial for the operation studies to be conducted to determine the gender and sexual maturity of Sturgeon fish and to the electronic brand projects that aim at investigating migration routes, migration time, habitat selectivity, breeding areas, and breeding biology of other fish.

Materials and Methods

The study was carried out at the Fish Disease Laboratory, Fisheries, Faculty of Agriculture, Kahramanmaraş Sütçü Imam University (Turkey). Rainbow trout has been used in surgery for 250-300 g in weight at 48 number. The fish tank was placed 500 liters at 6 number. Trout is expected 7 days to ensure adaptation to the environmental conditions. Fish were used 3 mm diameter pellets feed during the study period. Surgical operation was used operating table, forceps, pointed scalpel, scissors, catgut suture material in the needle holder scissors, cotton, alcohol, electronics brand (radio tag) waterproof tape, disinfectant and penicillin powder, plaster and waterproof tape. These materials is made in the laboratory disinfection or sterilization. For the procedure anesthesia to fishes was added 4 ml of 2-phenoxyethanol 10 liters of water into bucket. Fishes is provided inactivity completely in about 1 minutes in anesthetic solution. Fishes are given sustained mouth water and placed supine on the operating table prepared maximum care under aseptic conditions. For lack contamination in operation were sterile instruments to be used. Cross-sectional area has been cleared with the help of cotton excess mucus and disinfected with sterile saline. Fish anus to about 7 cm, ventral fins 3 cm, pectoral fins 2 cm, operculum 5 cm, so that the incision 3 cm long; puncture of a sterile scalpel sharp on the full abdominal cavity facing and made an incision by followed were opened muscle and layers subcutaneous connective tissue, skin. Electronics brands (radio tag) that will be placed have been disinfected with 96% ethyl alcohol. Electronic transmitter (radio tag) was inserted into the abdominal cavity. Then instead of these operations have been taken 1. sewing, 2. sewing and 3. sewing instead of the surgical needle. Operation place was applied waterproof tape, disinfectant and penicillin specified in the group. Groups are described Table 1

Table 1. Experimental groups

1. group	**2. group**	**3. group**	**4. group**	**5. group**	**6. group**
Control	Penicillin	Disinfectant	Waterproof tape	Disinfectants + waterproof tape	Penicillin + waterproof tape
7 number	8 number	8 number	8 number	8 number	8 number

Each group of fish during the experiment was given feed twice including daily morning and evening until regimens. During the experiment, the water in the tank containing the fish were taken into value oxygen, pH and temperature daily.

Results and Discussion

Rainbow trout has been provided successful survival of fish improvement using of antibiotics, disinfectants and waterproof tape after incision and placing electronic brand (radio tag) with surgical operations without resorting to euthanasia.

The most widely used anesthetics in the fisheries industry were MS-222, benzocaine, kinaldin, 2-Fenoksietanol, clove oil, klorbütanol, metomideyt, propanidit, etomideyt. Besides like the ketamine, the saffan, the halato, chloralhydrate, diazepam was used a anesthetic and sedative. But these used relatively less than others (Lemmer, 1993; Kanyılmaz et al., 2007). In this study, 2-Phenoxyethanol was preferred due to the very use in the fishing business and absence of toxic.

Live exposed anesthetic agent occur unresponsiveness after movement and loss of balance, before sedation, depending on the concentration and exposure time and finally disappear reflex action (Çetinkaya and Şahin, 2005). This study fishes were observed similar findings during anesthesia.

During surgical operation fish is performed oxygen enrichment and continuation of anesthesia with water anesthetic mixture by a suitable pipe mouth. The deep is provided the continued operation by controlling the temperature and to ensure remain moist. At the end of operation is expected the recovery in minutes in the post-operation tanks air-conditioned (Çetinkaya and Şahin, 2005; Kanyılmaz et al., 2007; Akyol and Ceylan, 2003). In this study, made of similar application fish has not been any loss during surgery.

Fish skin consists of two layers (Ekingen, 2001; Arda et al., 2005). Epidermis forms the uppermost layer is typically very thin (Demir, 2006). Epidermis is located secreting cells (goblet cells, mucous cells) mucoid substance (protein, glycoprotein, proteoglycan structure in). Therefore, This top skin is very slippery and It is coated with a layer of mucoid (Arda et al., 2005). Typically superficial is up to 250 microns the average thickness, consist of flat cells several times (10-30 times) (Ekingen, 2001). In this study, deep layer thickness has changed based on the size and sex of fish.

This study made by Pedersen and Andersen (1985) was boiled for 30 minutes boiling water to sterile materials to be used in surgical procedures. Also He waited 65% ethyl alcohol sewing thread and the operating table. We used sterile surgical gloves to avoid contamination. In this study, materials used in surgical procedures were sterilized 45 minutes at 121 ° C at 1 atmosphere autoclave. Also operating table has been cleared thoroughly disinfectant odorless, colorless, derived from salt and pure water 100% natural. Immediately before the surgical procedure was heated at ethenol electronics brands (radio tag) and operating table was wiped with 96% alcohol.

Works electronic transminatter (radio tag) in the world has started from the 17th century, especially in recent years, fishes economically important and endemic is used citations various known electronic tag placed inside the body in order to examine the behavior (Thorsteinsson, 2002; Lucas and Bubb, 2005; Enders et al., 2007; Nelson et al., 2007). This

study laboratory was placed in the abdominal cavity the fish with surgical operation electronic tag successfully.
In a study has been reported does not cause death on fish and 25 cm the radio tag (Lucas and Bubb, 2005). In this study there has been death losses arising from any radio tag.
In care and tracking surgical wound in humans is important be registered the condition of the wound bed, swelling, color, smell, infection, pain, condition of the wound edge, regularly to follow daily and using a form. Especially to stages evaluation and followed by open wounds, after receiving the approval of the patient, the photographing process can be an important record of the development. However, taking picture of the wound may contain problems according structure socio-cultural to the patient's (Yüceyar, 2008),. In this study is taken photograph followed by performing daily in a days 5th 10th 15th and created a form as in the maintenance and tracking of surgical wounds in humans (Table 2-3-4-4).
According to Pedersen and Andersen (1985) from surgical operation has observed inflammation and redness over incision 5-7 days. Inflammation disappeared decrease in 4-8 days. Location of the incision is completely healed 24-34 days. In this study It was observed in waterproof band group and control 5th days only inflammation and erythema. Location of the incision was observed complete recovery 15th day with penicillin, disinfectant, disinfectant + waterproof tape; 10th days without any contamination penicillin + with waterproof tape. However, in the control group not applied anything were observed redness and inflammation 5th day. Completely healing recorded 20th day in the control group not implemented anything; 15 days in group penicillin, disinfectant and disinfectant + waterproof tape; 10th days the group penicillin + waterproof tape
Before starting surgical operation fishes, antibiotic can provide against infection using a protective dose. At the end of the operation recommended to continue to practice antibiotic 1-4 weeks (ScottWeber et al., 2009). In this study is used to close location incision immediately after surgery antibiotics (penicillin) to be contaminated at the surgical site.

Conclusion

First time in Turkey, rainbow trout has been finalized successfully placing electronics brands (radio tag) and applied to such an operation technique.

In human and veterinary medicine has been very difficult really apply in fish such a study looks very simple. So far fishes haven't been made such a surgical intervention. With this study; If rainbow trout implemented necessary of rules antisepsis after the operation, they could stay successfully live; fishes can be done in surgical intervention the future; especially In enzymatic studies with liver biopsy; the examination of histological structure of the liver and It has been put forward may be of a very important contribution to studies as ultrasound taking of cystic structure in the presence of internal organs.

In improving the incision of fish has been used for the first time successfully antibiotics, disinfectants and waterproof tape

Rainbow trout has been provided successful survival of fish after incision improvement using of antibiotics, disinfectants and waterproof tape and electronic brand (radio tag) placing with surgical operations without resorting to euthanasia. This research, fish in the surgery can be done in the future, in particular, it has put forward would be very significant contribution to the internal organs biopsies. Furthermore, the fish are used to improve the location of the incision the first antibiotic, disinfectant and waterproof tapes. These study results, Sturgeon will make a significant contribution penicillin + waterproof improving soon 10 days place the surgical operation the study in electronics brand such as other fish migration routes, migration time, habitat selectivity, breeding areas, breeding biology and operating activities used to determine sex and sexual maturity.

Abstract

Cattle farming is the leading branch of livestock production in almost all countries of the world. In livestock production it is by far in the first place, despite the constant increase in production of pork and poultry in the world. The aim of this paper is the influence of lactation on reproductive characteristics (age of cows at first insemination, gestation length, service period duration and inter-calving interval duration) in Simmental cows reared on the farm "Mountain Good Nevesinje". The farm is located on 4 locations (Morine, Sopilja, Kovačice and Pomakovci). Based on the data obtained from the population register (selection agency) and monitored reproductive characteristics (age of cow - heifers at first insemination, gestation duration, service period and inter-calving interval duration) in the first three calvings, ie. three lactations, what follows can be concluded: the average age of a cow (heifer) at first conception was 16.84 months, and all were successfully inseminated in 2011. Duration of gestation, depending on the order of the calf, ranged between 288.20 days (first calf) and 287.20 days (second calf). The average service period, or inter-calving interval for the first three lactations (three calvings) amounted to 136.64 days and 423.44 days. Minimum duration of service period, and therefore inter-calving interval was in the third lactation and amounted to 136.64 days, or 397.20 days.

Key words: *lactation, reproductive characteristics of cows and Simmental cattle*

Introduction

The advantage of cattle breeding in comparison with other branches of livestock production is the use of available reserves of forage, namely those that are produced in the fields and meadows, as well as those used by going out on pastures. The base of production is keeping or breeding of cattle and as its main products we have milk and calves, and therefore the production of beef. Yield and quality (composition) of milk are partly hereditary characteristics, ie. they depend on the breed (genotype) of cows. (Mitić et al, 1987); Looper, 2012). Khan et al. (1996) point out that cows age during the calving are affected by the age of cows, especially young cows in early lactation. Reproductive efficiency is the main factor that determines the success of production and economic efficiency in dairy herds (Diskin, 2008). Reproduction of cattle is one of the most important phases of livestock production, because at that stage the heads which are going to replace the herd are provided, as well as for milk production and fattening, and meat production. Many years of intensive selection of dairy cattle breed focused on high milk production or milk production, has significantly influenced the reduction of their fertility, and reproductive efficiency (Rodriguez-Martinez et al., 2008). The main objective of this study was the influence of lactation on reproductive characteristics in Simmental cows reared on the "Planinsko Dobro Nevesinje" farm (age of cow at first insemination, gestation length, service period and inter-calving interval duration).

Materials and methods

By the method of randomly selected sample of 15 cows in first three lactations (a total of 45 cows) the following indicators were observed (age of cows at first insemination, gestation length, service period and inter-calving interval duration). Each cow was identified, ie. had its pedigree with the registration number, date of birth, order of lactation, date of insemination, gestation length, service period and inter-calving interval. Observations were carried out on the farm "Planinsko Dobro Nevesinje", which, among other things, deals with the breeding and cultivation of dairy cows or production of milk. The basic data processing and testing of the significance of differences between the tested parameters was performed using conventional variation - statistical methods and analysis of variance (Hadživuković, 1991), and calculations of the coefficients of phenotypic correlation connection between the established parameters was performed according to the model for the appropriate sample (Latinović, 1996).

Results and discussion

According to the textbook literature, cows (heifers), depending on the race, reach sexual maturity between 11 and 15 months. They are sexually active throughout the year, and the gestation lasts between 278 and 288 days, although some minor deviations that are caused by abiotic factors are possible. Accordingly, in Tables 1 and 2, the results of our tests are determined in terms of age of cows (heifers) at their first conception, gestation duration, inter-calving interval, and service period duration for the I, II and III lactation, ie. calving of cows. A series of genetic and non-genetic factors affect the service period: cattle breed, the amount of daily milk production, the parity of calving, nutrition and housing, health condition of cows on the farm, the state of the reproductive organs of cows, estrus detection, timely insemination, etc. (Orešnik, 2009) .

Table 1. Average values and variability of age of cows, inter-calving period and service period in the first three lactations

(n – 15 + 15 + 15 = 45)

Lactation	**Indicators**	$\bar{x}$	$S_{\bar{x}}$	**S**	**C.V. (%)**
I	Age of cows – first insemination (months)	17,87	0,55	2,13	11,92
	Inter-calving period (days)	437,07	10,32	39,99	9,15
	Service period (days)	148,87	6,13	23,76	15,96
II	Age of cows – first insemination (months)	16,20	0,28	1,09	6,73
	Inter-calving period (days)	436,07	18,50	71,64	16,43
	Service period (days)	151,07	7,95	30,81	20,30
III	Age of cows – first insemination (months)	16,44	0,49	1,90	11,58
	Inter-calving period (days)	397,20	9,85	38,15	9,60
	Service period (days)	110,00	9,62	37,27	9,62
I+II+III	***Age of cows – first insemination (months)***	***16,84***	***0,27***	***1,91***	***11,34***
	Inter-calving period (days)	***423,44***	***8,02***	***53,78***	***12,70***
	Service period (days)	***136,64***	***53,60***	***35,95***	***26,31***

The data in Table 1 show that the average age of the three groups of cows at first successful insemination was 16.84 months, respectively 17.87 months (group of cows that is monitored during the first lactation - first calving), 16.20 months (cows during the second lactation – the

second calving) and 16.44 months (third lactation cows - the third calving). The differences in terms of age of cows at first insemination were not statistically significant (P> 0.05).

Table 2. Average values and the variability of the duration of gestation depending on the age of the cow and gender of the calf (days)

Gestation	Calf gender	n	$\bar{x}$	$S_{\bar{x}}$	S	C.V. (%)
I	♂	9	288,11	0,77	2,15	0,75
	♀	6	288,33	0,66	1,63	0,56
	♂ + ♀	15	288,20	0,49	1,90	0,66
II	♂	8	287,25	0,45	1,28	0,45
	♀	7	287,14	0,59	1,57	0,55
	♂ + ♀	15	287,20	0,35	1,37	0,48
III	♂	6	288,50	0,56	1,38	0,48
	♀	9	287,67	0,60	1,80	0,63
	♂ + ♀	15	288,00	0,43	1,65	0,57
I+II+III	♂	***23***	***287,91***	***0,35***	***1,70***	***0,59***
	♀	***22***	***287,68***	***0,36***	***1,67***	***0,58***
	♂ + ♀	***45***	***287,80***	***0,25***	***1,65***	***0,57***

The duration of gestation, regardless of the order of lactation calf gender was approximately the same, and in average the duration of gestation in the first three lactation periods for both genders was 287.80 days (Table 2). In addition, absolute and relative measures of variability in terms of the duration of gestation were very small (CV - less than 1%), and the determined differences between the duration of gestation (Table 3) were not statistically significant (P> 0.05).

Table 3. The significance of differences in age of cows, gestation, inter-caving interval duration and service period duration in the first three lactations
(n - 15 + 15 + 15 = 45)

Indicators	Lactation	Average	Difference	Significance
Age of cows, months	I-II	17,87-16,20	1,67	Ns
	I-III	17,87-16,44	1,43	ns
	II-III	16,20-16,44	-0,24	ns
Duration of gestation, days	I-II	288,20-287,20	1.00	Ns
	I-III	288,20-288,00	0,20	ns
	II- III	287,20-288,00	-0,80	ns

	I-III	437,07-397,20	39,87	**
	II-III	436,07-397,20	38,87	*
Service period, days	I-II	148,87-151,07	-2,20	Ns
	I-III	148,87-110,00	38,87	**
	II-III	151,07-110,00	41,07	***

***P<0,001; **P<0,01; *P<0,05; ^{nc}P>0,05

In contrast to the duration of gestation of cows, the duration of inter-calving interval, and service period in particular showed large variability, both in absolute (S) and in a relative (C.V.%) measures of variability (Table 1). In general (the first three lactations), the coefficient of variation was 38.92% (service period duration) and 12.70% (inter-calving period).

Conclusion

Based on the data from the system records (selection service) and monitoring of the reproductive characteristics (age of cow - heifers at first insemination, gestation duration, service period and inter-calving interval duration) during the first three calvings ie. three lactations, the following conclusions can be derived:

- The average age of the cows (heifers) at first conception was 16.84 months, and all were successfully inseminated in 2011. Duration of pregnancy, depending on the order of the calf, ranged between 288.20 days (first calf) and 287.20 days (second calf).
- The average service period duration, or inter-calving intervals duration for the first three lactations (three calvings) amounted to 136.64 days and 423.44 days. The minimum duration of service period, and therefore inter-calving interval during the third lactation and the amount is 136.64 days, or 397.20 days.

Abstract

The aim of this study is the effect of the order of lactation on production characteristics (milk yield, yield and fat content in milk, yield and protein content) and determination of phenotypic correlation connection (r_p) between production characteristics, and statistical significance of the difference in the first three lactations of Simmental cows grown on the farm "Planinsko Dobro Nevesinje". Duration of the first lactation was the longest (372.07 days) and the shortest was (321,80 days) in the third production lactation, averaging 347.69 days (for all three lactations). The duration of production lactation is directly reflected on the yield of milk, which in the first lactation was 8019.73 kg, 7864.87 kg in the second, and 7341.40 kg in the third. Although the first lactation was the longest, and the third was the shortest, the daily production per cow was the highest in the third lactation (23.02 kg), followed by the second lactation (22.87 kg) and the lowest production was in the first lactation (21.70 kg), ie. with the aging of the cows the production of milk increased. In relation to production lactation (whole), milk yield, calculated in standard lactation (305 days), was averaging at 7,272.93 kg. Between milk yield throughout the whole lactation and milk yield in standard lactation there is a strong positive correlation connection. With increasing milk yield in standard lactation, protein content, and especially milk fat content decreased.

Key words: lactation, production characteristics, Simmental cows.

Introduction

In livestock production, milk is the most important product, while in a human consumption it is one of the most important foods. In developed countries the average daily consumption of milk per capita is 1 liter (Tošić et al., 2002). In addition, a significant number of non-genetic factors affects the milk yield (the effect of lactation on milk production of cows and milk composition, the effect of the order of lactation on cow milk production and milk composition, milking influence, the influence of estrus, breeding and health, the impact of nutrition during breeding on future milk production, the impact of nutrition during lactation, the impact of environmental conditions on cow milk production and milk composition, water content, fat centent, protein content, lactose and mineral substances in milk during lactation (Mitić et al., 1987; Looper, 2012). The effect of lactation on yield, milk fat yield and milk fat content, protein yield and protein content in milk was examined by many authors (Nenadović, 1974; Uremović 1980, Panić et al., 1983; Skalicki, 1983).

The main objective of this study was to evaluate the production characteristics (milk yield, milk fat yield and milk fat content, protein yield and protein content) that affect lactation.

Materials and methods

The tests were conducted on the farm "Planinsko Dobro Nevesinje", which, among other things, deals with the breeding and cultivation of dairy cows, and milk production. On this farm, if it is operating at its full capacity, milk production can be organized with 543 dairy cows and related categories of cows. Simmental breed of cattle imported from Czech Republic are used for the production of milk (and meat). By the method of random selection, 15 cows in the first three lactations (a total of 45 cows) were selected and the following parameters were observed: milk yield, milk fat yield and milk fat content, protein yield and protein content. The basic data processing and testing the significance of differences between the investigated parameters was performed using conventional variation - statistical methods and the analysis of variance (Hadživuković, 1991), and the calculating of the coefficients of phenotypic correlation connection between the established parameters was performed according to the model for the appropriate sample (Latinović, 1996).

Results and Discussion

In the analysis of the data the indicators of productivity of cows are presented in the table, ie. milk production (production and standard lactation), and milk yield (kg), yield (kg) and the content of milk fat (%) and proteins for the first three lactations of dairy cows which were analyzed.

Table 1. Average values and variability of the duration of lactation and milk production (n - 15 + 15 + 15 = 45)

Lactation	**Indicators**	$\bar{x}$	$S_{\bar{x}}$	S	C.V. (%)
I	Lactation duration (days)	372,07	8,88	34,40	9,25
	Daily milk production, per cow, kg	21,70	0,51	1,99	9,17
	Milk yield (PL), kg	8.019,73	103,19	399,66	4,98
	Milk yield (SL), kg	7.300,00	121,49	470,52	6,44
II	Lactation duration (days)	349,20	16,75	64,88	18,58
	Daily milk production, per cow, kg	22,87	0,55	2,13	9,31
	Milk yield (PL), kg	7.864,87	207.84	804,96	10,23
	Milk yield (SL), kg	7.373,67	82,87	320,96	4,35
III	Lactation duration (days)	321,80	13,79	53,40	16,59
	Daily milk production, per cow, kg	23,02	0,50	1,94	8,43
	Milk yield (PL), kg	7.341,40	116,94	452,92	6,17
	Milk yield (SL), kg	7.145,13	120,59	467,03	6,54
I+II+III	***Lactation duration (days)***	***347,69***	***8,18***	***54,86***	***15,78***
	Daily milk production, per cow, kg	***22,53***	***0,31***	***2,05***	***9,09***
	Milk yield (PL), kg	***7.742,00***	***111,42***	***747,40***	***9,65***
	Milk yield (SL), kg	***7.272,93***	***64,96***	***435,79***	***5,99***

In Table 1, we see that the duration of the first lactation period was 372.07 days, for the second it was 349,20 days, and for the third it was 321,80 days, averaging 347.69 days for all three lactations. In addition to the fact that all three lactations lasted much longer than the standard lactation duration (305 days), the variability between cows was high, especially in the second lactation, C.V. - 18.58%. With the aging of cows, the duration of lactation was

shortened, approaching the standard lactation, and daily milk production increased. The highest daily milk production per cow was in the third lactation (23.02 kg), and lowest was in the first (21.70 kg), while the average daily production for all three lactations was 22.53 kg (Table 8).

Analogously, the milk yield in the longest production lactation (whole) was the largest and vice versa. In the first lactation production average milk yield per cow was the highest (8019.73 kg), and the lowest was in the third lactation (7341.40 kg), averaging 7742.00 kg for all three of lactations. Converted to the standard lactation (305 days), milk yield per cow was the largest in the second lactation (7,373.67 kg), slightly lower in the first (7,300.00 kg) and the lowest in the third lactation (7145.13 kg), averaging 7272.93 kg of milk.

Table 2. The significance of the difference in the duration of lactation, daily milk production, yield and content of milk fat and protein

(n - 15 + 15 + 15 = 45)

***P<0,001; **P<0,01; *P<0,05; ^{ns}P>0,05.

M.Y. (P.L.) = milk yield (production lactation), kg; M.Y. (S.L.) = milk yield (standard lactation), kg; L.D. = lactation duration, days; M.F.Y. = milk fat yield, kg; M.F.C. = milk fat content, %. P.Y. = protein yield, kg; P.C. = protein content, %.

In the preceding section it was said that the duration of the first lactation was the longest (372.07 days) and the shortest (321,80 days) was in the third lactation production. The results show that the established differences between the first and third lactation (50.27 days), and between second and third lactation (27.40 days) were statistically confirmed at the level of P <0.01 and P <0.05. The difference found between the duration of the first and second lactation production (22.87 days) were not statistically significant (P> 0.05).

In terms of average daily milk production the only thing that was statistically significant (P <0.05) was observed difference (-1.32 kg) between the first and third lactation. The observed

difference between the first and second (-1.17 kg), as well as the second and third lactation (-0.15 kg) were not statistically significant (P> 0.05).
Duration of production lactation is directly reflected in the average milk yield and the significance of difference confirmed by data presented in Table 2. The difference found between the first and second lactation (154.86 kg) was not statistically significant (P> 0.05), while the difference between the first and third (678.33 kg), and the second and third lactation respectively (523.47 kg) was statistically significant and was confirmed at the level of P <0.001 and P <0.05.

Table 3. Coefficients of phenotypic correlation between duration of lactation, milk yield, milk fat yield and fat content, protein yield and protein content

(N = 45)

Indicators	M.Y. (P.L.)	L.D.	M.F.Y.	M.F.C.	P.Y.	P.C.
M.Y. (P.L.)	1,000	0,840***	0,948***	0,140ns	0,955***	0,040ns
L.D.		1,000	0,803***	-0,046ns	0,841***	0,072ns

M.F.C.				1,000	-0,086ns	0,455**
P.Y.					1,000	0,111ns
P.C.						1,000
M.Y. (S.L.)	0,634***	-	0,598***	-0,163ns	0,633***	-0,001ns

***P<0,001; **P<0,01; HCP>0,05.

M.Y. (P.L.) = milk yield (production lactation – whole lactation), kg; M.Y. (S.L.) = milk yield (standard lactation), kg; L.D. = lactation duration, days; M.F.Y. = milk fat yield, kg; M.F.C. = milk fat content, %. P.Y. = protein yield, kg; P.C. = protein content, %.

The presented data shows that between milk yield in the production lactation and milk yield in standard lactation there is a strong positive correlation connection and that the determined correlation coefficient (rp = 0.634) was statistically confirmed at the level of P <0.001. Very strong positive correlation connection is found between milk yield and the duration of production lactation (whole) (rp = 0.840), and the determined coefficient was confirmed at the level of P <0.001.
The full positive correlation connection was found between milk yield (production lactation), the yield of milk fat (rp = 0.948 ***), ie protein yield (rp = 0.955 ***), and between the yield of milk (standard lactation), the yield of milk fat (rp = 0.598 ***), and strong correlation connection was found in the yield of protein (rp = 0.633 ***). Between the yield of milk (whole lactation), fat content and protein content, as well as between the yield of milk (standard lactation), fat content and protein content there was found a very weak correlation connection, in fact, there was not even a positive (whole lactation) or negative (standard lactation) correlation connection, and determined coefficients were not statistically significant (P> 0.05).
Between the duration of production lactation, milk fat yield, protein yield a statistically significant value of correlation coefficients was found (P <0.001), rp = 0.803 (M.F.Y.) and rp = 0.841 (P.C.), ie. there is a very strong correlation connection. The duration of lactation did not affect the fat content and protein content, and the value of correlation coefficients stood at -0.046 (M.F.C.), ie. 0,072 (P.C.), and are not statistically confirmed (P> 0.05).
Between M.F.Y. and P.Y. the absolute positive correlation connection (rp = 0.950 ***) was revealed, between M.F.Y and M.F.C. (rp = -0,062ns) or P.C. (rp = 0,093ns) there was not statistically significant correlation connection (P> 0.05), as well as between M.F.C. and P.Y. (rp = 0,086ns), while between M.F.C. and P.C. a statistically highly significant positive correlation was found (P <0.01), rp = 0.455. Between P.Y. and P.C. there is a very weak

positive correlation, and identified coefficient of correlation (rp = 0.111) was not statistically confirmed (P> 0.05).

Conclusion

From what we have stated above, it follows that in the examined cows, grown on the "Planinsko Dobro Nevesinje" farm, the yield and the quality of milk in the first three lactations were at a satisfactory (solid) level. In accordance to that and in accordance with the breeding program of the said farms there is a need to implement appropriate selection measures, ie. on the basis of individual assessment of production and reproductive characteristics, to extract, if necessary, a certain number of cows from the production and perform 'overhaul' of the herd.

Abstract

Morphometric and histological examination of testes in Landes ganders was performed at one-, two- and seven years of age. The testicular morphometry included the following parameters – weight, length and width, diameter of seminiferous tubules (ST), ratio between ST volume and interstitial connective tissue volume. During the breeding season (from the end of December to the end of May) at the studied ages, the weight and size of testes increased greatly. In all investigated males the left testicle was significantly bigger. During the non-breeding season the testicular parenchyma regressed and testes weight decreased too. Contrary to our preliminary expectations significant differences in testicular development depending on age - between one- and two-years old on one hand and seven years old on the other were not found.

Key words: *Landes goose, gander, testes, morphology, histology*

Introduction

The changes in testicular tissue of birds are determined by two primary factors – the age (Bochukov et al., 1995; Gerzilov et al., 2015) and the season (Mori and George, 1978; Deviche et al., 2011; Leska et al, 2012; Islam et al., 2013). In many birds, testes undergo dramatic annual changes in size and, as such, are among the most anatomically and physiologically plastic organs found in adult vertebrates (Deviche et al., 2011). The seasonal dynamics of morphological testicular changes in ganders consists in restoration of spermatogenesis at the beginning of the breeding season, followed by a period of normal spermatogenesis until occurrence of the spermatogenous tissue regression during the non-breeding season (Mori and George, 1978; Leska et al., 2012). In some male birds, including ganders, genetically encoded restoration of reproduction activity is efficient enough to provoke a moderate elevation of testosterone concentrations during the autumn, resulting in substantial development of gonads and sexual behaviour (Leska et al., 2012)

The present study aimed to investigate the anatomical and histological status of testes in Landes ganders related to birds' age and breeding season.

Material and methods

Landes ganders hatched at the same time were used for morphological and histological analysis of testes as followed: 3 ganders during the first breeding season aged 10 months (slaughter in April); 3 ganders after finishing the first breeding season aged 12 months (slaughter in June), 3 ganders during the second season aged 22 months (slaughter in April next year) and one 7-year-old gander slaughtered during the breeding season (in April). The birds were reared in free-range family farm with free access to pasture. Before being slaughtered, the live weight (kg) of birds was individually determined. After dissection of carcasses, testes were removed and the following morphometric measurements were done before the histological processing: weight (g), length, and width (mm). Weight studies were performed by means of analytical OHAUS 2000 scales with precision of 0.01 g (fig. 1).

Fig. 1. Weighing testicles
(Д) – right testis; (Л) – left testis

The length and width of testes were measured with a Vernier caliper with precision of 0.1 mm. Pieces from the equatorial part of the testicular parenchyma, 0.5×0.5×0.5 cm of size were collected for histological and morphometric examinations. Specimens were fixed in fresh Bouin's solition for 72 hours, then submitted to routine procedures: removal of the fixative in ascending alcohol series, clearing with xylene, embedding in paraffin, cutting on a Reichert microtome, mounting of sections 6–7 μm thick on glass slides and staining with haematoxylin-eosin. Examinations were performed with Jenaval light microscope, and findings were documented with a CETI camera. The diameter of seminiferous tubules (μm) was determined by measurements of approximately 30 tubular transverse sections using a standardised eyepiece micrometer. The relative volume (%) of seminiferous tubules and interstitial tissue were determined by the method of Pakenas (1968) on the basis of 30 measurements per testis, using an ocular grid with four hairs of different length, located at specific intervals over the grid circle. The morphometric measurements of testes are presented as mean±SEM.

Results and discussion

During the first breeding season, an active spermatogenesis was observed in seminiferous tubules. All generations of germ cells – spermatogonia, spermatocytes, prespermatids, spermatids and spermatozoa (Fig. 2) were present. The interstitial tissues appeared as thin bands, containing relatively large Leydig cells. During the non-breeding season, testes underwent changes in both seminiferous tubules and in the interstitial connective tissue. The curvature of seminiferous tubules was reduced their lumen has become cleft-like with reduced presence of most germ cell generations except for spermatogonia. In some tubules, detritus cell masses were found out. The interstitial tissue occupied a considerable part of the testicular parenchyma and a variety of cells were present within (Fig. 3). During the second breeding season, the observed histological features were almost the same as during the first breeding season. The artefacts observed in seminiferous tubules reflected the different stages of occurring spermatogenesis. Spermatozoa were attached to the Sertoli cells and formed characteristic groups to the lumen, resembling wheat ears. In the interstitial connective tissue, relatively large Leydig cells could be observed (Fig. 4). The histological picture in testes of the 7-year-old gander was similar to that observed in for the previous studied age (Fig. 5). The results from the weight and macromorphometric studies of testes are presented in Table 1. The weight of the left testis exceeded almost twice that of the right one for all ages and seasons. There was not, however, a similar relationship for the length and width of these organs. Testicular weight during the first breeding season exceeded considerably the weight during the non-breeding season. The values of the gonadosomatic index were higher for all ages during the period of reproductive activities. The data obtained from the measurement of seminiferous tubules' diameters are presented in Fig. 6. It shows that largest diameters were those during the second breeding season, i.e. at 2 years of age. In all ganders during the breeding season, seminiferous tubular diameters exceeded 4–4.5 times the respective values during the non-breeding season. The ratios of seminiferous tubules/intesrtitial connective tissue volumes demonstrated that seminiferous tubules' volume in ganders was the greater during the second breeding season. During the non-breeding season, the proportion of the interstitial tissue was larger – 54.20:45.80 (Fig. 7).

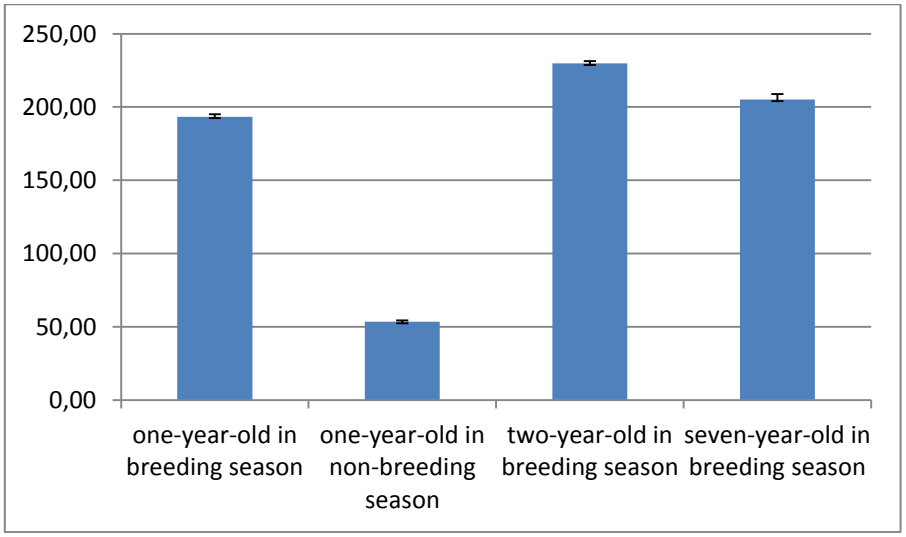

Fig. 6. Seminiferous tubules' diameter (µm) in ganders at a different age and during different seasons.

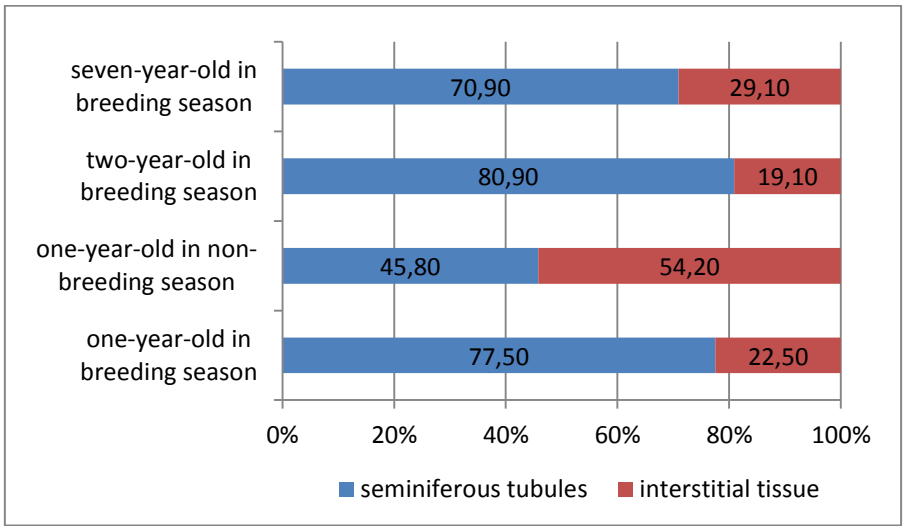

Fig. 7. Seminiferous tubules to interstitial connective tissue ratios

In the present study, signs of actively occurring spermatogenesis were observed in all studied birds during the breeding season. However, we did not found out clearly visible septa, in agreement with the findings of other authors (Bowles, 2014). The presence of anastomoses among seminiferous tubules, which is specific for birds according to Bowles (2014), was not clearly identified. Our results confirmed the presence of cyclic changes in testes in line with other reports (Mori and George, 1978; Lin and Jones, 1990; Deviche et al., 2011; Leska et al., 2012). During the breeding season, all germ cell generations were observed in seminiferous tubules. This specific feature reflecting the different stages of spermatogenesis in birds was described long ago (Johnson, 1961). Out of the breeding season, regression was demonstrated, manifested with reduced weight of testes, reduced presence of germ cells in seminiferous tubules which were present only to the spermatogonia level. After the period of active sexual stimulation, testes atrophied, but never attained the size from the beginning of the breeding season (McDonald, www.scottemcdonald.com).

The weight measurements showed that the left testis was considerably heavier than the right counterpart regardless of the season. During the non-breeding season, the weight of testes sharply decreased compared to the same age during the breeding season. In birds with marked seasonal pattern of reproduction, the growth testes take about 45 days (Blanco et al., 2007). Differences in the size and weight between the left and right testis o birds are also reported by other researchers (Calhim and Birkhead, 2006; Denk and Kempenaeres, 2006; Noirault et al., 2006; Bull et al., 2007).

The dimensions of seminiferous tubules in birds at different ages corresponded to the weight of testes. The lower weight during the non-breeding season was due to the reduced seminiferous tubular size and higher relative presence of interstitial tissue in the testicular parenchyma.

The investigation of volumes of seminiferous tubules and interstitial tissue showed a superiority of seminiferous tubules over the interstitial connective tissue. The seminiferous tubules to interstitial tissue volume ratios in ganders during the breeding season corresponded to findings in birds from the Icteridae family (Lupold et al., 2009). The increased volume of seminiferous tubules is responsible for the observed seasonal hypertrophy of birds' testes (Pollock and Orosz, 2002).

Conclusion

The observed histological picture of testes during the breeding season in Landes ganders at various ages confirmed the occurrence of active spermatogenesis in them. During the non-breeding season, the presence of the different germ cell generations was reduced, with only spermatogonia being present. The established values of the different morphometric indices were logically interrelated and also reflected age- and season-related differences.

Abstract

Antiparasitic agents based on Avermectin have main place amount modern veterinary products. Those agents have wide specter of activity and high efficiency. Studies in recent years show that Ivermectin based products have highest efficiency. One of most popular medicines in Russian Federation is Novomek. Due to the fact that Ivermectin is able to cause theratogenic and embryotoxic effects do not recommend using it in pregnant animals. However, information about negative effect of Ivermectin to male reproductive system in scientific literature is absent. This fact determines the relevance of our work. Investigation of karyopathic and cytotoxic effect of antiparasitic product Novomek to spermathogenic epithelium of laboratory mice was carried. Novomek was injected singly subcutaneously in doses of 0.2; 0.4 and 100μg/kg. Control group of mice was intacted. Changers in condition of cells were measured after 12 hours from beginning of experiment. Those pathologies as lagging of single chromosomes and groups of chromosomes and forming of chromosome bridges in anaphase and telophase were observed in experimental groups in comparison to control animals. Observed pathologies were directly connected with damages of chromosomes and may cause genetic heterogeneity of daughter cells. Also they cause disorders of process of division and cytokinesis. Under increasing of Novomek dose amount of cells with agglutination of chromosomes increase significantly. Thus, karyopathic and cytotoxic effect of Novomek single injection to spermathogenic epithelium of experimental animals is established. Therefore, that product may be used carefully to breeding animals in reproductive season.

Keywords: *Pathology, tested cells, white mice, Novomek.*

Introduction

Antiparasitic agents based on Avermectin have main place amount modern veterinary products. Those agents have wide specter of activity and high efficiency. Studies in recent years show that Ivermectin based products have highest efficiency. Due to the fact that Ivermectin is able to cause theratogenic and embryotoxic effects do not recommend using it in pregnant animals. However, information about negative effect of Ivermectin to male reproductive system in scientific literature is absent. This fact determines the relevance of our work. The aim of our investigation was research of degree of karyopatic and cytotoxic effects of Novomek to mice testis cells division.

Materials and methods

Investigations were carried out on males of white mice at 18-20g weight. Novomek was injected singly subcutaneously at doses of 0.2; 0.4 and 100μg/kg. Control group of mice was intacted. Every group consisted from 5 mice. Animals after 12 hours were decapitated. After necropsy testes were allocated and stamp-smears were prepared which were fixed by May-

Grunvald and painted by Romanovsky-Giemsa. Subsequently stamps were microscoped and a counter of devising cells was estimated. The form, size and color of nuclei were accounted. Analysis of incidence of cells with karyopatic and cytotoxic damages was investigated on detached and flattened cells with count not less than 1000 cells in every stamp. We used meiotic index (MI) is a percentage of devising cells to common number of cells. Micronuclei were identified like a round chromatins bodies wit smooth margins and size about 1/3 of nucleus which lay separately from base nucleus, did not brake light and were situated in one plane with base nucleus (Sivkova, 2011). Furthermore, dual nuclei, fragmentation and vacuolization of nuclei, earlier divergation of chromatids in prophase, pathologies of division and citotomia were identified. For the statistical processing we used software package STATISTICA 6.

Results and discussion

Data of analysis of karyopatic changes in experimental and control mice are presented in diagrams.

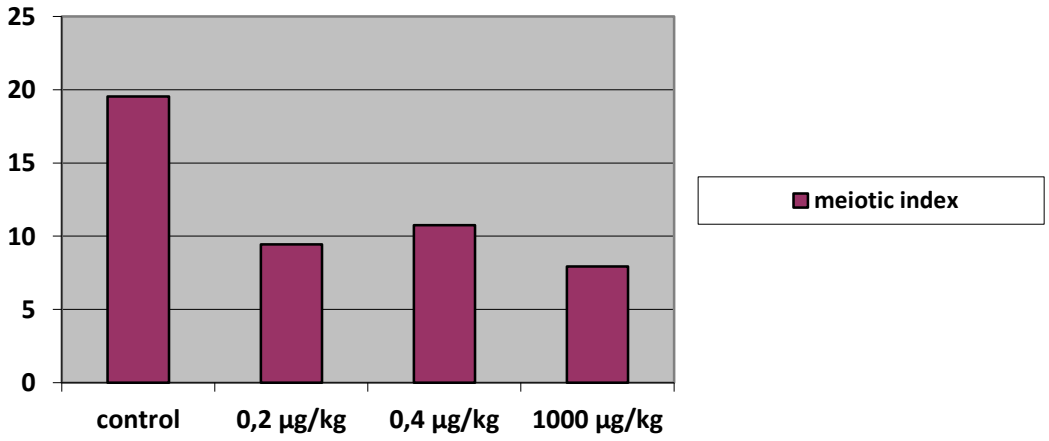

Fig 1 Changes of meiotic index (%) after 12 hours after Novomek injection in testis cells of white mice

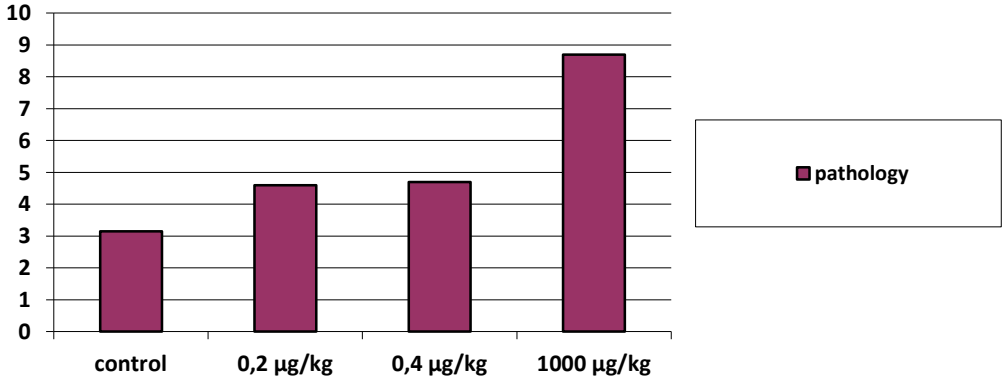

Fig. 2. Changes of pathology of meiosis (%) to amount of meiotic cells in testes of white mice at 12 hours after injection of Novomek

It is known that pathological mitoses in normal tissues in 3% of cells and less are found (Alov, 1972). Authors of this work observe high proliferative activity of testis cells (MI, %) in control group of animals (Fig.1). Thus metaphase with lagging of chromosomes and ana- and telophase with lagging of chromosomes and groups of chromosomes were in the leading place

among observed pathologies but were in limits of physiological norm. Activity of cells division in experimental groups after Novomek injection decreases more than twice, an increase of doses effects to changing of MI not significantly.

Percentage of pathologies ranged within normal limits at the all time of experiment. Thus growth of amount of pathologies to number of divising cells determines of dose (Fig.2).

When comparing the ratios of the figures we observed the predominance of metaphases and prophases over anaphases and telophases, which indicate a blocking of the process of cell division in the early stages of meiosis. In comparison with the intact group increases the number of cells with bridges in anaphase and telophase. This pathology progresses with increasing doses of Ivermectin. Abnormal findings can be directly linked with damage to chromosomes and, as a rule, lead to genotypic heterogeneity of daughter cells and breaks during the final stages of division and inhibits cytokinesis (Sivkova, 2011).

The number of cells with the agglutination of chromosomes increases significantly. This pathology is often found in tumor cells and after influence of mitotic poisons. Swelling, chromosomes lose the right shape and is bonded surfaces, form irregularly lumpy mass. Divergation of chromosomes not occures, and cell dies (Alov, 1972). During the experiment we recorded pathology such as multipolar meiosis, lagging chromosomes, groups of chromosomes at all stages of cell division. These pathologies are associated with chromosome damage and the staff of the division that breaks during meiotic cytokinesis and delays, and may cause the death of cells.

Conclusion

Analyzing the results, we concluded that the Novomek substantially inhibits the activity of dividing spermatocytes, which can lead to poor fertility of animals. Range of karyopatic effects in the experimental groups was much wider in comparison with the control group, two types of pathology (agglutination of chromosomes and ana - telophase with bridges) was in direct proportion to the increase of dosage. Obtained in the experiment, the data allow us to talk about the negative impact of Ivermektin on the reproductive system of males and the need for controlled drug pedigree animals. We recommend not use drugs based on the Ivermektin for a few days before the use of breeding males.

COMBINED INFLUENCE OF BACILLUS SUBTILIS AND FASCIOLA HEPATICA SOMATIC EXTRACT TO SPERMATHOGENIC EPITHELIUM OF LABORATORY AND FARM ANIMALS

E.V. KRASNIKOVA[1], Tatiana N. SIVKOVA[1*], S.A. SHURAKOV[2]

Abstract

Research of pathogenic influence of bacteria and trematoda was performed on laboratory mice and sheep. The first group of mice was fed with probiotic *Bacillus subtilis* in therapeutic doses in a period of 10 days. The second group was once intraperitoneal injected by *Fasciola hepatica* extract in dose of 100μg. The third group was fed by probiotic and injected by helminthes extract. The control group was intact. Sheep were spontaneously infected with *Fasciola hepatica* and also we used *B.subtilis* for desoldering in 10 days period. From laboratory animals testes were obtained. Smears prints of testes were colored by Romanovsky-Giemsa method. Amount of normal and pathology figures of meiosis were counted. Other part of testes were stained in 10%-formalin and used for standard histological assay. Testes of experimental sheep were obtained after emasculation and were held histological procedures.

Karyopatical and histological investigations showed that the feeding with *B. subtilis* does not induce notable changes in condition of spermathogenic epithelium. However, intraperitoneal injection of *F. hepatica* extract to laboratory mice had negative effect on cells. Joint influence of both biological agents also caused karyopatic changers. Mitotic index reduced and amount of pathologies reach the high level. Dystrophic and scleroplastic changes in experimental mice and infected sheep were occurred after feeding of probiotic. Therefore, bacterial culture using during treatment of fasciolosis is not justified.

Key words: *Bacillus subtilis, testes, division, pathomorphology.*

Introduction

Nowadays, including of different probiotics into the therapy of parasitic diseases is recommended for introduction the antagonistic bacteria to host's organism. One of those biological products is Sporovit from antagonistic active strain of *Bacillus subtilis* 12B. The high affectivity and economic benefit of those bacilli is established at infections and parasitic diseases (Gavrilieva, 2013; Neprimerova and Sivkova, 2012; Timoshok, 2012) However, information about cooperative effect of helminthes and *B.subtilis* metabolites absent in Russian and foreign literature.

Due to wide distribution of helminthiasis in farm animals, the aim of our scientific work was investigation of karyopatic effect of Sporivit on reproduction cells of animals. As fasciolosis is a one of most dangerous helminthiasis with worldwide distribution males of white mice after once introperitoneal injection of *Fasciola hepatica* extract were chosen as a laboratory model.

Materials and methods

The first group of mice was fed with probiotic *Bacillus subtilis* in therapeutic doses at the 10th day. The second group was once intraperitoneal injected by *Fasciola hepatica* extract in dose of 100μg. The third group was fed by probiotic and injected by helminthes extract. The

control group was intact. Conditions of living and feeding of experimental mice were remained at the all period of work and meet hygienic requirements.
After 48 hours from injection of extract, the animals were killed by the method of cervical dislocation. From laboratory animals testes were obtained. Smears prints of testes were colored by Romanovsky-Giemsa method. Amount of normal and pathology figures of meiosis were counted. Other part of testes were stained in 10%-formalin and used for standard histological assay.
Investigations on farm animals were carried out on the Romanov sheep breed 4 months old naturally infected with helminthiasis. After 10-days feeding of Sporovit in therapeutic doses lambs were emasculated by the open method and testes were collected for histological examination. Testes from animals stained in 10%-formalin immediately and used for standard histological assay.
The wiring of tissues and organs by the growing spirit of the fortress was carried out by hystoprocessor (Leica TP 1020) with automatic cycle within 18 hours. After ending of the wiring material was flood into the paraffin medium Hystomix using Thermo Scientific Histostar. Slices thick of 2-3μm were made from paraffin blocks using semiautomatic microtome Leica. Prepared slices were painted with hematoxylin and eosin and by Van Gison method. Painted specimens were investigated using light microscope Leica with eyepiece magnification of 10 and lens magnification of 10, 40 and 100. Most interesting objects were photographed using visual analysis system of picture by digital camera Infinity 1 and kept in the computer's memory.

Results and discussion

General condition of control and experimental animals stained good at the all period of experiment. Results of cells division activity changing are presented in diagram.

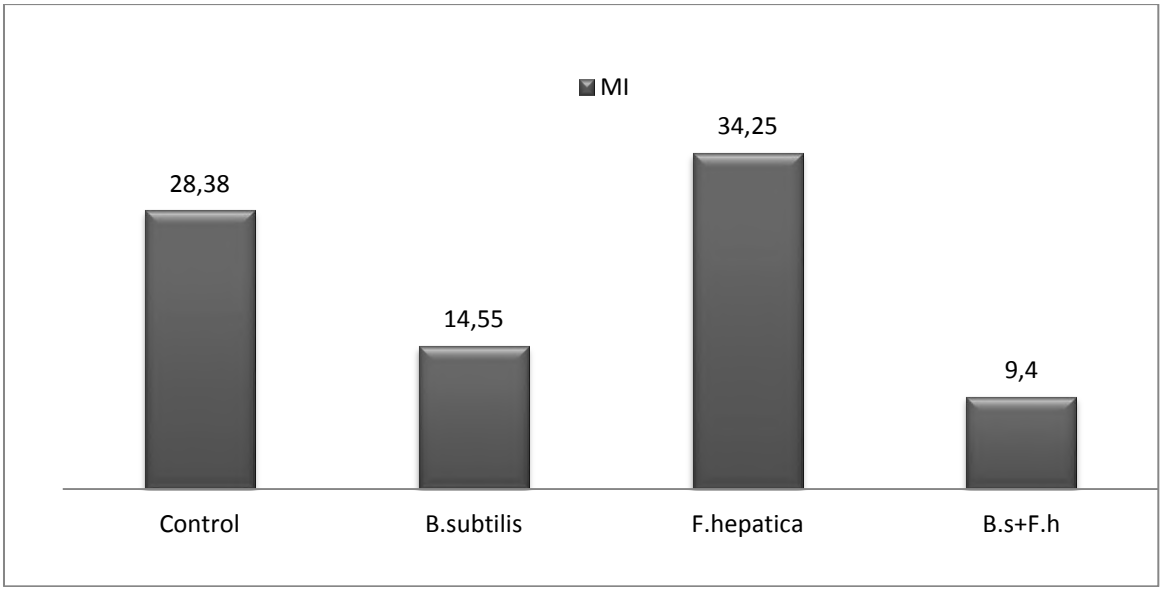

Diagram. Frequency of karyopatic consequence in mice testes after *F.hepatica* extracts injection and product of *B.subtilis* feeding

Under *F.hepatica* somatic proteins affect we observed disturbance of the process of dividing spermatogenic epithelium and growth of meiosis index (MI) after 48 hours in comparison with control data. Amount of pathology figures of division also exceed twice a control value.

Premature divergence of chromosomes in metaphase and the tripolar anaphase were detected more frequently among pathology figures of division.
Ten-day feeding with biological product of *B. subtilis* reduced the meiosis index in the testis of experimental mice, thus, level of pathology figures was approximately twice higher than the control value. The most pathological changes apparent as the backlog of individual chromosomes in metaphase and anaphase. Those anomalies occur as a result of damage of the mitotic spindle. The level of other pathological changes did not exceeded of normal physiological level.

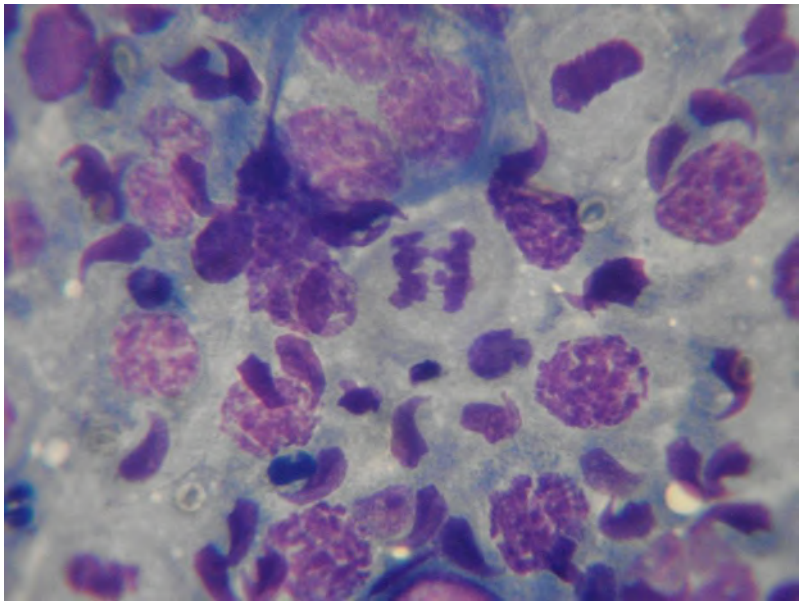

Fig 1. Testis of mouse. Anaphase with lagging of chromosomes and chromosome bridge (10x100)

Special attention should be paid to the detection of anomalies such as agglutination of chromosomes such. In this pathology so severe damage to chromosome structure occurs, that chromatin loses its ability to normal helix, but instead stick together in a shapeless mass, and further cell division is blocked. However, the number of cells with tendency to agglutinate chromosomes was small.
Based on the above observations, it follows that karyopathic effect of *B. subtilis* in relation to spermatogenic epithelium occur to a small extent. Formed due to pathogenic exposure to defective sexual products are not able to function normally and are eliminated from the body.

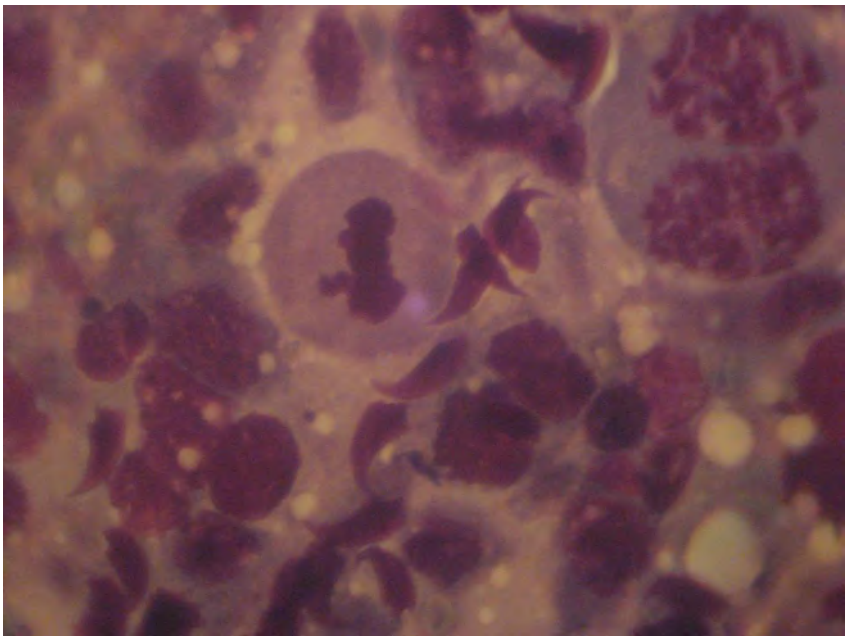

Fig 2. Testis of mouse. Premature divergence of chromosomes in metaphase (10x100)

The feeding of Sporovit to white mice in a period of 10 days before injection of the extract in 3 times reduced the meiosis index of seminiferous epithelium. The number of pathology division in the experimental group of animals was two times higher than in controls, and did not differ significantly from the results obtained from the extract of *Fasciola* without watering probiotic. The number of individual pathologies associated with abnormalities of the staff of the division, was not beyond physiological values. Therefore, changes were not specific and directional in nature. Meanwhile, the number of metaphases with premature chromosomes under the simultaneous action of *F. hepatica* and *B. subtilis* decreased by half compared to monoeffect of trematodes extract, however, was higher than in the case of the impact of the biological product Spirovit. Chromosome damage in the form of agglutination in all cases was absent.

The appearance of cells with micronucleus is significant because it is absent in previously experiments. Forming of micronucleus suggests the fact that process of cell's division was not blocked and meiosis finished with damage of nucleomorphology.

Thus, we can expect that biological active substances from probiotic strain of *B.subtilis* do not have their own high karyopathic effect on reproductive cells of laboratory animals but are not able to reduce karyopathic effect of *F.hepatica* extract. Therefore, suitability of Sporovit treatment in complex therapy of fascioliasis was not suggested.

Information about pathology of reproductive system of farm animals at fascioliasis is practically absent. Since we established after karyopatic assays a negative effect of *Fasciola* extract on division of spermatogenic epithelium the question about morphology of organs was detected.

Histological investigation showed that stromal edema of the testis of laboratory animals after once injection of *F.hepatica* extract occurred. Spermatogenesis decreases significantly and as a result a part of tubules empties. In the retained activity tubules sperm cells are fragmented and are in a state of agglutination. Founding changes indicate a significant decrease in reproductive function in experimental animals.

Pathomorphological changes were detected in testes of mice after application of *B.subtilis* culture. Normal tissue of testis was visible at the all parts of organ. The structure of spermatogenic epithelium was relatively preserved, but not in all tubules. Division of cells was expressed unevenly and in some parts was weak.

Often the tail parts of spermatozoa were in agglutination and the presence of separately located nucleated and the tail parts were detected. Some tubules were lined by a single layer of flattened cells, contained in the lumens group of sperm and single discretionary cells of seminiferous epithelium. In the stroma of the organ was detected a small group of randomly located fibroblasts.

Also we registered damages in mice testis after simultaneously effect of *F.hepatica* extract and *B.subtilis.* External layer of testis was thick and particularly delaminated due to edema. Despite the fact that normal tissue of the testis was present in all fields of view, and the layer structure of seminiferous epithelium in the tubular part was relatively preserved, often noted agglutination the tail parts and the fragmentation of the sperm cells. In the central parts of some tubules from the ruins of the sexual products were formed thin filaments. Some tubules were lined by a single layer of flattened cells, contained group of sperm and single discretionary cells of seminiferous epithelium. In the stroma were randomly located small group of fibroblasts. Therefore, the effect of biologically active substances of *B. subtilis* and somatic extract of *F. hepatica* leads to the development of dystrophic and scleral plastic processes in the reproductive organs, and adversely affects the formation of sexual products.

The study of the tissue of the testes of lambs after watering of Sporovit have caused particular interest. The outer shell is much thickened, and presented fibrous structures with large full-blooded thick-walled arterial blood vessels and thin-blooded veins. Visible areas angiomatosis are presented. The layer structure of seminiferous epithelium can be traced clearly. Distinguishable single mitoses were in the basal layer cells. Cells are in a state of degeneration, focal epidermal desquamation.

Spermatogenesis cannot be observed in all tubules, significantly weakened, sometimes marked the tail parts agglutination of spermatozoa, the presence of separately located nucleated and the tail parts in the form of a thin eosinophilic filamentary structures and eosinophilic masses of character. Stroma with marked edema, partially sclerotic, contains single thick-walled vessels of weak blood supply. In appendage – common scleral plastic changes, dilated ducts, sometimes significantly. In the ejaculatory ducts was not content. Pronounced degenerative changes of seminiferous epithelium were visible. Common peritonectomy sclerosis on the appendage with atrophic changes in the epithelium of the VAS deferens occurred.

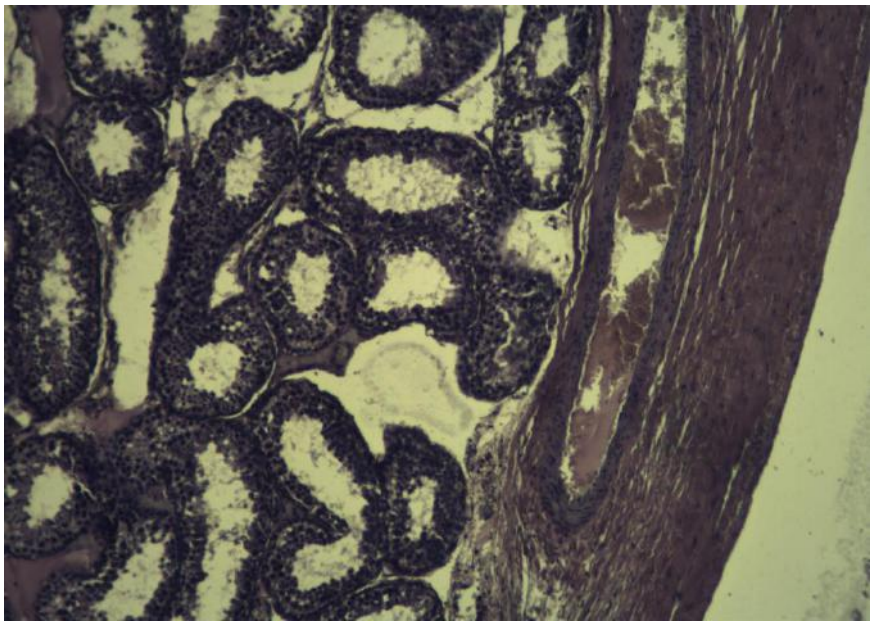

Fig 3. Testis of lamb. Dystrophy and focal desquamation of epithelium. Blood vessel with weak filling (10x10)

Conclusion

Our studies confirm a marked karyopathic effect of the *Fasciola* extract and culture of *B. subtilis* 12B on the seminiferous epithelium of laboratory and farm animals, which manifests itself in increasing the number of abnormalities of cell division. On the background of experimental and spontaneous effects of the products of metabolism of helminths after oral application of probiotic preparation in the testes occur degenerative and scleroplastic processes occur, which negatively affects the reproductive function of animals.

Abstract

In today's swine breeding, we should highlight the major economic indicators, on which the efforts of all professionals involved in the pork production technologies are aimed. This is the organization level of intense reproduction of pigs, including expanded reproduction, making maximum use of the reproductive capacity of the breeding stock, increasing productivity, increasing the livability of youngsters. In breeding Large White breed of swine, which is the main maternal breed in most systems of crossbreeding and hybridization, great attention is paid to the selection of sows that possess the highest reproductive qualities. Their offspring is bred for rearing stock and for creating and improving lines and family. The aim of our study was to conduct a comparative assessment of the reproductive performance of Large White breed of sows on the qualities of their offspring, the study of heritability and the correlation between reproductive traits in hybrid breeding in conditions of the Selection Center of the OJSC "Permskii Swine Complex" in Krasnokamsk District of Perm krai. On the basis of the carried out research we established that the genetic similarities between daughters and mothers by straight-line correlation showed that the highest rate of heritability was recorded on fetal macrosomia, i.e. the variability of this trait is more influenced by the difference of genotypes. We noticed that other productivity traits (prolificacy, nest mass at birth, lactescence, the number of heads to weaning, nests mass before weaning) had low heritability rates, i.e. the variability of these traits is influenced by housing conditions.

Keywords: *swine production, Large White breed, sows*

Introduction

In today's swine breeding, we should highlight the major economic indicators, on which the efforts of all professionals involved in the pork production technologies are aimed. This is the organization level of intense reproduction of pigs, including expanded reproduction, making maximum use of the reproductive capacity of the breeding stock, increasing productivity, increasing the livability of youngsters (Khlopitskii, 2009; Filatov, 2002; Vangen, 1986);

The efficiency of reproduction is largely determined by the cost of herd breeding and management. It is therefore important to select high-yielding primipara sows, which in the future will preserve high breeding qualities [5, 10]. Effectiveness of screening and selection process depends heavily on the accuracy and objectivity of evaluation indicators of productive qualities heritability. Since heritability is not only a property of characteristics, but also of populations, it is necessary to determine its level in each specific condition for each individual groups or lines (Garai, 2007, 2004; Dudka, 2002; Buchova, 2010)

Large White breed of swine is widely recognized as one of the best, most specialized selected on a number of commercially useful and technological characteristics. In this regard, it is widely spread in our country, including in the area of the Urals.

In selection of Large White breed of swine, which is the main maternal breed in most systems of crossbreeding and hybridization, great attention is paid to the selection of sows that possess the highest reproductive qualities. Their offspring is bred for rearing stock and for creating and improving lines and family. Among the main factors that affect the efficiency of

selection, inheritance is also of great significance to those characteristics by which to filter. From practice, it is known that selection of animals only by phenotypes does not contribute to the qualitative improvement of herd for a long time, and not always from highly productive parents the same valuable offspring are obtained. Selection by related or own animal productivity is effective only for those characteristics that have high inheritance. Quantitative traits are characterized by low level of inheritance, and therefore require more advanced selection methods – evaluation of parental genotypes on quality of offspring, individual selection, determining the best combinations (Rybalko and Birta, 2009; Shtakelberg, 2005; Peškovičová, 1998).

Selecting parent types and lines is carried out primarily by reproductive qualities, multifetation, safety, ability of sows to display their mothering qualities well. Purpose of maternal lines – compilation of breeding stock at all levels of hybridization programmes (Gaisbertus, 2008; Suslina, 2010).

The aim of this work is to assess reproductive qualities of sows of Large White breed.

To achieve this goal, the following tasks were solved:

To carry out a comparative analysis of reproductive qualities of mothers and daughters in pure-bred Large White breed of swine.

To study the characteristics and correlation of reproductive traits in mothers and daughters.

Materials and methods

Investigations were conducted in conditions of the Selection Center of the OJSC "Permskii Swine Complex" in Krasnokamsk District of Perm krai on pure-bred sows of Large White breed (254 heads). The data of pedigree animal cards served as material for research. Assessment of reproductive qualities were conducted by generally accepted methods and indicators. The study examined productivity of mothers and daughters, as well as the characteristics and correlation of such traits as multifetation, macrofetation, lactescence, number of piglets and sows, piglet weight at weaning. At the time of the research animals were in identical conditions of housing and feeding. Generated databases were processed statistically in Excel.

Results and discussion

The average duration of use of all sows that were used in the experiment was 3.64 ± 0.06 of farrowing. For the full sample ($n = 254$) obtained data on the productivity of mothers and daughters of Large White breed is presented in table 1.

In the evaluation of their own productivity while achieving 100 kg of live weight, precocity in daughters made up 192.8 days, 3.9% higher compared to the precocity of mothers. Fat thickness over 6-7 breast vertebra in daughters was 2.3 cm, that is 0.06 cm less than in mothers. Body length of mothers was at 1.0 cm more than body length of daughters. Therewith it was established, that daughters surpass mothers on macrofetation by 0.07 kg, lactescence by 2.8 kg, the number of piglets at weaning by 0.5 heads, when nests mass at weaning aged 2 months by 5.8 kg.

Table 1. Productivity of mothers and daughters of Large White breed

Indicator	Mothers	Daughters
Assessment per 100 kg		
Precocity, days	200.60 ± 0.32	192.80 ± 0.33
Fat thickness over 6-7 breast vertebra, cm	2.36 ± 0.07	2.30 ± 0.07
Body length, cm	123.20 ± 0.07	122.20 ± 0.07
Data on farrowing		
Multifetation, heads	13.20 ± 0.04	12.10 ± 0.06
Nest mass at birth, kg	18.60 ± 0.05	17.80 ± 0.08
Macrofetation, kg	1.42 ± 0.03	1.49 ± 0.04
Data on lactescence		
Quantity, heads	9.90 ± 0.02	10.60 ± 0.04
Lactescence, kg	65.60 ± 0.19	68.40 ± 0.25
Mass of 1 animal, kg	6.58 ± 0.01	6.49 ± 0.20
Data on weaning		
Quantity, heads	10.00 ± 0.20	10.50 ± 0.03
Mass of nest aged 2 months, kg	224.10 ± 0.58	229.90 ± 0.79
Mass of 1 animal, kg	22.30 ± 0.04	21.90 ± 0.06

At the same time, mothers maintain supremacy for multifetation by 1.1 head per farrowing, nest mass at birth by 0.8 kg and for 1 animal weight at weaning in the age of 2 months by 0.4 kg. Thus, daughters having a lower multifetation, but better lactescence, preserve to weaning more by 5.0% piglets.

When calculating the heritability ratio based on the straight-line correlation method was used the formula $h^2 = 2rd/m$. Heritability ratio is equal to double coefficient of phenotypic correlation between characteristics of mothers and their daughters. This formula applies to the cases where differences in the diversity of traits in parents and offspring are insignificant. Heritability ratio is widely used in the practice of selection work. It is used to predict the efficiency of selection. Heritability ratios of reproductive traits in pigs are presented in table 2.

Table 2. Heritability ratios of reproductive traits in sows

Indicator	Heritability ratio
Multifetation	0.22
Nest mass at birth	0.30
Macrofetation	0.58
Lactescence	0.28
Quantity of animals before weaning	0.06
Nest mass before weaning	0.26

In determining the genetic similarities between daughters and mothers by the method of straight-line correlation it was found that the greatest coefficient of heritability was recorded on macrofetation, i.e. the variability of this trait is more influenced by the difference of genotypes. In other characteristics of productivity (multifetation, nest mass at birth, lactescence, number of animals to weaning, nest mass to weaning) a low value of heritability coefficients was observed, i.e. the variability of these traits is affected by housing conditions.

Study of correlation relationship showed that among individual reproductive traits there is a positive or negative relationship (table 3).

Table 3. Reproductive traits correlation coefficients

Indicator	Mothers	Daughters
Multifetation × macrofetation	-0.46	-0.44
Multifetation × lactescence	-0.14	-0.05
Multifetation × quantity of piglets at weaning	0.03	0.02
Multifetation × nest mass at weaning	-0.11	-0.04
Macrofetation × lactescence	0.41	0.37
Macrofetation × quantity of piglets at weaning	0.13	0.16
Macrofetation × nest mass at weaning	0.36	0.37
Lactescence × quantity of piglets at weaning	0.61	0.65
Lactescence × nest mass at weaning	0.82	0.84
Nest mass at weaning × quantity of piglets at weaning	0.69	0.70

The most important phenotypic correlation coefficients were observed in sows-mothers between such traits as macrofetation and lactescence (r = + 0.41), macrofetation and mass of nests at weaning (r = + 0.36), lactescence, the number of piglets at weaning and mass of nests at weaning (r = +0.61, + 0.82), weight of nests and the number of piglets at weaning (r = + 0.69). Positive and reliable correlations for sows-daughters were established between their macrofetation and lactescence (r = + 0.37); macrofetation and mass of nests at weaning (r = 0.37), lactescence, the number of piglets at weaning and mass of nests at weaning (r = + 0.65, + 0.84), the presence of live pigs to weaning and mass of nests at weaning (r = + 0.70).

Conclusions

Based on the research the following conclusions are drawn:

The lack of statistically reliable indicators of heritability suggests that the variability is phenotypic traits considered depends mainly on the influence of environmental conditions and weakly determined genetically.

Analysis of the relationship of reproductive traits in sows suggests that in populations of Large White breed of swine, reliable correlation coefficients were obtained between macrofetation, lactescence and mass of nest at weaning; lactescence and the number of piglets at weaning and mass of nest at weaning; between the mass and the number of nests piglets at weaning, which gives the opportunity to engage in effective selection of one of these traits.

Use in further selection work received genetic herd parameters of Large White breed of swine will increase the effect of selection.

Abstract

Inadequate content and structure of carbohydrates in livestock diet can cause metabolic disorders that, in turn, may lead to long-term effects on health and productivity. The appropriate structure of carbohydrates in the diet is very important for digestion in the rumen and to provide an adequate amount of energy for microbial protein yield and maintenance of a stable level of fermentation. This research was conducted to determine the effects of seed rates in the mixture forage pea + oat. Also, aim was to define cutting stages on changes in the structure and ratios of fractions of carbohydrate biomass mixture. We used two different rates of pea and oat (2/4 Pea: 2/4 Oat- mixture R_1, 3/4 Pea : 1/4 Oat- mixture R_2) and three different cutting stages of early flowering of field pea stage- phase P_1, pods forming stage -phase P_2, early seed forming stage-phase P_3). The results show that the ratio of crops did not significantly affect the amount of total carbohydrates (CHO) and lignin (ADL), and the mixture with a higher proportion of pea had significantly higher content of non-structural carbohydrates (NFC). The minimum lignin content was determined in flowering pea, while significantly higher content was recorded in the second and third stage of the pea development. Analysis by CNCPS model showed that both factors had a significant impact on the change in the ratios of certain fractions of carbohydrates. Fraction CB makes the biggest part of all fractions and with CB_2 and CB_3 together makes up over 50% of the total fraction. Fraction CC, which is related to lignin and unavailable to the animal significantly increased with phase-change cutting (164.0 g kg^{-1} CHO in phase P_1 to 181.9gkg^{-1} CHO in phase P_3).
Keywords: CNCPS, pea, oat, fractions, biomass.

Introduction

With the development of the scientific field of animal nutrition, many nutritional models have been created and perfected. Most nutritional models are based on the needs of different animal species and categories for a specific concentration of certain nutrients in the diet. They, as a base for nutritionally balanced meals, take the amount of energy the animal enters through the meal which is needed for the animal to perform its vital functions and production. Considering that the main sources of energy in feed for ruminants are carbohydrates, it can be understood how important the representation of certain forms of these nutrients in the diet is.

Carbohydrates (CHO) are a major component of net energy needed for maintenance of the basic life functions and milk production in ruminants. In addition, they are the main source of energy for the growth of microorganisms in the rumen and the production of microbial protein. Carbohydrates make up over 65% of dry matter and the largest part of nutrients in dairy cow meals (Varga et al., 1998). The amount and the representation of all forms of carbohydrates in the diet affect the composition of milk, as they are a precursors for lactose, fats and proteins.

In the plant structure, carbohydrates are represented in two basic forms as structural (FC) and nonstructural carbohydrates (NSC). Inadequate content and ratio of these substances in the diet can cause serious metabolic disorders (acidosis, abomasum dislocation, ketosis), which can cause long-term effects (Marković, 2015). The differences in the amount and chemical

characteristics of FC and NSC in the diet can affect the performance of the animals. High levels of fiber in the diet reduce digestibility and limit the capacity of rumen for other nutrients (Mertens, 1997). The lower intake of digestible NCS reduces milk production. On the other hand, with low levels of fiber in the diet, there is a negative effect on the fermentation in the rumen (Lanzas, 2007).

The most important factor affecting the nutritional value and the representation of certain nutrients in biomass is the stage of plant development at the moment of cutting for consumption or conservation. As the plant becomes more mature, the content of protein, energy, calcium and phosphorus is reduced and ratio of fiber is increased. This is accompanied with an increase in the percentage of lignin, which is indigestible and unavailable to the animal, resulting in decrease of the energy value of nutrients (Zeremski et al., 1989, Grubić et al., 1996).

The decline in the nutritional value of plants with their maturity occurs due to reduced digestibility of leaf and due to the increase of the ratio of stems as less digestible parts with the higher proportion of fiber, especially lignin, and due to the flattening and rotting. Along with the decline in nutritional value, the energy value of the feed reduces (Grubić and Adamovic, 2003). In addition, the nutritional value of forage is influenced by other factors as well. So, there may be significant differences in the chemical composition of certain plant species, but, also, within cultivars of the same species. Consequently, the prevalence of specific plant species in the mixtures can significantly influence the share of individual carbohydrate fraction in biomass

The amount of individual fractions of CHO, FC and NSC in plant material is of great importance for the passage of these nutrients through the digestive tract. Their relative share in the structure of carbohydrates determines the rate of degradation and the possibility of using these nutrients by animal itself and by microorganisms of the rumen.

The aim of this study is to evaluate the changes in the amount of CHO and representation of individual fractions in biomass of mixtures of annual legume and cereal, depending on the stage of exploitation and the ratio between cereal-legume in the mixture. The results will give an insight into the possibility of combining this kind of feed with other bulk meals when balancing the diet of different species and categories of ruminants.

Materials and method

Binary mixtures of field pea and oats are sown on the experimental plot of the Institute for forage crops Kruševac, Serbia. Two factorial experiment was established in autumn in 2012, on October the 20th by randomized block design with three replications per treatment. The first factor (A), is ratio of germinated seed in mixtures. The ratios were 120 pea seeds and 120 oat grains in the first mixture (A1 – 2/4:2/4) and 180 pea grains and 60 oat grain in second (A2 – 3/4:1/4). The second factor is a phase of cutting of biomass with three sub-stages: B1 – a cutting of biomass at the start of flowering pea (10% of flowering), B2 – a cutting of biomass at forming the first pods on 2/3 plants of pea, and B3 - cutting of biomass at forming green seeds in 2/3 pods. Both mixtures were sown on plots of 20 m^2 with three replications for each stage of cutting. With each repetition has been taken by one kilogram of green (fresh) biomass for chemical analysis.

In DM of mixture., the amount of total carbohydrates (CHO), non-fibrous carbohydrates (NFC), monosaccharides and disaccharides (TESC), acid detergent fiber (ADF), neutral detergent fiber (NDF) and the amount of lignin (ADL) were determined.

Crude carbohydrate (CHO) cell fractionation was performed according to the Net Carbohydrate and Protein System. The characterization of the CHO fractions was applied in this system. Simple sugars which ferment very quickly were designated as fraction of CA carbohydrates. In addition to simple sugars, this fraction contains organic acids, which are

structurally most similar to carbohydrates. CB fraction of CHO was the largest faction in nutrients. It includes a large variety of different compounds with variable degradation speeds, solubility and degradability. Considering the degradation speed it was divided into three sub-fractions: CB_1, CB_2 and CB_3.

Sub-fraction CB_1 was represented by starch which was largely broken down in the rumen and is accessible to animals. Sub-fraction CB_2 was soluble fiber, consisting of β-glucans and pectin substances that are defined as dietary fiber, because they can not be digested by the mammalian enzymes. Slow-degradable sub-fraction CB_3 was available cell wall with a very low rate of degradation. Fraction CC was the inaccessible part of the cell wall of which the largest part is lignin.

The analysis of variance was conducted using the results of chemical analysis of silage quality. The statistically significant differences for all tested parameters between treatments were tested by LSD test (StatSoft, 2006).

Results and discussion

By the chemical analysis of the mixtures, the content of structural and non-structural carbohydrates in dry matter of DM biomass was determined, as well as trends in change in the representation of these fractions by cutting stages (Table 1).

The ratio of legumes and cereals did not significantly affect the amount of total carbohydrates, while the stage change and the maturing of plants influenced the significant increase of their quantity. In both mixtures the amount of CHO was over 700 gkg^{-1} DM, which is in line with the results of Das et al. (2015).

Table 1. Structural and non-structural carbohydrates in biomass of pea-oat mixtures $g\ kg^{-1}$ DM

$\overline{X}$ B_1		676.7c	171.2a	41.92c	390.4a	492.2b	401.1b	68.3b
$\overline{X}$ B_2		708.5b	154.2b	55.49a	342.9c	542.3a	416.2a	76.0a
$\overline{X}$ B_3		729.6a	125.0c	50.75b	358.3b	539.6a	377.6c	74.5a

The total amount of CHO in the mixture biomass, NFC comprises about 45-55%. The mixture A_1 contained significantly more soluble, simple sugars (monosaccharides and disaccharides - TESC), NDF and ADF compared to the mixture A_2. The assumption is that the higher the proportion of oats in the mixture affected the greater amount of these fractions of carbohydrates in the mixture A_1. Starch and TESC in the structure of the NFC comprises about 50%. Increasing the share of pea in the mixture reduces the proportion of TESC in NFC. This is a very important considering the suitability of biomass of the mixtures for silage. These results confirm the allegations of (Đordjević and Dinić, (2007), Dinić et al., (2008) that the mixtures of peas with cereals are significantly easier to ensilage than biomass of pure pea crop because of the greater amount of readily soluble carbohydrates.

Quantity of TESC significantly decreased with the change of the utilization stage. The change of starch amount in the biomass mixture shows sinusoidal trend depending on the stage of exploitation. With the change of stage from B_1 to B_2, there was a tendency of significant increase of starch amount from 41.92 to 55.49 gkg^{-1} DM, while in stage B_3 there was decrease of the quantity of starch to 50.75 gkg^{-1} DM. The values obtained for the amount of starch in both mixtures are significantly less than those reported by Kocer and Albayrak (2012) for oat biomass. These results indicate that the pea significantly reduces the amount of starch in the biomass of the mixture compared to oat in monoculture.

The amount of NDF in bulk feed is the best single indicator of the consumption potential for ruminants. It is a reliable criterion in formulating a ration for high-production dairy cows (Marković, 2015). In the observed treatments, amount of NDF and ADF was statistically significantly higher in the mixture A^1 (554.3 and 409.1 gkg^{-1} DM) in relation to the mixture A_2 (495.1 and 387.4 gkg^{-1} DM). This is due to greater representation of oats in the mixture A_1. Oats biomass had significantly higher values of NDF and ADF in relation to pea biomass (Kocer and Albayrak, 2012, Omokanye, 2014).

Average values for NDF and ADF in the observed mixtures of pea and oats were in accordance with the results of Aasen et al. (2004). With the ripening of plants, there was a significant increase in NDF in stages B_2 and B_3 compared to the stage B_1, which is in accordance with the results of Aasen et al. (2004). The amount of ADF in the mixture biomass is increased to the stage of pod formation. At the stage of seed filling in pea, declining trend for the amount of the ADF was determined.

There were no significant differences in the level of ADL in the mixtures. This indicates that the ratio of peas and oats did not have a substantial effect on the amount of ADL in the mixture biomass. At the stage of pod formation and seed filling, there was a significant increase in ADL until the stage of flowering in pea. The obtained values for ADL both in both mixtures of peas and oats (over 70 gkg^{-1} DM) and for all three stages of utilization are significantly higher than the values stated in the NRC. Also, for similar mixtures of vetch and oats, Lithourgidis et al. (2006) showed significantly lower values for ADL (55 gkg^{-1} DM).

Table 2. Carbohydrate fraction of biomass mixture of pea-oat by CNCPS

In this model, CHO are divided into five fractions by the speed and degree of degradation in the digestive tract. Generally speaking, mixtures of peas and oats have proven to be a better source of fermentable sugars (CA fraction) compared to the results of Das et al., (2015) in their research of oat monoculture, but are in accordance with the results that same authors obtained for cowpea. These results are consistent with the results of Kamble et al. (2011) and

Gupta et al. (2011), who stated that legumes have a significantly higher CA compared to the plants of the grass family.

In contrast to these results, the same conclusion can not be drawn when comparing mixtures of legumes and cereals. Significantly higher amounts of CA (274.6 gkg^{-1} CHO) and CB_3 (356.6 gkg^{-1} CHO) fractions were found in the mixture A_1 compared to CA (212.5 gkg^{-1} CHO) and CB_3 (304.6 gkg^{-1} CHO) for the mixture A_2. In contrast, a larger proportion of peas in mixture A_2 resulted in the significantly larger amount of CB_2 and CC fractions. Das et al. (2015) reported significantly higher levels of CB_2 in oats monoculture (561 gkg^{-1} CHO) in relation to our results for the mixtures A1 (124.7 gkg^{-1} CHO) and A_2 (229.0 gkg^{-1} CHO). It can be assumed that competition between peas and corn in the mixture led to changes in the representation of certain factions in the structure of CHO. The ratio of peas and oats in the mixture had no significant impact on the amount of CB_1 fraction consisting of starch.

Change of the maturation stage led to changes in the amount of all the monitored fractions. Fraction CA and CB_1 have opposite trends with the change of time of mowing. The amount of CA fractions decreases from flowering stage - B_1 (267.2 g kg^{-1}CHO) to the stage of pod formation - B_2 (221.2 g kg^{-1}CHO) and then again there is an increase in seed filling stage - B_3 (242.2 g kg^{-1} CHO). This fact is important from the point of ensiling because lactic acid bacteria used easy-soluble sugars (CA fraction) in the fermentation process and the production of lactic acid. In contrast to CA fraction, the amount of CB fraction, consisting of starch, is the highest in the phase B_2 (78.3 g kg^{-1} CHO), while the phases of B_1 and B_3 values were statistically significantly lower. Generally speaking, CB_2 is the least represented fraction in CHO with a share of less than 8%. Fraction CB_2 had the significantly lowest value in stage B_3. The most abundant fraction of CHO in mixtures of peas and oats was CB_3 with a share of 30-35% CHO. With ripening stage change?, CB_3 fraction was significantly increased by 315.0 g kg^{-1}CHO in stage B_1 to 344.6 g kg^{-1}CHO in stage B_3. The fraction with the highest lignin content increased significantly with the beginning of pod formation in comparison to the stage of flowering which is in line with the increasing amounts of lignin in biomass mixture. Between stages B_2 and B_3 was no statistically significant difference in the amount of CC.

Conclusions

Carbohydrates are the main source of energy for livestock to perform basic life functions, milk production, the growth of microorganisms in the rumen and production of microbial protein. In this experiment, the results indicate that the stage of maturity (factor B) has a more significant impact than the ratio of peas and oats in the mixture (factor A) on the change of certain fractions of CHO, the ratio between structural and nonstructural carbohydrates. The ratio of peas and oats in the mixture did not significantly affect the amount of CHO, starch and ADL. Higher representation of NDF and ADF in mixture A_1 is due to higher ratio of oats in the biomass of mixture. Larger amounts of CA, CB_1 and CB_3 were detected in the mixture A_1, while CB_2 and CC were more abundant in mixtures with greater ratio of peas.Most abundant fraction in mixtures (30-35% of CHO) was the slow-degradable fraction CB_3, which is available cell wall with a very low rate of degradation. The amount of unavailable carbohydrates, fraction CC, was significantly higher after the formation of pods and grain filling to the stage of flowering. Stage of plant development had a significant impact on all parameters.

Abstract

Algeria has a real potential for achieving food security. Agriculture sector accounts for 11% of GDP. However, despite reform policies and public investments, agricultural production fell by 30% over the last thirty years. Agricultural holdings are characterized by small sizes, low productivity and serious technical deficiencies. To address these problems, the state implemented new policies (*e.g.* Renewal of Agricultural and Rural Economy program, Agriculture Act, Law on Agricultural Orientation). The main lines of the new policy are agricultural revival, rural areas revitalisation and capacity building. The new legal framework gives a great importance to research and extension. The paper provides an overview on public agricultural extension and advisory services (EAS) in Algeria. It is based on a cross-checking of secondary information with primary data collected by a semi-structured interview with the director of the Directorate of Training, Research and Extension (DFRV) at the Ministry of Agriculture and a focus group discussion with the staff of the National Institute for Agricultural Extension (INVA) carried out in March-May 2015. The main extension program, Programme for Strengthening Human Capacities and Technical Assistance (PRCHAT), was launched by INVA in 2009. It aims at expanding the intervention capacity of public support and development structures, strengthening coordination mechanisms and decentralizing services for agriculture and rural development. Apart from advice provided by public extension agents, farmers rely also on other advisory services providers. Most of farm managers are illiterate which complicate extension work. EAS play an important role in agricultural and rural development. Therefore, political and institutional environment should be improved, coordination between researchers and extension agents strengthened and involvement of farmers fostered.

Keywords: *Agricultural extension, Rural development, Policy, Algeria.*

Introduction

Algeria has a high agricultural potential. Agriculture, with 11% of GDP, plays a very important role in the Algerian economy (Maragnani *et al*., 2012; Si Youcef, 2013). However, the low agriculture productivity makes food import necessary, only 25% of food needs are met by domestic production (Belabas, 2010). In general, crop productivity is weak compared with neighbouring Morocco, whereas the yield is at least double overseas (Bedrani, 2002). Several factors have hampered agriculture development in Algeria, including land tenure constraints, lack of investment, insufficient access to input, reduced water availability, low levels of education and agricultural training, lack of effective extension services support and marketing channel constraints (Laoubi and Yamao, 2012).

Despite policy reforms and public investments the agricultural sector, previously dominant in the Algerian economy, witnessed a 30% production fall over the last thirty years (Si Youcef, 2013). To deal with this problem, the state implemented new policies; Renewal of

Agricultural and Rural Economy program (PREAR, *Programme de Renouveau Agricole et Rural*) and new legislation as the Agriculture Act (law No. 08-16 of August 3, 2008) (MADR, 2008) and the Law on Agricultural Orientation (adopted in 2008). The main lines of this new political framework are:
- Agricultural Revival: intensification and modernization of the agriculture sector;
- Rural Renewal: watershed protection and integrated development of mountain areas, development of the Southern Highlands, control of erosion and desertification;
- Capacity Building and Technical Assistance: modernization of administration; fostering of training, extension and research; strengthening of agricultural control and protection services.

The new policy framework gives a great importance to research and extension. The Ministry of Agriculture considers agricultural extension as a cornerstone to improve farmers' technical skills.
The paper aims at providing an overview on public agricultural extension and advisory services (EAS) in Algeria.

Material and methods

The manuscript is based on a cross-checking and validation of secondary information, from different sources (*e.g.* IFPRI, GFRAS, MARD), with primary data collected by a semi-structured interview (SSI) with the director of the Directorate of Training, Research and Extension (DFRV) at the Ministry of Agriculture, Mr. Louardi Guezlane, and a focus group discussion (FGD) with the staff of the National Institute for Agricultural Extension (INVA) carried out in March-May 2015. Other semi-structured interviews were carried out with trainers of different agricultural training institutes (*ITMAS* of Medea, Ain Temouchent and Ain Taya), heads of extension services of several agricultural directorates (e.g. Chlef, Ain Defla, Tissemsilt, Algiers) and heads of extension departments of different technical institutes (National Institute of Plant Protection - INPV, National Centre of Control and seeds and seedlings Certification - CNCC, Technical Institute of Field Crops (cereals/forages) - ITGC; National Institute of Soil, Irrigation and Drainage - INSID, Technical Institute of Industrial Crops and Gardening - ITCMI). The following issues were addressed in SSIs and FGD: policy frameworks and governance, main cooperation projects, financing, human resources, gender, advisory methods and media, and monitoring and evaluation. Secondary data were collected also from quarterly, semi-annual and annual reports and daily or weekly briefings issued by different institutions mentioned above.

Results and discussion

According to Benfrid (1997), agricultural extension in Algeria is often reduced to the decomposition of the technical package, a set of topics to raise the awareness of the farmer. Farmers are considered as passive receptors. The Worldwide Extension Study (WWES) showed that Algeria has a total of 834 public extension staff of which 722 are field-level extension staff. About 82% of the field-level extension workers are male, with 65% of them holding a 2-3 year agricultural diploma. Most of the women extension workers are field-level (130 women staff) with 46% of them having a MSc/agricultural engineer degree (IFPRI, 2012).
The Ministry of Agriculture delegates extension to the Directorate of Agricultural Services. Within the institutional framework for extension the primary responsibility for program planning falls at the local and national levels and the primary linkages are agricultural schools and input supply firms. Farmer organizations have a role in helping set extension priorities and promoting farmer-to-farmer extension activities. Small-scale subsistence farmers and large commercial farmers are the clientele most targeted by extension activities

(IFPRI, 2012).
The Global Forum for Rural Advisory Services (GFRAS) identifies 13 public extension providers in Algeria (GFRAS, 2013). The main institutes and research centres that have a stake in agricultural extension in Algeria are (Korichi, 2010): National Institute of Agronomical Research of Algeria (INRAA); ITGC; ITCMI; CNCC; INPV; Technical Institute of Livestock (ITELV); National Institute of Orchards and Vineyards (ITAFV); INSID; National Institute of Forest Research (INRF); National Centre of Artificial Insemination and Genetic Breeding (CNIAAG). The High Commissariat for the Steppe Development (HCDS) and Commissariat for Agricultural Development of Saharan Regions (CDARS) are active in marginal and less favoured areas (Korichi, 2010). However, a crucial role in the agricultural extension system is played by INVA (Box 1).

Box 1. Mission of the National Institute of Agricultural Extension (INVA).

The main missions of INVA are:
1. Studies and investigations (systems, approaches and extension methodology; communication channels, means and techniques).
2. Technical support and activities in rural areas by establishment of coordination and facilitation mechanisms; developing campaigns and programs of national interest; organizing, monitoring and evaluating extension activities; developing training programs; and organization and evaluating capacity building cycles.
3. Production and dissemination of extension materials (*e.g.* audiovisual media) and dissemination of information on all types of media.
4. Capitalization, processing and dissemination of information: creation of an agricultural data bank; processing and disseminating information.

Source: Korichi (2010).

The primary extension method is through demos, workshops and field days followed by farmer field visits. Radio programs are the main means of ICT (IFPRI, 2012). The Ministry of Agriculture has a network of demonstration units preferentially located at farmer level and in the 69 stations of the centres and institutions disseminated in Algeria (Korichi, 2010).
National agricultural extension services through their regional stations located in all the provinces (*i.e. Wilayas*) of the country implement various extension activities for farmers on different topics according to crop and livestock species that characterize each region. Extension at *wilaya* level is ensured by the collaboration of various agricultural institutions, such as chambers of agriculture and technical institutes (Laoubi *et al*., 2010).
In order to better coordinate the main agricultural research and extension programs towards farmers was launched in 2009 by INVA a programme called PRCHAT1 (*Programme de Renforcement des Capacites Humaines et d'Assistance Technique* / Programme for Strengthening Human Capacities and Technical Assistance). The main aim of this program is to improve and enhance human capacities and technical assistance regarding different programs of rural and agricultural renewal through: expanding the intervention capacity of support and development structures (INRA, INPV, ITGC, ITCMI, etc.); strengthening coordination and consultation mechanisms; and bringing technical structures to local level. The program also aims at: correcting the gaps of human resources (both technical and administrative) in implementation, training and development activities; improving the capacity of central and decentralized administrative structures for a permanent and effective follow-up of PREAR; improving the capacity of research structures and development of technical guidance; setting up a network of demonstration units; setting up a network of farmer field schools; mobilizing competencies and infrastructure; and intensifying programs of mass extension. Several decrees have been issued by the Ministry of Agriculture related to

extension and training actions funding such as the decrees n°916 to 920/2008. An important budget was dedicated to these programs towards farmers, rural population and technical agents involved in the PREAR. The extension strategy and operational plan for the five-year period, 2010-2014, focuses on participatory planning, intensive training of extension workers, development of multi-media materials, and processes for managing, monitoring and evaluating actions. These activities are intended to be applied by extension staff to support the policies, strategies and priority programs of agricultural and rural development.
The balance of PRCHAT1 activities (2010-2014), showed a significant dynamic in extension area. According to DFRV, 284,935 people were trained, including 116,823 technicians, 162,413 farmers and herders, and 5700 other stakeholders (*e.g.* agricultural and rural development projects managers) (Table 1).

Table 1. Balance of activities carried out in the framework of PRCHAT1, period 2010-2014.

		49,319 young people dealing with
	297 projects including 207 national projects (National Program of	
Remark: Actions and projects dealt with all topics mainly strategic ones		

Source: DFRV (2015)

Since January 2015, the DFRV launched PRCHAT2. The new program is a continuation of PRCHAT1. Its aims are: access to quality extension by all stakeholders; specifying the place and role of each actor in the extension system; creation of a training engineering unit to improve training offer quality; institutionalisation of more comprehensive training agreements; introduction of monitoring / evaluation tools focused on training quality; and mobilization of additional financial resources.
The results of the first quarter of 2015 encompass the advent of Multiannual Programme (2015-2019) and the starting of PRCHAT2 program. The number of trainees in the first quarter of 2015 had a decline compared to the first quarter of 2014 (Table 2). This is due to the qualitative approach adopted in PRCHAT2 program: group training has been limited, for pedagogical and organizational reasons, for a better impact on trainees.

Table 2. Global population trained in Algeria and abroad in the framework of PRCHAT2 program; first quarter of 2015.

Global population trained in Algeria

Source: DFRV (2015).

Many partners are involved in the implementation of training actions:
- Institutions of MADR: Direction of Agricultural Services, chambers of agriculture, training centres and institutions, technical institutes and research centres, etc.
- Other institutions *e.g.* training institutions of the Ministry of Education and Professional Training;
- Foreign institutions and organizations: Arab Center for the Studies of Arid Zones and Dry Lands (ACSAD), International Atomic Energy Agency (IAEA), DG SANCO, CIHEAM, EFSA, ICARDA, UNDP...

Moreover, in the framework of the implementation of a three-years, 2015-2017, institutional partnership (PROFAS - *Programme Algéro-Français de Formations Supérieures*) between DFRV (MADR) and the French Ministry of Agriculture for 2015 many actions have been carried out: support for the establishment of a national agricultural training engineering unit; support for the redefinition of the role of training institutions; exchange of experience between Algerian and French technical institutes; support for the establishment of a platform for inter-ministerial dialogue on training in and qualification of the agricultural sector.

Conclusion

Algeria has developed an important support system including measures to promote professional organizations and institutions and to support agricultural production. However, nowadays, Algerian farmers are increasingly asked to respond to the challenges facing them. The profound changes occurring in the agricultural environment also require them to have more knowledge. The availability of effective and efficient extension is highly desired.

Due of its status, the national system of agricultural extension led by INVA, und under the institutional and political supervision and guidance of DFRV at the Ministry of Agriculture, could be an answer to the needs of pooling local resources and opening to international networks. This is related to the need to restructure the system, from the organizational and functional points of view, and to strengthen its human resources by mobilizing sectoral competences and external resources. Analysis of informational needs of farmers should

constitute the basis for building the extension offer. The new agricultural training and extension programs (PRCHAT1 and PRCHAT2) are going in this direction and should allow strengthening the agricultural extension system and improving its performance so that it can appropriately contribute to the sustainable development of Algerian agriculture and rural areas.

DETERMINANTS OF ACCESS TO AGRICULTURAL CREDITS FOR SMALL SCALE FARMERS IN THE SOUTHERN PROVINCE OF RWANDA

Edouard MUSABANGANJI[1]*, Antoine KARANGWA[2], Philippe LEBAILLY[1]

[1]University of Liège, Gembloux Agro-Bio Tech, Economy and Rural Development Unit, Belgium
[2]University of Rwanda, College of Agriculture, Animal Sciences and Veterinary Medicine, Rwanda

Abstract

This study investigated the determinants of financial inclusion for small scale farmers by focusing on the access to formal and informal agricultural credits in the Southern Province of Rwanda. Data were collected from 310 farmers from Huye and Nyamagabe districts through an open-ended structured questionnaire and analysed using the binary logistic regression method. The major findings, on one hand, showed that among the requested and approved agricultural loans, 87.2% and 12.7% were from informal and formal financial institutions respectively. Among those who accessed agricultural credits, 59.7% were from Huye and 40.3% from Nyamagabe. On the other hand, it was revealed that the household characteristics and the community attributes are the most important determinants. Those household characteristics include household income and expenditure, Ubudehe socio-economic category of the household, off-farm employment and the size of the land owned by the household whereas community attributes involve residence area, transport and informal financial services availability. Regarding farmer characteristics, the education level was found to be the only factor affecting the smallholder farmers' access to agricultural credit. In light of the findings, it was recommended to conduct sensitization sessions focusing on the importance of agricultural credits for smallholder farmers especially in the areas with high level of poverty. In addition, there is need to work on alleviating the formal agricultural credits access barriers, and to conduct a study on the dynamics of informal and formal agricultural credits up take and usage by smallholder farmers to explore all dimensions of financial inclusion in the study area.

Keywords: *agricultural credit, small scale farmers, Southern Province, Rwanda*

Introduction

The economy of Rwanda is highly depending on agriculture which employs 87.3% of economically active population and contributes up to 36% in the GDP (Gisaro, 2013). More than 70% of its adult population live in rural areas (NISR, 2012a) and rely mostly on agriculture for their daily livelihoods. Given the importance of agriculture to national economy, the raising of agricultural productivity and farmer’s income remains the priority of the Rwandan government. The agricultural credit through microfinance institutions has been selected along with other mechanisms to achieve the main goal of transforming and modernizing the agricultural sector highlighted in different agriculture-related programs and strategies. The importance of credit for rural development is even more pronounced for developing countries with largely subsistence farming systems such as Rwanda (Muhongayire *et al.*, 2013), where, there are two major sources of agricultural credit namely formal institution and informal institution sources (NISR, 2012a). The first comprises development and commercial banks, microfinance institutions, and Saving and Credit Cooperatives (SACCOs) while the latter is made by internal value chain financing agents, agricultural

cooperatives, farmers' associations, tontines, loans clubs from Non-Government Organizations, friends and neighbors.

In the literature, it has been shown that agricultural credit is a tool to expand agricultural production (Balogun and Yusuf, 2011) and to promote the standard of living by breaking vicious cycle of poverty of small scale farmers (Ayegba and Ikani, 2013). It serves to improve the household welfare by increasing the total consumption levels and impacting positively the demand for children's health care and education, as well as leisure (Armendariz and Morduch, 2005). Agricultural credit is also seen as an important financial support that a small farmer can get in order to bridge the gap between his income and expenditure (Khan *et al.*, 2011).

In rural areas, the availability of agricultural credit and financial services is perceived as a critical matter but the access to these financial services by rural farmers is another one. This, because their availability does not guarantee their accessibility. As argued by Duy *et al.* (2012), the success of credit provision for poverty reduction depends on the possible access by poor households to credit-providing institutions. According to De Klerk *et al.* (2013), in sub-Saharan Africa, where most people still live in rural areas and agriculture is the mainstay of the rural economy, access to financial services of all kinds appears still to be poor. In this line, Anyanwu (2004) states that collateral, credit rationing, preference for high income clients and large loans, bureaucratic and lengthy procedures of providing loan in the formal sector keep poor people outside the boundary of the formal sector financial institutions in developing countries. According to Swinnen and Gow (1999), for most banks, financing agriculture is a high risk activity because of low profitability in the sector. As asserted by DID (2010), the other problem of lack of access is related to the fact that the farmer is faced with financing needs related to his family. The author also argues that women face significant family burdens related to child rearing, healthcare, clothing and other basic family needs, and this situation often leads them to exhibit greater aversion to risk and, therefore, be less inclined to use credit as a development tool.

In Rwanda, besides the fact that some of rural credits are not adapted to the activities and profile of farmers, a number of factors – including lack of awareness of rural farmers regarding rural credits availability and utility, fearness to take credit, difficulty to meet eligibility criteria for farmers to access bank credit, high interest rate on bank credits, physical access-distance to formal financial institutions, poverty and other deprivations – have been identified as limiting the access of rural farmers to credits (MINAGRI, 2009; NISR, 2012a). The Government of Rwanda, through various mechanisms such as setting up projects, task forces, funds and local saving and credit schemes as SACCOs in each administrative sector tried to find out solutions to overcome the aforementioned hindrances. Despite all the efforts made, Muhongayire *et al.* (2013) affirm that, access to formal credit remains steadily low even as the national economy is considerably growing. A study by NISR (2012a) reveals that in 2012, 71.9% of adult population were financially included (or have had access to formal and/or informal financial products) but only 7.4% applied for agricultural credit and 90.5% of them were approved. Agricultural inputs are less affordable to farmers because of lack of domestic sources of fertilizer and high cost of pesticide, while most farmers are poor and lack access to credit to finance inputs (IPAR, 2009). Consequently, agricultural productivity is still low and for some food crops such as maize, rice and other selected priority crops, the country relies on imports and many rural households are living in poverty with 44.9% in poverty and 24.1% in extreme poverty (NISR, 2012b).

While it has been shown that the level of investment in agricultural activities is correlated with agricultural productivity which goes together with improving food security and reducing poverty (Khan *et al.*, 2011; Zeller *et al.*, 1997), the following concern arises in the context of

rural areas of Rwanda where, according to NISR(2012b), smallholder farmers still face low productivity and poor living conditions: What are the factors affecting the access to both formal and informal agricultural credits for smallholder farmers?
Studies (for example, Sebakambwe, 2012; Muhongayire *et al.*, 2013) have documented the issue of rural credit in Rwanda but none has been conducted to study the accessibility of agricultural credits in Southern Rwanda from the point of view of the demand side. Therefore, this study seeks to identify the determinants of access to formal and informal agricultural credits for smallholder farmers in the Southern Province of Rwanda.

Materials and Methods

This study was carried out in Huye and Nyamagabe districts of the Southern Province of Rwanda, a purposively selected study area. The choice of this area was motivated by the highest level of poverty prevailing in this Province (56.5%), and to enhance the situation understanding, the districts of Huye and Nyamagabe were selected as they are respectively least poor and poorest in this Province (NISR, 2012b). The study used a sample of 310 farmers determined using the Cochran (1963) sampling formula based on the financial access strand of 71.9% in Rwanda (NISR, 2012a). Sampling frames were obtained from heads of six agricultural cooperatives selected in the two districts (three in each). A simple random selection technique with probability proportional to size was used to obtain the number of interviewed farmers in each of the cooperatives. The data collection was performed from January to March 2015 and used an open-ended structured questionnaire highlighting the main features pertaining to the objective of the study. Given that our model has a dichotomous dependent variable with two values, 1 (when the farmer is having access to agricultural credit) or 0 (otherwise), data were analysed using the binomial logistic regression method following Hosmer and Lemeshew (1989). The set of explanatory variables is made by continuous and categorical/dichotomous variables on the community and institutional characteristics, socioeconomic and demographic situation, land and dwelling endowment among others.

Results and Discussions

The descriptive analysis reveals that among the requested and approved agricultural loans, 87.2% were from informal sources while only 12.7% were from formal financial institutions. The study shows that 59.7% of those who accessed agricultural credits were from Huye district and 40.3% from Nyamagabe district.

Regarding Ubudehe socio-economic categories namely first category (people in abject poverty), second category (very poor people), third category (poor people), fourth category (resourceful poor people), fifth category (food rich people) and the sixth category (money rich people) (NISR, 2012c), the results showed that 37.5% of farmers from Nyamagabe district are in the first and second socio-economic categories. Those from Huye district in those very same first and second categories accounted for 32.3%. Among the interviewed farmers, 62.6% and 66.5%, respectively, from Nyamagabe and Huye districts are counted in the third socio-economic categories. All interviewed farmers from Nyamagabe district belong only to the first three categories whereas 1.3% of the respondents from Huye district are in the fourth category. None of the sampled farmers is in the fifth and sixth socio-economic categories.

Concerning the factors affecting the access to agricultural credits, the results of the logit estimation are presented in Table 1.

Table 1. Binomial Logistic Regression model: Estimation results

-2Loglikelihood=226.345 Cox and Snell R^2=0.280 Nagelkerke R^2=0.405
Hosmer and Lemeshow test: Chi-square=6.768, p-value=0.562

The study reveals that the level of income of the household head and informal financial services availability in the neighborhood are the most significant variables. The availability of informal financial services increases the probability of having access to agricultural credit by 383.3% whereas the level of income of the household decreases the probability of accessing agricultural credit by 104.6%. This empirical finding supports the assertion that higher income households may be less risk vulnerable and have less demand for credit because they have enough capital from previous earnings (Nunung *et al.*, 2005). The significantly positive coefficient of the size of the land owned by the household variable in the model suggests that the size of the land increases a farmer’s likelihood of having access to agricultural credit.

The results show that being a resident of Huye district increases the probability of having access to agricultural credit by 61.2%. Rural farmer's access to agricultural credit is also positively affected by off-farm employment in the household and transport availability in the community. High level of education of the farmer and Ubudehe socio-economic category of

the household are also positively significant in determining the probability of having access to agricultural credit. The empirical model reveals that an increase in one level among Ubudehe socio-economic categories multiplies the likelihood of having access to agricultural credit by 1.5 and the level of education of the farmer increases the probability of having access to agricultural credit by 40.3%. This appears very intuitive and evident as a literate and/or a wealthier farmer is likely to have a better understanding and then be opened for financial products and services than an illiterate and/or poor farmer who is less likely to manage his business with success. The results show that when the household monthly expenditure is perceived as high compared to its monthly income, the probability of having access to agricultural credit decreases by 92.4%. This may be explained by the fact that when the small scale farmer faces financing needs related to his family (consumption expenditure, education, health and leisure) and to his farm (purchasing inputs, rent for land, cost of post-harvest technology, …) which require an amount greater than the income from his farm, this may lead to an increase in the risk of his ability to repay the loan and then, to less demand for agricultural credit.

However, the estimated coefficients on gender, house ownership, livestock ownership, distance from home to micro finance institutions, time taken by the loan procedures in formal institutions, farm profitability and the number of the household members are not statistically significant and were not found to be factors affecting the access to agricultural credits. These results are not in line with those found in the literature (for example, Sebakambwe, 2012; Anyanwu, 2004; Swinnen and Gow, 1999) in regards to rural credits. This may find its explanation in the fact that in rural areas, where the level of poverty is high with subsistence agriculture, farmers mostly rely on agriculture-related activities funding from informal financial institutions which are mostly found in the neighborhood, and where the gender of the applicant, the collateral and the guarantor are not among the main requirements.

Conclusion

This empirical study investigated the determinants of access to formal and informal agricultural credit by smallholder farmers from the Southern Province of Rwanda. The results revealed that the household characteristics and the community attributes are the most important factors, affecting the farmers' access to agricultural credit. The transport and informal financial services availability at community level have been found as the most significant determinants of agricultural credit access. The residence area, the level of education of the farmer, the Ubudehe socio-economic status of the household and off-farm employment in the household are also positively associated with the likelihood of having access to agricultural credit. The level of household income, the size of the land owned by the household and the level of household monthly expenditure are negatively affecting the farmers' access to agricultural credit. In light of the findings, the following recommendations emerge: the sensitization sessions focusing on the importance of agricultural credits in enhancing the smallholder farmers' operating conditions are needed especially in the areas with high level of poverty; for formal agricultural credits, policymakers should work on alleviating the access barriers; and, to explore the three dimensions of financial inclusion for small scale farmers in this area, a study on the dynamics of informal and formal agricultural credits up take and usage is necessary.

Abstract

The practice of irrigated agriculture in Burkina Faso still suffers by the weak control of technical-economic parameters for an agricultural production capable to ensure sufficient income to irrigating producers. Therefore, the efficient valuation and profitability of irrigated infrastructures remain mitigated. To overcome this deficiency, a study for the development of a technical-economic referential of irrigated crops is an alternative to produce information with a view to orient the irrigated agricultural holdings in Burkina Faso on irrigated production methods. This study is conducted in this perspective.

The study is based on panel data collected through an agricultural accounting observatory of irrigated crops in sixteen irrigated perimeters during three agricultural seasons, each consisted of a dry season and a rainy season. It performs an analysis of gross margins, cost prices of irrigated crops and capital income and labor of irrigated agricultural holdings.

In the analytical process of economic parameters, purpose of the present article, two approaches are used: the first approach is based on the comparison of study parameters according to the crops grown, while the second is a comparison by type of irrigated schemes.

Keywords : *technical-economic referential, panel data, irrigated crop, agricultural holding.*

Introduction

Agriculture in Burkina Faso is highly dependent on weather conditions. Seventy-five percent of agricultural production in the country is rainfed. Since the drought of the 1970s, the development of irrigated agriculture became essential to improve agricultural production and secure food resources of households.

In spite of efforts to increase investment in developing irrigated areas, the results in terms of valorization, however, remain mixed. For instance, in large areas, they are between 79 and 100% during the wet season and 55 to 100% during the dry season. Also the yields of major irrigated cereal crops globally are weak on the average: 3.5 to 4.5 t/ha both in the rainy and dry seasons for the rice and 2.5 to 3 t/ha during the two seasons for maize) (MAH, 2011).

Despite the difficulties of developing irrigated areas, their profitability remains low. Indeed, the internal rate of return hardly exceeds 20%, regardless of the type of development.

In short, the practice of irrigated agriculture in Burkina Faso still suffers from the weak control of technical and economic parameters for an efficient agricultural production that can ensure food security and fight against poverty.

To address this concern, the study of the development of a technical and economic repository for irrigated crops in Burkina Faso turned out such as an alternative tool to produce information to guide and properly improve the practices of irrigated crops.

Worldwide, agriculture repositories are established through methods mainly focused on the observation of farming practices over time in order to establish a diagnosis for better guide. For instance, development of technical and economic repository of Guyana crops and

livestock production (CGERG, 2002) based on observations of farming practices that lasted 4 years helped out (among other economic indicators) average prices, gross margins and technical data related to crop production. The same process was used in a study in Mali to establish a technical and economic database of the Diffusion of Irrigation and Production Technologies (RTE/DTIP). Essential information sought concerned the determination of the main production areas of horticultural and arboricultural crops, the farmers operating accounts, the crops yields, the labor's values.
The approach for the establishment of agricultural frameworks for improved efficiency in production was applied in South Vietnam for rice, in Wallonia for the evaluation of performance and profitability in agriculture; this is in order to make available to the agricultural world tools that improve activities performance. For these studies, a common thread emerges: it is the implementation of a collection method based on 3 years (minimum) of observations. According to Lebailly et al. (2000), the observatory based on a semi-permanent sample of holdings, provides food for thought on agricultural policies to be formulated. Indeed, agricultural policies determine widely the economic situation of the farmers and, therefore their strategic reasoning (Ansaloni and Fouilleux, 2006). For most of the cited studies, the analysis consisted of comparing parameters and information production for the orientation of policy makers and practitioners. Pierrot (1990) gives evidence of comparative approach by asserting that technical-economic research on the study of functioning of the exploitations allows building a relevant device to compare their performances with a structured reference table. This approach facilitates the formulation of diagnostics and adapted agricultural advice.
As part of this paper, our choice fell on corn, rice and onions because of the strong momentum observed around these crops, both technically and economically (according to statistics).

Materials and methods

In the case of Burkina Faso, the study for the development of technical and economic standard was driven through the establishment of an observatory of irrigated agriculture accounts for the entire national territory. It consisted of conducting surveys during agricultural seasons (both dry and rainy season) from 2009 to 2012. 16 irrigated areas were selected according to criteria relating to the agro-climatic zone, the size and the schemes of water pumping system. At each site, 10 randomly selected farmers were followed for all crops grown in irrigated and rainfed.

The collected data have focused on the structure and activities of monitored farms, the crops acreage (rainfed and irrigated), the production system, the activities of the production ways, the means used and the acquisition modes, the fees, the yields, the post-harvest activities, products and different destinations (consumption, market).

The compilation of the data collected was carried out using a database created with MS-Access. After encoding data, they have been cleaned (using statistical methods and additional investigation) to remove missing data and outliers. The rate of these outliers and missing data is globally estimated at 4%.

To ensure the quality of the collected data, a method of replacing missing data or outliers was used (by using the mean, median or mode).

However, given that extreme values or outliers can influence the average and make it unstable, median observations were used.

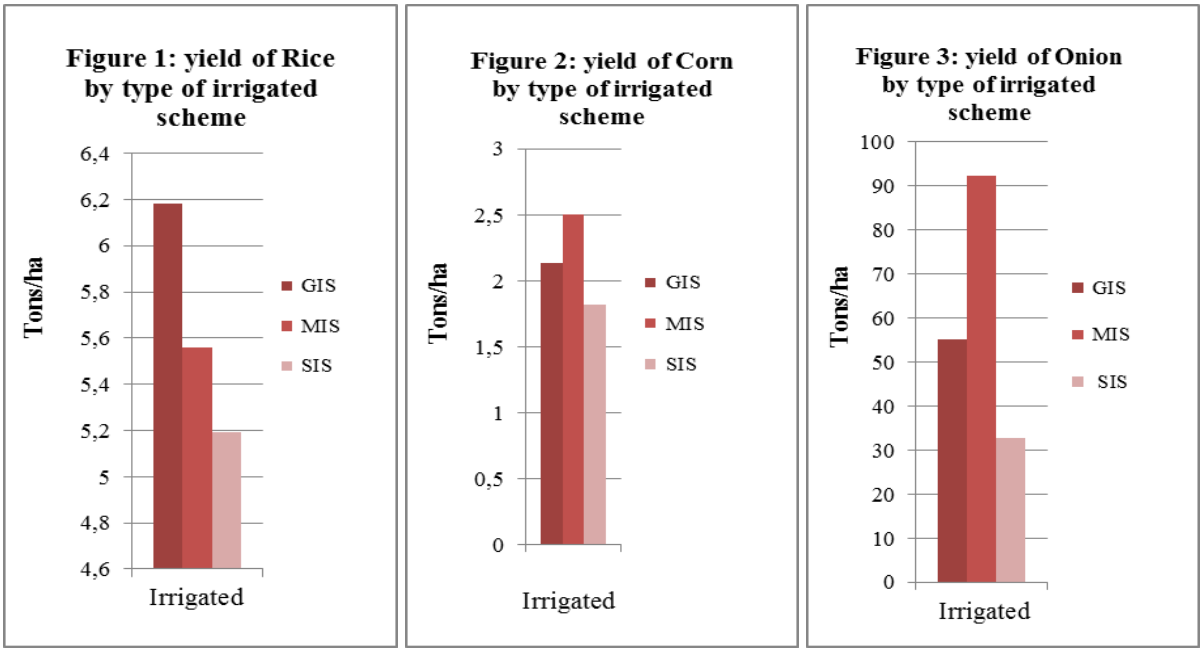
Also, procedures have been incorporated into the database for the calculation of economic indicators such as gross margins, cost, and labor income of irrigated farms.

From the database, the data taking into account only the producers regularly monitored during the period were used for the analyses. SPSS and MS-Excel were used for data processing and the calculation of economic parameters. The analyses consisted of comparing different crops according to the production system and the typology of irrigated schemes.

One difficulty in the constitution of the base sample was the high mobility of producers. Therefore in this study, only regularly monitored producers were selected.

Results and discussion

The results show some technical indicators for crops like rice, corn and onion. As part of the technical indicators, the figures below show the performance of crops depending on the irrigated scheme[15]: great irrigated scheme (GIS), medium irrigated scheme (MIS) and small irrigated scheme (SIS).

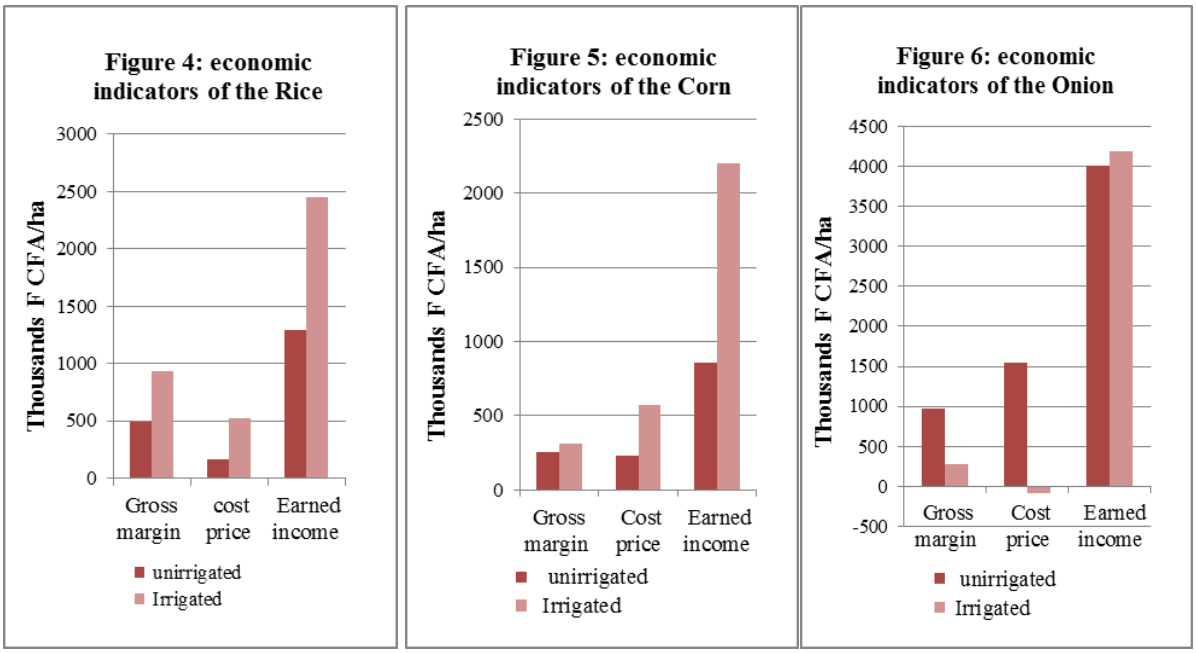


Yield of irrigated rice is higher in large irrigated areas and is around 6 tons per hectare (figure 1). This is probably due to the use of modern means and compliance with good agricultural practices in the production of large-scale rice, unlike small and medium areas in which production is still of family type.

Corn and onion production on medium area perimeters, have the highest yields (figures 2 and 3), which can be explained by the fact that these irrigated crops are generally produced on medium areas. Their productions controlled over large areas are extremely rare (or almost nonexistent for onion).

[15] GIS : area ≥ 100 ha ; MIS : 20 ha ≤ area < 100 ha; SIS : area < 20 ha

Concerning the economic indicators, the following figures show the gross margins, cost, and the income of the studied crops.



In light of these economic indicators for corn and rice, we have the same trends for the three studied indicators. The gross margins, cost and labor incomes for these two crops are higher for irrigated agriculture. This is justified by the fact that irrigated agriculture has more charges than unirrigated agriculture. These cereal crops irrigated are also more productive than those cultivated in pluvial. Figures 4 and 5 illustrate this fact.

The special case of onion illustrated by the figure 6 could be explained by the fact that onion is grown mainly in the dry season (irrigated) and especially on small areas without the introduction of large means. This makes these productions very vulnerable.

Conclusion

The establishment of the technical and economic repository on irrigated agriculture based on farmers practice in Burkina Faso is in a process of producing relevant information to help orient the stakeholders in the practice of irrigation.

By establishing the importance of irrigated production through the production of these few indicators, the study is looking at the effects of irrigation on agricultural production in terms of efficiency. With climate change, water is becoming increasingly scarce over time. We believe that a good control of irrigation systems combined with good agricultural practices should lead to increased productivity and yields, and improve the living standards of the producers. The next step will be a complete analysis of technical and economic parameters of other cultures.

In order to improve the living standards of producers, Burkina Faso could guide and support irrigated rice farmers to better optimize the means of production and move towards professionalization of their activity. In a context of quest of food security, the fight against poverty and climate change, agricultural consultancy in the area of irrigation should move towards the practice of irrigated crops of high productivity and high value. As such, the production of corn and onion, profitable crops, should be encouraged in areas equipped with water control.

SYSTEMIC ANALYSIS OF TECHNICAL EFFICIENCY OF IRRIGATED FARMS IN BURKINA FASO

Abstract

In this study, the "Data Envelopment Analysis" (DEA) and a systemic approach is applied to assess technical efficiency of irrigated farms across 13 regions of Burkina-Faso. Ordinary Least Squares method is used to identify technical efficiency determinants.

Data were collected during three agricultural campaigns, from 125 farms in three regions differentiated by three main parameters: (1) zones irrigation capacities; (2) two types of irrigation and; (3) two different modes of water drainage.

We seek to establish a causal link between farms efficiency and household socio-demographic factors and the above mentioned endogenous parameters. Over the survey entire period and whatever the parameters are; the average inefficiency scores (6.33±5.71) is high. By improving their resource allocation strategies, irrigated farms would be able to reduce their pure technical inefficiency scores (5.06 ± 4.98) and; thus quintupled their production.

Such inefficiency scores did not significantly vary with zones irrigation capacity. But farms using pumping for irrigation are relatively more efficient. Farms are more efficient in dry season than in rainy season. Invariably, technical efficiency is negatively correlated with the farms size. Optimal acreage allows increasing production by 30%. Also, we notice that farms efficiency levels are significantly influenced by household size, labour employability, land tenure and crop diversification.

Keywords: *irrigated farms, technical efficiency, DEA, systemic analysis.*

Introduction

In Sub-Sahara Africa (SSA), specifically in Burkina-Faso, production systems are highly affected by rains variability. The reduction of pluviometric gradient is a clue of climate change; and these modifications threaten the people's livelihoods (Sivakumar, 1998).

Therefore policy makers decided to develop strategies and programs to enhance rural population resilience to livelihoods vulnerability and food insecurity. And one of their focuses is water irrigation systems as a main tool to improve farming productivity (Rosegrant and Cline, 2003; Diouf, 2008; CILSS, 2010).

In Burkina-Faso, the implementation of these policies were supported by World Bank and other National Funds; and it permitted to increase the share of irrigated crops in the agricultural Gross Domestic Product (GDP) from 2.12% in 2005 to 8.33% in 2010. Regarding the National GDP, it increased from 1.9% in 2006 to 3.1% in 2008 (MAH, 2011).

In west-Africa to date, irrigation systems scaled at farm level "small irrigation" is the most common. Due to its low investment cost, it is accessible to small farmers and vulnerable

groups. But (MAHRH, 2004) noticed that, besides the availability of water and land; results of empirical surveys on small scale irrigation systems efficiency vary greatly.
Firstly, there are important fluctuations of acreages and yields (decreasing yields) over years; with no diagnosis to determine the real causes (MAH, 2011). These fluctuations lead to difficulties to plan and identify the optimal acreage of a profitable farm. The factual approach gives realistic information and captures better farms production systems complexity.
On the other side, it is noticed an apparent inefficiency of irrigated farms whatever the production season. Previous studies on irrigated crops such as rice and leguminous have shown that farmers technical efficiency is low (Kaboré and Taondyandé, 2007; CAPES, 2011). These results are confirmed in SSA countries by Audibert and al. (2003) and Nuama (2010) in Ivory Coast; Adégbidi (2003) in Benin; Diagne and al. (2013) in Senegal.
Despite the weaknesses of irrigated agriculture in SSA, stakeholders still interested to support and fund the sector.
This contrasted situation leads to wonder on how and which strategies to improve irrigated farms' technical efficiency; regarding its importance towards food security and poverty reduction. Before answering this question, we need to diagnose small scale irrigated related to production efficiency.
To provide some insights to these questions, this study compares irrigated farms technical efficiency and identifies the factors influencing this efficiency.
Specifically, the paper will evolve as following:
comparative analysis of irrigated farms technical efficiency with parameters such as: the regions' irrigation capacities; national typology of irrigated schemes; water uses patterns and agricultural seasons;
irrigated farms technical efficiency scores determinants' identification.

Materials and methods

The paper is drawn on systemic modeling theory, which was proofed to fit agricultural farms characterization regarding their technical and economic features (Adégbidi, 2003; Djagni, 2007). According to Abatania (2012), multi-purposes phenomenon cannot be captured using the classical approach, which does not allow comparison between actions; as in the case of farming production. While, the systemic modeling refers to the farms' scale analyses and permits to characterize and compare performances of associated production systems.
In this study, irrigated farm is defined as a Decision Making Unit (DMU) using irrigation for agricultural production during the dry or the rainy season. Each farm is distinguished by its irrigation capacity, the type of irrigated scheme and water collection methods used.
Due to vulnerability and risk aversion, a DMU can diversify its activities by combining crop production during the rainy season and others types of activities (animal breeding, services, gold panning, etc.). A DMU can integrate several production systems (irrigated or non-irrigated) which can be located in different geographical areas (equipped plots or non-equipped plots).
For a specified DMU, there are interactions between dry season activities and rainy season activities, which lead to inseparability of allocation resources for production decisions. Then, the systemic approach allows assessing the impact of the rainy season production and other types of production on the dry season irrigated production; and to capture the system inner performance (Figure1).

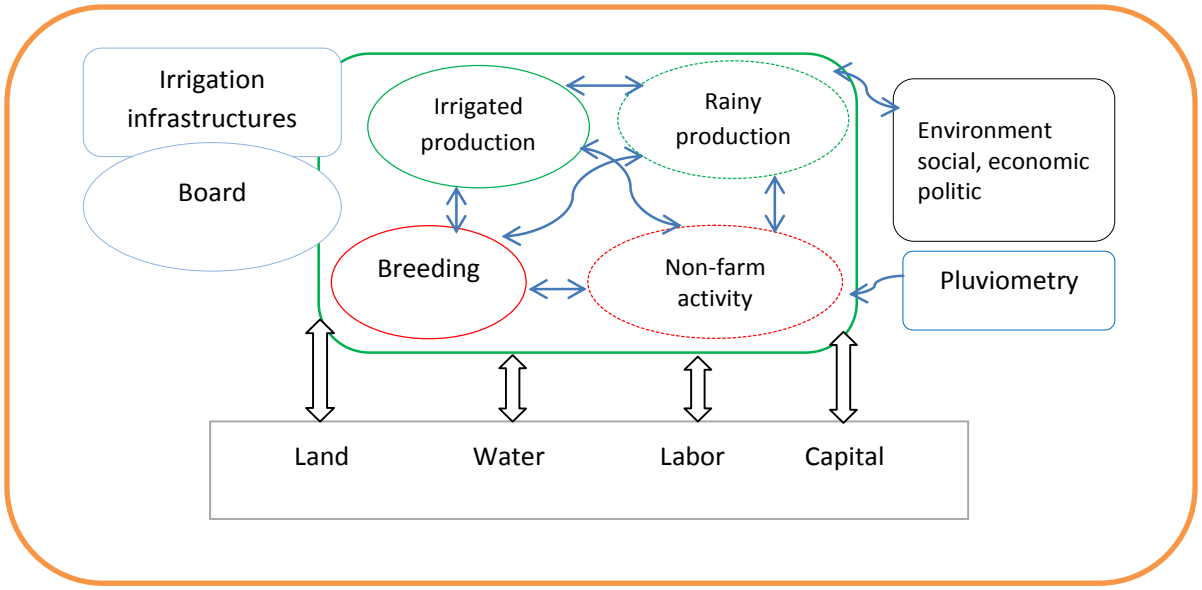

Figure 1: Theoretical framework
Source : Authors' representation

In this study the authors used the DEA method to assess irrigated farm technical efficiency and scale efficiency. We adopt the output oriented function because agricultural policies used in Burkina-Faso target yields increase instead of inputs reduction [5]. Therefore, both methods BCC and CCR may give realistic information under constant return to scale.

At the start of the process of building the study sample, we had the idea to develop the major work done at the national level in irrigated agriculture.
Starting from this idea, the option was taken to consider zoning, which divides the country into three main areas; having major irrigation potential.
Each area includes irrigated areas classified according to their size. In addition to the irrigated area size, which is a factor of discrimination; we considered the method used for conveying the water (with or without pumping).
This last parameter can be considered de facto as an important element of farm performance differentiation, particularly in terms of production costs and hence production results.
A total of 16 irrigated schemes were selected for sampling. On each irrigation scheme, 10 farms were selected randomly.
A sample of 160 farms was then constituted for monitoring. For various reasons (death, economic and land mobility of farmers, etc.), only 125 irrigated farms have been assiduously followed during three years. These farms are scattered across the country and represent several facets of irrigated agriculture.
The studied farms are characterized by production systems (irrigated and / or rainfed), which are characterized by some crop diversification. Diversification levels calculated from the transformed Herfindahl index (THI) were 81.8 % (for 23 crops) and 77.3% (for 19 crops), during the rainy season and dry season, respectively. A total of 25 different crops (cereals, horticultural crops, tubers) were counted.
Data were collected through interviews and agricultural accounts tracking methods. The observations lasted three (03) agricultural campaigns: from 2009 to 2012. Each agricultural campaign includes two cropping seasons : a rainy season that lasts from may to september and a dry season, from october to april. Panel data have been collected and includes : information about socio-demographic characteristics of the household's head (gender, age, marital status, educational level and origin of the manager ; size and number of household assets, land

tenure) ; farm resources and type of operation in the production process; techno-economic and synthetic accounting data (agricultural yield, gross margin, operating income, value added, cost, operating costs, etc.).
Usually, the used factors are: land, inputs and labor. In our case, the choice of variables was made according to the literature and our empirical knowledge of irrigated production practices.
Accounting for observations criteria and the convexity assumption imposed on the production frontier, our analyses focused ultimately on 321 DMUs.
The model output is an aggregate indicator that represents the sum of the values at market prices (FCFA) of all vegetable productions in the dry and rainy seasons. The inputs are: (1) total acreage (Ha); (2) total value of the seeds (FCFA); (3) total amount of fertilizer (NPK) (kg); (4) total quantity of fertilizer (Urea) (kg); (5) amount of labor used for all cultures (Man/Day); (6) capital in monetary values (FCFA): depreciation of equipment, agricultural and irrigation equipment, and buildings.

Results and discussion

3.1. Global Technical Inefficiency scores

Descriptive statistics of technical inefficiency scores of CCR or CRS models are presented in Table 1. During the period of research, farms Global Technical Inefficiency (GTIn) did not vary significantly. Regardless of cropping seasons, the mean score for global technical inefficiency, after bias correction by the method of (Simar and Wilson, 1998), is 6.33 (± 5.71). The score dispersion range includes less than 24 % of DMUs (see Figure 3). However, it seems relatively high; meaning low levels of efficiency and; subsequently opportunities to increase production through productivity gains. Surveyed farms should multiply their average production levels by 6.33 in order to reach the production frontier.
Studies conducted in Burkina-Faso (Ouédraogo and Kaboré, 1996) and elsewhere in the Sahel (Nyemeck, 2008) obtained similar conclusions, although with more varied efficiency scores, ranging from 16% to 74%.

Table 1. Descriptive statistics of Global Technical Inefficiency (GTIn) scores

Variables	Observations	Mean	St. D.	Min	Max
GTIn Scores biaised	321	4,89	4,36	1	44,24
GTIn Scores unbiaised	321	6,33	5,71	1,21	60,06
Biais	321	-1,44	1,38	-15,81	-0,20

Source : Authors` elaboration

To refine GTIn scores, factual analysis have been done using parameters such as: agricultural campaigns (years), cropping seasons, type of irrigated acreages, technics to collect water and types of production systems. The purpose is to disaggregate the global score into sub-scores related to each above mentioned parameters. Inefficiency sub-scores were compared using t-tests.
From this comparison, rainy season average inefficiency score is superior to dry season score, significantly. As crops are irrigated during the rainy season; irrigation is probably reducing the farm inefficiency level.
This result is intuitive given the fact that, irrigation practice requires more discipline in agricultural practices and production factors allocation. This is shown by the average inefficiency score of irrigated farms which is higher than the non-irrigated farms at 10% (see figure2). The decrease in irrigated crops efficiency would be linked to difficulties experienced by producers, following poor rainfall during the second agricultural campaign. In addition,

some crops planted during the dry season of the 3rd agricultural campaign (2010-2011) could not complete their production cycle. This inefficiency score may also be due to misallocation of water resources for crops; or could be interpreted as an inadequate consideration of climate risks into irrigated production schemes.

Farms with larger irrigated acreage seem significantly more inefficient than smaller irrigation acreage. This result is subject to questions and raises discussions on the overall performance of different types of size Indeed, as stated in the introduction, large irrigated acreages were regarded as entities with low economic and financial profitability; and where inefficiencies were observed in the majority of farms. In the context of Burkina Faso, renewed performance of large irrigated acreages could be induced by the combined effects of the return of specialized government offices in the process of framing and organizing producers; the support supplied to farmers organizations through subsidized agricultural inputs, etc.

In addition, the analysis shows that there is a negative correlation between the scores of GTIn and farm size (see Figure 3). From this, it follows that small farms have higher levels of inefficiency that large farms. Some explain the larger farms better efficiency with economies of scale.

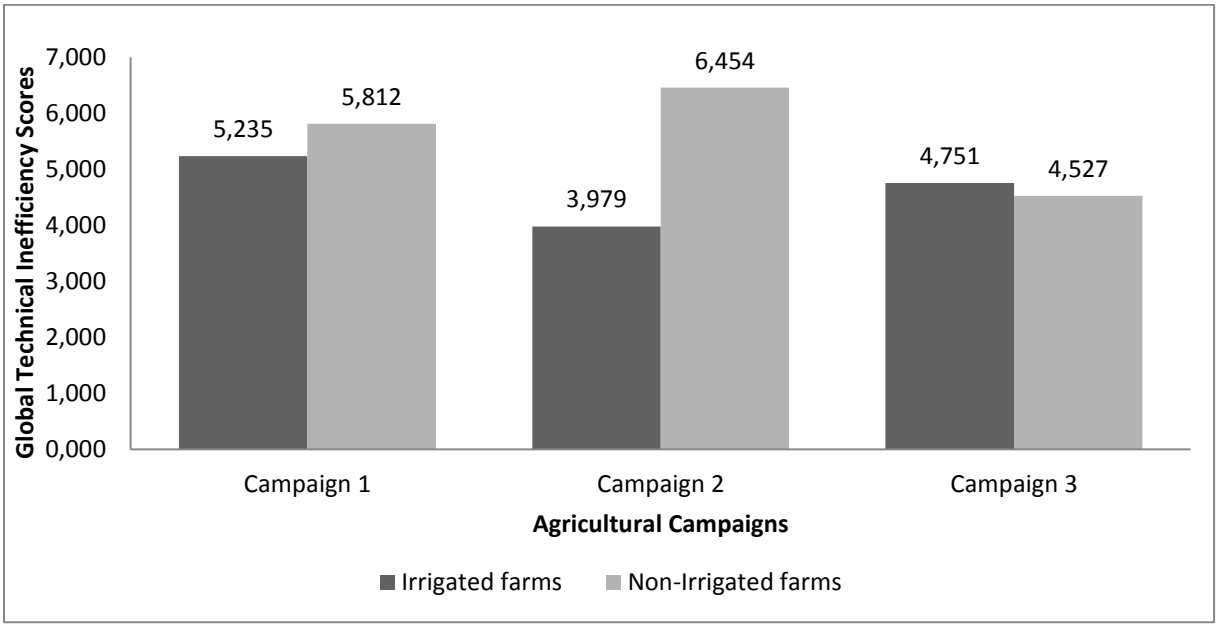

Figure 2: Global technical inefficiency over campaigns

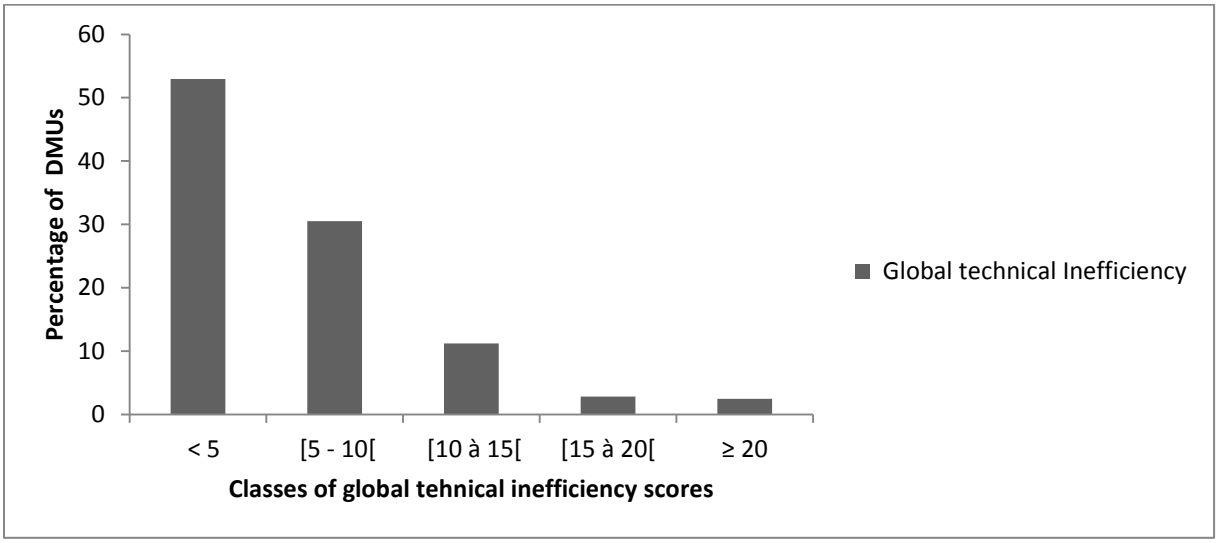

Figure 3 : Global technical inefficiency scores distribution

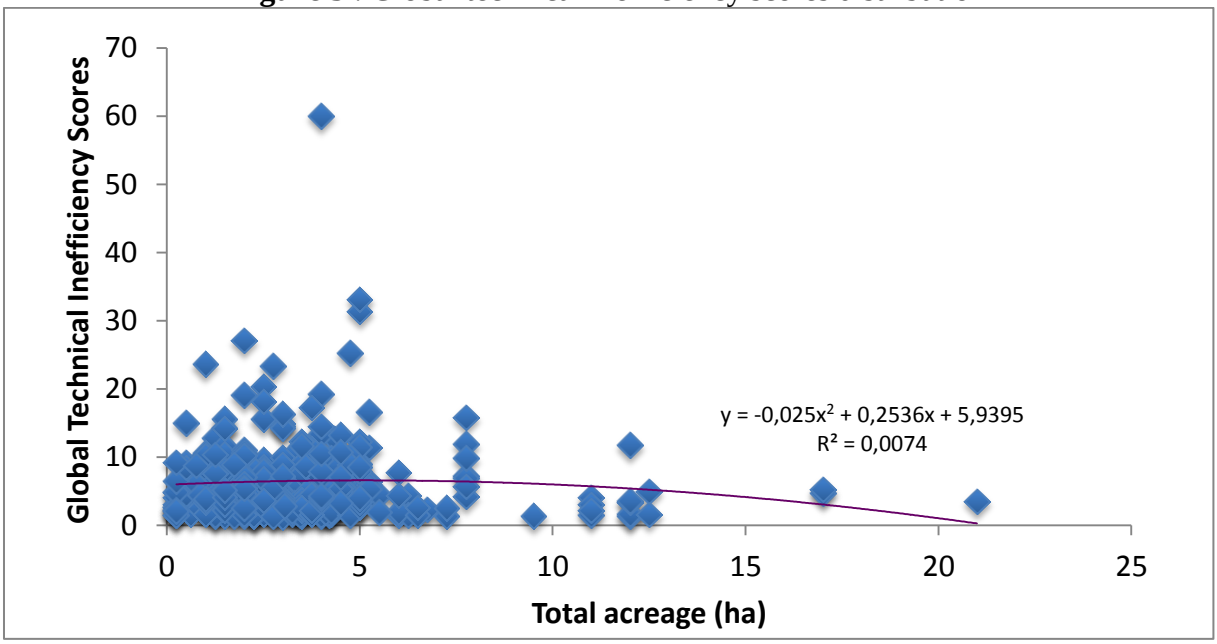

Figure 4: Distribution of the global technical inefficiency in terms of farm size

3.2. The Pure Technical Inefficiency and Scale Inefficiency

The global technical inefficiency is the result of pure technical inefficiency and scale inefficiency. The pure technical inefficiency refers to how inherently a DMU allocates its factors of production to achieve maximum production. The inefficiency of scale refers to the optimal size that allows a DMU to be on the production frontier. The analysis of these two parameters helps to refine and complete the development of the preceding paragraphs. As shown in Tables 5 and 6, it appears that the average scores of the pure technical inefficiency and the scale inefficiency for the observed farms are 5.06 (± 4.98) and 1.41 (± 0.86), respectively. In other words, these farms should improve the use of production factors in order to reduce the distance from the production frontier that is 5.06 points: therefore production could be quintupled. Also, optimal sizes allow these farms to increase their efficiency by 30%.

Figure 5 shows that globally, levels of pure technical inefficiency of farms decreased over time. This is probably due to effects of continuous technological learning, precisely for irrigation practice.

The increase of pure technical efficiency scores over time follows the same trend as the global technical inefficiency. While the scale efficiency decreased significantly from the 2nd to the 3rd cropping year. This increase in farms´ technical performance is expected in light of the new agricultural policies applied by Burkina-Faso government to support producers, since the 2008 food crisis.

Moreover, we note that throughout the period of observation, pure technical inefficiency of farms is significantly higher in the rainy season than in the dry season. In addition, farms with irrigated crops are significantly less inefficient than those practicing non-irrigated crops.

Statistically, it appears that, inefficiency scores average of farms on large irrigated schemes is significantly lower than those on small irrigated scheme. In addition, farms using pumps are significantly more efficient than those without pumps system. Irrigation without pumps is usually done through open canals downstream of dams. Such systems tend to waste more water than when it is pumped.

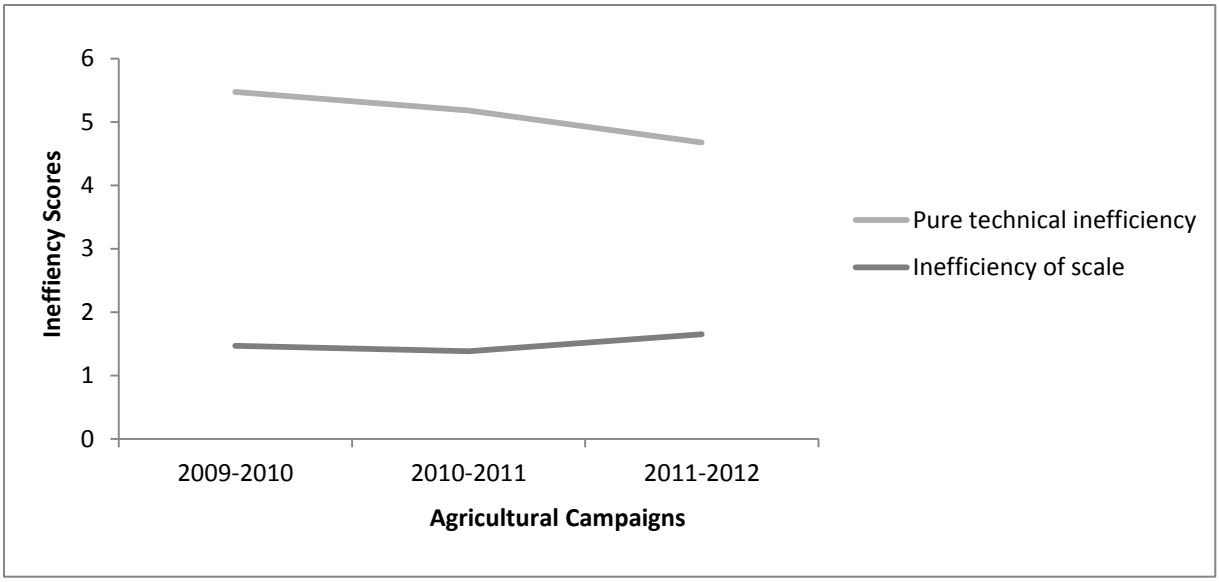

Figure 5: Pure technical inefficiency and scale inefficiency over campaigns

3.3. Factors explaining Technical Inefficiency

Table 2 . Results of technical inefficiency determinants OLS Model

Variable	CRS (TIn)	VRS (PTIn)	SE (SIn)
Gender	0,34 (0,90)	0,63 (0,84)	-0,33 (0,30)
Education level	0,16 (0,37)	0,11 (0,31)	0,07 (0,07)
Age	0,05 (0,03)	0,01 (0,03)	0,01 (0,01)
Irrigation (dummy)	-2,22 (0,88)*	-2,00 (0,79)**	0,06 (0,10)
Ratio paid /non-paid	-0,84 (0,46)*	-0,84 (0,43)*	-0,03 (0,09)
Number of Crops	-1,42 (0,35)***	-1,12 (0,31)***	-0,04 (0,06)
Household Size	0,09 (0,06)*	0,14 (0,04)***	-0,03 (0,01)***
Breeding Income	-0,00 (0,00)***	0,00 (0,00)***	0,00 (0,00)
Land Tenure	1,31 (1,27)	-2,34 (1,33)*	-0,80 (0,39)**
Constante	5,01 (2,53)*	2,51 (2,38)	2,42 (0,67)
R^2	0,08	0,10	0,12

* Significant at 10% level; ** Significant at the 5% level; *** Significant at the 1 %

The results of the regression estimation in Table 2 show that the socio-demographic variables such as gender, age and education level of farmers do not have a significant effect on technical efficiency level. This result is surprising because those are factors which should have improved the farms' efficiency (Gurgand, 1993; Phillips, 1994; Coelli and Fleming, 2004; Hasnah and al., 2004).

Irrigation practice has a positive impact on the global technical efficiency and pure technical efficiency of farms. I Irrigation might improve the water supply to crops; which improves the productivity through a better combination of farm inputs.

Considering the systemic approach that takes into account all crops grown by each farm, it turns out that crop diversification might be a key factor to significantly reduce the global technical inefficiency and the pure technical inefficiency.

Household size was revealed as a positive determinant of farms inefficiency. A large household size affects negatively the level of technical efficiency. But on the opposite, it reduces scale inefficiency.

The ratio of paid/non-paid worker is significant at 10%; and positively correlated with global technical efficiency and pure technical efficiency. This indicates that the use of hired workers, can significantly improve efficiency. From an economic point of view, this result indicates that it is probably profitable to contract hired labor

In addition, livestock production does not influence technical efficiency. This suggest that biophysical and monetary transfers between crops and livestock productions are not strong enough to impact significantly the farm production.

Following the partial assumption of variable returns to scale, the regression results show that land tenure plays a decisive role on pure technical efficiency. Confirming (Nyemeck, 2008) ; private land tenure promotes better production resources allocation.

In the current case, private land ownership would increase production by 2.34 (±1.33). However, land property rights reduce the inefficiency of scale. Therefore, land tenure policies should be set and easy to implement to permit to farmers to get better ownership rights.

Conclusion

The study analyzed irrigated farms technical efficiency in Burkina Faso, using panel data over a three-years period and a systemic approach; to estimate irrigated farm efficiency and to identify factors affecting these efficiency scores.

The results show that technical inefficiency of the studied farms is relatively low and has declined significantly over the three years of observations; unlike the inefficiency of scale. In addition, large irrigated schemes seem to be more efficient than the small ones. Also, the surveyed farms are more efficient during the dry season than during the rainy season. The practice of irrigation improves farms' efficiency.

Household head socio-demographic variables such as age, sex, and education level do not significantly influence efficiency. It is the same for livestock income. In return, the practice of irrigation, increased labor, crop diversification, household size and land tenure significantly determine the levels of efficiency of irrigated farms.

In terms of policy implication and strategies, one could recommend that :

- land reform underway in Burkina Faso should been accelerated to help securing farmers tenure in order to increase their efficiency ;
- irrigation is promoted with incentives towards crops diversification.

Abstract

The foreign trade of food products in Bosnia and Herzegovina (B&H) has been investigated for recent period of three years (2012-2014). This research based on analysis of official data in B&H institution in the aim to established trend of trade of food, live animals, drinks and tobacco. In B&H, approximately the annually import of agricultural and food product is over 2 billion of Bosnian convertible marks (BAM) and export about 400 million BAM. Food production is a strategic interest of every country. The coverage of import by export was the highest (22.7%) in 2013 year, than (21.6%) in 2012 year and the lowest (18.4%) in 2014 year. During investigated period was established deficit of trade in B&H. According to potential of natural, social and economic resources in B&H, there is possibility for developing economy through increasing production, on the base of introduction modern technology and efficient use of capacity of domestic companies. Those enhancement will contribute to decrease import of food product. The key issues are defined of the food industry and the possibility of improving and enhancing foreign trade is suggested.

Key words: *food products, import, export, foreign trade of goods.*

Introduction

Food industry in B&H passes through the complex stages of recovery from the damage that occurred in the last decade of the 20th century, due to the war. In this period of political and economic destabilization of the Bosnia and Herzegovina's food industry, along with other economic sectors has done damage over 4 billion euros (IMF,1996). In the post-war period has started reconstruction of an economy that is in the transition phase included in the privatization program which is still ongoing. Also, the economy of Bosna and Herzegovina's develops on the specific connection but separately organized two separate economics i.e. economy of Republic of Srpska (RS) and economy of Federation of Bosnia and Herzegovina (FB&H). The add complexity is existing numerous economies of Canton within Federation of Bosnia and Herzegovina (FB&H). This organization influenced demographic changes, urbanization, local market and governance structures and processes, rural depopulation, industrial and agricultural modernization (FAO, 2014). The development altogether economy branch can help to identify and manage trade-offs and to build synergies which will allow more integrated and cost-effective planning, decision-making, implementing, monitoring and evaluating, (McCornick et al., 2008) program of agricultural production and food processing industry, to be more competitive.

During a few decades large area of arable land did not used for agricultural production and land did not protected from degradation, and land properties change with result in a decline in land quality. The data of estimates suggest that 5 - 6 million hectares of arable land worldwide are irreversibly lost each year as a result of soil erosion, salinization and other degradation processes. The land degradation affects agricultural productivity and productivity growth and food security which is influenced by economic, environmental and institutional factors. The important role of the farmer responses to land degradation and its potential

impacts on agriculture productivity and food security (Wiebe, 2003). The necessity is to improve the economic environment for farmers by developing market infrastructure, correcting distorted price incentives, and encouraging rural income growth and diversification (Radosavac, 2014).

In recent years, the food industry in B&H has a dynamic development, which includes the increase in production, especially agricultural products such as milk, certain species of fruit and vegetables. In this period of recovery, the food industry does not realize the possible volume of production because of the problems that accompany a particular congregation low level of utilization of the existing capacity of the manufacture. The main aspiration is to maximize the value of constructed capacities for processing raw potential, and thus to ensure conditions for increase of the unemployed population, an increase in production of agricultural products, increase exports while reducing imports and decrease in trade deficit with the maximum use of local resources (Radosavac and Pejanovic, 2012).

An Export of food products represents an important economic activity for the development of agriculture and food industry of B&H. In order to achieve better results in foreign trade with other countries in the region, it is necessary to explore the market and its products adapted to the requirements and needs of foreign consumers.

The aim of this work is to analyse of foreign trade of food products of B&H and the estimation of the possibilities of improving and expanding foreign trade, increasing competitiveness and exports, encouraging investment and entrepreneurship development.

Materials and methods

Paper is based on an extended literature review and data from different sources were used officially Agency of Statistics of B&H (ASB&H, 2015). Foreign Trade Chamber of B&H Chamber of Commerce of Republic of Srpska (MOFTER, 2015). Obtained data were used for analysis of import and export on the Standard International Trade Classification (SITC), for three years period 2011-2014. All obtained data were analyzed by using scientific descriptive methods, methods of analysis and synthesis attained and comparative analysis method.

Results and discussion

B&H has favorable conditions for development of agriculture and food industry. Natural resources in the RS and the Federation B&H, which are separate entities of B&H, represent the basic potential for the development of agriculture and food industry.

According to the structure of the products imported in all industries, from the food industry among the top 20 products imported are wheat, bread, biscuits, cakes, chocolate, various food products and beer. Most of the food products that are imported into B&H, can be produced in in the country, whose production has not been started.

Despite the favourable climatic conditions and production capacity of food industry, still there are numerous problems in this sector. The primary problems are that large areas of agricultural land not cultivated for many years and small abundance of domestic animals which can not satisfy even the minimum needs of the processing capacity and consumption.

Furthermore, key issues that arise in the food industry are: excessive import and unfair competition in the domestic market, low-cost finished products, the lack of state incentives for the production and export, the problem about funding etc., which leads to a reduction in productivity and competitiveness.

The countries with the greatest economic potential and political significance in region are Croatia and Serbia. Economic leader of the Western Balkans (WB) is the Croatia with the most competitive processing industry. There is great potential for trade growth in many countries of WB opposite the economic crisis that hit most countries. The recovery will

depend on economic developments in the EU, and the rapid recovery will influence the improvement of trade among the WB countries, attracting foreign investment, finding financial assistance from friendly and neighbouring countries.
During period of investigation in B&H, the volumes of foreign trade of food, drinks and tobacco was the highest (3.111 mil. BAM) in 2012 year and decline to 3.078 mil BAM in 2013 and the lowest 2986 mil.BAM. (ASB&H, 2014). Within total foreign trade in this period values of food, drinks and tobacco export variate from 568 mil. BAM (2013), 552 mil. BAM (2012) to 464 mil. BAM in 2014 year. The import of food, drinks and tobacco was five time higher than export in each year. The highest import 2558 mil. BAM was in 2012 , and the lowest 2509 mil. BAM in 2013. The import in 2014 was 2522 mil. BAM (fig. 1.). Bosnia and Herzegovina had deficit in foreign trade of food, beverages and tobacco in all three years of study. The largest deficit (-2.058 mil. BAM) was in 2014 and the lowest (-1941 mil. BAM) in 2013 year (Figure 1).

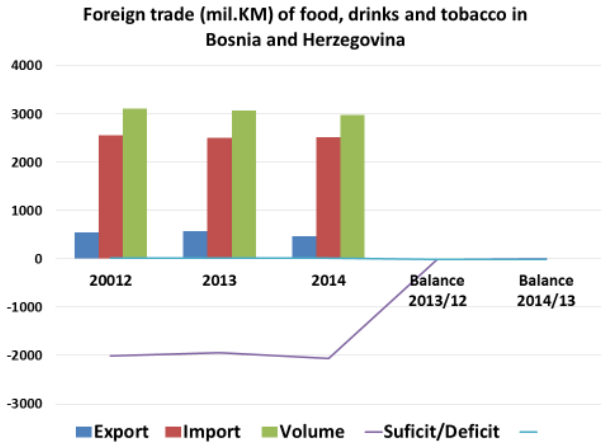

Figure 1. Foreign trade of food, drinks and tobacco in Bosnia and Herzegovina

Figure 2. Share of trade of food in total foreign trade of Bosnia and Herzegovina

Merchandise trade is based on the processing of primary products such as raw materials, semi-finished and finished products with a low added value. In commodity trade usually involved food products vegetables, fruit, confectionery, cereals behind the industrial product: petroleum products, gas, electricity articles of paper pulp, metals, aluminum profiles, textile products.
The share of food, drinks and tobacco in foreign trade variates in import and export in studied period. The value of export of food, drinks and tobacco have share of 7% in 2012 year, 6.8% in 2013 and 5.3% in 2014 year in compare to total foreign trade in B&H. The share of import of food, drinks and tobacco was 16.8% in 2012, 16.5% in 2013 and12% in 2014 year. For each year of trade, were registered deficit which was 27.1% in 2012, 28.6% in 2013 and 27.4% in 2014. The balance for the export varied from -0.2% for 2013/2012, and -1.5% for 2014/2013, while for the import the balance was -0.3% in 2013/12, and -0.9% for 2014/13. The balance for the suficit/deficit ratio was 1.5% for 2013/12 and -1.2% for 2014/13 (Figure 2).
The coverage of import by export was the highest 22.7% in 2013 year, than 21.6% in 2012 year and the lowest 18.4% in 2014 year (Figure 3).

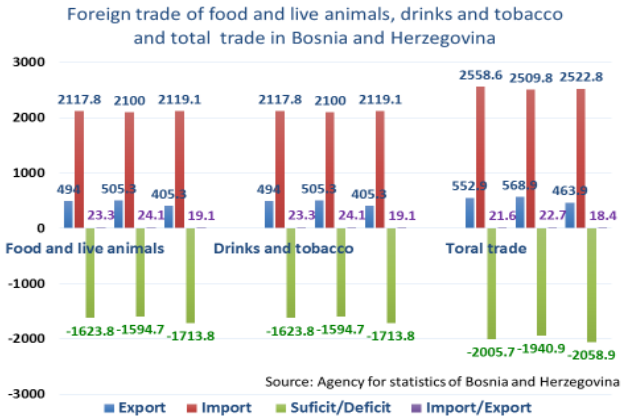

Figure 3. Coverage of import by export of food live drinks and tobacco in Bosnia and Herzegovina trade

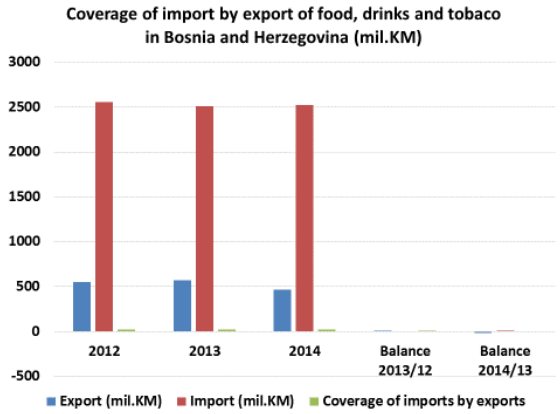

Figure 4. Comparison of foreign trade of food and animals with trade of drinks and tobacco in total in Bosnia Herzegovina

According to foreign trade data we found that in total export of food, drinks and tobacco, the share of export food and live animal was 494.0 mil. BAM in 2012 year, 505.3 mil. BAM in 2013 and 405.3 mil.BAM in 2014 year, while share of foreign trade of drinks and tobacco was 58.9 mil. BAM in 2012 year, 63.6 mil. BAM in 2013 and 58.6 mil.BAM in 2014 year (Figure 4).

The share of food and live animals in total in import was 2117,8 mil.BAM wit deficit -1623.8mil.BAM in 2012 year, while in 2013 year 2100 mil.BAM with deficit -1594.7mil.BAM and in 2014 year 2119.1 mil.BAM with the highest deficit -1713.8 mil.BAM. For the drinks and tobacco the share of import was 440.8mil.BAM in 2012 year, 409.8 mil.BAM in 2013 year and 403.7 mil.BAM in 2014 year. Deficit of trade of drinks and tobacco was -381.9 mil.BAM in 2012 year, -346.2 mil.BAM in 2013 year, -345.1 mil.BAM in 2014 year. (ISFB&H, 2014).

The coverage of import by export in 2014 year was 19.1% for food and live animals, and 14.5% for drinks and tobacco.

Due to insufficient domestic capacity utilization in B&H, there is a very large import of all types of food products, especially products of lower quality than domestic products. The largest import of food products originating from neighbouring countries Croatia and Serbia, with which B&H and RS have concluded a free trade agreement, with 0% tariff rate for imports.

Conclusion

In this study were established no-balance of export and import of food, drinks and tobacco in B&H for the three years period 2012-2014. Although there are high potential for food production in B&H, the four fold is higher import than export of food, drinks and tobacco. The coverage import by export variates and was 21.6% in 2012 year, tightly higher 22.7% in 2013 and decreased in 2014 year (18.4%). The high VAT rate of 17%, in comparison to other countries where the VAT ranges from 5-8% what contribute to a significant reduction of competition and import of low quality products with low price what and automatically created unfair competition.

The value and trend of foreign trade of food, drinks and tobacco of B&H have negative influence on domestic production and agricultural producers. In the future is necessary resolve key problems between production and consumption, domestic savings and investment levels,

as well as optimize of utilization of country's available resources: water, land, good geographical location, neighborhood to the EU market, workers, staff.

Bosnia and Herzegovina can make progress of production and trade of food products on the base of developing new program of investment, modernization of processing capacity, innovative technology of production in cooperation with the Western Balkan Countries and developed Countries in EU and all over the World. The high potential is possible realize by increasing export to Croatia. The Government measure and support of the Ministry of Agriculture, Water Management and Forestry have important role for increasing export food product and protection domestic production from unfair foreign competition.

THE EFFECT OF GLOBAL G.A.P. ON THE FINANCIAL RESULTS OF AGRICULTURAL HOLDINGS IN BOSNIA HERZEGOVINA

Borko SORAJIĆ[1*], Tea ZERDELIĆ[2]

[1]Faculty of Agriculture, University of East Sarajevo, Bosnia and Herzegovina

Abstract

Aspects of the protection of natural resources, environmental management, workplace safety, animal health and well-being, food safety, healthcare and the general principles promoted by standardization i.e. the norms and demands of GLOBAL G.A.P. are rarely applied in most Bosnian and Herzegovian agricultural holdings. The markets of most transition economies, including Bosnia and Herzegovina, are flooded with goods of dubious quality in terms of biological value and hygiene. The once achieved quality of the product that aims to be constantly competitive in the foreign market requires much more than just tradition and a well-designed label. In this study a comparison was made between the agricultural holdings which apply the standard and those which base their production on the conventional “ad hoc” system. The effects of the application of standards on the overall business of agricultural holdings that produce fruits and vegetables were examined. Ultimately, as proof, we will see a reduction in production costs and an improvement in overall financial results of the agricultural holdings that were being examined.

Key words: *quality, standardisation, GlobalG.A.P., production costs, financial results.*

Introduction

Quality concern refers to the procurement of raw materials, finished product production, storage, sale, distribution, waste disposal, consumer information and other relevant characteristics, as seen through the prism of cost reduction of agricultural products. Nowadays, the product certification of production according to the GLOBALG.A.P. norms appears as one of the key recommendations of retail chains directed towards the agricultural product suppliers.

The aim of this study is to determine the importance of the implementation of standards and their impact on the overall costs of production at the selected agricultural holdings which are subcontractors of the agri-businesses (the “Voćar Piramida” company from Visoko; the agricultural cooperative “Gračanka”, and “PMV-VIP” from Gradačac). The analysis of production costs proved the improvements in business and the competitiveness in the domestic market, as well as the EU market, of those agricultural holdings which implement the GLOBALG.A.P. standards in relation to those agricultural holdings which base their food production on the conventional “ad hoc” system.

The implementation of the above mentioned standard has proven that the realisation of the achieved market value of production is better and securer, and it leads to the reduction of the overall costs of production, thus increasing productivity. In addition to cost reduction (of all inputs required for production, with an emphasis on the chemical plant protection products and mineral fertilizers), non-measurable positive effects and merits for the broader community through environmental improvement also occur. It is necessary to prove that the application of the GLOBALG.A.P. standards increases the solvency and efficiency of agricultural holdings, as well as its competitiveness in the domestic market and the EU market, which ultimately leads to better financial results in relation to the holdings which base their production on the conventional means of production.

Materials and methods

On the way to joining the European agricultural sector, agricultural holdings in Bosnia and Herzegovina have to undergo fundamental changes i.e. the tasks of conducting organizational and economic measures in order to comply with the EU standards. The situation in the field of records and business analysis of agricultural holdings is particularly complex. This kind of situation puts the owners at a disadvantage because they are unable to quantify investment or achieved results. The most important data necessary to make such decisions relates to costs of production, as well as the results achieved during the year. This data is used to calculate the business performance of agricultural holdings. Such a record system should serve the agricultural holding for the purpose of adjusting its own production. The big problem for achieving large scale production is the fragmentation of the areas of agricultural holdings. The solution to this problem could be found in association of the agricultural producers into cooperatives.

Modern managerial functions of product quality management system using the GLOBALG.A.P. system and other standards increase the success of the business through reduction of the overall costs. The comparison was made between the actual financial results from the annual financial statements, taking into account actions that are taken in a given year in terms improving the product quality and control of business processes. The research was conducted in three agri-businesses : Voćar Piramida” Visoko, ZZ „Gračanka“ Gračanica i „PMG-VIP“ Gradačac, which trade in both purchased and self-grown produce in the agrarian sector. The cooperatives organise a significant volume of production with an impressive number of subcontractors.

Table 1. The structure of the areas of production of agricultural holdings in 2014

Agricultiral cooperative	Arable land/ha	Total area in production/ha	Fruits	Vegetables	Other - grains
Z Z „Gračanka“ Gračanica	118	109	41	23	45
„Voćar Piramida“ Visoko	64	38	25	4	9
„PMG-VIP“ Gradačac	52	44	16	9	19
T O T A L	234	191	82	36	73

These cooperatives successfully completed the certification process of GLOBALG.AP standards three years ago, which contributed to the producers, in north-eastern Bosnia and Herzegovina, placing large amounts of fresh fruits and vegetables on the demanding European Union market.

Regardless of the fact that the focus of the research included only three legal agri-businesses, we can claim with certainty that these rationales could be roughly applied to the total area of Bosnia and Herzegovina.

All household members are capable of working on any basis.

In order to facilitate the application and understanding of the GG, the level of education is very important. 60% of subjects have secondary and tertiary education which enables the application of GG.

Number of persons in the household shows that these are agricultural holdings that have good prospects of development.

In the majority of subjects (70%), the quality of agricultural products is above average i.e. falls into the high quality category.

The problems which these holdings face in their businesses are diverse: low prices, poor equipment and machinery, poor solvency etc.

The majority of agricultural holdings owners stated that they owned only one part of the equipment and even those parts were outdated; the smaller percentage of the holdings are satisfied with their machinery and tools.

Subjects are not satisfied with the amount of training concerning the modernization of production which they received from the agricultural entities. They would like to participate in more seminars and training.

The surface area of the holdings is very important in terms of reducing the costs of utilization of tools and machinery, the largest number of subjects is in the 'over 3 hectares' group

All surveyed agricultural holdings are of mixed type.

As regards to the storage space, all surveyed holdings gave a satisfactory solution.

The value chain requires a radical change that would improve the position of agricultural producers.

The majority (44%) have stated that the effects of the GLOBALG.A.P. certification are very positive.

The research used the subject breakdown method: financial results and costs, as well as the calculation of the cost price of a product unit before and after the introduction of GLOBALG.A.P.

Results and discussion

The analysis was focused on five kinds of fruit: plums, apples, pears, raspberries and blueberries, and three kinds of vegetables: tomatoes, peppers and cucumbers.

Table 2. The distribution of values among the stakeholders in the value chain of fruit

Serial No.	**Name of the fruit variety**	**Price in BAM[16]**		
		Agricultural holding	**Agricultural cooperative**	**Market**
1.	*Plum*	0.80	1.00	1.60
2.	*Apple*	0.60	0.85	1.10
3.	*Pear*	1.00	1.25	1.60
4.	*Raspberry*	3.00	4.20	6.80
5.	*Blueberry*	3.50	4.80	7.50

In the analysis of the value chain of the individual fruit crops it is evident that the distribution is mainly at the detriment of the producers, the buyers (ZZ „Gračanka"; „Voćar Piramida" Visoko; „PMG-VIP" Gradačac) have a significantly higher value which is a result of storage and possible processing. If the buyers (the analysed legal entities) and exporters are relative in the aspect of trade, than the profit of all the listed fruit varieties is 100% higher compared to the price of the products purchased from the agricultural holdings.

[16] BAM-Bosnian Covertible mark is Bosnian currency

Table 3. The distribution of values among the stakeholders in the value chain of vegetables

Serial No.	**Name of the vegetable variety**	**Price in BAM**		
		Agricultural holding	**Agricultural cooperative**	**Market**
1.	*Tomato*	0.60	0.80	1.00
2.	*Pepper*	1.80	2.20	2.80
3.	*Cucumber*	0.30	0.40	0.60

The difference in relations in the value chain of vegetable crops is not significant. True, there are significant financial investments from buyers, including manpower for the reception and processing, use of storage and cooling capacities, the use of equipment, etc. All these costs burden the product with 25 - 30% on average.
Analysis of the structure of financial results was done before the introduction of GLOBALG.A.P (2011-2012) and after the introduction of GLOBALG.A.P. (2013-2014)

Table 4. The structure and disposition of total revenues for 2011-2012 before the introduction of GLOBALG.A.P. and for 2013-2014, after the introduction of GLOBALG.A.P.

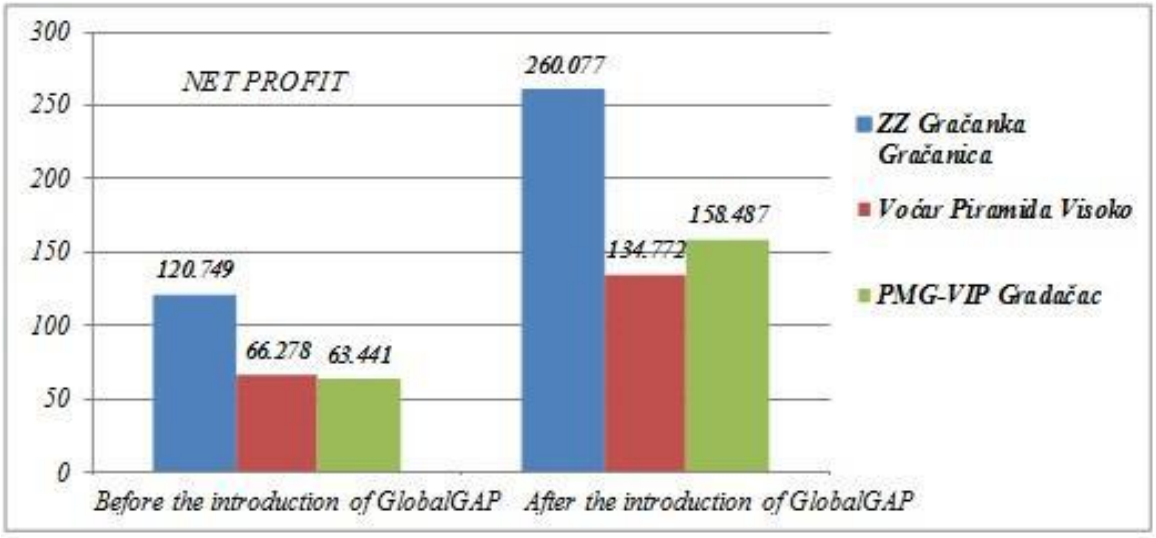
9.Gross profit (4-8)	***134.165***	***73.652***	***70.490***	***288.967***	***149.746***	***176.096***
10. Loss (8-4)	-	-	-	-	-	-
11. Income tax expense	***13.416***	***7.365***	***7.049***	***28.890***	***14.974***	***17.609***

12. Net profit (9-11)	***120.749***	***66.287***	***63.441***	***260.077***	***134.772***	***158.487***
13. Net loss	-	-	-	-	-	-



Graph 1. Financial indicators of agricultural legal subjects with and without GLOBALG.A.P.

Through the analysis of the individual business performance the average revenue of certain types of products for the international market has increased by 32%, whilst the turnover and the price in the domestic market have increased by 22%. In relation to the total of other revenues with the same production volume and the same product structure, the gain is 100% higher in the period of the GLOBALG.A.P certificate. The reason for this is the increase in the prices of final products.

Graph 2: *A comparison of profits in BAM with and without GLOBALG.A.P. for agricultural subjects*

Based on the results obtained by comparative analysis, it can be concluded that the introduction of GLOBALG.A.P. into the business philosophy of all the agricultural subjects was profitable (which means that the price of the funding sources was covered and the achieved accumulation is significantly higher in the period of GLOBALG.A.P. performance compared to the period without the certification), and the operating revenue was increased in both domestic and foreign markets.

Conclusion

The level of knowledge of all participants in the value chain of the processes is very low and there is no vertical and horizontal synchronisation. The agricultural subjects (who were the focus of the research) that deal with the purchase and processing of fruits and vegetables are lacking initiative for a higher degree of the processing of the product, in order to achieve greater added value for the product for all participants in the value chain. The producer gets the lowest value of all participants in the value chain (two or three times less compared to the final market price). Standardization is inevitable in agriculture and the food industry. The gap in the modernization of production could be bridged by the use of traditional knowledge and skills and their integration into the standards. The fact is that the certified product is export-oriented and highly profitable. The analysis of the individual business performance determined the increase of the average revenue of certain types of products for the international market by 32%, whilst the turnover and the price in the domestic market have increased by 22%. In relation to the total of other revenues with the same production volume and the same product structure, the gain is 100% higher in the period of the GLOBALG.A.P certificate. The reason for this is the increase in the prices of final products.

THE ROLE OF SUSTAINABLE REPORTING TO PERFORMANCE MANAGEMENT IN THE RETAIL FOOD

Radojko LUKIC[1], Srdjan M. LALIC[2], Ivica MATOVIC[3]

[1]Faculty of Economics, University of Belgrade, Serbia
[2]Faculty of Business Economics Bijeljina, University of East Sarajevo, Bosnia and Herzegovina
*Corresponding author: rlukic@ekof.bg.ac.rs

Abstract

Lately, the greater the role and importance of sustainable reporting as an instrument of performance management in all economic sectors, including food retailers. The sustainable development concept is increasingly used in the food sector because of its importance. It is applied across the entire food value chain. The characteristics of integrated sustainable food system are: environment - energy and climate changes, water use, biodiversities, land use, soil health; sociality - development, animal welfare, social equity, and economics - food safety and nutrition. What is predominantly used in the retail sale of food, (which is member of the value chain), is the sustainable development. In that context, considerable importance in modern retail is given to the effective protection from loss, as well as the rational food waste treatment, including packaging. A special sustainability indicators system is developed in the food retail. It enables more effective control of the concept applying effects of sustainable development in food retailing. All this contributes to creating sustainable value in food retail. This is particularly important for food retailers during the economic crisis.

(**JEL Classification:** D40 L81 M41)
Keywords: *sustainable value, food value chain, food waste treatment, organic food value chain, sustainable reporting*

Introduction

Lately, most of the attention is paid to the sustainable development concept application and its effects. According to the United Nations, sustainable development is defined "*as development that will meet the needs of the present without compromising the ability of future generations to satisfy their own needs*" (Our Common Future, World Commission on Environment and Development - WCED, 1987). It integrates three dimensions: environmental, social and economic, and requires interdisciplinary approach to the analysis of sustainable development. The primary elements of sustainable development (which is usually displayed in the form of a spider web) are: natural resources, food, water and land; policy and control, economic development, technology, social issues related to the employment of the poor, human rights and democratic participation; health; population, education, environment, lifestyle, values and power. Sustainable development is therefore a key element of the environmental policy (Nilsson, 2012).

Significant attention, both in theory and in practice, is dedicated to the development of an appropriate system of sustainable reporting (Golini, 2011; Lukic, 2011; Lukic, 2012; Lukic, 2013; Smith, 2008; Soosay, 2012). A research, (for example, a Fortune 500 company), determined that sustainable development reporting is done largely through the websites in all economic sectors, including retail. Reporting on the development of green practices via the website is much higher in the retail and service than in manufacturing. There are a number of initiatives for sustainable development in the retail business: The global reporting initiative (Global Reporting Initiative), Stock Market Indices of sustainable reporting (Johannesburg Stock Exchange - JSE), Project on disclosure of carbon emissions, water consumption disclosure Project, Dow Jones sustainable Index, and the Global Compact of the United

Nations. A special international standard of organization is developed (ISO 2600 for Social Responsibility), which allows (to all firms, but also to the retailers) improving the general conditions of work, and has a positive impact on sustainable development. Its main characteristics are: state organization, human rights, labour practices, the environment, fair operating practices, customer's issues, community involvement and development (Bekele, 2012).Global retailers define their criteria for sustainable business. The ultimate effect of the development and implementation of sustainable development are to improve the performance of retail companies measured by sustainable value. In this paper, the term sustainable value to include the effects of applying the concept of sustainable development in retail foods. The main objective of this research is to analyze the most important issues for sustainable value in food retail. The main contribution of this study is that it suggests ways for the scaling up of sustainable value in food retail. Likewise, indicating a need given the importance of the introduction of a special sustainable reporting in modern retail food companies.

Material and Methods

Research methodology of given hypothesis is based on the study of literature, norms, and comparative analysis of empirical data by country, types of shops and food categories. Analyzed original empirical data were collected from the literature, and corporate annual reports. Significant attention, both in theory and in practice, is dedicated to the development of an appropriate system of sustainable reporting. A research, (for example, a Fortune 500 company), determined that sustainable development reporting is done largely through the websites in all economic sectors, including retail. Regarding it, there are certain differences in individual sectors of the economy. Reporting on the development of green practices via the website is much higher in the retail and service than in manufacturing. Given the fact that the unequal application of sustainable reporting, rather a low level, in the retail sector of food, limited the comparability of sustainable data globally.

Results and Discussion

Recently, considerable attention, both in theory and in practice, is dedicated to the sustainable development of retail, especially consumer goods (food). It is quite understandable taking into account that *sector of retail consumer goods is very important* in the world by the revenue generated by sales and number of employees. They are, by their geographical origin, mainly from the United States, Germany and France. The essential features of global retailers of consumer goods share in total revenues of the top 250 retailers in 2013 were: % retail revenue from foreign operations 23.2%, average countries 4.9% and % single country operators 41.7% (Source: Deloitte - Global Power of Retailing Report 2015).The food industry is the first in the European Union by its revenue, with more than 8 million employees (Manzini, 2013). France, Germany, and the United Kingdom are the countries with significant retail trade in food . In addition to the development of private brands, the essential characteristics of the modern food retail is growing sales of organic food. Having considered its nature, food *value chain* is specific compared to other products. The typical life cycle of food value chains is the production, processing, distribution, retail, consumption and waste treatment. Integrated value chain of food and supply chain has been incorporating increasingly sustainable dimensions in recent years. The so-called sustainable food value chain is being developed. Sustainable supply chain is different for each type of food. *The value chain is specific to each category of organic food* (Table 1, Figure 1).

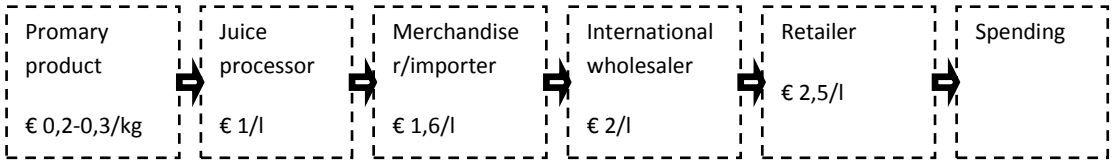

Figure 1. The value chain of organic production in Serbia - the case of apple juice

Specific *indicators for measuring sustainable value in the food sector* are developed. Environmental impact indicators are: biodiversities, climate / energy, waste, toxicity and water. Indicators of social impact: the right of workers and social health care. Indicators of economic impact are: profitability of farms, livelihoods – wage, and the elasticity of the value chain. A special system of sustainable indicators of food supply chain is developed. Table 2 shows sustainable indicators for food supply chain in the United Kingdom. Global retailers develop their indicators of sustainable business (Maria A.O. Dos, 2013).

Table 2. Sustainable indicators for food supply chain in the United Kingdom

Fazes	Economy	Social	Environment
Agriculture	Output Productivity Profitability Market Import vs. Domestic Distribution of import	Employees Average salary Dangerous matter Health and care Fair trade	Environmental reporting Animal welfare Energy usage Water usage Packing usage Waste Harvest loss Diversity of breeds
Processing	Output Productivity Profitability Market Import vs. Domestic Distribution of import	Employees Average salary Dangerous matter Health and care Fair trade	Environmental reporting Energy usage Water usage Packing usage Waste Food loss

Global retail company *Wal-Mart* gives special attention to the issue of sustainable development and sustainable cost effective management in the function of optimizing operational and financial performance (i.e., creation of additional value). It has developed an adequate network of sustainable value, which is displayed in Figure 2.

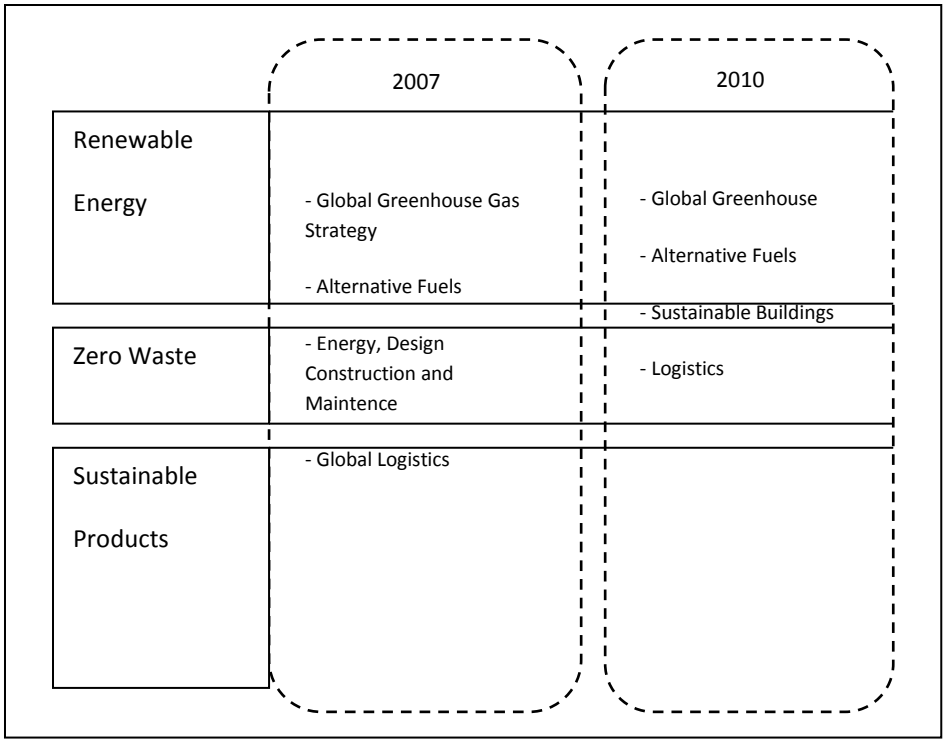

Figure 2. Wal-Mart's Sustainable Value Networks

Source: Lukic, (2013)

Wal-Mart achieved significant cost savings from reducing carbon dioxide emissions, ensuring efficient transport vehicles (in terms of fuel consumption) and making special packaging. Since 2005 company Wal-Mart regularly publishes (on the website) annual report on sustainable development and its sustainability objectives are: 1) the use of 100% renewable energy, 2) providing zero waste, and 3) the sale of products that are sustainable to environment and people (Lukic, 2013). These goals are achieved through reduction of carbon dioxide emissions, increase of energy efficiency, reduction of transportation costs, waste reduction and recycling, packaging and so on.Walmart plans to build such stores with 25-30% greater energy efficiency, which will produce up to 30% less carbon dioxide emissions. Also, the plan is to carry out the reduction of carbon dioxide emissions by 20% in existing stores around the world (Lukic, 2013). It will be beneficial to reduction of overall costs and increase of profits at the time, with the maximum satisfaction of the needs and desires of consumers.
Sustainability is integral part of the new business model - global strategies of operations of *Delhaize Group*. Companies Delhaize Group significant attention to the development and application of the concept of sustainable development and creating sustainable value in their business. The effects are visual in terms of energetic efficiency, reduction of water consumption, waste treatment, safety of food and health, environmental protection, human resource management, corporative social responsibility (Table 3). It has a positive impact on its overall business and financial performance.

Table 3. Zero Waste in Delhaize Group

	2020 Zero Waste Goals	2014 Progress
Recycling **(*)**	80% of waste will be recycled	58% of waste recycled
Food Donations **(*)**	100% of stores and warehouses will have Food Donation Programs in place to maximize the amount of surplus food that is donated to food recovery charities	We have a long history of contributing unsold food to food banks, and are now determining how to maximize those donations. New reporting against this target will start in 2015. 27 000 tonnes of food donated to food banks
Greenhouse Gas Emissions	Achieve 20% reduction in CO_2 equivalent emissions per m² of sales area (against 2008 baseline)	0.599 tonnes CO_2 e / m² 8% reduction since 2008 14% reduction since 2008 for operating companies excluding Delhaize Serbia
Refrigerants **(+)**	Refrigerants will be 80% ozone-friendly and will have an average global warming potential (GWP) of 2230 or lower	55% of refrigerants are ozone-friendly, based on total refrigerants in our systems 2362 average GWP, based on total refrigerants in our systems

Conclusion

The main objective of this research is to analyze the most important issues for sustainable value in food retail.. The main contribution of this study is that it suggests ways for the scaling up of sustainable value in food retail. Likewise, indicating a need given the importance of the introduction of a special sustainable reporting in modern retail food companies. Given the fact that the unequal application of sustainable reporting, rather a low level, in the retail sector of food, limited the comparability of sustainable data globally.

Recently, considerable attention has been paid, both in theory and in practice, to sustainable development in food retail. It is quite understandable when one takes into account the fact that the food retail sector is one of the most important in the world by the revenue from sales and number of employees. In this context, sustainable reporting is increasingly important as a significant instrument for performance management of retail food chains.

Typical lifecycle of food value chains is production, processing, distribution, retail, consumption and waste treatment. Integrated food values chain or food supply chain has been increasingly incorporating sustainable dimension in recent years. A sustainable food value chain is developed. As a part of that, great attention is paid to effective management of losses and food waste, including packaging. Specific indicators have been developed to control the effects of sustainable development in the food retail market. The effects of this are improved performances of food retailers. In addition, there are significant benefits in terms of health and safety and for the buyers of food, as well as environmental protection.

Lately, the development of sustainable organic food has an increasing importance in both global level and the individual countries. The value chain of organic food production is specific. In modern retail, the share of organic food in total sales has increased. This tendency will continue in the future.

Abstract

Bosnia and Herzegovina (BaH) is exporter of electricity, which is mainly produced from water potential and coal. Significant reserves for production of additional quantities of electricity are found in agriculture and forest waste. One of renewable energy sources is crop residues biomass after harvesting. The subject of research is possibility of utilization of grain residues biomass for electricity production. The research objective is to evaluate economic efficiency of investment in construction of biomass plant of installed capacity of 300 kW. The analysis made for a municipality in the northern Bosnia and Herzegovina (Pelagicevo) confirmed that 3,000 ha of arable land under small grains and maize can ensure 12 thousands tones of biomass annually, out of which 30% can be extracted for electricity production. In the biomass power plant (active power of 250 kW) out of 2,100 tons of biomass, 1.5 million kWh of electricity can be produced. The analysis of economic efficiency of investment of 967,504 KM (KM=convertible mark) into construction of biomass power plant, conducted by dynamic methods of investment evaluation confirmed that such investment is in a long term efficient since its twenty-year net present value, by using a discount rate of 8%, is positive (NPV=90,213 KM), the invested money pay back in 18.08 years and internal rate of return (IRR=9.19%) is higher than the cost of capital from which the project is financed. In addition to individual financial benefits for investor, social benefits of these investments are also important (pollution reduction, production of "green energy", increase in employment, additional income for farmers, etc.).

Keywords: *crop residues, biomass, biomass plant, project appraisal, economic efficiency.*

Introduction

Biomass is a renewable resource of biological origin. Biomass is becoming increasingly interesting worldwide. It is the most commonly used directly as energy for heating, cooking and water heating, but it can also be used to produce electricity and heat, and recently it has been increasingly used for biofuel production. As defined in the Rulebook on promotion of electricity generation from renewable sources and efficient cogeneration (Offical Gazzete of the Republic of Srpska, 2013) biomass means the biodegradable fraction of products, waste and residues from biological origin from agriculture and forestry, including plant and animal matters and related industries including fisheries with aquaculture, as well as biodegradable fraction of industrial and municipal waste. Biomass can be easily converted into usable energy sources such as methane or transport fuels (ethanol and biodiesel). There are various technologies of exploitation of energy from biomass: direct heating, converting heat into electrical energy by converting it to another form of fuel such as liquid biofuels or combustible biogas. It should be borne in mind that the use of biomass for heat energy does not increase the CO_2 content in the atmosphere, does not create the greenhouse effect and does not affect the global climate change.

Most of the energy in the world is produced from fossil fuels, which are enormously consumed and the world is in danger of disappearance due to the depletion of their limited

reserves. Therefore, the sources of renewable energy are becoming more and more important. The European Union member states have committed themselves to ensure 20% of share of renewable energy in total energy consumption in the EU (2009/28/EC) by the year of 2020. Biomass will have a significant contribution to achieving this goal. Since the "green" energy produced from renewable energy sources is more expensive than the energy from fossil fuels, special measures are necessary to encourage its production, which is usually done through incentives for collection price or tax incentives for investing in renewable energy sources (Tica et al., 2012).

Biomass can be divided into four groups: wood biomass (sawdust and scrap wood processing), residues from agriculture (straw, corn stalks, husks, pits, etc.), animal wastes and residues and biomass from waste (garbage). The focus of further research is the biomass of plant residues from agriculture or energy production from this biomass. The assessment of the energy potential of biomass was researched by numerous authors, analyzing the situation in different countries, for example Scarlat et al. (2007) for the new EU member states and candidate countries, Liu and Farmer (2010) and Gallagher et al. (2011) in the USA, Stiehler et al. (2011) in Germany, and Jasiulewicz Janiszevwska (2012) in Poland, Jing et al. (2012) in China and Glithero et al. (2013) in England. The selection of equipment for biomass power plant is based on the proper selection of the cogeneration facility. To make a decision on construction of such a facility, all relevant facts should be considered and market, economic, environmental and social justification according to the laws should be checked, as well as the conditions in the energy market.

Materials and methods

The subject of the research presented in this paper is the possibility of building a biomass power plant that would use crop residues from agriculture as fuel.

The objective of the research is to test and prove the economic justification of investment of 967,504 KM (remark: 1 KM = 0.51129 EUR) in the construction and use of biomass power plant of 250 kW. The dynamic methods of evaluation of the investment efficiency are used: payback period, net present value and internal rate of return (Vaško, 2001; Orsag and Dedi, 2011).

(Discounted) Payback period method (p) – time period when investment cost (I) and cumulative discounted net cash flows (Vt) equals:

$$I = \sum_{t=1}^{p} Vt$$

Net present value method (NSV) – the difference in net cash flow (Vt) discounted by discount rate of 8% and subsequent investment (I):

$$NSV = \sum_{t=1}^{20} \frac{Vt}{(1+d)^t} - I$$

Internal rate of return method (r):

$$\sum_{t=1}^{20} \frac{Vt}{(1+r)^t} = I$$

The case of establishment of a biomass power plant in the municipality Pelagicevo has been analysed. Municipality of Pelagicevo is located in Posavina, in the north of Bosnia and

Herzegovina, it covers the area of 178 km^2 and is mostly agricultural. Technical and economic parameters of analyzed investments are shown in table 1.

Table 1: Main technical and financial parameters of the project

Project title	Solid biomass power plant in Pelagicevo	
Project location	Pelagicevo	
The power of plant	kW	250
The annual output	kWh	1,500,000
The value of investments in KM (inclu VAT)		967,504

Results and discussion

Energy sector in BaH has enormous development potential. For a number of years, BaH is the only in the region with a positive balance of imports and exports of electricity, and it is the eighth country in Europe in terms of hydropower potential, which currently uses only just a little bit over one-third (38%). Moreover, it is estimated that BaH has significant potential to produce energy from renewable sources (wind, solar, biomass and geothermal energy), according to some indicators, these potentials are 30% higher than the EU average (Energetski institut Hrvoje Požar, 2008).

The prerequisite for the implementation of the investment project is to determine the incentives of electricity generation from renewable energy sources in terms of the right to a guaranteed purchase price ("feed-in" tariffs) in terms of article 6 of the Rulebook on promotion of electricity generation from renewable sources and efficient cogeneration (Offical Gazzete of the Republic of Srpska, 2013), or guaranteed purchase/collection price of 0.2413 KM/kWh.

Procurement Market

Given the projected capacity of biomass power plants, the procurement market of raw materials (biomass) is limited only to the municipality of Pelagicevo. In the municipality, there is about 9,600 ha of arable land, of which (only) 3,600 ha is cultivated. About 3,000 ha of arable land is under grains and corn, and after the harvest there remains about 12 thousand tons of biomass, of which up to 30% can be used to produce electricity and heat. Huge potential for biomass production is in uncultivated areas, due to the fact that with the clearing of undergrowth or mowing of wild plants, significant additional amounts of biomass can be provided, at low cost. In addition, 1,515 hectares are under forest, and after the whole planning and regular cutting, there are remains of wood residues (small branches), which are generally not used because they are unsuitable for heating. All this confirms that for the biomass power plant in Pelagicevo there are sufficient raw materials in the area, and the municipality (about 2 thousand tons of biomass are annual needs of power plant), and in case of the lack of it, the additional quantities could be purchased from the territory of neighbouring municipalities; Donji Žabar, Šamac, Gradačac and the Brčko District; and without additional transport costs.

Sales Market

It is estimated that the demand for energy in the world by 2040 will be doubled (US Energy Information Administration, 2013), so the sales market of products, whose production is subject of investing, is characterized by growing demand. The increase of world electricity production, in addition to hydro potential, a significant share of other renewable sources, including both biogas and biomass is anticipated. According to the Bosnia and Herzegovina Energy Sector Study (Energetski institut Hrvoje Požar, 2008), the use of electricity in BaH by

2020 will increase by 50%, with projected reduction in the share of individual households use in total use to 41%. The price of electricity in BaH (in 2013 it is 0.080 EUR/kWh) is the lowest in Europe (EU-28 average in 2013 was 0.199 EUR/kWh) (EUROSTAT, 2015). Generally, from the standpoint of sales market in the future, we can expect an increase in the use of electricity and an increase in its price, in Bosnia and Herzegovina, and the region as well as in Europe.

Technical and technological analysis

In Bosnia and Herzegovina, especially in Posavina, remains of grains are of a specific importance for the production of energy from renewable sources. Biomass ratio of cereals (maize, wheat, barley) is 1:1, i.e. the weight of biomass is equal to the quantity of grain (Brkic et al., 2007). The plant residues must be primarily returned to the soil and ploughing between 30 and 70% of this mass is recommended, which means that for the energy application, at least 30% is available. In the municipality of Pelagicevo, at the area of about 3,000 ha, 3,543 tons of wheat, 8,383 tons of corn and 98 t of barley are produced (seven-year average, 2007-12) (Statistical Yearbook of the Republic of Srpska, 2011 and 2013). Electricity produced from biomass would be produced by gasification process in the fixed-bed gasifier with a dual flame of installed power of 250 kW. The total estimated electricity production of this power plant annually amounts to 1,500,000 kWh, and based on the installed active power of solid biomass electric power plant of 250 kW, and 6,000 hours a year work of a power plant.

The structure of investment in a biomass power plant

Investments in biomass power plant consist of the investments in the procurement of fixed assets and the amount of required permanent working capital in total amount of 967,504 KM (approximately 495,000 EUR). They consist of the following: investments in the procurement of construction land, construction of the facility, initial investment (projects, approvals and permits), the construction of substations and procurement of equipment for power plant. The own funds of the investor are 392,524 KM (40.5%), loan 500,000 KM (51.7%) and the EBRD loan subsidy for energy efficiency of 75,000 KM (7.75%). The loan is for the period of 5 years with a grace period of 12 months and interest rate of 8%.

SWOT analyses

The main strengths, weaknesses, opportunities and threats of this investment are summarized in the following table.

Table 2: The project SWOT analysis

Strengths	*Weaknesses*
unused biomass around the power plant; available equipment and technology for biomass power plant; contribution to the environment protection,	lack of knowledge and experience in the production of energy from renewable sources; insufficient own capital; dependence of raw materials suppliers.
Opportunities	*Threats*
growing consumption and demand for electricity; expected growth of electricity price; obligation to produce more energy from renewable sources.	weakly accessible and expensive credits; lack of incentives for the production energy from renewable sources; the risk of changes in legislation (guaranteed quantities and prices).

Economic and financial analysis

Economic and financial analysis of the investment in a power plant using biomass in Pelagicevo was conducted for a period of 20 years, although this investment, with proper periodic maintenance, can bring benefits and revenues for significantly longer period. Because of amortization of equipment, in the year 10, it is envisaged to replace the system for biomass gasification and gas generators for biomass. It would include the investment of 547,771 KM, and the same should be done in the year 20, if the production of electricity from this power station is to be continued. Amortization calculation was made according to annual depreciation rates prescribed in the Regulations on the application of the Law on corporate income tax (Offical Gazzete of the Republic of Srpska, 2006). Total investment expenditures are the following: material costs (biomass), the cost of service, salary expenses, depreciation and cost of financing (interest). Annual expenses are highest at the beginning (322,791 KM) and the lowest at the end of the period of investment exploitation (274,969 KM). Revenue is derived from sales of 1,500,000 kWh of electricity at the price of 0.2413 KM/kWh and are the constant during all these years (361,950 KM). The annual gross profit is 39,259 KM at the begining, and 86,981 KM in the end of the period.

Income Statement is modified into net cash flow of the project of solid biomass power plant in Pelagicevo, and it receives (returns) invested money from the sale of electricity. Since the analysis was performed for the first 20 years of the investment, and the equipment (which will be replaced after 10 years) and the facility can be used much longer, in the end of the year 20 the land, buildings and equipment have residual (liquidation) value of 150,947 KM.

Cash outflow of solid biomass power plants in Pelagicevo are the investments into fixed and current assets at the beginning of the project, and subsequent operating costs of the power plant. The expenditures in the cash flow include the repayment of the interest and all the payments to the state.

Project evaluation by dynamic methods

With the discounted cash flows of the project of solid biomass power plant in Pelagicevo by the discount rate of 8%, its net present value at the end of the year 20 is positive and it is 90,213 KM. Disccounted payback period is 18.08 years. Internal rate of return of the project is 9.19%.

The parameters of dynamic evaluation of investments in the biomass power plant indicate that this investment is on the borderline of profitability. Similar results in the case of the production of pellets from straw were made by Zekic et al. (2014), who concluded that the production of pellets from straw is uneconomical. The economics of biofuel production is closely linked to the price of fossil fuels. Since biofuels are more expensive, their production is worth only if the government subsidizes part of the cost.

Analysis of sensitivity

For discounting, discount rate of 8% is selected, which is closest to the price of the external sources of financing (interest rate=7.75%). Additional analysis was done for alternative discount rates, the lower of 6% and 7% and higher of 9% and 10%, which are in the range of most common interest rates on investment loans in BaH. Understandably, internal rate of return remains the same, and only NPV and payback period are changed.

Table 3: Results of analyses of sensitivity to the change of discount rate

Interest rate	*6%*	*7%*	*8%*	*9%*	*10%*
NPV (KM)	278,069	177,863	90,213	13,229	-54,662
Payback period (years)	15.20	16.48	18.08	19.75	23.24

Analysis of sensitivity of the project showed that lower discount rate (e.g. as a result of concessional credit conditions) improves efficiency of the investment. On the other side

discount rate of 10% significantly deteriorates the image of the investment in the solid biomass power plant, because its NPV is negative and the payback period is extended to 23.2 years.

Socio-economic assessment of the project

In addition to individual benefits for investors, the project brings environmental and social benefits in terms of increased production of electricity from renewable sources. Other social benefits from the realization of the investment of the project of solid biomass power plant in Pelagicevo (shown on the twenty-year level) are: employment of 4 workers; higher capacity utilization at the suppliers of equipment and services on the basis of increasing their production and sales; the environmentally sound disposal of plant residues in agricultural production; providing additional income of 2.5 million KM for farmers from sale of straw; taxes on purchased equipment; income tax of about 145 thousand KM. The project has a special contribution to the municipality of Pelagicevo, which belongs to underdeveloped municipalities of the Republic of Srpska. The widest social contribution of this project is to reduce pollution of the atmosphere

Conclusion

Biomass, as a renewable source of biological origin, becomes more interesting and more frequently used, worldwide. One of the forms of biomasses, is biomass from plant residues from agriculture, which, among other things, can be used for production of electricity.

Analysis of cost effectiveness of investing 967,504 KM in construction solid biomass power plant in Pelagicevo confirms that such investment is profitable, but in the long terms, because of the following:
Twenty-year net present value with a discount rate of 8% is positive (NPV=+90,213 KM);
Invested money is returned to the investor after 18 years (p=18.08 years), i.e. before the expiration of the technological life of the plant;
The rate of return is higher than the cost of capital which financed the project (r=9.19%).

The sensitivity analysis shows that the project could not endure the discount rate (and thus the price of capital) of more than 10%, because the NPV becomes negative, and the payback period exceeding 23 years. Compared to other investment alternatives, the potential investor will certainly think of projects that may bring a faster return on invested funds and higher net present value than the analyzed investment in electricity generation from biomass. It would therefore be neccessary to provide greater incentives for this type of investments, in order to have greater use of biomass for generating electricity, with simultaneous promotion of the benefits of using this type of energy and increase its use.

A STUDY OF BULGARIAN DAIRY FARMS PROFITABILITY BEFORE AND AFTER ABOLITION OF MILK QUOTAS

Vassil STOYCHEV, Bozhidar IVANOV

Institute of Agricultural Economics, Sofia, Bulgaria
*Corresponding author: vasilst@mail.bg, bozidar_ivanov@yahoo.co.uk

Abstract

The milk quotas were first introduced in 1984 under the Dairy Produce Quota Regulations which reflects the Common Agricultural Policy CAP of European Community (EC). Originally, they were run until 1989 but have been extended several times. The quota system was implemented in Bulgaria in 2007 according to accession treaty with the EU.

The system provided quota rent for all farmers in the dairy sector, however the most advantaged were less productive and efficient holdings. The average productivity per dairy cow in Bulgaria is less than 60% of EU average, which poses Bulgarian dairy farmers in more vulnerable position when policy is changed. A tentative view indicates that dairy production after the quota removal is likely to contract in several member states including Bulgaria which makes the topic actual.

This paper studies profitability of Bulgarian dairy farms after abolishment of milk quotas. Based on developed econometric model authors make an assumption about decrease in farm profitability in 2015 and 2016.

Keywords: *abolition of milk quotas, dairy, farm profitability, Bulgaria*

Introduction

The milk quotas were first introduced in 1984 under the Dairy Produce Quota Regulations which reflects the change in CAP and Common Market Organization of EC. This new policy for milk replaced price support system. In the years before quota system price stimulus caused increase in dairy milk production leading to milk surplus and inability of intervention system to handle the produced volumes (produced volume was with 20 % more than quantity common market can absorb and expenditure on dairy support become the single biggest item in the CAP budget). The aim of the quotas was to contain the production as each member state and each dairy farm has reference quantity, based on production in 1981 plus 2 % of volume. But that rule was flexible for some countries taking other years as base (for Ireland it was 1983). There was also correction in the quota if milk fat level is more than reference level. If quantity exceeds set quota a super-levy payment was due according to Donnellian (et al.), 2014. Originally milk quota system was intended to run until 1989 but have been extended several times until 31 March 2015.

The system of milk quotas has been implemented in Bulgaria since 2007 after accession to the EU according to Regulation (EC) 1234/2007. Since then Bulgarian dairy farms are under pressure. They have to comply with new, higher hygiene standards imposed by the EU and also with increasing competition from imported raw and processed milk (SMP, WMP, condensed milk). The average productivity per dairy cow in Bulgaria is less than 60% of the EU average, which poses Bulgarian dairy farmers in more vulnerable position. The quota was not a binding factor for specialized holdings because between 2007 and 2013 it had never been reached. The highest achievement was in 2008/2009, for both produced milk 88.5% and direct deliveries 71.2%. In the following years quotas had been increased, but quantity of purchased milk had decreased. (MAF, Agricultural Report) Milk quotas were freely tradable

but prices did not change during the examined period. The presented study examines the profitability of specialized Bulgarian dairy farms based on Farm Accountancy Data Network (FADN) data and makes an extrapolation for years after quota (included 2016) based on econometric model.

A tentative view indicates that dairy production after the quotas is likely to contract in several member states including Bulgaria (A detailed study can be found in report "Smooth Phasing-out of the Milk Quotas", 2014) Because of its binding characteristic after removing quotas there is an incentive to increase production for countries where production was limited. According to Donnellian (et al.,) 2014, expansion of production should take place in lower cost regions (with mild climate) not constrained from competition of other agricultural sectors for environmental factors. Countries where production is likely to expand are Ireland, Austria, Belgium, Denmark, Germany, France, the Netherlands and Poland. According to an external report for EU commission (Ernst &Young, 2013) price volatility constitutes one of the greater challenges that dairy producers will have to face in the near future.

Materials and methods

The difference between farm gate milk price under quota and marginal cost for production is described as quota rent. The quota rent cannot be evaluated directly, because there is no economic indicator to measure it. But when quota is tradable its opportunity cost is available as price farmers are willing to pay for additional quota. (For a more detailed theoretical explanation and modeling please read "Economic analysis of the effects of the expiry of EU milk quota system" by Bouamra-Mechemache et al., 2008). Reduction in price volatility and inability for EU producers to avail from international marketing opportunities due to rising global demand for milk and milk products are other effects of the quotas (Donnellian et al., 2014)

Our work hypothesis claim: quota removal will decrease profitability of specialized milk holdings due to increase of the volume of production and competitiveness in the EU milk market, which is likely to lead to a price decline.

Development of profitability of Bulgarian dairy farms is explored on farm level for the period from 2007 to 2016. The approach we use is similar to that used by Van Berkum (2009) exploring the gross margins of dairy farms in new EU member states and candidate countries (revenues minus the cost of variable inputs). We add subsidies to revenues.

An econometric model was built in order to evaluate the profitability after quota abolition due to continuance of time series (until 2012). It is a non-spatial, dynamic, system of equations, where the solution estimates the average profitability per farm. Model has two types of specifications:

Mathematical, based on models developed for Forecast Support Group of Economic Research Service (ERS) of US in the 1970s from Ezekiel, Foote, Fox, Nerlove, Waugh, (Judge, 1977) and a consortium of econometric modeling scholars: Johnson and Rausser (1982). Variables used into the model are divided into exogenous and endogenous (calculated in the model), such as elasticity, regression coefficients and intercepts. Values of elasticity are positive.

Logical, it constructs model based on logical and regression relationships between variables, thus constituting the system of model equations. GDP Deflator[17] was used to reflect the growth of GDP. Government policies on national and EU level are shown by subsidies. An estimation has been made for subsidies based on expected average number of dairy cows per holding and area applicable for support[18]. We expect process of concentration of milk production will continue therefore average farm herd size will grow. Influence of external to the milk market factors are represented through price of raw milk.

Limitations: The length of time series that we receive from FADN database is too short. Some costs as Other livestock specific costs and some specific types of support as LFA subsidies are not included.

Dairy farm income (DFI) is calculated in equation (1) using: Cows‘ milk and milk products (CMMP), Total subsidies (TS), Feed for grazing livestock (FGL) and Total external factors (TEF). TEF is compound variable from FADN database which includes external costs for the farm - wages paid, rents paid and interests paid.

(1) DFI = CMMP + TS - FGL - TEF

We can make suggestion for TS and in order to solve (1) we have to construct modeling equations for CMMP, FGL, TEF. We are applying regression to find significant relations between variables.

Table 1. Regression analysis

Independent variable	CMMP	TEF	FGL
TS	0.61	0.85	0.60
GDP Deflator		0.74	

Significance F is below 0.07. We do not apply regression to all the variables because some are interdependent like average number of Dairy cows (DC) and FGL. Based on regression coefficients in table 1 model equations can be constructed, as follows:

(2) $CMMP = f(x_1, x_2) = \alpha_1 + \varepsilon_1 \beta_1 x_1 + \varepsilon_2 \beta_2 x_2 + \xi_1$

(3) $FGL = f(x_1, x_2, x_3) = \alpha_2 + \varepsilon_3 \beta_3 x_1 + \varepsilon_4 \beta_4 x_2 + \varepsilon_5 \beta_5 x_3 + \xi_2$

(4) $TEF = f(x_1, x_4, x_5) = \alpha_3 + \varepsilon_6 \beta_6 x_1 + . \varepsilon_7 \beta_7 . x_4 + . \varepsilon_8 \beta_8 . x_5 + \xi_3$

where:

α- intercept
β - regression coefficient
ε - elasticity, $0 < \varepsilon < 1$
ξ - factor error

Variable x_1 represent total subsidies (TS). It is compound variable and consists of sum of Subsidies Dairying and Single Area Payment from FADN database. Variable x_2 represent

[17] GDP Deflator is a ratio of nominal GDP to real GDP in the country. Deflator includes only domestic goods and not anything that is imported and it is a measure of the prices of all goods and services.

[18] Subsidies are fixed as amount and are dependent from the number of applicants in any specific year.

Raw milk price (RMP). Variable x_3 represent number of DC. Variable x_4 represent CMMP. Variable x_5 represent GDP Deflator.

Data used: FADN Public Database, Dynamic Reporting Tool (typology TF8, group 5 - specialist milk producers); reports of Ministry of Agriculture and Food (MAF) of Bulgaria; reports of Bulgarian National Statistical Institute (NSI). Values for GDP Deflator and milk price projections for 2015 and 2016 are taken from Milk model of Bulgarian dairy sector developed under project "Creation of Center for Agri-Policy Analysis (CAPA)“ in the Institute of Agricultural Economics (IAE) in cooperation with Food and Agricultural Policy Research Institute (FAPRI), University of Missouri-Columbia. Model of farm profitability was developed using MS Excel 2007 software.

Results and discussion

Modeling results in table 2 shows that the incomes of dairy holding increased after accession of the country to the EU. An exception is identified for 2010, when there is a significant decrease, which can be explained by world financial crisis complemented by a decrease in milk price. The profitability trend during the quota period (from 2007 to 2014) slightly increase attributed as to enhancement of the payments and aids received by farmers and the higher purchase price of milk. It should be mentioned that the purchase price of milk in Bulgaria lags compared to average EU milk price. In 2007, the gap between Bulgarian and EU average milk price is about 24%, which through next year gradually declines, as in 2014, the EU average annual milk price is 16% higher than price obtained by Bulgarian farmers.

The reasons for price divergence are different, as the main one is prescribed to differences in the quality of milk and milk characteristics. The standard employed by dairies in Bulgaria is to buy milk with fat content at 3.6%, which is less than common milk delivery practice found in other member states. Another issue is the quality of milk delivered by dairy farm in Bulgaria, as nowadays also and more severe in previous years a significant part of milk does not meet the EU standards. Nowadays, about 50% of cow milk is provided by farms incompatible with the EU standards, as up to 20-25% of that milk is delivered to dairy establishments.

Results illustrated in Table 2 indicate dairy holdings profitability after quota abolishment will fall probably by 13% on average for 2015 and 2016 compared with the period 2007-2014. It happens despite a rise in subsidies, which farmers will eventually get after the implementation of new CAP 2020. In new CAP 2020, the coupled support designated to dairy production will be heightened by almost 80% in comparison with the average support in the period 2007-2013. The estimated aggregated aids per head in 2015 and 2016 will be very similar to the payments received by farmers in 2014. The income decrease assessed after quota removal is primarily due to the fall in prices of raw milk. The raw milk in 2015 and 2016 is expected to decline by 11% and 6% in 2016 respectively. Those calculations are taken as exogenous from CAPA dairy model, representing the partial equilibrium model of Bulgarian dairy sector. In this relation it is interesting to investigate the role of quota removal in the assumed price fall, which is also prompted by the ban placed by Russia for import of dairy products from EU countries. Of course, the slowed and unstable demand of dairy products in 2015 also contributes to this decline of milk price and reveals the huge uncertainty on the dairy global market. Regarding the influence of Russian ban, Bulgaria is indirectly affected, as the direct export to Russia of dairy goods is very minor but Bulgarian farmers and dairy companies are impacted by the austerity pressure of cheaper dairy products coming from other EU countries re-allocated to other markets after the closure of Russian market.

It is not possible however to make precise evaluation of other factors leading to price decline currently because it is hard to isolate their influence on the milk price. The reduction of milk price inevitably will eventuate to a drop in the farmers' incomes and profitability. Farmers will face profitability cut and it will exacerbate in case they do not boost up their productivity and costs efficiency. The good news for farmers is that there is a lot of room to hoist up the productivity and milk yield, which may safeguard farmers' incomes during next years, when the market pressure from quota removal and market uncertainty will dominate and unleash. But we have to take into account that we study specialized dairy holdings on average, there will be more profitable and less profitable farms. These conclusions confirm our hypothesis.

Table 2 Modeling results

Year	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016
CMMP	7771	9146	11325	10297	12528	12048	12306.9	12841.3	12183.1	12270
TS	406	1062	1204	1056	1200	2002	2505	2486.2	2428.5	2583.8
FGL	4590	5568	7107	7357	8401	8265	8368.0	8621.0	8358.5	8912.8
TEF	817	1682	2562	2237	2331	3059	3092.8	3176	3104.6	3244
DFI	**2770**	**2958**	**2860**	**1759**	**2996**	**2726**	**3351.2**	**3530.3**	**3048.4**	**2697**

Conclusions

The study shows that profitability of average farm after abolition of the quotas will probably diminish to some extent, which is mainly attributed to a lower worldwide prices expected and projected. The increase in subsidizing related to coupled aid and area based payments is very likely not to offset the outrunning growth of operational and nonspecific costs in the future, because we assume that holdings will specialize in milk production and biggest part of feeding will be procured externally. The price of grain feeding which is the major part of the cow's diet is assumed to grow slightly in 2015 and 2016 compared to 2014. Despite the price of coarse feeding in the projected years (2015, 2016) is expected to decline slimly the shift to most purchased feeding input will push the operational costs up.

We can expect that some of the farmers in the lower part of the profitability bias will leave the sector. Therefore, the issue with efficiency becomes very relevant and vital, as improvement in the productivity and lessening the fixed and specific costs per cow are envisaged as ultimately important. That is possible if farms invest in pure-breed cattle[19] with higher milk yield and new equipment.

YOUNG FARMER'S ATTITUDES TOWARDS THE BUSINESS COOPERATION

Đurđica ŽUTINIĆ[1]*, Lari HADELAN[1], Marina TOMIĆ[2], Aleksandar NEDANOV[1]

[1]University of Zagreb Faculty of Agriculture, Department of agricultural economics and rural development, Croatia
[2]University of Zagreb Faculty of Agriculture, Department of marketing in agriculture, Croatia
*Corresponding author: dzutinic@agr.hr

Abstract

Business cooperation and networking is one of the basic preconditions for increase economic and social competitiveness of Croatian family farms, and for reviving other economic activities in rural areas. The paper describes some fragmented results from a study conducted among the young farmers in the Croatian continental region. We focused on their attitudes and intention regarding business cooperation in agriculture. The aim of the paper was to describe socio-demographic and professional characteristics of young farmers and to examine whether they perceive the co-operative model as a possible solution to strengthen their business competitiveness. The analysis is based on a survey conducted in December 2014, on a sample of 170 respondents from 18 to 40 years of age. The data were processed by standard statistical techniques for analysis of frequency distributions, percentages and average values, and some pairs of variables have been valued by usual tests (chi-square test and C coefficient). The results indicate that only 49.4% of surveyed young farmers are involved in some form of business co-operation (associations, cooperatives and producer organizations) in agriculture. The majority of respondents (63.9%) consider that the 'cooperative model' is essential for development of agriculture and socio-economic revitalization of Croatian rural areas. Among the group of farmers who operate independently, 45.3% have expressed willingness to be actively involved in establishment of cooperative.

Keywords: *young farmers, attitudes, business cooperation, cooperative*

Introduction

On a global level, agriculture and food sector are facing with numerous challenges such is ensuring food safety (quality and cheap food) in the condition of intensive world's growing population, climate changes and limited natural resources, increasing demands for raw material (biofuels) and sustainable ecosystem management. To overcome these challenges essential forms of collaboration/cooperation in agriculture and in the food value chain are necessary (KPMG International, 2014). Advantages of business and networking in agriculture are in: overcoming individual business constraints and resources, increasing innovation of companies/farms and their products, integrating business operations, reducing/sharing business risk, facilitating access and distribution of business information, promotion of knowledge and innovation, increasing bargaining power, economies of scale and in strengthening position on existing and new markets (Juračak et al., 2000).

According to the social and economic characteristics, Croatian agriculture is mainly positioned on small scale businesses and non-competitive part of agriculture (Nedanov and Žutinić, 2015).[20] These limiting the possibilities of efficient use of agricultural resources for production of healthy local food products and slowdown demographic and economic

[20] In domestic agriculture dominating family farms (96% - 2014) with limited production capacity and inadequate production structure (small holdings, prevailing of low profit activities, small and fragmented production, etc.).

revitalization of the Croatian rural area. Business cooperation and networking are one of a basic precondition for increasing economic and social competitiveness of family farms and for reviving other economic activities in rural areas.
The paper describes partial results from the research study about business cooperation among young farmers in the Croatian continental region. The purpose of the project was to estimate the current situation of business cooperation in agriculture and to gain insight into the perception and preferences of young farmers regarding entrepreneurship and business synergies.
The systematic research on the farmer's business collaboration has been conducted in relatively few. Relevant literature is mainly focused on formal cooperation within cooperatives, producer organizations, business networks and others (Wilson et al., 2014). Gramzow and Petrick (2007) on the examples of post socialist states emphasize the lack of experience and management skills as a common reason for unsustainable joint entrepreneurial farmer initiatives in the agricultural sector. De Regt and Vuylsteke (2011) argued that insufficient aligned of economic policy and institutional framework often resulting with long and complex process of obtaining state aid support which in practice slow down potential of business cooperation among agro-holders (de Regt and Vuylsteke, 2011: 14).
Due the role in the revitalization of EU agricultural sector, issue of engaging the youth in/and entrepreneurship is frequently topic of experts in political discussion, analysis and formal document. However, empirical evidence of entrepreneurial characteristics and intention among young farmers regarding business cooperation are poor.
The aim of paper is to describe socio-demographic and professional characteristics of young farmers and to examine whether they perceive the co-operative model as a possible solution for strengthening their business competitiveness.

Materials and methods

In compliance with EU support within *Young Farmers schemes* (2015-2020), the criterion variable to determine research sample is respondent aged (no more than 40 years old). The sample was composed on collected addresses from the database of the *Croatian Association of Young Farmers* and *Extension Service*. The survey was conducted in December 2014, through the face to face and online questionnaire surveys in continental Croatian regions. The sample included 170 young farmers which are equally distributed through the 14 counties.[21]
For the purpose of paper, the socio-economic characteristic and set of statements about business cooperation in agriculture are included in our analysis. A Likert five-level scale (5= strongly agree to 1 strongly disagree) is used to measure degree of agreement with relevant statements. The data were processed by univariate analysis to measure frequency distributions, percentages and average values, and for some pairs of variables have been valued by usual tests (chi-square test and C coefficient) at level of significance 5% ($p<0.05$). Data were analyzed with the SPSS software package.

Results and discussion

Basic socio-demographic and economic indicators

A summary description of socio-economic characteristics of young farmers is given in Table 1. Majority of the respondents is male (81.9%) who traditionally appears in Croatian agriculture as a sole legal land owner and other productive resources. This is also confirmed by this research where just 4 respondents are young female single holder (total of 44 respondents).

[21] According to Farm Register (2014) Croatian had recorded total of 132.88 family farms, while only 14,078 (10.6%) of holders have less than 40 years. This study included 1.2% of these farms.

Table 1. Basic socio-demographic indicators of respondents (N = 170)

Sample characteristics		N	%
Individual characteristics			
Sex	Male	139	81.8
	Female	31	18.2
Age	18-30 years	89	52.4
	31-40 years	81	47.6
Education level	Basic school	7	4.1
	Secondary school	99	58.2
	High school or university	64	37.7
Marital status	Single	78	45.9
	Married	92	54.1

	10.1 - 50	37	21.8
	≥ 50.1	16	9.4
Main activity on the farm	Crop production	112	65.9
	Animal production	36	21.2
	Mixed crop and animal production	22	12.9

** includes owned and leased farm land; difference to 100% include respondents who didn't answer on this question.*
Source: Questionnaire Survey – own research (2014)

The low farmer level of (formal) education and insufficient of agricultural skills is one of the major development obstacles of family farming sector in Croatia (Žutinić and Markovina, 2009). Data of formal education of respondents indicated that they are significantly better educated than the averaged Croatian farmer. The majority of them (95.9%) have completed secondary school, college or university, while 73.5% of them have some kind of professional education in the field of agriculture (e.g. courses, agricultural school or faculty). Furthermore, 95.9% of respondents are computer literacy and using e-mail and internet for business purposes.

According to the research results, the average farm of young farmers used 17.2 hectares of agricultural land which is significantly above national average (2012 – 5.6 hectares), but at the range between 0.3 and 150 hectares. Two-thirds of surveyed farmers have crop production (arable farming, vegetables in greenhouses, horticulture, viticulture, olive growing, and production of flowers) as a predominant production activity. In livestock production, most of them engaged in the milk production and dealing with cattle fattening. A relatively small number of farms are processing its own products (22.9%). In addition, 29.4% of respondents are providing agricultural machinery services, agritourism (6.3%) and storage services for agricultural products (3.5%). Agriculture is the main source of income for about two-thirds of households (63.5%), 11.2% have the equally income from agriculture and non-agriculture, while 25.3% of them achieves most of income outside the agriculture.

Estimation and attitudes toward business cooperation

The development of business cooperation depends on whether farmers estimate the cooperation beneficial to their business (Kovačić et al., 2001). The survey results show that less than half of respondents (49.4%) are involved in some formal business cooperation in agriculture. In this subgroup (N=84) most of them are members of agricultural associations

(60.7%)[22], cooperatives (11.9%), producer organizations (4.7%) and 22.6% are contractually cooperate with the processing companies. Respondents are estimated the current situation of business cooperation in domestic agriculture as poor and very poor (75.7%, mean=2.12). The main reasons for this situation are „*insufficient knowledge of farmer*“ (mean=4.07), afterward „*low level of awareness*“ (mean=4.03), „*farmer individualism and the importance of personal interests*“ and „*lack of institutional and financial support*“ (mean=3.98).
Almost all respondents (91%) estimating ‘encouraging business corporation’ as a very important fact in national agriculture, especially when we are talking about joint appearance on the market, joint sales promotion and joint processing of their products (Table 2).

Table 2. What aspect of business cooperation you consider as most important?

Aspect of cooperation	Degree of agreement (%)*			Mean	Rang
	1 + 2	3	4+5		
Joining for common land use	51.2	23.5	25.3	2.57	9
Joint production	30.6	32.9	36.5	3.07	8
Shared storage and processing	13.6	18.8	67.6	3.83	4
Joint processing of agricultural products	10,6	20.6	68.8	3.85	3
Joint appearance on the market	3.6	13.5	82.9	4.63	1
Mutual lending	27.7	24.1	48.2	3.24	7
Joint use of agricultural machinery and equipment	15.9	21.2	62.9	3.74	5
Joint procurement of raw materials	22.4	10.0	67.6	3.71	6
Joint sales promotion	5.5	14.7	80.0	4.27	2

* 1=completely not important; 2= not important; 3= neither important, neither not important; 4= important; 5= very important
Source: Questionnaire Survey – own research (2014)

On the question “What form of cooperation is the most acceptable for young farmers?” - the largest number of respondents are emphasize ‘production organizations’ (27.1%), ‘cooperatives’ (25.9%), ‘agricultural associations’ (19.4%), ‘contractual cooperation with processing company’ (14.1%) and ‘clusters of complementary activities’ (5.3%).[23]

Perception of the cooperatives
The recent researches shows that the involvement of the Croatian population in cooperative entrepreneurship is an insufficient and wherefore they have marginal role in the development of agriculture and rural areas (Babić and Račić, 2012; Nedanov and Žutinić, 2015). Therefore one of the research aims was to determine how young farmers perceive cooperatives and are they seen cooperative organizing as a possible solution to strengthen their business competitiveness?
For measuring perception of respondents about the cooperatives we have used 11 statements which are shown in Table 3. Table data illustrates that majority of respondents (78.0%) perceive cooperatives exclusively as economic organization whose business depends on mutual cooperation and the quality of interpersonal relationship. Also, two-third of respondents agreed that cooperatives contributing to the sustainable development of agriculture and rural areas. At the same time, less than half of respondents expressed disagreement with statements that describes the cooperative in a negative context (v5; v8; v9; v2; v7), which can be explained by their inexperience and insufficient level of knowledge about cooperative enterprise model. However, the majority of respondents (63.9%) consider

[22] It is non-profit association of farmers which purpose are to promote agricultural activities and to foster communication and dialogue with administrative departments, experts and scholars in the field of agriculture.

[23] The difference to 100% include respondents (8.2%) whose gives answers: “*it’s better to work alone*”, “*I have a contract with intermediary agent”*, “*I’m not sure, because I don’t have experience”* and other.

that ‘cooperative model’ is essential for agriculture development and socio-economic revitalization of Croatian rural areas.

Table 3. The acceptance intensity of attitudes towards cooperative model

Statement	level of agreement * %			Mean
	1 + 2	3	4+5	
v1. – Co-ops. ensuring better business stability and security for their members.	8.2	28.2	63.6	3.72
v2. - Democratic principles slow and cumbersome operating decisions of cooperatives (1 member - 1 vote).	29.5	32.9	37.6	3.08
v3. – Co-ops. are economic organizations whose business results depend on mutual collaboration and the quality of relationship among members.	3.5	17.6	78.9	4.00
v4. – Co-op. are focused on conservation and sustainable use of local inputs.	11.8	38.8	49.4	3.48
v5. – Co-ops. cannot be efficient because they nourish moral principles and values.	48.8	32.9	18.3	2.62

v10. – Co-op. are increasing trust and solidarity on the village (social capital).	13.5	34.7	51.8	3.49
v11. – Co-op. model is essential for agriculture development and socio-economic revitalization of Croatian rural areas.	63.9	20.5	15.9	2.32

*1= strongly disagree; 2= disagree; 3= neither agree, neither disagree/do not know; 4= agree; 5= strongly agree
Source: Questionnaire Survey – own research (2014)

Contingency analysis (chi-test) has shown that are no significant differences between the socio-economic determinants of young farmers and their perception of the cooperative. Statistically significant differences were observed in only two statement, with respect to the dominant production (v2. p=0.04; Cc=0.39 and v11. p=0.1; Cc=0.43).

Numerous experience around world shows that young people can achieved their own entrepreneurial initiatives and employability by organizing a cooperative. In the subgroup of business independently farmers (N=86), 45.3% of respondent have expressed willingness to be actively involved in the foundation of cooperative, 32.6% do not know, while 22.1% are not interested in this type of cooperation. These shows that the relatively big share of young farmers in Croatia still do not see the cooperative model as a possible solution to overcome their business obstacles.

Conclusion

A summary of the basic research findings on attitudes of young farmers regarding business cooperation in family farming and their perception towards cooperative organizing are as follows:

According to socio-economic characteristic the majority of young farmers (95.9%) are well educated (completed secondary school or higher) and they are computer literacy. The average farm of young farmers used 17.2 hectares of agricultural land and the main farming activities is crop production. Agriculture is the main source of income for about two-thirds of respondents (63.5%).

The survey results show that less than half of young farmer (49.4%) are involved in some formal business cooperation in agriculture. They estimated the current situation of business cooperation in domestic agriculture as poor and very poor (75.7%). More than half of respondent farmers emphasize ‘production organizations’ (27.1%), and ‘cooperatives’ (25.9%) as most acceptable business model for young farmers.

Research analysis of young farmer attitudes towards cooperatives illustrates that majority of them (78.0%) perceive cooperatives exclusively as economic organization. Most of young farmers (63.9%) consider ‘cooperative model’ as an essential for Croatian agriculture and rural development. Among group of business independently farmers (N=86) less than half respondents have expressed willingness to be actively involved in the foundation of cooperative (45.3%)

Long-term empirical research in this and similar fields are required to raise general awareness of the Croatian farmers regarding the benefits of business cooperation.

Abstract

Agriculture sector employs about 31% of the labour force and generates 14% of GDP in Egypt. Yet many challenges hinder the development of this vital sector including weak role of extension and advisory services (EAS).

The present paper aims at analysing the contribution of public EAS to agriculture development in Egypt. A review of secondary data was used to give a general overview of the current status of EAS, policy framework and governance structures, main cooperation projects dealing with agricultural/rural EAS as well as human resources and gender issues within EAS context.

EAS played a great role in Egypt's agriculture development for many years. Extension system is currently in a transitional period and is moving towards decentralization of programming decisions and operations from one hand, and being involved in community development, not only agriculture focus, from another hand. EAS face great challenges *i.e.* lack of organizational and institutional coordination, decreasing number of extension workers, difficulty in convincing farmers to change their old and traditional agricultural practices.

Agriculture extension has great potential in achieving sustainable rural development by providing the solutions to field-based problems, improving the income of rural families, enhancing agricultural productivity by increasing input use efficiency and, finally, paying special attention to rural women and youth. It is important to realize that farmers, rural families and rural communities are the ultimate target of EAS. Therefore, all the institutional arrangements for improving, activating and enhancing the mutual cooperation and collective work of the Agricultural Knowledge and Innovation System (AKIS) sub-systems must focus and over emphasize on the characteristics, problems and needs of extension sub-system.

Keywords: *Egypt, Extension and Advisory Services, Farmers, Rural Families, Gender*

Introduction

Egypt is an agricultural-based country, where agriculture incubates about 31% of the labor force (MALR, 2009) and its share in GDP is about 14.5% (CAPMAS, 2006). Yet many challenges hinders the progress and development of this vital sector i.e. deterioration of natural resources, youth migration from rural areas, gender inequality, poor rural infrastructure, weak role of extension services (MALR, 2009).

Agriculture in Egypt witnessed significant developments over the last two decades with direct effects on the role of the agricultural sector in national income formation and promoting exports. Such developments have affected farmers' delivery system as related to the cropping structure, applied technology, levels of income, and farmers' response to market changes (MALR, 2009).

Agriculture sector growth rates have widely differed from one period to another due to the effect of general economic conditions, and development and investment efforts. The 1981/1982 – 1986/1987 period witnessed higher growth, estimated at an annual rate of 3%

during this period, while the 1987/1988 – 1991/1992 period was at an average annual rate of 2% (MALR, 2009). However, in the same time population size increased and reached 72,798,031 inhabitants of which about 41,427106 inhabit rural areas representing about 56.90% (CAPMAS, 2006).

In addition to many threats and challenges that face the agricultural sector and rural areas of Egypt (i.e. small and fragmented land holdings, water shortage and droughts, natural resources and environmental problems, poverty, poor health and malnutrition). High pressures and strains on the country's economy have resulted in poor or weak infrastructure and have pushed rural people deeper into poverty. In this situation, the majority of people is forced to live in poor living conditions and is deprived of basic facilities of life (Mohammed, 2005).

Agriculture extension services played a great role in Egypt's agriculture development for many years, depending upon transfer of information to the public sector. Extension system is currently in a transitional period and is moving towards decentralization of programming decisions and operations from one hand, and being involved in community development not only agriculture focus from another hand. The agriculture extension services face great challenges i.e. lack of organizational and institutional coordination which weakened their role, decreasing number of extension workers, difficulty to convince farmers to change their old or traditional agricultural practices (Shalaby et al, 2011). The number of extension workers in Egypt is 6604 of which 5359 male and 1245 female (Central Administration for Agriculture Extension "CAAE", 2012).

The current study's main objective is to explore the contribution of public agricultural extension and advisory services (EAS) to agriculture development in Egypt. Thus it covers three main themes: overview on agriculture sector, current challenges and limitations; history of agriculture extension in Egypt and its evolution; and role of the Central Administration of Agriculture Extension (CAAE) and its main activities, in order to analyse the current extension challenges.

Material and Methods

In order to achieve objectives, the work was based on extended secondary data review to give a general overview of the current status of extension services, policy frameworks and governance structures of (EAS) in Egypt, main cooperation projects dealing with agricultural/rural advisory/extension services, additionally human resources and gender issues within EAS context.

The main sources were some Egyptian ministries and authorities (*e.g.* Ministry of Agriculture and Land Reclamation, CAAE, Central agency for organization and administration) as well as some international organizations (*e.g.* FAO). The approach adopted is at the same time descriptive and explorative. Various analytical tools were used in order to give comprehensive overview about extension in Egypt, including quantitative and qualitative methods. SWOT analysis was used to verify the current condition of agriculture extension.

Results and Discussion

An overview on the agriculture sector and challenges

Agricultural development efforts during the 1980s, the 1990s and the first years of the twenty first century had achieved great successes in plant production with all its components, due to expanding agricultural areas and improving land productivity. Agricultural areas have increased from around 2 465 400 ha in 1980 to around 3 544 800 ha in 2007, an increase of 44% during this period. The cropping area has increased from 4 662 000 ha in 1980 to 6 468 000 ha in 2007. Livestock/crop production is an excellent example of an integrated production system where fodder crops and agricultural residues provide the feed for animals. The majority of small farmers (about 90% of farmers) follow this system.

More than 95% of the landowners hold less than two hectares each. Only less than 5% own 2.1 ha or more. Almost all livestock are raised through livestock/crop production integrated systems. Crop production includes field crops, vegetables, fruit and forest trees, and medicinal, aromatic and ornamental plants. The annual total cropped area is estimated at 6 468 000 ha, giving a cropping intensity of about 183% in 2007.
Limited land, limited water and rapidly growing population require continuing intensification of production on a limited natural resource base. Moreover, changes in the socio-economic environment have been brought about by changes in urbanization and higher incomes and the need for more export earnings or substitution of imports (El-Nahrawy, 2011).
Agriculture and rural extension is one of the means to alleviate poverty and improve food security, as it promotes transfer and exchange of information to enable and ensure small farmers and rural people accessibility but this is related to developments in institutional systems (Rivera et al., 2001).
Hence agriculture extension is no longer tied to agriculture only or even rural people alone, but extension is a multifunctional process that could be related to health, education, industry, tourism. People in rural areas in Egypt are engaged in farm and non-farm activities, for instance the average annual income of rural families from agricultural enterprises amounts to 4648 L.E. (Egyptian pounds) and about L.E. 2676.5 from non-agriculture activities (CAPMAS, 2012).

History of Agriculture Extension in Egypt

Agriculture extension in Egypt is mainly governmental and it evolved through five stages (Central Administration of Agriculture Extension “CAAE”, 2014).
First stage, “scattered” extension services efforts distinguished this stage among unspecialized groups or organizations i.e. agriculture cooperatives and some commercial institutions, in addition to some visits carried out by engineers working in family farms to provide such services to large scale farmers to aware and help them increase their productivity.
Second stage, extension services were to some extent determined and supervised by various authorities, upon issuing the Village reform act no. 30/1944. This act aimed at establishing agricultural groups covering an area of about 15,000 Feddans to promote agriculture reform and also forming an agriculture council for each group responsible for dissemination of Ministry of Agriculture guidelines, beside providing some technical lectures. This stage was marked in general by the absence of an independent agricultural extension service system and was considered as “secondary” job for some agricultural non-specialized organizations and there were no services targeting small-scale farmers.
Third stage, resulted as a response to solve the problems of the previous stage via unification and independency of the extension system to provide outstanding services within an organizational framework in 1953. This stage was affected by two events, first the extension conference in the Near East held in Syria in 1953, which encouraged the establishment of independent extension services. FAO recommended in the conference to establish agriculture extension centres in the region. The second event was the 1952 revolution which paid attention to agriculture extension as one of the important programs for social and economic development.
Forth stage, agriculture extension evolved between 1953 and 1983 (thirteen years). From 1953 to 1958 agriculture extension was recognized as an official organization in Egypt, by establishing an Agriculture extension department under the umbrella of the General administration of agricultural culture in the Ministry of Agriculture and included four branches at the central level: programs, training and technical services, agricultural units, model fields and cooperatives services, and rural organizations. Whereas at the local level agriculture extension was represented only by a supervisor or an assistant supervisor at the

governorate level along with an extension engineer at the district level (markaz) in the agriculture unit. These agricultural units reached at that time about 62 units.
From 1963 to 1964, the Agriculture extension department became the General administration of agriculture extension and training, and for first time research and extension means were included,
Then between 1964 and 1968 training was separated again and the Central administration for agriculture extension (CAAE) became directly under the supervision of Ministry of Agriculture.
In 1968-1976 the High council for agriculture extension was established by the ministerial decree no. 251/1968 and formed by representatives from universities, high agricultural institutions, farmers, cooperatives, research and services departments related to the Ministry of agriculture. This council played a consultative role to address agriculture problems and suggest appropriate solutions, recommendations to direct extension policy. This decree was followed by another one no. 478/1968 that organizes the General administration for agriculture extension. This period was distinguished by paying more attention to agricultural research and its activities were extended from improving agriculture production to rural developmental activities.
In 1976 -1979 there were additional organizational changes, and this period was marked by the establishment of new directorates to expand extension activities. Within the period 1979-1983 the agriculture extension administration was re-organized by the ministerial decree no. 151/1979 to maximize the agriculture production via educational activities to farmers using demonstration fields and modern visual and audio-visual aids.
Fifth stage, from 1983 till now, agriculture extension administration became under the supervision of the Agricultural research centre (ARC) by the ministerial decree no. 744/1982, to integrate agriculture extension with agriculture research. Accordingly, three divisions were established; agricultural researches, production and stations, and agriculture extension.
In spite of all these efforts, agriculture extension faced many problems regarding the continuous change in its title besides spatial and organizational problems since 1983-1990 until the organized framework and structure assigned by ARC and MALR and approved by the Central agency for organization and administration (CAOA). Though CAAE is still a dependent body at the level of administration.

The role of the Central Administration of Agriculture Extension (CAAE)

CAAE is responsible about reducing the productive gab in various fields to increase self-reliance rate of strategic crops, incorporate both research and extension activities, participate in providing and dissemination of technologies in rural areas regarding production and marketing of field and horticulture crops, besides animal production and rural development. Additionally, CAAE develops new extension methodologies i.e. participatory extension via farmers' field schools (FFS), farmer-to-farmer extension (FTF) and incorporation of population and environment culture within agriculture extension (APEX). CAAE encourages the bottom-up approach in extension program planning in various agriculture production fields, supervision and monitoring extension and training programs in the governorates, responds to farmers' new educational needs within globalization context. Moreover, it is concerned with human resources development through internal and external training, producing agriculture programs and using media audio- visual aids besides participating in local and international exhibitions. Finally, CAAE aims at increasing the productive efficiency of rural families by implementing small-scale projects and providing awareness in nutritional extension and rationalization of consumption, population, health and environmental areas.

CAAE organizational structure, as illustrated in figure 1, is composed from 21 departments and covers nine geographical areas in Egypt. There are specialists, i.e. in rural development (RD), sugar crops, new lands, at both governorate and agricultural units levels, besides extensionists at village level. CAAE possesses 4 information support centers in 4 main areas in Ismailia governorate, in Malawy (Menia governorate), Mariout (Alexandria governorate) and Dekernis (Dakhlia governorate) (Central Administration for Agriculture Extension “CAAE”, 2014).

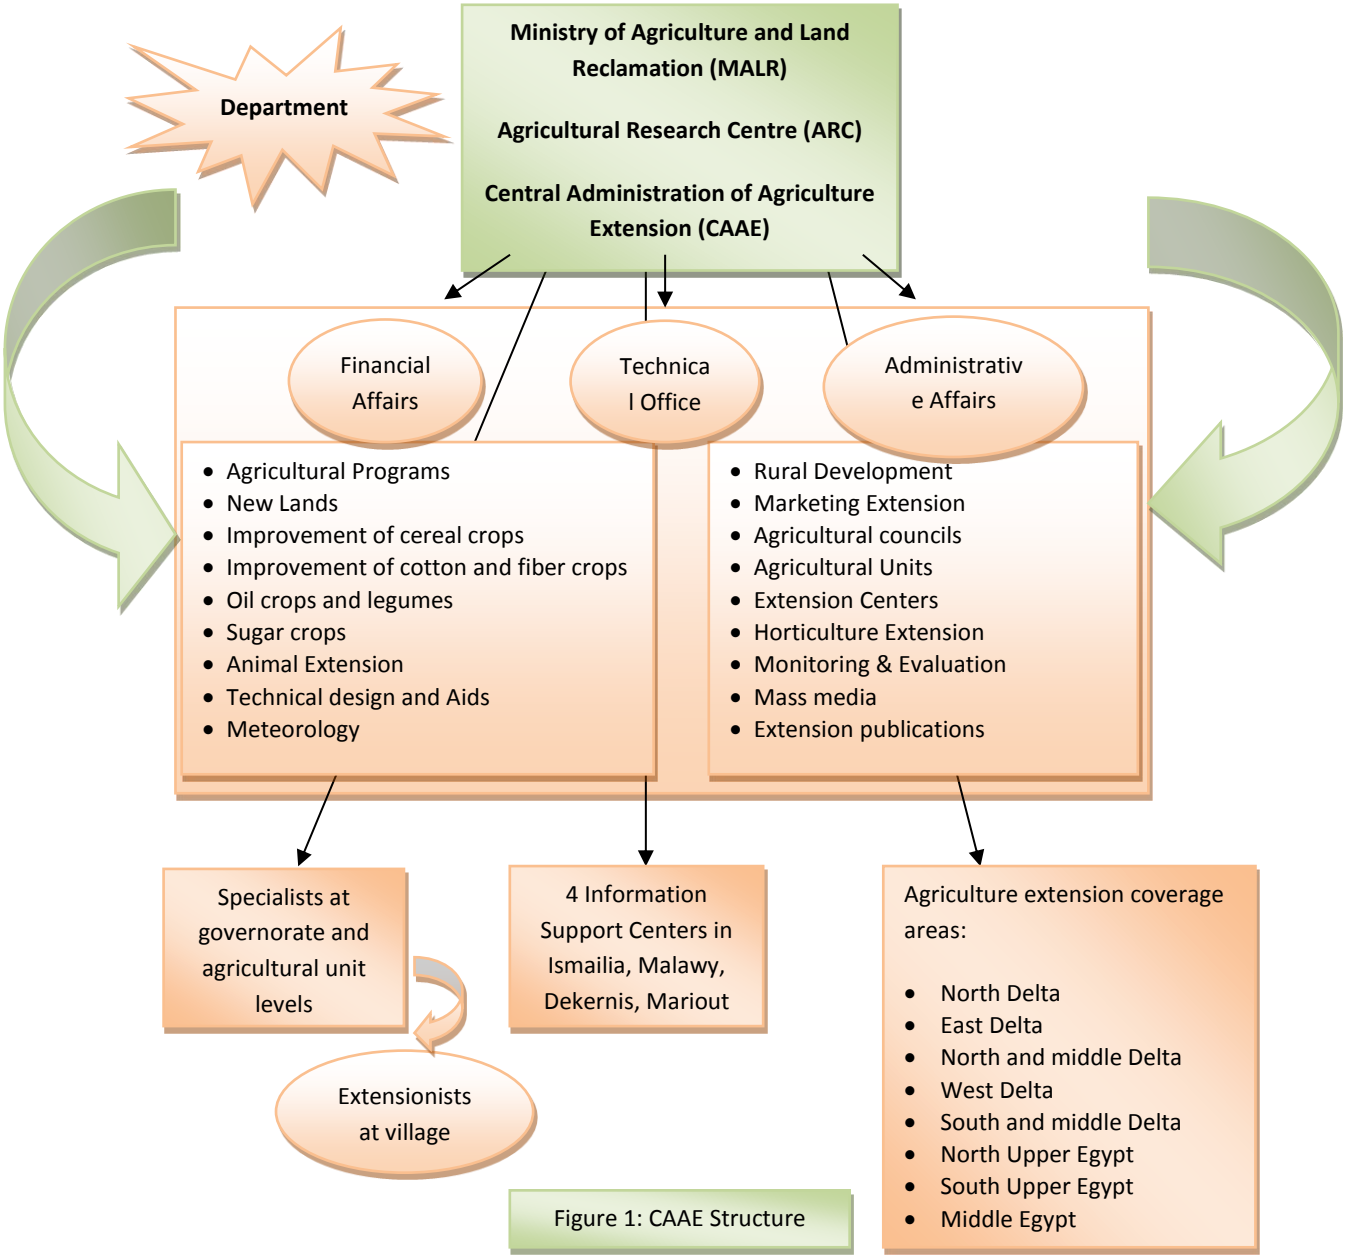

Figure 1: CAAE Structure

Current challenges, expected role and future vision

Egypt’s agricultural extension services had been delivered by vast network of specialized research institutions, central laboratories, regional research stations and extension services. The transfer of knowledge was largely top-down and one-way, from extension workers to farmers.

Extension services faced two main challenges weak links and slow communication between extension and research; and the lack of farmers’ participation in setting priorities.

To address these challenges, the extension units needed to move away from a reactive mode to a more proactive one and to see the beneficiaries of their services not simply as receivers of information, but also as providers of information (FAO, 2010).

There were various and diversified experiences that adopted new approaches in order to face the challenges within the new developments for instance MALR and FAO along with some Egyptian organizations launched two projects tackling ICT in extension and RD were implemented, first the Virtual Extension and Research Communication Network (VERCON) initiated in 2000 and second Rural and Agricultural Development Communication Network (RADCON) initiated in 2004. Both projects aimed at strengthening communication among stakeholders in agricultural and RD, RADCON was built on the experience of VERCON. In addition to farmers field schools (FFS) approach, which is part of long-term strategy of sustainable agriculture development applied by MALR and aims at improving the standard of living of rural inhabitants from gender perspective, by increasing their skills and access to knowledge. FFS was initiated for first time in Fayoum governorate in 1989 to improve tomato crop by establishing 3 female farmers' schools followed by IPM-FFS in 1999.

In the last years agriculture extension faced problems and its role weakened but it still has an important and vital role to play with farmers, rural people and their communities, thus extension services as mentioned no longer depend on agriculture or helping farmers only but to expand and extend their role to cover all people's livelihoods. Therefore, improving crops, animal wealth, poultry, fishery, water resources from one hand and people's life quality and living standards from another hand is what ought to be the coming role of extension in Egypt and in developing countries. In order to evaluate the current challenges facing agriculture extension, SWOT analysis was carried out based on review of literature as illustrated in table 1.

Table 1. SWOT analysis of current agriculture extension condition in Egypt

Strengths	**Weaknesses**
Extension service providers exist either public or private Legislations availability Experienced extension staff Farmers increased demand to improve their conditions via extension services The existence of the Sustainable agricultural development strategy	Low number of extension workers Weak role of agricultural cooperatives No gender balance in extension providers and recipients Budget constraints Extension workers overloaded with reporting for agriculture land violations
Opportunities	**Threats**
Incentives to attract young extension workers Improved coordination and cooperation among relevant stakeholders Training for young extension workers Decentralization with minimum supervision at ministry level	Limited markets access to small-scale farmers Losses in agricultural lands Scarcity and deterioration in natural resources Poverty and food insecurity High marketing competition locally and internationally

Source: Review of literature and CAAE

Conclusions

Agricultural extension and advisory services (AEAS) is one of the tools through which agricultural production and productivity could be promoted. Since improving AEAS in Egypt is essential and urgent, any strategy or policy for enhancing their roles in the promotion of agriculture should be based on achieving the following four main objectives or functions:

1) Achieving food security through technology transfer, to produce more food for satisfying the mounting demands of the ever-increasing population;

2) Human Capital / Resources Development, through improving the behavior (the Knowledge, Attitudes, Aspirations and Practices / Skills - KAAP / KAAS), of each individual producer;
3) Social Capital Development, by getting farmers better organized through two different mechanisms: a) Networking through establishing collaborative relationships in production and marketing, among farmers, and, b) Encouraging producers to form or establish farmers organizations as Civil Society Organizations / NGOs or Community Based Organizations for production and / or marketing of specific commodities or crops;
4) Sustainable Management of the Natural Resource Base, through conserving and sustaining the available natural resources (especially water and land), and avoiding their depletion, pollution or deterioration (El-Shafie, E. M. 2014).
Finally, without a clear strategy and re-structuring CAAE, hiring young extension workers and applying new participatory approaches that assure coordination and integration among research, farmers and extension, then no progress will take place.

FARMERS' INFORMATION ABOUT THE POTENTIAL IMPACTS OF CLIMATE CHANGE IN BEHEIRA GOVERNORATE IN EGYPT

Medhat ABDELWAHAB*, Gamal ASRAN

Rural Sociology and Agricultural Extension department, Faculty of agriculture, Cairo University, Egypt
*Corresponding author: medhatwahab@gmail.com

Abstract

Climate change is different from most of the other environmental problems. It acquires a universal dimension as it transcends countries national boundaries and constitutes a threat to the entire world. Egypt is one of the vulnerable countries to the potential impacts of Climate Change. Therefore Farmers' information (FI) about the potential impacts of climate change on Egypt (PICCE) is the main question of this study. The objectives of the study were: to measure the FI about PICCE, and to identify the relationship between the "FI about PICCE" and some of respondents' personal and socio-economic characteristics

This study was conducted in Beheira Governorate, which is located northwest of the Nile Delta, near the Mediterranean Sea Coast in Egypt. Field data were collected during January and February 2015 by a pretested form through personal interviews with a sample of 172 farmers. Frequencies, percentages, maximum, minimum, range, and Pearson correlation coefficient were used for data presentation and analysis.

The most important results are as follows: The majority of the responding farmers fall in the medium and high categories of FI about PICCE by 57.6% and 34.3%, respectively. Compared to only 8.1% of them that fall in low category of FI about PICCE. While, the majority of respondents (96.0%) are unaware that these Risks and threats caused by climate change/global warming. Also, statistically significant correlation relationships were found between the respondents' total score of FI about PICCE and household size, size of farm holding, and exposure to information sources.

Keywords: *farmers' information, climate change, Egypt*

Introduction

Climate change is not a far-off problem. It is happening now and is having very real consequences on people's lives. Climate change is disrupting national economies, costing us dearly today and even more tomorrow. But there is a growing recognition that affordable, scalable solutions are available now that will enable us all to leapfrog to cleaner, more resilient economies (UN Climate Summit, 2014). It is different from most of the other environmental problems. It acquires a universal dimension as it transcends countries national boundaries and constitutes a threat to the entire world. Successive increase in surface air temperature has been confirmed worldwide. Over the past 100 years, the universal average of surface air temperature progressively increased by 0.3 - 0.6°C. The Intergovernmental Panel on Climate Change (IPCC) studies concluded that an increase would, if the situation remained unchanged, lead to serious problems, such as sea water level rise bearing the threat of low laying areas getting drowned. It would also affect fresh water resources and crop production it asserts the spread of many diseases (EEAA, 2015).

Africa is the most effected continent (DMCDD, 2011). As well as Egypt is one of the vulnerable countries to the potential impacts of climate change. There has been a general increase in summer temperatures averaged over the country as a result of human influence on climate (Met, 2011). Given that Egypt's population, land-use and agriculture, as well as its economic activity are all constrained along a narrow T-shaped strip of land along the Nile

and the deltaic coast, it is extremely vulnerable to any adverse impacts on its coastal zones and water availability from the Nile. (Agrawala *et al*., 2004). Egypt's unique geography provides a serious challenge for adaptation to the changing climate and makes change in sea level or the flow of the Nile an extreme threat to Egypt's population and economy (Sterman, 2009). So Egypt faces serious risks from climate change. With 88% of its water coming from the Nile River (the Nile) and 97% of its population living along the Nile River Delta (the Nile Delta), a substantial reduction in flow of the Nile would pose a serious risk to Egypt. In addition, sea level rise (SLR) threatens settlements and agriculture in the Nile Delta and also in the Red Sea. Egypt is already hot and dry. Higher temperatures alone threaten to evaporate more water, increase the need for water supplies, create more heat stress, exacerbate already high levels of air pollution, and drive away tourists (Smith *et al*., 2013)

However, the climate change crisis is still a growing reality, which will require continued response not only from all of us. This global climate crisis calls for an urgent and holistic response, which tackles both the causes and the effects of climate change. Systems, policies, business practices, attitudes and lifestyles need to change – primarily in North but also in South – for the sake of future generations. (DMCDD, 2011).Adaptation priorities for coastal zones and the agriculture sector in the adaptation entail: conducting a national program for integrated coastal zones management; improving current crop patterns; developing a calendar to be adapted to the projected climate changes; improving the on-farm irrigation system; and developing a special fund program for adaptation and risk reduction activities for coastal zones and the agriculture sector (EEAA and UNFCC, 2010).

To confront these adverse impacts of climate change on Egypt, the Prime Minister re-established in 2007 a National Climate Change Committee consisting of scientists and experts from different ministries and relevant bodies responsible to manage climate in Egypt and to set a strategy to adapt to potential global changes (Saber, 2009).

Farmers' information (FI) about the potential impact of climate change on Egypt (PICCE) is the main question of this study. Because they are from the most affected groups by these negative impacts, therefore they must modify their behavior to avoid or adapt to these impacts. Therefore the objectives of this study were:

- Measuring the level of FI about PICCE;

- Identifying the relationship between "FI about PICCE" and some of respondents' personal and socio-economic characteristics.

Materials and Methods

This study was conducted in "El-Kanays" village, in "Kafr El-Dawar" District, Beheira Governorate, located northwest of the Nile Delta, near the Mediterranean Sea Coast in Egypt. Field data were collected during January and February 2015 by a pretested form through personal interviews with a sample of 172 farmers, representing more than 10% of the total holders of agricultural land in the village. Frequencies, percentages, maximum, minimum, range, and Pearson correlation coefficient were used for data presentation and analysis.

The dependent variable for this study "FI about PICCE" was measured by a scale consisting of 14 sentences representing the potential impacts of climate change on Egypt in 4 areas: Water Resources, Human health, Agriculture and Food, and Socio-Economic. There were two alternative responses for each sentence; know and don't know; they were assigned with values: 1 and 0, respectively. The total score for each respondent consist of his total responses' degrees about the 14 sentences of the scale. Then the respondents were divided into three categories according to their total scores.

Results and Discussion

The results in table 1 show that: With regard to the farmers' information (FI) about the potential impacts of climate change on Egypt (PICCE) in the area of Water Resources, the majority of responding farmers (63.4%) fall in the Medium category. And regarding the FI about PICCE in the area of Human health, more than a half of the respondents (51.2%) don't know it versus less than a half of them that know it, while the majority of them fall in the medium categories of the FI about PICCE in the areas of Agriculture and Food, and Socio-Economics with percentages 58.7% and 52.3%, respectively.

And regarding the FI about PICCE in all areas, the results in table 1 show also that: The majority of the respondents fall in the middle and high categories by 57.6% and 34.3% respectively. Compared to only 8.1% of them that fall in low category.

Table 1. Distribution of sample by FI about PICCE categories

Information categories	Frequency	%
Water Resources		
High (4)	47	27.3
Medium (2-3)	109	63.4
Low (1)	10	5.8
Don't know (0)	6	3.5
Total	**172**	**100.0**
Human health		
Know (1)	84	48.8
Don't know (0)	88	51.2
Total	**172**	**100.0**
Agriculture and Food		
High (4-5)	36	20.9
Medium (2-3)	101	58.7
Low (1)	16	9.3
Don't know (0)	19	11.0
Total	**172**	**100.0**
Socio-Economics		
High (4)	55	32.0
Medium (2-3)	90	52.3
Low (1)	15	8.7
Don't know (0)	12	7.0
Total	**172**	**100.0**
All Areas		
High (10-13)	59	34.3
Medium (6-9)	99	57.6
Low (2-5)	14	8.1
Total	**172**	**100.0**

Source: Calculated from field data

The results in table 2 indicate: statistically significant and positive correlation relationships were found between the respondents' score of FI about PICCE in the area of Water Resources and formal education years and size of farm holding, while there was a statistically significant and negative correlation relationship with household size. On the other side no statistically significant correlation relationships were found between the respondents' score of FI about PICCE in the area of human health and any of respondents' characteristics. And

regarding agriculture and food a statistically significant and positive correlation relationship was found between the respondents' score of FI about PICCE and size of farm holding. There were statistically significant and positive correlation relationships found between the respondents' score of FI about PICCE in the area of socio-economics and size of farm holding and exposure to information sources, while there was a statistically significant and negative correlation relationship with age.

Regarding FI about PICCE in all areas, the results in table 2 indicate also: statistically significant and positive correlation relationships were found between the respondents' score of FI about PICCE and size of farm holding and exposure to information sources, while there was a statistically significant and negative correlation relationship with household size.

Table 2. Pearson correlation coefficient between the degree of FI-PECC and their personal and socio-economic characteristics.

Respondents' characteristics	Respondents' score of FI about PICCE				
	Water Resources	Human health	Agriculture and Food	Socio-Economics	All Areas
Age	0.032	0.031	0.021	- 0.166*	- 0.050
Formal Education years	0.150*	0.112	0.029	0.006	0.113
Annual income	- 0.009	- 0.019	0.011	0.030	0.013
Father formal Education years	- 0.063	0.047	- 0.073	0.173*	0.029
Mother formal Education years	- 0.073	0.039	- 0.014	0.190*	0.063
Household size	- 0.189*	0.043	- 0.113	- 0.123	- 0.198**
Size of farm holding	0.174*	0.026	0.150*	0.254**	0.226**
Exposure to information sources	0.080	0.113	0.060	0.174*	0.182*
** Correlation is significant at the 0.01 level				* Correlation is significant at the 0.05 level	

Source: Calculated from field data

Conclusion

The findings show generally that the majority of the responding farmers fall in the medium and high categories of FI about PICCE in all areas except the area of human health. Therefore the trend of FI about PICCE level is high. But in the same time 96.0% of respondents are unaware of these negative effects, which are well-known and already happening now in Egypt due to climate change/global warming.

Therefore, there is a significant need to extension development programs and awareness raising campaigns for farmers about these negative effects and their relationship with climate change in Egypt, as well as the importance of adoption the sustainable practices to reduce, face and adapt to these potential risks.

Acknowledgement

We acknowledge and highly appreciate the efforts of our colleague Dr. Ehab Abd El-Khalek Mohamed Heikal, a lecturer of rural sociology, for his significant efforts to achieve this study especially during field work and data collection.

Abstract

Today food security and hunger eradication are technically and politically among the two priorities on the international, regional and national agenda due to their impact on agriculture productivity, economic development, food price spikes and climate change. Across developing countries, including those of the Mediterranean, rural women assume critical roles in attaining each of the pillars of food security: availability, access, and utilization. However, their roles are under evaluated and constrained by limitations on their access to resources, services and labor market opportunities. Most of the developing countries of the Mediterranean (lack of data combined with gender - based perceptions) have limited awareness and appreciation of the rural women's productive roles and contributions to food security and fighting the hunger. The inequitable distribution of rights, resources and power as well as repressive cultural rules ad norms, constrain greatly the ability of women to take an effective part in achieving food security and reducing famine expansion. In most developing countries the question which is under continuous bargaining is how to integrate gender across this thematic area? The direct answer which is well recognized should be through the promotion of gender equality and women empowerment in the area of public administration, local governance, human rights and anticorruption. Particular attention should be given to laws concerning property and inheritance. For most developing Countries, it is out of discussion that land ownership is a major determinant of the ability of rural women to improve the productivity of the land they use. However, beside elimination of existing discriminatory legal provision, it is needed to have appropriate strategies at the country level, allocating responsibilities across the appropriate departments - in particular education, health, employment, social affairs, agriculture and rural development. A shift from top down technically driven strategies and programmes to bottom - up participatory ones are urgently needed . Further more social and cultural norms and the gendered division of roles they impose, must be challenged. Empowerment of women is required due to its instrumental value being a condition for society to benefit from the increased contribution of women to food, security, adequate nutrition and poverty eradication.

Key words : *food security, hunger, gender, strategies empowerment, women.*

Introduction

Of the many global challenges we face today, perhaps the most significant and on the longest duration is that of providing food security and eliminating hunger. This challenge is compounded by developments such as the rise and volatility of food prices, the shift from food crops to biofuels in major food exporting countries, the neglect of agriculture in many developing countries, especially in terms of investments in infrastructure, and the looming threat of climate change with its predicted adverse effects on food production.

Persistent hunger and malnutrition is a problem affecting millions of people, the majority of whom are women and girls. Food and nutrition insecurity is a political, economic and environmental issue, but, most importantly, it is a gender justice issue; stark gender inequalities are both a cause and an outcome of unjust food access, consumption and

production. Hunger, malnutrition and poverty are intrinsically human phenomena, yet they are too often discussed in abstract, de-contextualized ways that are far removed from peoples own experiences and fail to adequately understand how they engage in food systems. In particular food security and nutrition programmes often fail to examine the different contributions made by women and men within these systems, and the specific constraints they face: there is also a failure to link experiences of food insecurity and malnutrition on the ground with the gendered inequalities that often lie at the heart of food systems at global, regional, national, local and household levels (FAO, ADB, 2013).

Country examples demonstrate the importance of capacity building, dissemination of information, gender-sensitive statistics, legal assistance, mobilization and advocacy in enhancing women's right, increasing their capability to eradicate poverty, fighting hunger and facing food insecurity. Lessons learned from various contexts that have produced tangible results need to be better shared and good practices scaled up.

Women as food producers

The FAO reports that women comprise around 43 percent of the agricultural labour force in developing countries. The percentage is as high as, or even higher than 80 percent in some countries in sub-Saharan Africa (FAO, 2011): the vast majority of food production that is attributable to women makes them the principle agents of food security and household welfare in rural areas (IFAD, 2009). Gender analysis shows us that women literally feed the world, as producers, processors, cooks and servers of food. However women's vast contribution to food productions, and their key role as consumers and family careers, is still largely misunderstood and underestimated (Sweetman, 2012). Indeed there is little detailed focus on who producing our food, and only a limited amount of gender disaggregated data (UN women, 2013). The available information indicates that women and often girls are heavily involved in all aspects of agricultural productions, processing and distribution. They are, therefore, vital contributors to food security, yet ironically much of their work, both paid and unpaid, is unrecognized. There is also little information on women's specific knowledge and skills in relation to agricultural production, on gender divisions of agricultural labor and on the specific ways in which there is access to productive resource often limited by inherent social and economic norms. Women despite of their vital contribution, they often do not take credit for much of their farming labor and the other household tasks they perform, which directly contribute to food availability and access. Moreover, due to their specific roles in food production, many women are the repositories of knowledge about cultivation, processing and preservation of nutrition and locally adopted crop varieties. Given the right possibilities, such knowledge can allow women to be innovative leaders in sustainable agriculture. Unfortunately, despite their wealth of knowledge and capacity, women farmers are neglected by policy makers, often not being recognized as productive farmers. For sustainability we need long term efforts to increase production, stabilize food availability, and improve distribution. Here the role of women as farmers, as consumers and as family food managers can prove pivotal.

Gendered food production constraints

Women are key players in the farming sector, women's role in food production within agriculture is even greater. In many societies women supply most of the labor needed to produce food crops and often control the use or sale of food produce growth on plots they manage. Improving women's productivity in agriculture not only increases food availability for household but also raises women's incomes and enhances food security due to women spending patterns (FAO, 2011). However, the symmetries in ownership, of access to, and control of livelihood assets such as land, water, energy, credit, knowledge and labor negatively affect women's food production. Women ability for own or inherit land is

restricted in much of in developing countries. Globally women own less than 20% of agricultural land (World conference on Family Farming, 2011).
Insecurity of land tenear for women results in lower investment and potential environmental degradation, it compromises future production potential and increases food insecurity. The lower production reduces not only women's potential income, but, also the availability of food for household consumption. In this connection it is important to focus on gendering land questions instead of treating land issues only in terms of land rights of women (Jakson, 2003). Gendering land questions requires more ethnographic research of social relations around land.
A gender role of women hinders access to technology, agricultural training and rural infrastructure (WB, FAO and IFAD, 2009). Involving young women and men in training opportunities from the start has proved to be a successful strategy in ensuring food security and sustainable livelihoods for households.This is also the case concerning the access of education and new technologies. Women's limited access to technology resulted in failure to address women's time constraints to agricultural activities. However, adoption of new technology depends on many things, including the availability of required assets to implement the technology, how local women and men view the perceived benefits, the way the information is shared, and local gender roles and other socio cultural constraints.
Even when women have access to land for food production and access to improved technology, they face more constraints than men in accessing complementary resources for success. They have less access to credit, and less access to inputs such as fertilizers, and they are less likely to benefit from agricultural extension services and therefore they have less access to improved technology. These constraints are not only costly to food security but also to economic growth (World Bank, 2009). There are numerous studies outlining women's limited access to markets compared with men (Kabeer and Humphrey, 1991; Kabeer, 2012; UNDESA, 2009). Changes in policy and regulatory frameworks are needed to create an equal playing field for women and men in market participation. Other major constraint is that many women in developing countries have less access to resources such as credit and financial capital, that could improve their lives sustainability and facilitate their entry into markets (IAASTD, 2009). Limited access to resources sustainability reduces women's ability to invest in new technology or adopt new agricultural techniques (FAO, 2009).

Gender and food security

Food security, at the individual, household, national, regional and global levels is achieved when all people of all times, have physical, social and economic access to sufficient, safe, and nutrition food to meet dietary needs and food preference for a healthy and active life (FAO, 2003). The "at all times" element of food security definition makes risk and associated vulnerability an important element of the food security concept.
Today the world has enough food to feed everyone, yet an estimated 854 million people worldwide are still undernourished (FAO, 2006 a and b). Poverty not food availability is the major driver of food insecurity, but the two are not always limited. Poorer households headed by women have demonstrated that they often succeeded in providing more nutritional food for their children than those headed by men (Kennedy and Peter, 1992). This demonstrates the importance of greater – based knowledge and roles with regard to food security.
Improvements in agricultural productivity are necessary to increase rural household incomes and access to available food but are not sufficient to ensure food security. Food security not only requires an adequate supply of food but also entails availability, access and utilization by all men and women of all ages. Gender – based inequalities all along the food production chain from farm to plate impend the attainment of food and nutritional security.

Nutritional security requires that household members have access not only to food, but also to health care, a hygienic environment, and knowledge of personal hygiene. Food security is necessary but not sufficient for ensuring nutrition security (IFAD, 2001).
There is differences in food security analyzed on national level with that analyzed at the household one. At the national level, food security implies not only the importance of national production, but, also the country's access to food from the global market, its foreign exchange earnings, and its citizen's consumer choices. Regarding the household food security it is conditioned by household's own food production and household members' ability to purchase food on the right quality and diversity in the market place.

Food security: gender equality and women's empowerment

Provision of equal opportunities for men and women, boys and girls, is necessary for all the full realization of their contribution to sustainable development. Therefore achieving gender equality and women's empowerment is important. In this regard, some areas to be considered include: equal education at all levels and achieving universal access to and quality of education is also important in promoting gender equality and empowerment of women and in shaping values and creating the necessary skilled and productive labor force, further important areas to be carefully considered are: ensuring equal participation of women in decision-making; equal access to assets and resources, ensuring equal employment opportunities for women and equal pay for equal work and promoting gender equality policies supported by gender disaggregated data (WFP, 2009; UN university, 2012).
According to FAO, 2006, the gendered aspects of food security are visible along the four pillars of food security: availability, access, utilization and stability. For FAO, ADB, 2013, gender inequality both leads to and result in food insecurity. According to estimates women and girls make up to 60% of world's chronically hungry and little progress has been made in ensuring the equal right to food for women enshrined in the convention on limitation of all forms of discrimination both in education and employment (Spoeldoch, 2011) and world food programme gender policy report (2009).
Individually as a group, institutions or nation can play an important role towards gender equality by:
Offer education particularly to children;
Increase women employment
Involvement in policies and social activities; and
Arrange social protection programmes.
In addition, there is high potentiality to eradicate poverty and achieve food security through directing further efforts and work towards:
Generate awareness among public and rural society.
Provide possibilities to girls and young women to further their education
In this connection governments can have an important task to challenge the poverty problems and food security by improving policies and adjusting their structures, giving the needed attention to the following five core areas:
Facilitating agricultural markets and trade;
Improving agricultural productivity;
Investing in public infrastructure for agricultural growth;
Reducing rural vulnerability and insecurity and
Improving agricultural policy and institutions.
Looking to rural women's empowerment the future implies that the following issues should be carefully considered:

What are the keys areas where new and interventions are necessary to make measurable and accelerated progress in rural women's empowerment? What gaps need to be addressed? What is the role of different stakeholders?
How can existing policy commitments to rural women's economic, legal, and political empowerment be more effectively translated into concrete actions on the ground? What measures and strategies have been successful and how can those be scaled up?
What current challenges and emerging trends have an adverse impact on the situation of rural women? How can those be addressed by different stakeholders?
What are good practice strategies for gender-responsive rural development poverty and hunger eradication and food and nutrition security?
What changes do we need to empower women smallholders and achieve food security?

Concluding remarks and recommendations

The majority of the rural poor are small holder farmers, who are responsible for most global food productions. Helping them to improve farm productivity through better access, to resources, technologies, markets and organizations will be critical for both poverty eradication and food security. Small holder farmers will need affordable access to technologies, and infrastructure to sustainability transform food systems.
Poverty cannot be eradicated without addressing the pervasive inequalities in incomes and economic opportunities between and within countries, between rural and urban areas and between men and women. Reducing such inequalities will need to start with improving access for the poor to productive resources, basic services and social protection.
Greater access to information, organizations, and resources is important for poor women, who disproportionately lack access compared for their men access compared for their men counter parts. Capacity building is needed for poor women in particular, as cultural and other gender-specific constraints have hindered them from greater engagement in market.
Having access to food of sufficient quality does not automatically translate into good nutritional status for individuals. Women's role in food utilization for food security is perhaps the most critical and outweighs the importance of their role in food productions and how they spend the income they earn.
There is now a growing recognition in policy that women's role is essential to food and nutrition security. Such policies tend to focus on increasing women's productive and economic capacity. This only a partial solution, failing to address the entrenched gender inequalities that prevent many women and girls from living a fulfilled life, free from hunger, poverty, and discrimination.
The precarious state of hunger and malnutrition in the world and the disproportionate in the world and the disproportionate impacts on women and girls highlight a conundrum. There is sufficient evidence to show why people are hungry and malnourished, but existing approaches- in terms of policy and practice- are failing to make headway in bringing about the substantive changes needed to ensure no one goes hungry.
Ensuring food security is both the most basic of development issues and the most complex. Gender inequalities are a significant part of problem and reducing those inequalities will be critical part of the solution. The inequalities women as producers reduce the potential productivity of agriculture and hence of overall food availability in countries, regions and worldwide. Failing to overcome the inequalities most rural women are facing; the crucial issues concerning eradication of poverty, fighting hunger, reaching food security and tackling food crisis will totally evaporate.

Abstract

The capacity production in rural area was estimated at 16 farms holdings in the municipality of Žabljak. Within these estimated farm holdings are 3 cattle breeding and 13 combined direction of production. Among investigated farms were established differences for number of livestock, arable lands, number of employed member on family farm. The livestock number was different, depending on type of farms. In average on 10 ha of arable land, on cattle breeding farms there were 9 livestock, while on farms with combined direction of production there were 11.46 livestock. These farm holdings deal exclusively with organic-ecological production and are mainly focused on livestock production, with a dominant breeding of sheep and cattle. In average 4.7 members per farm holdings on cattle breeding farms and 5.3 members on combined farms were registered. In the rural area of Žabljak municipality the number of employed people per farm holding is lower than average value in Montenegro. Production is partly intended for the market because one part of the product reserves is for their own needs. In the municipality of Žabljak the quantity of production for market is approximately equal for nutrition. In average on both type of farm holdings, the share of own cost (80.8%), purchase (15.3%) and services (4.0%) is in structure of total production cost. The income of production per 1 ha of arable land was higher on cattle breeding (500 euros) than on combined, while income per one full time employee (4129 euros) on combined farm holdings as well per one family member (1675 euros) was higher than on cattle breeding farm holdings (2897 euros and 1241 euros) in this municipality.

Keywords: *rural area, production, farms, Žabljak.*

Introduction

The geographic, climatic and biological characteristics of the municipality of Žabljak is in accordance with the most stringent criteria for the production of pure organic food, organic agriculture and of very high quality (The Municipal Assembly of Žabljak, 2012). In the villages of municipality of Žabljak, the main activity of the population is livestock production. The importance of animal production is great, considering that livestock breeding and the production of animal products are the main sources of income from the agricultural production of farm holdings (Bajcetic, 1982; Bastajic, 2004). That means that the current existence of individual agricultural producers, as well as increasing income and commodity exchange of these farm holdings are primarily related to increasing livestock production (regardless of racial composition of livestock and the degree of intensification of production) (Bulatovic, 2001; Ceranic et al. 2009). However, the lack of livestock feed, as a factor in the function of livestock production, is not restricted because of small area of existing farmland (Bastajic, 2002; Bastajic, 2006). The main cause is an irrational and disorganized use of existing sources of livestock feed, especially natural meadows and pastures as a primary source livestock feed (Krstic, et al., 2003). The existing climatic conditions and existing agricultural capacity and subjects can provide a greater volume of production, but only a

certain quality and structure. Natural factors, particularly in the mountain area, of this region, have influence to management system and narrowed the structure of production in agriculture, which led to specificity of agricultural production (Birovljev&Tomic, 2001; Sredojevic, 2006).

The aim of this paper is the analysis of the productive capacity in rural areas of the municipality of Žabljak, based on estimation capacity of farms holdings of cattle breeding and combined direction of production, connected to size of farms, production cost, purchase and services, employment of the members of family and income per unit of land and per farm.

Material and method

Analysis of organizational and economic conditions (family members, land, livestock, and structure of production) and the results of the final production (income, value of the final production, and structure of production costs) of individual farms in rural area of municipality of Žabljak can indicate trends of interest to the extent of agricultural policy in this area. In this paper it was conducted the analysis of production for 16 farms of the municipality of Žabljak. For obtaining data it was used a questionnaire in a year-round survey in 2014. The survey included an above-average size of farm holdings, which are focused on a market-oriented production.

Results and Discussion

Organizational and economic conditions

The investigation included farms with large families in municipality of Žabljak. Combined direction (cattle breeding and sheep breeding) of production is related to the family with a large number of members, which requires the continuous involvement of at least one family member. For the researched farm holdings are characterized at least two family members permanently employed in their own possession, that approximately at every second household comes per one family member employed full-time, and that only one person works abroad of hundreds of work-age family members (table 1).

Table 1. Family members and the labor force on the farms in the municipality of Žabljak

Direction of production	Number of farm holdings	Total members per farm holdings	Work on the farm			Total of employes on farm holdings	
			Full time	Part time	Seasonal	In country	Abroad
Cattle breeding	3	4.7	2	1	1.3	2	-
Combined	13	5.3	2.2	1.5	0.8	5	-
Total	16	5.2	2.1	1.4	0.9	7	-

Source: Author’s elaboration based on the questionnaire survey results.

In Žabljak municipality there are in average 12 ha of arable land per farm holdings, which is approximately to maximum of land. Households with a combined direction of production have over 1 hectare larger surface area than farms with cattle production direction. All studied farm holdings use land under the annuity. In this regard stand out to farm holdings with a combined direction of production in Žabljak municipality use under the lease in average 6.19 ha (table 2). The land under lease in relation to family members, in average is 3.57 ha, that exceeds the national average. Earlier studies have shown that the category of farm households with an arable land over 10 ha, mostly participate in using of land under lease, which is connected to the number of working-age family members. In Žabljak municipality, the relationship between the land area and members of family is more favorable on farm holdings with combined direction of production than on farms with cattle breeding, as the only branch of animal husbandry. On this phenomenon, in addition to the direction of production, other

factors have influence including significant regional specificities and the possibility of using land in social ownership that is not involved in an organized production (Bastajic, 2006; Krastic et al., 2003).

Table 2. Average ownership of land per farm holdings of municipality of Žabljak

Direction of production	Number of farm holdings	Available arable land				
		Own land (ha)	Under lease		Total (ha)	Per family member
			ha	%		
Cattle breeding	3	11.04	0.53	4.58	11.57	2.48
Combined	13	12.80	6.19	32.59	18.99	3.57
Total	16	12.47	5.13	29.14	17.60	3.39

Source: Author’s elaboration based on the questionnaire survey results.

Analysed farm holdings possess on average 11 livestock units or more than one livestock units per 10 ha of arable land. Definitely the proportions between livestock and arable land on the mountain farm holdings would not be possible in our conditions in the non-use of socially owned land in feeding (pasture) cattle (Ceranic et al., 2009). This finding goes in favour of the fact that farm holdings with a combined direction of production absolutely and relatively have greater representation of livestock from other farm holdings, because precisely sheep breeding is more closely involved in the use of our own and community pastures (table 3).

Table 3. Average number of livestock at the end of 2014 in farms of the municipality of Žabljak

Direction of production	Number of farm holdings	Cattle		Sheep		Livestock number on 10 ha of arable land
		Total	Cows	Total	Breeding sheep	
Cattle breeding	3	27	14	-	-	9.00
Combined	13	177	83	615	549	11.46
Total	16	204	97	615	549	11.15

Source: Author’s elaboration based on the questionnaire survey results.

The structure of final production is in line with the direction of production. For farm holdings with the cattle direction of production, this branch participates with 60% in the final production, which is characteristic of highly specialized farms. Although, farm holdings with a combined direction of production are focused on livestock production and on this criterion they have the characteristic of specialized holdings, but their production is diversified. The representation of sheep breeding with (30%) in the structure of the final production on these farm holdings has resulted in reduction of crop production. Analysed farms are equal by the structure of the product realization (table 4).

Table 4. The structure of the final production of agriculture in farms of the municipality of Žabljak

Direction of production	Number of farm holdings	Field		Fruit		Cattle breeding		Sheep breeding		Other		Total	
		€	%	€	%	€	%	€	%	€	%	€	%

The final production in farms of the municipality of Žabljak

The market participates in the structure of realization of the final production from 3/4, which illustrates the market orientation of these farm holdings. The high share of commodity production in the total production is related to the nature of livestock production (table 5).

Table 5. Values of agricultural production in farms of municipality Žabljak

Direction of production	Number of farm holdings	Final production					
		For the nutrition		For the market		Total	
		€	%	€	%	€	%

Total	16	46546	26.4	129901	73.6	176447	100

Source: Author's elaboration based on the questionnaire survey results.

For the analysis of the intensity of production on farms are used data related to the cost of materials and services. Individual production participates in the material costs of reproduction with 80%, which is a significant feature of the reproduction of farm holdings in the mountain region. Households with a combined direction of production show a lower share of individual production in the structure of the material costs (table 6), which can be explained by the nature of the technological process in the sheep breeding (Bastajic, 2006).

Table 6. The structure of production costs in farms of the municipality of Žabljak

Direction of production	Production costs								
	Own		Purchase		Services		Total		
	€	%	€	%	€	%	€	%	€ / ha
Cattle breeding	16470	83.2	1880	9.5	1440	7.3	19790	100.0	56983
Combined	117690	80.4	23470	16.0	5150	3.5	146310	100.0	59259

Source: Author's elaboration based on the questionnaire survey results.

The value of final agricultural production per farm holdings is higher in the direction of the combined production than in the cattle breeding, which can be associated with the number of family members and the larger capacity of the land in farm holdings with a combined direction of production. Direction of production equalizes more or less final production per household regardless of the geographical location of the farms. Reducing the final production by a unit of arable land, by the employee on the farm and by the family member incurred significant differences (Ceranic, et al., 2009).

Table 7. The value of the final (net) production (in euros) in farms of the municipality of Žabljak

Direction of production	Total per farm	By 1 ha of arable land	By one full time employee	By one family member
Cattle breeding	7376	637	3688	1580
Combined	11870	625	5511	2236
Total	11028	626	5189	2125

Source: Author's elaboration based on the questionnaire survey results.

The value of the final production per 1 ha of arable land was approximately equal (in euros) in both, farms with the combined direction of production and farms of cattle breeding, in the municipality of Žabljak (table 7). In farms with the combined direction of production, with permanently one employee as well in case with employee a family member of owner of farm holdings, the final production (in euros) was higher than in farms of cattle breeding in municipality of Žabljak. Earlier studies (Bajcetic et al., 1982) showed that the highest value of the final production per unit of arable land are achieved by producers of vegetables in suburban areas, followed by the producers of eggs, tobacco and grape producers.

Table 8. Income from agricultural production in farms of the municipality of Žabljak

Direction of production	Total €	By 1 ha of arable land	By one full time employee	By one family member
Cattle breeding	5795	500	2897	1241
Combined	8894	468	4129	1675
Total	8313	472	3912	1602

Source: Author's elaboration based on the questionnaire survey results.

Significantly higher total income from agricultural production is realized by farm holdings with the combined direction of production (table 8). Households with the direction of cattle production from the municipality of Žabljak have less average income.

Conclusion

Based on the analyzed rural households in the municipality of Žabljak it may be concluded that there is a dominance of farms of combined direction of production. These farms employ a larger number of family members than farms with cattle direction of production. Also, farms with a combined direction of production with significant capacity of the land, as land in its ownership, and by the participation of the land are leased. Livestock is the backbone of agricultural production in rural households with combined direction of production (the share of cattle breeding and sheep breeding accounts for about 75% of total production).

Both types of farms (cattle and combined direction) have approximately the same results in terms of the realization of the final production, with a slightly more favorable valuation code have farms with a combined direction of production. Also, households with combined direction of production in the municipality of Žabljak show a lower share of own production in the structure of the material costs, which can be explained by the nature of the technological process in the sheep breeding.

The income of production per 1 ha of arable land was higher on cattle breeding (500 euros) than on combined, while income per one full time employee (4129 euros) on combined farm holdings as well per one family member (1675 euros) was higher than on cattle breeding farm holdings (2897 euros and 1241 euros) in this municipality. All this indicates that rural households with combined direction of production in the municipality of Žabljak have significant advantages to be exploited, both in terms of the organizational, and in terms of production characteristics.

However, it should be emphasized that the current utilization of agricultural capacities and potentials in municipality of Žabljak is very poor, which faces the material base of the rational employment of numerous agricultural populations in this region, which has a negative impact on the income and overall living conditions. Also, sporadic local experience, show that agriculture of mountain regions can achieve fairly good results.

PERISHABILITY AND POST-HARVEST MANAGEMENT OF SPICES IN IBADAN, NIGERIA

Catherine AKINPELU[1], Oyeboade ADEBAYO[2], Oluyemisi ADEWALE[1], Timothy FARIYIKE[1]

Abstract

During the post-harvest period, spice crops are subject to losses due to a variety of causes-chemical changes, insect damage, rodent attack, and growth of microorganisms. It therefore becomes imperative to examine the perishability and postharvest management of spices (indigenous and exotic) in Ibadan, Oyo State, Nigeria. A well-structured questionnaire was used to gather information from fifty (50) randomly selected farmers in Lagelu local government area of Ibadan, Oyo State. Data were analysed using descriptive statistics and regression analysis. The study revealed that more men (90%) than women were involved in spices production and 50% were in the age group "41-60 yrs" while 62% had an average household size of 6-10 people. Sixty-two percent of the farmers stored their spices in baskets, 34% used bags and 4% spread out their spices in the open space. The drying method mostly used was sun drying (90%), 8% air dried their produce and 2% oven dried. On the average, 48.67% of the spices were non-perishable, 19.78% were mildly perishable and 31.56% formed the highly perishable spices. The regression results revealed household size, initial capital outlay and location of farm as socio-economic variables affecting income generated on spice production. It is therefore worthy of note that the farmers perspective of spices in the study area is that they are mostly non-perishable.

Keywords*: Spices, Perishability, Post-harvest, Regression.*

Introduction

Spices are aromatic and pungent herbal substances used as condiments. These substances generally give a characteristic smack, flavor, color and aroma (Khan and Balick, 2001; Gurib-Fakim, 2006). In Nigeria, spices act as food buffer and create a source of income for the farmers and marketers. They are also known to possess medicinal and nutritional uses ranging from treatment of cough, pneumonia, appetite boosters, womb cleansing and several others (Sethberger *et al*, 1996).

Spice crops can be classified into various categories based on their degree of perishability: non-perishable, semi-perishable and perishable spices (Atibudhi, 2009). Studies indicated that post-harvest losses in non-perishable ranged between 10-15 percent; loss in semi-perishable crops, 15-30 percent and that of perishables 25-40 percent (Hussain, 1993). Estimates of postharvest losses in developing countries vary greatly from 1% to 50% or even higher (FAO, 1981). During the post-harvest period, spice crops are subject to losses due to a variety of causes: chemical changes, insect damage, rodent attack, and growth of microorganisms. By far the greatest losses occur through growth of microorganisms.

Different types of preservation principles such as application of heat (blanching, pasteurization, sterilization), removal of heat (cooling/freezing.), drying and dehydration, use of different chemicals and preservatives, irradiation and controlled/modified atmospheric storage have been practiced for extending the shelf life of perishable commodities. However, till date the most commonly adopted method for long-term preservation is the removal of

moisture due to less cost of operation with acceptable quality. The dehydrated foods have gained market acceptance because of their economic viability, higher degree of inhibition of microbial attack, lower cost involved in transportation, handling and storage, and minimum labour requirement for production and packaging (Atibudhi, 2009). A good amount of markets in the country and abroad can also be built up for dehydrated indigenous spices, which are known for their exotic flavour and other qualities.

The drying process for most of the spices produced in the country is usually either under sun or by using conventional dryers. However, most of these spices have a limited post-harvest shelf life due to mechanical, physiological and pathological factors. Post-harvest technologies which greatly influence the level of post-harvest losses include, grading, packaging, transportation and storage.

It therefore becomes important to examine the perishability and post-harvest management of these spices with the following objectives; to determine the socio-economic characteristics of the respondents, to examine the farmers' perspective of spices perishablilty along-side methods adopted in managing post-harvest losses amongst farmers in the study area and to identify the factors affecting income generated from spices production in Ibadan, Oyo State.

Material and Methods

Ibadan, the capital of Oyo State, is the largest city in Nigeria. It is located in the South-Western part of the Country. There are 11 local government areas (LGAs) in Ibadan and its environs.

Lagelu local government area in the metropolis of Ibadan was purposively selected for the study on the basis of concentration of spice farmers (though still meager compared to other food crops) in Ibadan, Oyo state. Five (5) villages; Edun, Lalupon, Apatere, Lagun and Iyana-offa were purposively selected on the basis of their production of spices in the L.G.A. Primary data were collected from a sample of fifty (50) farmers (10 farmers from each village) through random sampling technique.

Well-structured questionnaires and interviews formed the means of data collection. Data collected were analysed using descriptive statistics, regression analysis and ranking. The perspective on perishability were measured using the 3-point scale as non-perishable =1, mildly perishable = 2 and highly perishable = 3.

Also, the linear regression model used was specified in the general form as:

$Y = f(x_1, x_2, x_3, x_4, x_5)$

Where:

Y = Income from spices in ₦/ bag
X_1 = Age (Years)
X_2 = Household size
X_3 = Educational Level
X_4 = Initial Capital Outlay
X_5 = Location of spices

Results and Discussion

Socio-economic Characteristics of Respondents

The result of the analysis in table 1 showed more male respondents (90%) than females. Half of the respondents were in the age group 41-60 yrs showing most of the respondents as matured and elderly people. About 96% of the respondents were married, 66% were Muslims depicting the dominance of that religious sect in the study area.

Furthermore, 44% of the respondents were primary school certificate holders which formed the highest proportion of the respondents. More than half of the respondents (62%) had an

average household size of 6-10 people. The predominant ethnic group was the Yoruba tribe (100%) while 84% of the respondents took up farming as a major occupation. The highest average monthly income of the respondents which is in the range ₦0-50,000 was 68% showing most of the respondents as small-average income earners. Also, the highest years of experience in farming (11-25yrs) was 30% which invariably suggests that some of the respondents were well experienced in the cultivation of spices.

Table 1. Socio-economic characteristics of the respondents

Management of Post-harvest Losses

As shown in Figures 1 and 2 below, the methods commonly used in storing, preserving and drying spices generally among the respondents are sun-drying, air drying and oven drying locally, while storage is done in bags, baskets and spread out in the open space for air. Sixty-two percent of the farmers stored their spices in baskets, thirty – four percent used bags and four percent spread out their spices in the open space for proper aeration.

The drying method mostly used by the farmers (90%) was sun drying, while about 8% air dried their produce and 2% oven dried. Atibudhi (2009) in his study also highlighted sun-drying as the most prominent drying method used for spices and other food crops. This could be due to the cost effectiveness of sun drying method over other methods.

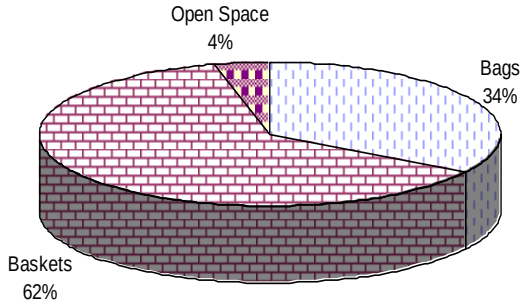

Fig. 1: Storage Medium for Spices

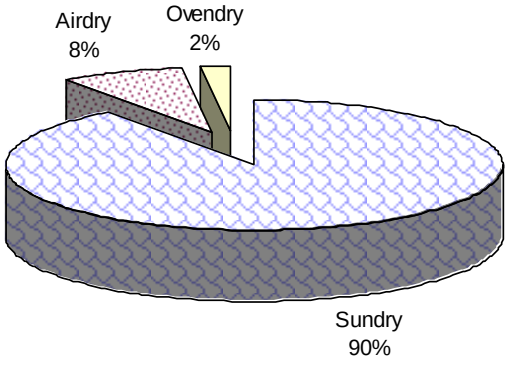

Fig. 2: Drying Methods for Spices

Perspective on Perishability of Spices

Nine spices (4 exotic & 5 indigenous) were sampled from the farmers. Data on the percentage shelf-life (high, moderate and low) of these spices were captured according to farmers' perspective and analysed using frequency distribution.

From the analysis in Table 2, *Tetrapleura tetraptera* and turmeric tied (88%) as the highest percentage of non-perishable spices. Also, garlic and *Parkia biglobossa* tied (38%) as the highest percentage mildly perishable spices. Ginger (80%) was singled out as the spice with highly perishable properties which could be as result of the high moisture content it carries. This supports the study by Atibudhi (2009) who buttressed that senescence takes place in ginger due to biochemical changes and high water content, which results in loss of production.

On the average, 48.67% of the spices had a high shelf-life, 19.78% had a moderate shelf-life and 31.56% averagely formed the low shelf-life category of spices. It is therefore worthy of note that the farmers perspective of spices in the study area is that on the average they possess a high shelf life.

Table 2. Respondents' Perspective on Shelf-life of Spices

SPICES	HIGH SHELF-LIFE (%)	MODERATE SHELF-LIFE (%)	LOW SHELF-LIFE (%)
Garlic	12.0	38.0	50.0
Black pepper	66.0	12.0	22.0
Hot pepper	6.0	34.0	60.0
Ginger	6.0	14.0	80.0

Factors Affecting Income Generated On Spice Production

The regression results in table 3; revealed household size, initial capital outlay and location of farm as socio-economic variables affecting income generated on spice production. This suggests that the low household size of the respondents could lead to the meager income generation from the production of spices in the study area, if their major source of labour is the farm family. Also, the initial capital outlay which was significant at $P<0.05$ showed that available capital invested in any production process vi-a-viz spices production will either enhance or minimize profitability. The significance of the location of the farm ($P<0.05$) however showed that, locational differences (weather conditions, pest and disease, accessibility to farm inputs amongst others) which exist in agricultural production might lead to an increase or a decrease in income generated. The socio-economic variables; such as age and educational level; did not affect income generated on spices production in Ibadan.

Table 3: Result of linear regression analysis

Variable	Coefficients	Standard Error	Y-Value
Constant			0.867
Age	-0.128	0.151	-1.050
Household-Size	0.329	0.136	2.715*

Source: Field survey 2012

Conclusion

Spices production in the study area is male dominated with elderly people as farmers.
Farming is the major occupation of the respondents and a meager income of ₦ 0 – 50,000 per month is realized by most of the farmers who have a production experience of 11-25 years the most. On the average, 48.67% of the spices had high shelf-life, 19.78% had moderate shelf-life and 31.56% averagely formed the spices with low shelf-life.

It is however worthy of note that the perception of these spices by the farmers in the study area is that on the average they possess a high shelf life. It is also recommended that more awareness on the medicinal, nutritional and economic importance of spices be reiterated so as to enhance production, improve the shelf-life of spices and create a balance between demand and supply of spices in Nigeria.

REMITTANCES, POVERTY AND INCOME INEQUALITY IN RURAL PAKISTAN: LINKAGES AND EMPIRICAL EVIDENCE

Khadija SHAMS

Shaheed Benazhir Bhutto Women University, Peshawar, Pakistan
*Corresponding author: kshams2008@gmail.com

Abstract

This paper analyses income inequalities in rural Pakistan. Using micro data (Survey 2008) allows us to decompose income inequality according to its different sources. Our dataset comprises all four provinces of Pakistan. To ensure representativeness, we decided to sample households in 10 districts (i.e. roughly one tenth of the total number of districts) across the country (stratified sampling). The number of districts has been selected in proportion with the size and population of each province. Two villages were chosen from each district. Within these predefined strata, households have been selected randomly. Our target was to achieve a total of 30 responses per village, that is 60 house-holds per district, yielding an overall sample size of N=600. Different variables are used in the paper: Monthly income of the household decomposed into five major income sources such as transfer income, agricultural income, non-farm income, rental income and livestock income. We calculate Gini coefficients and Theil indices both within and across the provinces and districts. We find that in-equality between districts is higher than within districts. A partial correlation analysis extends our descriptive investigation to reveal the different impacts of the various income sources on overall income inequalities. We observed that non-farm and transfer income have the strongest impact on income inequality across districts both in economic and econometric terms. While the former source of income is increasing inequality, transfer income tends to reduce in-equalities. Our analysis suggests important policy implications. It emphasises in particular the need for factor mobility to facilitate transfer income.

Keywords: Income inequality; poverty; remittances; economic development; rural Pakistan.

Introduction

All over the developing world policymakers are interested in devising new strategies for rebalancing skewed income distributions and reducing poverty. The choice of such strategies crucially hinges on an improved understanding of the sources of income inequality. Why do certain types of incomes go to particular groups of people? And what roles do variables such as land-ownership, migration and education play in improving income distribution and in lifting people out of poverty? Using primary household survey data, we identify different types of income to disentangle each source's impact on overall income inequality in Pakistan's four provinces. Our dataset is wide-ranging, providing rather detailed information on different districts across the country.

Other authors such as Adams and Alderman (1992) and Glewwe (1986) use panel data which covers up to three years, but are less detailed on the household level. We resort to a cross-sectional, yet well-designed, framework. Similarly, Adams (1994) uses three year panel data to analyse the impact of non-farm income on income inequality in rural Pakistan. He found that non-farm income represents an inequality-decreasing source of income. Ahmad (2000) found that moving from household-level to individual data leads to a further improvement in the distribution of income. Ahmad (2002) finds that within the given occupational groups in the four provinces of Pakistan, the highest level of inequality is observed among skilled workers (Gini coefficient of 0.299), followed by inequalities amongst the group of

legislators/officials (Gini coefficient of 0.273). In contrast to that, the Gini coefficient among unskilled workers is 0.180 and is the lowest within the professional class (Gini coefficient of only 0.136). This may have been due to the fact that many of them were government employees and the wage structure was more equal in the government sector. Anwar (2005) found that the wage incomes being more unevenly distributed than in rural areas. Moreover, income from self-employment was more deviated in urban areas than in rural areas as urban self-employment ranged from wealthy businessmen to poor workers, whereas the bulk of the rural self-employed were a rather homogeneous group being mostly employed in informal sector enterprises. Nugent and Walther (1982) find that periods of bad weather crowd out workers from the low-income group and increase inequality. Good weather, on the other hand, opens up more job opportunities for the workers from the low-income group and hence reduces imbalances in the income distribution.

Glewwe (1986) observed that labor income inequality accounts for slightly more than half of overall inequality in urban and estate sectors but not in the rural sector, where total inequality attributes largely to non-labor income and income from the sale of agricultural products (accounted for as profits). Adams and Alderman (1992) found that imbalances in land ownership are not the main drivers behind inequality in agricultural income. Instead, income from returns to labor and crop profits contributes the most. Anwar et al. (2004) suggest that unequal landownership is one of the most important causes of poverty and inequality in rural Pakistan as land is the principal asset in an agrarian economy.

Materials and methods

The total sample size 600 was used. There is random selection of 60 households within 10 predetermined districts across Pakistan’s provinces (stratified sampling). We assigned weights: Punjab (= 0.4), Sind (= 0.3), NWFP (= 0.2), Baluchistan (= 0.1). A detailed questionnaire presented a differentiated picture in terms of income sources and household characteristics. Our main limitation is the static perspective (i.e. we do not consider changes over time).

Income sources

The individual households’ total income may stem from up to five sources, y_i:

Transfer income (y_t) includes income earned from migration, both within (from rural to urban sector) and outside (abroad) of Pakistan. Income earned from the first kind of migration is treated as internal remittances; income from the latter as external remittances.

Agricultural income (y_a) includes net income (cash as well as in kind) from all crop production plus wage earnings from agricultural labour. Nonfarm income (y_{nf}) includes wage earnings from nonfarm labour including self-employment, government and private-sector employment. Rental income (y_r) includes rents received from ownership of assets including land, machinery (tractors, threshers), buildings, and water. Livestock income (y_l) includes net returns from traded livestock (cattle, poultry) plus imputed values of home-consumed livestock. The overall monthly income shares of the sample households are given as follows:

Table 1**:** Monthly income shares. N = 600 households.

Source: Survey 2008.

y_i	S_i
y_{nf}	18%
y_a	23%
y_t	30%
y_l	15%
y_r	14%

Distribution of sample households by income quintiles

The distribution of the sample households by income quintiles is shown in Table 2. Two points are worthwhile noticing: First, the shares of transfer, agricultural and livestock income are relatively higher in lower income quintiles as compared to the higher income quintiles and may be considered as major sources of income for the households belonging to lower income quintiles. In contrast to that, the shares of rental and nonfarm income tend to be higher in higher income quintiles. Second, the share of livestock income is lowest in the monthly income of the households reported in the top income quintile, whereas the share of rental income is lowest in the bottom quintile. Overall, we may say that the distribution is actually very similar for the bottom 4 quintiles and the differences really come with the richest quintile.

Table 2: Distribution of sample households by income quintiles.
Source: Survey 2008.
Note: All income shares are expressed in percentages.

Sample Distribution (%)	Income Groups (in PKR)	S_{nf}	S_t	S_a	S_r	S_l
Bottom quintile	1596-2526	16.4	31.9	23.9	9.0	18.8
2nd quintile	2550-3116	16.4	30.6	23.2	10.2	19.6
3rd quintile	3136-3359	13.2	33.1	23.6	10.3	19.8
4rth quintile	3365-4298	16.6	30.8	22.3	13.5	16.8
Top quintile	4371-6938	22.8	27.1	21.7	21.2	7.2

We can identify the impact of each of the different sources of income on overall income inequality as follows:

• breaking-down household's total income in the $n = 5$ sources:

$$y = \sum_{i=1}^{n=5} y_i,$$

• calculating weights of income source i:

$$w_i = \bar{y}_i / \bar{y},$$

where $\bar{y}_i$ represents the mean monthly income of source i and $\bar{y}$ is the mean of total monthly household income.

• calculating the correlation ratio between income source and total income:

$$R_i = \frac{cov(y_i, r)}{cov(y_i, r_i)}$$

where r is the ranking of total income such that higher income receives a higher rank and r_i expresses the corresponding ranking of income sources.

• determining the Gini coefficient associated with income source y_i:

$$G_i^2 = \frac{}{N \bar{y}_i} cov(y_i, r_i),$$

allows us to decompose the Gini coefficient for rural Pakistan $G_{rPk} = 0.189$[24] (Survey, 2008) to measure the contribution of the different income sources to overall income inequality c_i:[25]

Results and discussion

Income decompositions: Decomposing overall income inequality by income sources

Table 3, shows contribution to overall income inequality by each of the income sources as given below. According to the table, agricultural, nonfarm, rental and transfer income each contributes approximately one-fourth (i.e. 1/4) of the overall income inequality while livestock income hardly contributes to the total inequality.

Table 3: Contribution to overall income inequality by income source.

Source: Survey 2008.

y_i	w_i	R_i	G_i	c_i
y_a	0.23	0.99	0.17	0.21
y_l	0.15	0.13	0.16	0.02
y_{nf}	0.18	0.88	0.31	0.26
y_r	0.14	0.97	0.37	0.27
y_t	0.30	0.95	0.17	0.26

Inequality decomposition by regions: Decomposition of income inequality within and between provinces

Given the design of our survey, the sample is readily partitioned to differentiate between inequality within (I_w) and between (I_b) regions where it obviously holds that $I = I_b + I_w$.
Using this methodology we can first decompose the Theil Index on a more aggregate province level as follows:

$$I = \underbrace{\sum_{k=1}^{K=4} \frac{N_k}{N} \left(\frac{\bar{y}_k}{\bar{y}}\right) \ln\left(\frac{\bar{y}_k}{\bar{y}}\right)}_{Between} + \underbrace{\sum_{k=1}^{K=4} \left(\frac{N_k}{N} \frac{\bar{y}_k}{\bar{y}}\right) I_k}_{Within}$$
$$= 0.0016 + 0.0634 = 0.055$$

The results of above equation suggest that inequality on this level of aggregation is almost exclusively driven within rather than between the provinces.

Decomposition of income inequality between and within districts

[24] $\sum_{i=1}^{5} \text{wiRiGi} = 0.189$

[25] $c_i = w_i R_i \frac{G_i}{G_{rPk}}$

Unlike Gini coefficients, the Theil index has the property of additive decomposability. On the more disaggregated district level we have,

$$I = \underbrace{\sum_{j=1}^{J=10} \frac{N_j}{N}\left(\frac{\bar{y}_j}{\bar{y}}\right) ln\left(\frac{\bar{y}_j}{\bar{y}}\right)}_{Between} + \underbrace{\sum_{j=1}^{J=10}\left(\frac{N_j}{N}\frac{\bar{y}_j}{\bar{y}}\right) I_j}_{Within}$$
$$= 0.0535 + 0.0015 = 0.055,$$

$$R_b = \frac{I_b}{I} = \frac{0.0535}{0.0550} = 0.97.$$

which reveals that 97% of total inequality is explained by inequality between districts and inequality within the districts accounts for the remaining 3%.

Partial correlation analysis

In this section, we consider partial correlation coefficients to measure the statistical relationship between income inequality (G_j) and the shares of different income sources ($S_{i,j}$) across the districts, where all variables are expressed in terms of percentages and G_j represents the Gini coefficient as measure of overall income inequality in the j^{th} district and the share $S_{i,j}$ is defined as the ratio of average income of type i in district j over total average income in district j, as shown in Table 4, such that:

$$S_{a,j} = \frac{\bar{y}_{a,j}}{\bar{y}_j} \times 100$$
$$S_{t,j} = \frac{\bar{y}_{t,j}}{\bar{y}_j} \times 100$$
$$S_{nf,j} = \frac{\bar{y}_{nf,j}}{\bar{y}_j} \times 100$$
$$S_{r,j} = \frac{\bar{y}_{r,j}}{\bar{y}_j} \times 100$$
$$S_{l,j} = \frac{\bar{y}_{l,j}}{\bar{y}_j} \times 100$$

Table 4: Share of different income sources; by district.
Source: Survey 2008.
Note: All income shares are expressed in percentages.

District	Gini	Share of income source (%)				
	(%)	$S_{t,j}$	$S_{a,j}$	$S_{nf,j}$	$S_{r,j}$	$S_{l,j}$
Attock	5	27	22	26	19	6
Sahiwal	8	28	22	23	12	15
Layyah	5	29	23	20	10	18
Rahimyar Khan	5	30	23	18	10	18
Badin	2	33	23	17	10	17
Thatta	8	34	25	14	7	19
Mirpur khas	3	28	21	17	26	8
Dir	2	34	24	12	9	21
Malakand	4	29	22	13	16	20
Kalat	2	34	24	12	9	21

Table 5: Partial Correlation Analysis.

Note: *, ** and *** denote statistical significance at 10%, 5% and 1% levels respectively.

Partial Correlation of G_j with		
Variable	Corr.	Sig.
$S_{a,j}$	0.6494	0.114
$S_{t,j}$	-0.7354*	0.060
$S_{nf,j}$	0.7354*	0.060
$S_{r,j}$	0.6291	0.130
$S_{l,j}$	0.6517	0.113

Similar to a regression analysis, partial correlation seeks to measure a relationship between dependent and independent variable, whilst eliminating potential effects of a third variable. The partial correlation coefficients measure in this case the degree of statistical association between income source and district-wide Gini coefficient, where the latter one is considered as the dependent variable. Results are shown in Tables 5. Columns two and three report the partial correlation coefficient and the corresponding significance level, respectively. We find a strong positive and statistically significant correlation of 0.74 between the share of nonfarm income and income inequality across the districts. Thus, nonfarm income appears as inequality increasing source of income. In contrast to this, we detect a similarly strong (and also statistically significant) but negative correlation (-0.74) between the share of transfer income and income inequality. Unlike nonfarm income, transfer income is a source of income that is capable of reducing income inequalities in rural Pakistan. This result is in line with Shahbaz et al. (2014), exploring the dynamic linkages between income inequality, international remittances and economic growth using time series data over the period of 1976-2006, found that Pakistan is yet to benefit, in terms of reducing the gaps of income inequality, from the international flow of remittances and economic growth. Combes et al. (2014), using a cross country dataset (including both developing and underdeveloped countries), show that the level and the predictability of remittances and migration, reduce working poverty in receiving economies through their effects on labour market dynamics. Similarly, Beyene (2014), studies the effects of international remittances on poverty and inequality in Ethiopia using an urban household survey from 2004, finds a significant reduction in poverty, while inequality does not change with the inflow of international remittances.

Conclusion

We find that transfer income is the most important source of total monthly household income, accounting for almost 30% of its share. Shares of transfer, agricultural and livestock income are relatively higher in lower income groups as compared to higher income groups, shares of rental and nonfarm income tend to be higher in higher income groups. Agricultural, nonfarm, rental and transfer income each drive income inequality in the sample area to a similar degree. Livestock income hardly affects the results. Decomposing overall income inequality within and between districts reveals that overall inequality is largely determined by inequalities between (97%) rather than within districts. The partial correlation analysis confirms the

importance of transfer income in reducing income inequalities (negative estimated coefficient), in contrast, nonfarm income appears to increase inequality.
Policymakers should hence put more emphasis on transfer income in fighting in-equalities. For instance, they should try to foster its flows both between Pakistan and from the rest of the world. Particularly and initially try to increase factor mobility within the country by providing stronger technical education for the rural (and often poor) unskilled labour force so as to increase mobility and improve job opportunities within Pakistan as well as abroad. Furthermore, to raise the overall income level, policymakers should take steps to help poorer households send migrants abroad (the idea of "rural migration centers").

Acknowledgments

I would like to thank Luis Angeles, Sai Ding, Richard Harris, Alexander Kadow, Philippe LeMay-Boucher and seminar participants at the University of Glasgow for helpful comments. I am very grateful to the sample households for their patience and cooperation in data collection. The financial support of the Higher Education Commission (HEC) of Pakistan is acknowledged. All remaining errors are my own.

COMMON AGRICULTURAL POLICY IN POLAND – ACHIEVEMENTS AND EXPECTATIONS DURING MEMBERSHIP IN THE EUROPEAN UNION

Marek WIGIER

Institute of Agricultural and Food Economics – National Research Institute, Warsaw, Poland
*Corresponding author: wigier@ierigz.waw.pl

Abstract

The agribusiness in Poland is still important and significant subsystem of the national economy. The analysis of factors influencing on structural changes in Polish economy demonstrates that the economic growth model prevailing in Poland is based on classical production factors: labour, land and capital. In the period 2004-2013 creation modern economy, macroeconomic conditions, globalisation and integration processes determined structural changes in agribusiness sector. In Poland was observed an absolute decline in the share of agriculture in the value added in the economy, employment, trade and consumption. Decreasing importance of agriculture is accompanied by an increase in income. The share of primary agricultural products in the value of finished products follows a downward trend, thus increasing the value added in the food industry. This process is already taking place, with the support of the agricultural policy activities. The purpose of this study is to assess the degree of development of agribusiness and its importance for the national economy and the presentation the achievement and expectations related with Poland's membership in the EU.

Keywords: *agribusiness, economic development, public support, competitiveness*

Introduction

The extent and type of instruments of the Common Agricultural Policy (CAP) of the European Union (EU) result from the postulate of an active role of government in the process of eliminating inefficiencies of market mechanisms within the concept of market failure (cf. Bator 1958, pp. 157-175). This concept suggests that in the conditions of the market economy, the structure and size of supply are not reflected in adequate level of demand as a result of the lack of autonomous re-balancing mechanisms (Medema 2007, p. 33). In practice, the processes of allocation of goods and services, despite the assumption of conditions of perfect competition and complete information as attributes of a complete market, show a number of difficulties (Hayek 1939). As a result, the state of actual equilibrium achieved by the market is characterised by the allocation of goods and services, which does not comply with Pareto optimum (Baumol 1952). In broader terms, the concept of market failure is a trend in economic theory which identifies the scope and circumstances of observed defects of market mechanisms that lead to the perpetuation of market imbalances. In this context, one points out the positive aspects of market intervention by public authorities (Stiglitz 1989).

The neoclassical model of structural changes in agriculture emphasises the relationships between the farm size and the scale and efficiency of production (Wigier, 2014). According to this model, it is only an appropriate scale of production that can ensure high efficiency (Chavas 2001). Therefore, economic growth and the physical size of farms can: improve their competitive position on the market, make it possible to use of economies of scale, result in reduced production costs, increase the bargaining power in trade, etc. The modern agricultural holding is characterised by a high degree of complexity, diversity and integration. Thus, the allocation of resources in agriculture becomes increasingly dependent on market forces and forming networks of interbranch connections. The agricultural production is increasingly dependent on the progress in genetic research, the implementation of advanced manufacturing

technologies, the development of research regarding the health and nutritional values of food, the application of organic production criteria.
The agrarian structure in Poland, which currently undergoes transformations, leads to an absolute reduction in the number of farms and polarisation of the area. Agriculture as a sector involved in the creation of the GDP loses its importance to the other sectors of the economy. Therefore, a characteristic feature of the process is deagrarianisation of the national economy and the development of rural areas. Throughout this process, it is extremely important for the ongoing structural changes to result in the improvement of the competitive position of farms and long-term and sustainable rural development. Poland's accession to the EU has generated new economic and organisational conditions to support structural changes in the broadly defined food economy and rural areas (Poczta 2012). Policy instruments implemented within the CAP create chances for the stabilisation of structural policy conditions over the period of several production cycles, thus stimulating the desired changes in the area structure of farms, the improvements in the competitiveness of production, environmental protection and multi-functional development of rural areas. Thus they are a fundamental instrument supporting the process of modernisation of Polish rural areas and agriculture (Łopaciuk et al., 2014).

Materials and methods

The purpose of this study is to analyse the development of agribusiness in the years 2004-2013, which includes an analysis of changes in its structure, the degree of integration of its components, the identification of reasons for changes taking place due to the European integration processes as well as the determination of strength and nature of the connections between the agribusiness sector and its environment. Using the statistical and descriptive methods, has been carried an analysis of the Central Statistical Office macroeconomic data with regard to assessing the degree of the development of agribusiness and its importance to the national economy. To study the impact of investments and public support on structural change in agriculture was used also one of the data mining methods - Grade Data Analysis (GDA). It is a family of algorithms and heuristics to extract knowledge from large data sets. GDA examines the relationship of objects and their properties, allowing for both verifying conjecture as to the specifics of an analysed phenomenon and identifying relationships not grasped by intuition on or even being in conflict with it. In results the GDA was a convenient tool for comprehensive data analysis.

Results and discussion

The current situation of agro-food sector in Poland is the result of the effect of multiple factors, associated with economic cycles, geopolitical ones and the current generation-related changes. Both macroeconomic conditions that arise from the presence within EU structures and the presence within the Single Market and State aid programmes addressed to the agri-food sector under the CAP contribute to it. The structural changes in agriculture result from the concentration of production and land. The inflow of EU funds from the EU was an important incentive that triggered structural changes and hence the improvement of the effectiveness of farming and the competitiveness of agriculture. However, the public policy instruments currently in use, which were supposed to promote convergence of the regions, are not able to prevent farm polarisation. Economic disparities increase between commercial farms with strong links to the market and the farms that produce mainly for self-supply and are social in their nature. The development distance between rich regions or the ones becoming richer and the poor regions clearly gets larger. Rich areas develop due to the use of their potential and economic situation whereas the poor areas are stuck in stagnation (Wigier, 2013).

Despite structural changes, sometimes very deep, the Polish agriculture remains an important sector of Polish economy. This is, primarily, confirmed by the structure of employment and structure of land use. The sector plays an especially important role as it comes to social and economic development of rural areas. Since agriculture uses over half of the total area of the country for economic purposes, it sets the main functions and directions of land use and shapes the natural environment and landscape. The agricultural sector remains the place of work for almost 15% of the total number of working people. However, the number of people working in agriculture points to negative relations between the labour resources and land and capital resources thereby causing low efficiency of labour. On the other hand, from the perspective of Gross Domestic Product (GDP) generation the significance of the agricultural sector in Poland is decreasing. Systematically was decreasing the share of agriculture in gross value added (from 5.1% in 2004 to 3.3% in 2013), and transport (respectively from 7.2% to 6.0%), whereas increased the share of construction (from 5.6% to 7.4%), services sector (from 37.9% to 38.5%) and industry (from 25.4% to 25.8%). The share of food industry in gross value added in the economy increased in this period by 0.1 percentage points (pp) to a level of about 3.1%. In the structure of the all industry, the share of the food sector was stable (approx. 11.8%) (Figure 1). The share of agriculture in replacement and increasing of the assets remains significantly smaller. Investment inputs for this purpose are shaped below 2%, which leads to further decrease in the role of agriculture as owner of fixed assets in the national economy.

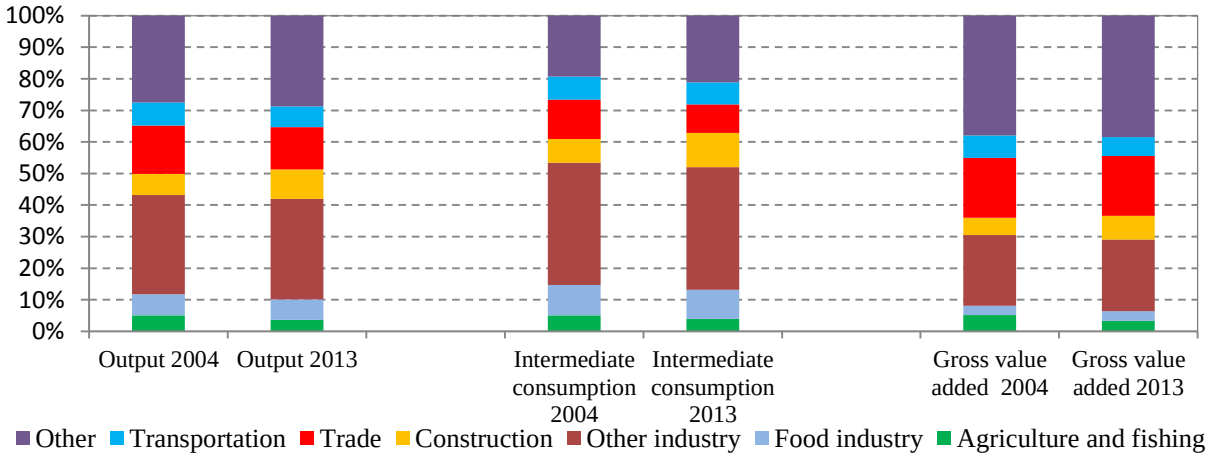
t, intermediate consumption and gross value added
of selected sectors



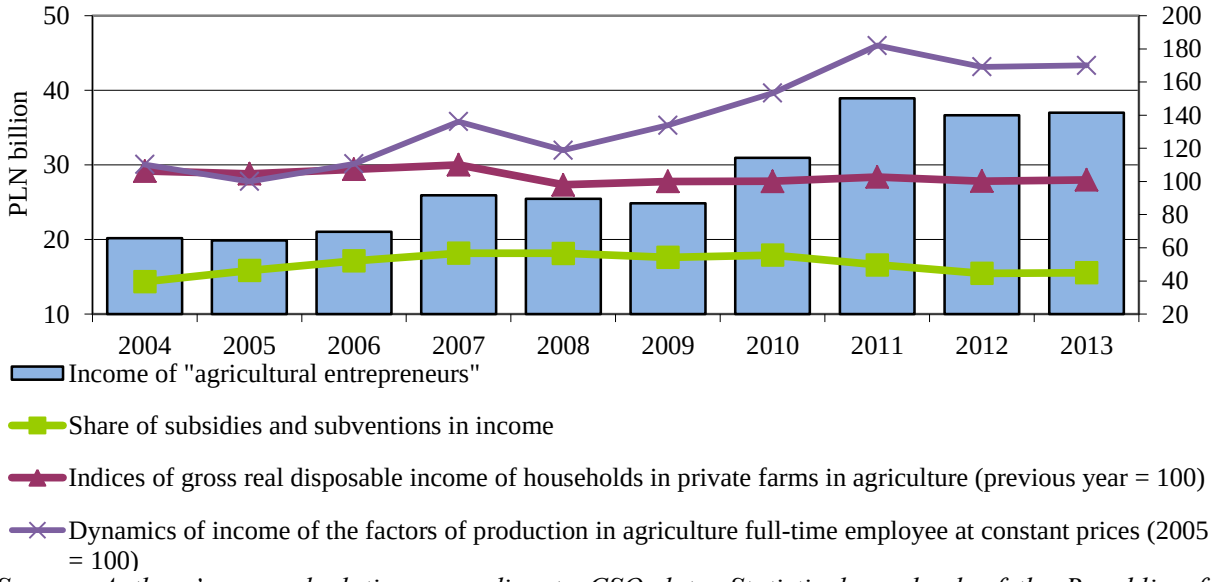
Source: Own calculations based on CSO data. Statistical yearbook of the Republic of Poland 2005 and 2014, www.stat.gov.pl, access date: 5 June 2015

There have been major changes in the agrarian structure which continued long-term trends. In the period preceding accession to the EU (1996-2002), large agricultural holdings (20-50 ha UAA), which took over arable land from small and medium agricultural holdings, but also from holdings of over 50 ha, developed dynamically. The growth in numbers was accompanied with the decrease of surface. The arable land of holdings below 1 ha grew, but their number dwindled. Following the accession to the EU, the number of holdings decreased by 28%, and their surface by 3%. The development of large holdings lost dynamics, but still arable land was taken over by holdings of the surface of 20 to 50 ha, for both smaller holdings, of which the number and area decreased, and bigger, the number of which, despite the decrease of the area, grew. The limiting of the number of the biggest holdings is relative to

the implementation of regulations limiting the area of family agricultural holdings and the ending of the lease period in second half of the previous decade. The number of holdings taking over land slightly increased. The number of holdings smaller than 1 ha decreased by 27%. To a slightly lesser extent the number of small and medium holdings decreased (from 25% to 16%). Their area also shrunk, including, to a largest extent, in the group of 10 to 20 ha (by 8%). These changes indicate that the Polish agriculture, despite major changes, is still to a large extent dispersed (Wigier, Darvasi 2012).

The income of the agricultural sector significantly increased after the accession to the EU. A sudden increase of income was noted in 2004 (over PLN (Polish zloty) 20 billion against less than 10 billion in 2002 and 2003), namely in the first year after Poland's accession to the EU and covering the national agriculture with the CAP income support system. In following years the dynamics of income growth was slowed down, yet a clear growing tendency was observed. In nominal prices their value in 2013 amounted to almost PLN 37 billion, as compared to less than PLN 10 billion in the pre-accession period (Figure 2). The growing income of the sector, combined with employment reduction, resulted in significant growth of income calculated per persons employed full time. In 2013 their amount was almost twice higher than in 2005 and almost twice as high compared with the pre-accession period. The share of subsidies and grants in income as a result of the implementation of direct payments and other measures investment aid schemes increased from 15 to more than 50 percent.

Figure 2. Income in the Polish agriculture and its dynamics in 2002-2013



Source: Authors' own calculation according to CSO data. Statistical yearbook of the Republic of Poland, www.stat.gov.pl, access date: 5 June 2015.

The integration with the EU created new conditions in Poland for the development of agriculture and food industry. Since 2002 the agro-food economy has been supported with the resources of programmes co-financed from the EU budget that penetrate and complement each other. These financial resources intended for agriculture development and paid from the EU budget may be divided into four groups according to their impact on growth and structural changes in agriculture:

entirely direct impact: modernisation of farms, early retirements and diversification of agricultural activity, setting up of young farmers;

entirely indirect impact: infrastructure, land drainage, land re-parcelling, afforestation, agri-environmental schemes, advisory services;

partly direct impact: direct payments, support for agricultural activity in less-favoured areas (LFA), market intervention expenditure, establishment of agricultural producer groups, establishment of micro-enterprises;
partly indirect impact: quality of life on rural areas, support to processing industry, PHARE programmes, LEADER programme, village renewal, training, technical assistance.
The EU funds had a significant share in the financing of transformations in agriculture until Poland's accession to the EU. The direct payments are the most common type of support; each year about 1.4 million of farmers use this form of support. The value of payments in the 2004-2013 period increased from ca. PLN 6 billion to PLN 14 billion per year. When calculated per one farm it reaches an average of ca. PLN 9 thousand, and this form of support is used by 87% of farms having an area of more than 1 ha. An equally important source of income (regardless of production, and only based on the farm's location) are payments for less-favoured areas (LFA). Each year these payments are granted to ca. 700 thousand farmers, i.e. half of those receiving direct payments. The land surface covered with LFA payments amounts to ca. 6.9 million ha. These payments are made to farmers on an annual basis. The manner of spending of the resources is not subject to settlement. Smaller farms usually allocate the granted payments to current needs and means of production (fuel, fertilisers), while the bigger ones also make investments. In the 2004-2013 period, the cumulative value of support for the agri-food sectors from three main sources of support, i.e. a grant from the national budget to Agricultural Social Insurance Fund , a grant from the national budget co-financing of the CAP, and payments from the EU budget, exceeded PLN 300 billion.
One of the noticeable effects of structural changes in the food sector is the agro-balance of foreign trade. Following years of stagnation or sluggish growth Polish foreign trade in agri-food products soared after EU accession. Previously a net importer of food products, Poland has become a net food exporter. In 2014 estimated export surplus amounted to about EUR 6 billion. The positive balance is generated by trade in products of the food industry, and the surplus is several times higher than deficit in agricultural trade (Figure 3). The share of the Polish agriculture in creating the added value following the accession to the EU shows a tendency to decrease. Currently it is at the level of 3-4%. At the same time, agriculture employs ca. 15% of the total number of employed people, which is indicative of low labour efficiency.

Figure 3 Polish foreign trade in agri-food products in 2004-2014 (EUR million)

Conclusion

After the Polish accession to the EU, major changes took place in the formulation and implementation of the agricultural policy. They consisted mainly in systematising the policy objectives and increasing the expenditure earmarked for financing of changes in agriculture

and rural areas. The inclusion of agricultural holdings in the CAP mechanisms contributed to the improvement in the income situation of most farmers. The fundamental significance for the increase in the level of the income of farms was held by subsidies (mainly in form of direct subsidies). The improvement in the competitiveness of agriculture is, however, dependent on the transformations of a structural nature (which precondition the improvement in the efficiency of utilising the factors of production) and the development of the whole national economy, especially in the context of the capacity for the creation of new jobs outside agriculture, also in the rural areas.

The structural changes taking place in the Polish agriculture, food industry and rural areas in the last decade became more dynamic Within the last decade there has taken place the dynamisation of structural changes occurring in Polish agriculture. As the most important should be recognised: a decrease in the number of farms with a simultaneous increase in the share taken by the largest farms; the decrease in employment in agriculture and the progressing concentration and specialisation of production. The size of the investment has increased noticeably, but their value still does not exceed the value of depreciation of fixed assets. The investments were mainly in machinery and to a much lesser extent in buildings and structures. The impact of individual CAP instruments is different. It ranges from the greatest impact – that of direct payments – to the slight significance of programmes supporting semi-subsistence farms or structural pension having only a minimal coverage. Combination of direct payments and cross-compliance requirements causes that this form of support plays the key role in providing basic public goods through sustainable agricultural land management (maintaining environmental quality of the landscape, biodiversity, access to water, climate stability and air quality) or public goods not related to the environment (activity in rural areas).

INNOVATION IN THE SECTOR OF FOOD AND BEVERAGE PRODUCTION ON THE POLISH EXAMPLE

Robert JADACH*, Stanisław MINTA

Abstract

Innovation is the basis of smart and sustainable economic growth through increasing production and distribution efficiency or introducing new products. In Europe, especially in the EU Member States, innovation can play a significant role in a dynamic growth of knowledge-based economy which is capable of creating new jobs, supports an increase in labour productivity and ensures social cohesion. Generally innovations in enterprises can rely on improvements of product, marketing or organizational. Over the past 20 years, the Polish food and beverage sector has undergone significant transformation. It is one of the sectors of the economy, which soon was reborn after the crisis related to the political transformation, becoming the important stimulator of economic growth. Through technological developments, technological, and organizational sector Poland came to the forefront of modern and innovative European food producers. This study shows how is changed level of innovation in Polish sector of food and beverage production in years 1998-2013. Source data for the research were secondary. Aim of the study was to determine the dynamics of changes in innovation in the food and beverage sector and comparing the level of innovation towards other industries in Poland. Obtained results showed increasing amount of innovation in the Polish food and beverage sector, but compare to other industries remained at a lower level.
Keywords: *innovation, food, beverage, innovation process*.

Introduction

The major sources of competitiveness of Polish food sector should include price advantage, which has been preserved in spite of price convergence process. Low price is the advantage of Polish food producers, but they will shrink, so it is necessary to implement such projects, which promote the formation of a sustainable advantage over its competitors. One of the factors thanks to which Polish food business operators may gain competitiveness is innovation. Innovation is an important element that allows the company to adapt to changing environmental conditions. Innovations decide on the pace and directions of development of the company. Innovations in the food sector are needed, of course, financial resources which provides the European Union. Polish food manufacturers use different programs to support innovation and reform in the company. Innovation in the food sector are needed, of course, financial resources which provides the European Union. Polish food manufacturers use different programs to support innovation and reform in the company. This program is called the Innovative Economy. The Programme Innovative Economy is one of six national programmes under National Strategic Reference Framework, which are co-financed from EU resources. This programme is directed mostly to all entrepreneurs who want to implement innovative projects connected with research and development, modern technologies, investments of high importance for the economy or implementation and use of information and communication technologies. The Programme aims at supporting innovativeness in its broad sense. This aid comprises both direct support for entrepreneurs, business support institutions and scientific entities providing entrepreneurs with high quality services, and

systemic support, ensuring development of institutional environment of innovative enterprises.

Materials and methods

The primary objective of this article is to present the issues related to innovation activities of food industry companies, as well as presenting some of its effects. In the paper I presented the percentage of food industry companies, which examined years have introduced innovations. The effects of innovative activities presented using data from the Central Statistical Office of Poland. Data on innovation in the food sector which took into account from the years 1998-2013. Cyclical surveys on innovation activities of enterprises, conducted in accordance with a standard, international methodology presented in Oslo Manual prepared under the aegis OECD and Eurostat, are, inter alia, the key source of information included in a scoreboard with results of innovation surveys in which the European Commission collected 25 indicators for monitoring the Innovation Union. The thematic section presented in the publication concerns innovation activities of innovation active enterprises as well as process and product innovative enterprises. The implementation of organisational and marketing innovations are also included in many breakdowns.

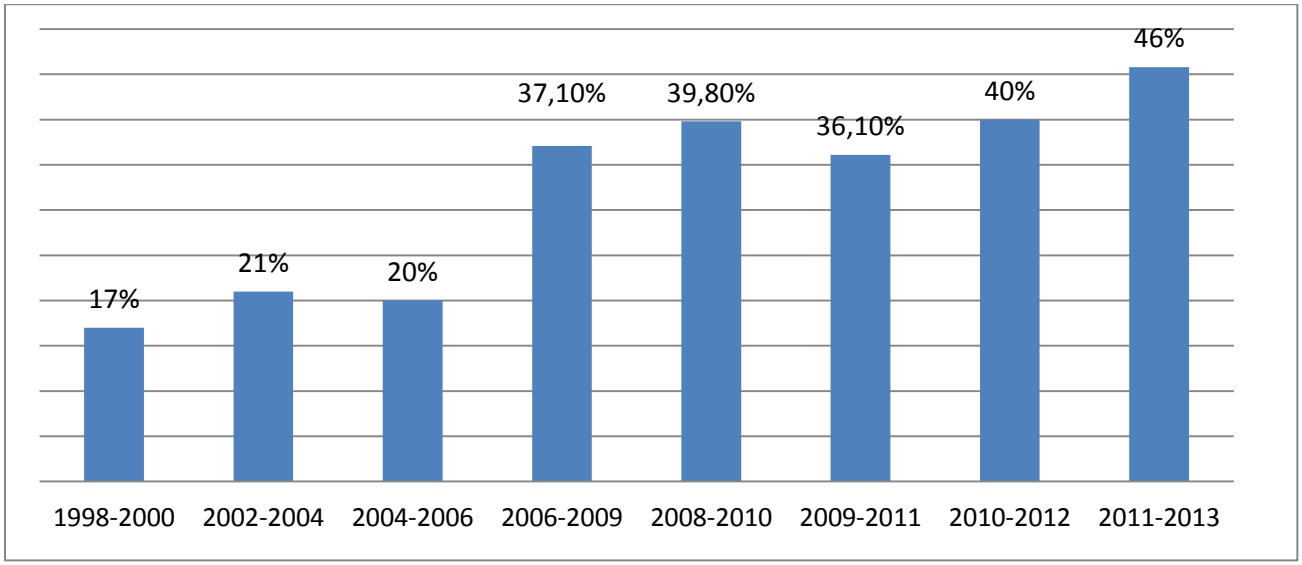

Figure 1. Industrial innovation active enterprises in the years 1998 - 2013 by NACE divisions - Manufacture of food products and beverages*
*source of information: Central Statistical Office of Poland

In the years 1998-2013 showed an increase in innovative activity of enterprises especially after the Polish accession to the European Union. Poland received massive financial support for the introduction of innovation in enterprises. Innovative activities embrace the activities of a scientific, technical, organizational, financial and commercial. As a result, Polish exports have increased in recent years. In 2009-2011 we observed a slight decrease in innovative activity of enterprises was caused by the economic crisis which also touch and Poland.

Results and discussion

In 2012, the value of production sold of the sector (excluding tax on goods and services and excise duties) amounted to 204.6 billion zł. (51,15 billion €). This corresponded to 21.4% of the sold manufacturing (which is one of the higher results in the European Union), and 18% of total industry sales. The sector employed 386 thousand people, equivalent to 18.9% of employees in the manufacturing sector and 15.6% of those employed in the industry. As you can see, then, the food sector is crucial for the Polish economy.

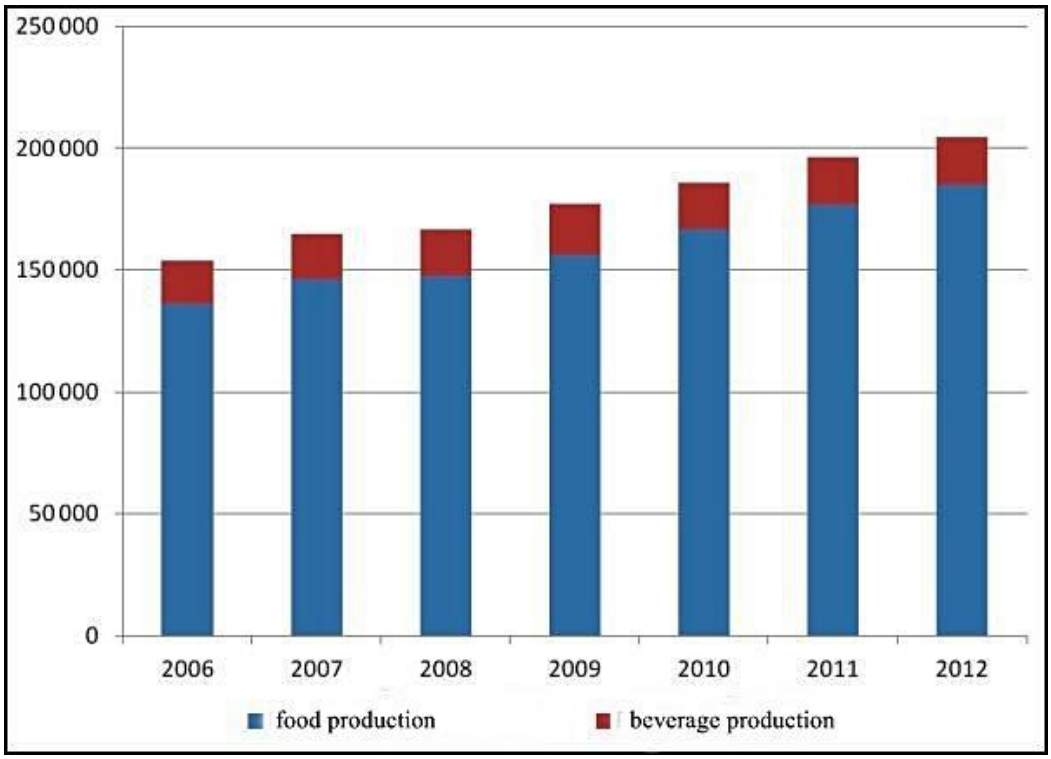

Figure 2. Value of production sold Polish food sector in the years 2006-2012. Own calculations *source of information: Central Statistical Office of Poland

Over the past 20 years, the Polish food sector has undergone significant transformation. It is one of the sectors of the economy, which soon was reborn after the crisis related to the political transformation, becoming the important stimulator of economic growth. Through technological developments, technological, and organizational sector Poland came to the forefront of modern and innovative European food producers. The result is a successful export of Polish enterprises. A major factor accelerating development of the sector was the Polish accession to the European Union in 2004. The reason was the large number of grants that allowed adaptation of plants to the standards required in the EU and innovation. The opening of European markets led to an increase in exports of agri-food products. Economic integration also meant the implementation in Poland of numerous foreign investments, which are an important source of innovation for the food industry.

Since 2004, Polish food exports increased more than fivefold, and trade surplus - thirteen. Despite the Russian embargo value of Polish food exports in 2014 to 2013 years increased by 4.5 percent. to 21.3 billion euros Of great importance they are also the Asian markets, as well as the Arab countries and North Africa.

Conclusion

Today, Poland is the eighth largest food exporter among the countries of the European Union. Our export hit are apples and mushrooms. We are the largest manufacturer in the European Union. These results would not be possible to achieve without strenuous effort to Polish farmers and exporters. These results would not be possible to achieve without strenuous effort to Polish farmers and exporters as well as innovation thanks to which Polish food has become competitive on the European market. Implementation of innovation has reduced manufacturing costs while introducing new products and technologies made Polish food is tasty, safe and competitively priced. Former President of the European Commission Romano

Prodi has stated that Bosnia and Herzegovina has a chance of joining the EU soon after Croatia, but it is entirely dependent on the country's progress. In the future, perhaps Bosnia and Herzegovina will be able to use funds from the European Union in this country because it is the potential similarly to Poland

COFFEE COOPERATIVES PROMOTING PEACEBUILDING AND SOCIO-ECONOMIC DEVELOPMENT OF FARMERS IN HUYE DISTRICT, SOUTHERN RWANDA

Gisaro M Ya-BITITI[1]*, Philippe LEBAILLY[3], Deo MBONYINKEBE[2]

[1]University of Rwanda, Rwanda
[2]Independent University of Kigali, Rwanda
[3]University of Liège, Gembloux Agro Bio Tech, Belgium

Abstract

Cooperative organisations play an important role in the peacebuilding efforts undertaken in the wake of the Rwanda genocide in1994. The genocide tore apart and destroyed large parts of the country's socio-economic and institutional foundations, its consequences are still evident. Coffee is the main source of income for approximatively 500.000 households. The paper aimed to analyze the impact of coffee cooperatives and the coffee washing stations in the peacebuilding socio-economic changes of coffee farmer's members in Huye District, Southern Province of Rwanda. A research surveyed selected 70 small coffee farmers from 3 cooperatives to measure socio-economic development of coffee washing stations on the growers. Results reveal that cooperatives increase production and improve the socio-economic households' income (86.5%). Jobs are created for women and girls especially during the harvesting and the coffee processing (98.7%). When farmers are working together, a synergy is created among them, by disucussion, exchanging experiences, which avoide discrimination, conflict, division between antagonist ethnic groups Hutu and Tutsi (67.1%). Results reveal that coffee cooperatives promote a spirit of understanding each other and the tolerance between farmers (72.3%). Cooperatives provide loans to the members through the "rotating funds: *Ibimina*". They also educate members through vocational trainings by enhancing and empowering farmers especially women and girls (97.1%). This is evidenced by the provision of adequate shelter, the observation of human rights, access to the medical insurance, school fees for children, undertaking entrepreneurial activities, unity and reconciliation between members, participating in the household's incomes allocation. Cooperatives uses various strategies in peacebuilding such as working together to construct new schools and houses, land inheritance for women, clubs for peacebuilding and visiting each others (74.3%).

Keywords: *coffee co-operative, coffee washing station, peace-building, socio-economic development, Rwanda.*

Introduction

The 1994 genocide in Rwanda tore apart and destroyed large parts of the country's socio-economic and institutional foundations, and its severe consequences are still evident. Cooperative organisations serve as a means to strengthen social cohesion and facilitate reconciliation and recovery the values of Rwandans especially while farmers are cultivating together or when they are treating their coffee cherries (Gisaro, 2013). Rwanda's economy is largely agriculture based. This sector provides above 61% of export revenues, principaly from coffee and tea (NBR, 2014). There are about 800 millions coffee plantations belonging to 500,000 households producers in Rwanda (OCIR-Café, 2013, Ngabitsinze, 2012). As the years go by, coffee production steadily decreased both in quantity and quality. National strategies focused on liberalisation of the coffee value-chain started in 1998, strongly invested in creation of Coffee Washing Stations (CWS) accross coffee productive areas and grouping

coffee growers into cooperatives. The purpose was to produce a fully washed coffee, high quality coffee for international market which is able to offer better income. The CWS were put in place and are justified by socio-economic advantages and services offered by coffee cooperatives. These advantages include the increase of coffee prices and revenues, access to proximity extension services, creation of jobs, access to health services, access to education,credit and better resettlement, markets amongst others. Based on the aforementioned statements, the following research questions were formulated: (i) Do the CWS and the cooperatives activities have significant impacts on the welfare of coffee growers? (ii) To what extent coffee cooperatives through their CWS improved peacebuilding and the socio-economic development of coffee producers?

Materials and Methods

Data were obtained from a field survey in Huye coffee cooperatives both based in Huye District in the mountain hills of Huye, Southern Province of Rwanda, from March to June 2014 during the coffee processing. The cooperatives AKM, HMC and KOAKAKA where taken into our study. All primary and secondary sources of data were used. Primary data were collected through interview, questionnaire and focus-group discussions. Interviews were conducted with management committee of the selected multi-purpose cooperatives and CWS. The questionnaire was administered with randomly selected 70 members of the selected coffee cooperative organizations. Guided by a purposive selection of respondents and based on a certain number of criteria previously set: (i) to be a coffee grower, having a minimum of 150 coffee trees with an experience of more than 5 years in coffee farming system; (ii) to prove a seniority of at least 5 years in the cooperative (iii) to have 3 dependent persons at the time of the investigations; (iv) to show evidence of an active involvement with the cooperative and to deliver the cherries to a CWS; (v) to be member of one of peace clubs at the cooperative level and to be an active participant in it is activities. The three cooperatives counted for a total of 2,811 members, of which 1,353 were from AKM, 142 from HMC and 1,316 from KOAKAKA. Interviews were done from 12 key informants especially the managers of the CWS and the cooperatives. The collected data was analyzed using descriptive statistics such as mean and percentages with regard to the different socio-economic variables provided by CWS and cooperatives.

Results and discussion

Economic benefits of the CWS and the cooperatives

The liberalization of the coffee sector has had a number of positive effects. The socio-economic impacts of the CWS and the cooperatives on the producers follow from the advantages and services offered to the coffee growers. Farmers have an incentive, increased income, to shift some production from semi-washed to fully washed coffee. Results reveal that a number of direct financial benefits, such as increased prices received for their cherries, employment opportunities, and better and easier access to loans, particularly access to credit

to purchase inputs such as fertilizer and agricultural inputs. Farmers also noted that their families are now better fed, that they are able to hire laborers, that they have help with marketing and sales, and that they receive some medicines for free. Farmers also reported that they benefit from access to coffee bicycles to transport coffee cherries and other productions. Less directly, farmers stated that they benefit from socializing with and learning from others. They felt their work was now easier (they no longer process cherries at home) and that they could spend time on other home activities. The prices given to the producer evolved irregularly with an average of 362.2Rwandan francs (Rwf) per kilo (0.4US$) against 460 to 500Rwf/kg that the CWS offered the speculative trader. (Figure1).

Figure 3. Prices of green coffee on local and international markets (2002-2012).

The treatment of coffee has valorized its quality through sellings (from 450Rwf/kg in2002 to 1.100Rwf/kg in 2010). With the presence of the CWS the producers received almost 3 times the prices of coffee on the local market. On the international market, the prices went up progressively. From 2002 until 2010, the mean prices was 2.71 times higher than local ones, with two extremes to the rise and to the decrease in 2006 (3.84 times passing from 527 to 2.022Rwf) and in 2005 (902 against 1.910Rwf, 2.11 times the local prices).

The Coffee Washing Station: source of jobs in the rural areas

The functionning of the CWS come with the creation of jobs by employment of a permanent staff and technical support, mainly during the harvesting season. The manpower teams (daily, occasional and seasonal) are reinforced every campaign in the activities of picking, transportation, sorting, treatment, drying, storage and marketing of the green coffee. The created jobs contribute to sustain the income and the perspectives of future especially for the vulnerable groups. These are notably women, widows and most abandoned social populations (98.7%). They are often victims of the discrimination and do not have access to the non-agricultural jobs. The treatment of cherries valorized the women's activities (89.4%). Through their activities the CWS showed evidence of gender integration in their daily tasks during the coffee campaign. Thus, they are the good way to promote gender and to give voices to the women and girls in rural areas of Huye District.

The dynamism of micro-finance activities through CWS and cooperatives

In Rwanda, farming world and the coffee production were not judged attractive for the financial institutions, due to the lack of loan guarantee. The cooperatives accelerated the

emergence the micro-finance programs into funds mobilization. Thus, CAPEC[26] micro-finance opened in Maraba sustains the activities of small income generating projects for members. The monthly interest rate is from 1 to 1.5% according to the kind of activity. The guaranty is solidarity based on the relationships and the mutual confidence between the members, thus constituting a pledge of guarantee to obtain the credit. The possession of a bank account number became obligatory to all members for the payment. Having a bank account has an economic and social advantage: the culture of saving, a sign of social elevation, providing a better vision, a change of mindset. Savings enhance the self-confidence, a sign of group encouragement in the time of taking loan. These activities are increasing their daily income.

Coffee Washing Station: factor of technological transfer in the farming world

The setting up of the CWS by the cooperatives introduced new technologies. Additional facilities have been created in the domains of mini-hydroelectric power stations and the tele-center that have been placed exclusively at disposal by cooperatives in favour of their members. The tele-center of AKM (Kizi) helps the community to reach the new fashions of modern communication, to facilitate access to the outside world like searching of new outlets for their coffee. It participates in the trainings and offer internet-café, the tele-show as well as a canteen for the inhabitants of the zone. A lot of activities are exercised there, notably the movies projected on the maintenance and the follow-up of coffee, the domestic agriculture, the market gardening, the domestic scheduling, hygiene, the community health, the first-aid, the basic literacy. The protection of the environment, the balanced food, the struggle against the sexually transferable illnesses such HIV-AIDS, the struggle against the ethnic discrimination, the prevention of conflicts, the unity and reconciliation, children rights are also developed in the tele-center.

The contribution of the CWS to the balance of the payments

In 2000 there were only two washing stations in the country (Nkora and Masaka,) neither of which worked, actually there are now 230. This has resulted in 32% increase in production of fully washed coffee. Coffee prices for fully washed increased from 1.6 US$/kg in 2003 to 3.7 US$/kg in 2013 while in the same period ordinary green coffee prices increased from 1.24 US$/kg to 2.6 US$/kg. The activities of the CWS and cooperatives in relation with the export of fully washed coffee brought significant foreign currencies in the country. Thus, the penetration of the foreign markets is strongly remunerative. The contribution to the commercial balance intensifies while reducing the strong dependency vis-a-vis the only one semi-washed product. These changes have important effects on the ground in Rwanda. Coffee continues to generate important export revenue for the country. While figures vary year-to-year, the country’s coffee exports stand at 19,573 metric tons in 2014 generating over US$57 million in revenue, a leap from US$38 million provided in 1995. The generated revenue increased the national economy and has contributed in the development of the country and the coffee farmers especially (NAEB, 2013, Ngabitsinze, 2012, Boudreaux, 2011).

Coffee Washing Station and its effects on the environment

The construction and the functionning of a CWS either improve or destroy the environmental conditions of its perimeter. The waste water released after fermentation in the environment

[26] Caisse Populaire d’Epargne et de Crédit.

constitute source of pollution. The solid organic matters constituting the pulp of coffee are decomposed specially designed pits. After decomposition, the pulp can be used as a fertilizer, rich in mineral elements, as it is the case in Maraba. In Karaba, on the other hand, the waste waters and the pulps of the Karambi station are not treated, recycled and poured in the pits that are destined to them. Therefore, they pollute the environment of the riparian populations and the food crops localized on the watershed of Kibingo river near Karambi for example. The management of a CWS should plan specific systems to control these sources of pollution efficiently, while treating the pulps of coffee useful for fertilizing farms. The results are significant in terms of essential compost manure for agriculture (65.3%).

Direct effects of the Coffee Washing Station

The CWS helped to produce a high quality coffee marketed at highly competitive prices. It improved the livelihood of the producers through monetarization of the farming economy as well as the technology transfer. They facilitate the extension actions in favour of coffee innovations through trainings to the members. Other advantages include (i) Giving chemical fertilizer (24.9 %), 22.8% for pesticides, insecticides, herbicides 22.4% provide seeds; (ii) The reduction in labour demands required in coffee processing activities for the vulnerable groups: households headed by children, widows and aged people (98.2%); (iii) The creation of jobs especially for women; (iv) The facilitation of the access to micro-credits (21.9%); (v) The access to electiricity and agri-inputs, the income generated by the sales of coffee which accumulate the capital and translated into signs of wealth within the households (76.5%).

Socio-economic advantages of the coffee cooperatives

Economic advantages

The coffee growers adhere with the purpose to protect their interests, to find satisfaction of their needs: better conditions, pecuniary advantages and various other services. Others adhere to get the facilities and agricultural inputs offered through the cooperative. Consequently, the members desire to acquire strength and the necessary synergy to improve their well-being.

Increase of income and purchasing power

The speciality coffee industry in Rwanda, has helped to change lives of the people. By growing better quality coffee, producers are earnings more. Higher incomes benefit farmers, their families, and their communities in a variety of ways: farmers can improve a home, pay medical expenses or school fees, or better ensure food security. When cooperatives earn a profit this allows them to hire workers, purchase capital, and support community projects such as improved schools. The cooperative helps to increase the incomes of its members. The producers are motivated and invest more in the production of high quality. The remunerative prices serve to improve their living conditions. The cooperative allows to the members to access inputs and agricultural facilities and to develop business spirit.

Negotiation power

The CWS through the cooperatives acquired a real power of negotiation with the local authorities, the charity organisations, and the rural development projects nearby. Some financial institutions are henceforth present in the farming zones of Maraba and Karaba since

2003, notably the Popular Bank of Rwanda, the micro-finance institutions, and the SACCO[27]. Belonging to a cooperative and participating actively in its activities, constitute a pledge of reliability and durability vis-a-vis the direct beneficiaries and it is supported by internal and external partners. The CWS and the cooperatives are therefore considered like important vectors and indispensable engines for the development of the farming world in the zone under survey. These organizations are important business entities in enhancing the economic condition of their members by improving their bargaining power and income.

Peacebuilding among social advantages of the cooperative

The cooperative create strong social ties which constitute a very important social capital for the members. These ties concern style of the social cohesion, mutual help, interrelations, courage, confidence, trainings, entrepreneurship, auto-creation, and enterprise mindset, amongst other. The adherence to the cooperative permitted a full bloom of the members while giving them the opportunity to exchange between them, to put forward themselves in the society and to assume their responsibilities. Often, these actors undertake in common social type activities (e.g. IBIMINA[28]) and economic activities outside the framework of their cooperatives. The cooperative helps also to tighten the ties of solidarity, involving often other family's members (58.4%). The cooperative reinforces the unity and reconciliation of the members torn and divided by 1994 genocide without distinction of sex, ethnic group, origin, religion, etc. (66.7%). The cooperative taught them to forgive mutually in order to reinforce the unit and the reconciliation (61.5%). Working together, farmers have new opportunities to interact with other. These repeated interactions may be helping to lessen the sense of ethnic distance among members of Rwandan’s society (56.1%).

Access to credit through cooperative

Source of credits and their use by the members

The loan constitutes an advantage for the members to join the cooperative. 87.8% of the respondents want to acquire credit against 12.2% that abstain themselves due to lack of repayment means. Most interviewees (91.6%) prefer to solicit the credit cash against 6.1% who wish to have phytosanitary products, and 2.3% agricultural facilities. The credit serve to cover the urgent needs: soldering, the purchase of seeds, the school supplies, emergencies such as illness. The guarantee is bound and is related to the harvest and the personality of the credit seeker. Cooperative helps member to benefit of fertilizers through the National Agricultural Export Development Board by refund during the harvesting period.

Table 2. Prices of fertilisers in Kizi/Maraba Market, June 2014(in Rwf/Kg).

Types of fertilizer	Coffee growers	Quantity (Kg)	(%) of coffee growers	Mean price/Kg	Total cost (Rwf)
Urea	5	60	6.25	490	29,400
DAP	3	36	3.75	600	21,600
NPK	72	1,119	90.00	560	62,640
Organic matter	80	984,727	100	-	-
Total	**80**		**100**		**677,640**

Source: Our calculations from field survey, June 2014.

[27] Saving and Credit Co-operative.
[28] IBIMINA : Tontines established by peasants, functioning as farmer’s association groups.

Factors hindering the coffee growers access to credits

The factors that limit the access to the credit are generally the uncertainty of the production (31.2%), the bad design of the project (20.0%), the lack of guarantee (17.5%), the high administrative cost (15.0%), the complicated procedures (8.8%), and the ignorance on the procedures to access the credits (7.5%). The cooperative prepared their members on how to access to the credit, contrary to non-members that solicit credits from the nearby banks.To overcome the blockages of access to the credit, the cooperative acts as an intermediary between the grower and the bank who bestows the credit. It plays the hinge role in favour of the members. The repayments are made by the cooperative, the organization of relay that subtracts the amount of the credit when the coffee cherries are delivered (Fig. 2).

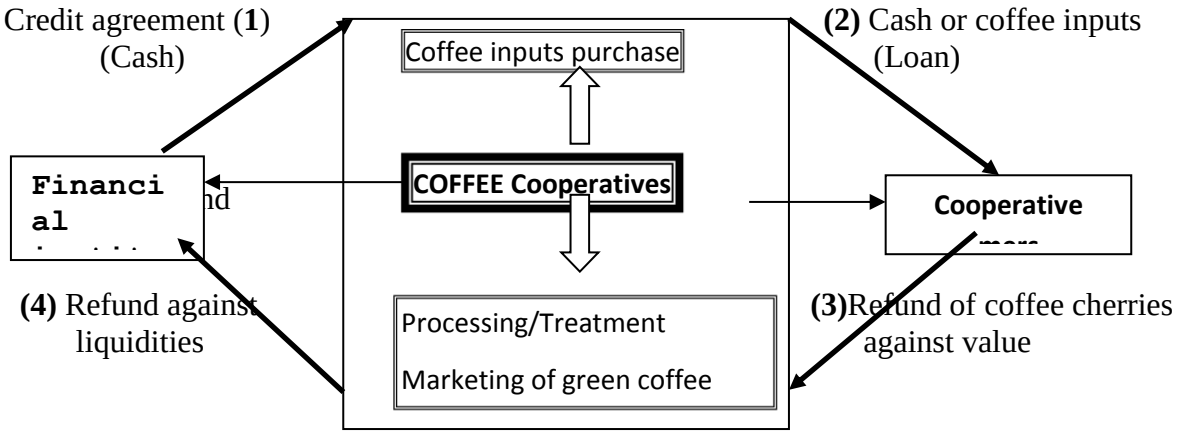

Figure 2. Channels of the demand and repayment of the credit through the cooperative.

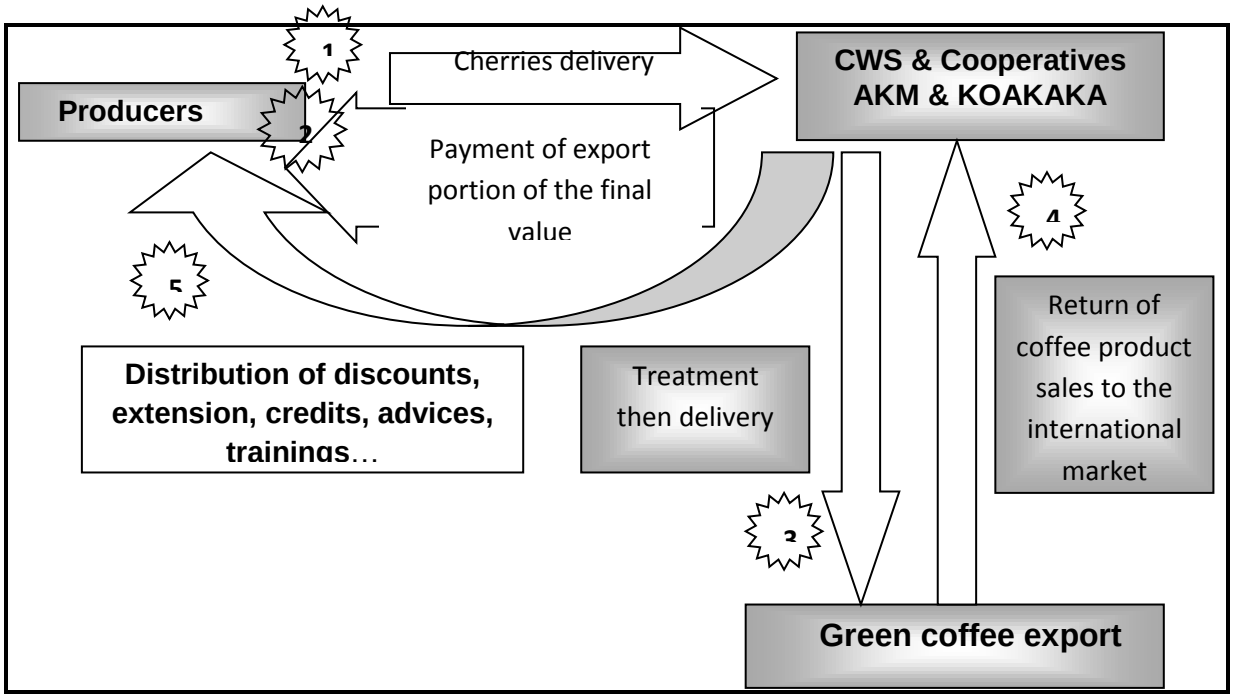

Figure 3. Process of sale and repayment of coffee through the cooperative.

The producer remains the main link in the production of coffee in Rwanda. Organized into cooperative, it is a means to benefit from the credit and other technical supports from NAEB. The producer delivering his cherries, receives part of its sale from the cooperative.

Conclusion

The coffee cooperatives and it is coffee washing stations has opened the perspectives of new jobs for the most vulnerable groups benefitting from no aid while especially fighting against poverty and the rural urban exodus of the young people. The jobs have provided income which has helped growers to improve their welfare which has the correlation to promote peacebuilding among members's families. Coffee became a visa to access cash credits, inputs or agricultural facilities. Through the credit-coffee system the coffee growers succeeded to pay eduction for their children. They benefit from a socio-economic advantages and services. However, the low level of education of the producers is a challenge to the growth of the cooperatives. The CWS and the cooperatives count a lot on outside supports (donnors and the state) instead of taking themselves in charge. Thus, they stay fragile without autonomy and because of their dependence. They are strongly competited by the private operators who buy, treat and export also the fully washed coffee. To guarantee the sustainability of their actions and the development of their members, the CWS and the cooperatives should position themselves better in order to be a lot more competitive on the market.

Acknowledgement

This paper is part of a PhD research presented at the University of Liège (Belgium) in May 2013 under the support of Wallonie Bruxelles International (WBI). I am very grateful to WBI for the financial support. I thank my supervisor Professor Philippe Lebailly, Head of Economy and Rural Development Unit at Gembloux Agro-Bio Tech, University of Liège, Belgium, for his assistance in necessary logistic requirements to attend the Agricultural Symosium 2015, held in Bosnia from 15-18 October 2015.

Abstract

The main objective of this study was to investigate the obstacles facing the Extension Workers (EWs) during their field work in the Kingdom of Saudi Arabia (KSA). The EWs' suggestions on how to face each obstacle. The study covered all the 67 EWs working in four Regions, namely: Al-Qassim, Najran, Asir and Jizan. Frequencies, percentages and averages were used for data presentation and analysis.

The most important results:

- The most important organizational and administrative obstacles facing the EWs, according to the average means were: insufficient financial incentives for extension worker; lack of allowances for the nature of extension work, insufficient physical facilities; small number of specialists in agricultural extension; incentives are not proportionate with performance.
- The most important technical and, production obstacles facing the EWs, according to the average means were: unavailability of farmers in their farms during the working hours, non-Saudi laborers are responsible of farms, relatively large number of farms are under the responsibility of EWs, inconvenient conditions of extension work, and overfocusing on the agricultural, rather than educational services.
- The most important EWs' suggestions to overcome the obstacles facing extension work were as follows: providing and supporting allowances and incentives, Increasing the number of EWs, providing both material resources for the extension work, appointing newly graduated EWs, redistributing and identifying work responsibilities, clarifying the functions of each department and each staff member, providing allowances and incentives, supporting specialists for extension work, liberating EWs from administrative work.

Keywords: *Obstacles, Agricultural Extension Worker, Saudi Arabia*

Introduction

Agricultural extension agency in the Kingdom received particular attention by those in charge of the Ministry of Agriculture, including the provision of support and budgets required for work, in addition to support of the agency with the qualified extension staff of specialists and extension workers and providing the suitable training to them through the specialized training courses or delegation for higher scientific degrees in the field of agricultural extension. The agricultural guide is a key element of the extension agency because he undertakes several roles and duties. Therefore, all types of material and human support of the extension agency are valueless unless the extension workers are highly efficient and effective (Okley and Garforth, 1990). In consideration of the important role of the agriculture extension agency in the provinces and governorates of the Kingdom, and through the extension workers working close to farmers in the departments of agriculture affairs and agriculture directorates and branches that are about 13 agriculture affairs departments and 12 agriculture directorates, and about one hundred twenty agriculture branches, and the low number of academic researches on the key obstacles of agricultural extension, in addition to the fact that one of the

researchers is considered a key responsible for the agricultural extension on the central level of the ministry, so the problem of this research is summarized in definition of the key obstacles of agricultural extension and suggestions for addressing them in the Kingdom of Saudi Arabia.

The Arab Agricultural Development Organization (AADO) (2009) indicated in a study recently conducted by it in that a key obstacle that reduces the efficiency and effectiveness of work is the weak and lack of qualification of extension workers. El-Shafie and Emad (2009) indicated low number of extension workers who work close to farmers in Egypt. The study of Shaker and Al-Zaydi (2002) indicated that they key problems and difficulties that encounter the extension workers on setting the agricultural extension programs include the assignment of extension workers to works that are not in line with the nature of their work, and the weak coordination between the agricultural extension and agricultural development organizations, unclear job duties of extension workers, low training opportunities, work pressure on the extension worker over his capacities, limited opportunities of job promotion, some extension workers don't understand the planning measures and insufficient capacities of extension work. To overcome these problems, the researchers recommended to increase the opportunity of attending training programs, particularly in the field of planning of extension programs, and the extension workers' dedication to perform their extension roles and duties, supply of capabilities for implementation of the extension work plans, provision of the audio and visual extension aides, provision of material incentives of extension personnel, drawing attention to farmers' participation in planning of the extension programs.

The agricultural extension department in the Ministry of Agriculture, Kingdom of Saudi Arabia (MADAE) (2010) noted that the obstacles that encounter extension work in the Kingdom include the low number of technicians working in the general departments and directorates of agriculture, failure of extension worker to be dedicated to the extension work, lack of farmers' attention to the symposiums and meetings organized by the agricultural extension agency, need to qualification and training of extension workers and reliance on the theoretical and applied approach combined, farmers' lack of understanding of the role and importance of extension worker, agriculture farmers' lack of understanding of the Ministry's direction in respect of the farm affairs due to the farmers' lack of presence in their farms.

The primary objective of this research is to examine the key obstacles of agricultural extension works and the means of addressing them in the Kingdom of Saudi Arabia through the following secondary objectives:

Determination of the key administrative and technical obstacles of agricultural extension work in area of the research.

Exploring the personal, economic and social traits of the respondents, including: age, place of residency and establishment, job title, education, job grade, salary, major, years of experience in agricultural work and extension, period of study of the extension courses by the respondents and its sufficiency, the respondents' enrollment in training programs, job satisfaction, extension workers motivation for completion in the area of the research.

Identification of the suggestions of extension workers on who to overcome the obstacles that encounter them.

Material and Methods

This study was conducted in the areas of Qassim, Assir, Jazan and Najran in the Kingdom of Saudi Arabia, due to their agricultural importance and position in the Kingdom. These areas meet the suitable agricultural capacities that make them the best areas of the Kingdom in terms of agriculture such as water, environment and lands suitable for agriculture. In addition, these areas found attention and care of the state. Several establishments and agricultural branches of government were established. Four agricultural affairs departments were

established with forty branched. The agricultural loans by the Agricultural Development Fund for farmers in the four areas in 2007/2008 were approximately SAR 277 million that represent about 27% of the loans provided in all regions of Saudi Arabia (Saudi Arabian Agricultural Bank, 2007/2008: p. 25). The research community includes extension workers who work in Qassim, Assir, Najran and Jazan (n= 67).

Procedural definition of the study:

Extension worker: every employee who works in the section of agricultural extension in the general departments and directorates or agricultural branches, and he assumes the extension duties whether the job title is specialist, researcher, engineer, agricultural technician or any other nomination.

Job satisfaction: The overall attitude of extension workers with their work. It is measured through 23 sentences.

Motivation for achievement: This is set of factors that motivate the individual to be good at his work, and it is measured through 23 sentences.

Obstacles: these are the difficulties and problems that encounter the extension work from the extension workers' perspective.

Data Collection:

The researcher depended on the post questionnaire as a means for data collection, and respondents were followed up through the telephone calls to complete or confirm some data. The questionnaire included many questions that serve the objectives of the research. The questionnaire form contains four sections. Section one is related to the personal, economic, social and job properties of the extension workers, such as: age, place of birth, place of residence, education, specialization, job title, grade, years of experience in agricultural work, years of experience in extension work, pre-service training andpost-service training. Section two is related to the scales of job satisfaction and motivation for achievement. Section three handles the obstacles that encounter the extension workers during the performance of their extension duties and how to overcome them from their perspective.

The repetitions, percentages and arithmetic means were used to present and analyze the data.

Results and dicsusion

Impediments of agricultural extension work and proposed solutions: Data of the study reveal many problems and difficulties, including technical, administrative, production and organizational problems and difficulties that encounter the respondent extension workers during their undertaking of the extension roles and duties. The results show that there are problems and difficulties related to factors out of the extension regulation that may be related to social and environmental sides.

the key organizational and administrative obstacles that encounter extension workers in the area of the research according to the arithmetic means are: low material incentives of the extension worker, lack of any cost of living allowance, low material capabilities in the extension system, lack of extension specialists in the extension system. The incentives provided to extension workers are not related to the performance level, by arithmetic means of 2.75, 2.73, 2.61, 2.51 and 2.47 respectively. These results assure the importance and effect of the factors related to the material sides for the respondent extension workers. The respondents considered these sides are the key obstacles that reduce the efficiency and effectiveness of agricultural extension work. These results may be attributed to the fact that officials in the Ministry of agriculture don't understand the rule and importance of the extension worker's work. Unlike their colleagues in the other government sectors that provide many incentives and allowances that may constitute 25-50% of salary, no incentives or allowances are allocated to them. In addition, it can be interpreted based on that the ministry's system doesn't

differentiate the white collars and blue collars under the hard weather and topography conditions. In addition, the increase of income has become a key matter that any employee seeks under the high inflation and rise of the costs of living in the Kingdom of Saudi Arabia.
The least important organizational and administrative obstacles from the respondent extension workers are: "strategy of extension work in the ministry is indefinite", "responsibilities and duties are unclear and indefinite", "double supervision of extension workers", "multiplicity and conflict of instructions given to the extension worker", "unclear of concept and objectives of extension work of extension workers", by arithmetic means of 1.76, 1.75, 1.75, 1.71 and 1.62. The low importance of these obstacles, from the perspective of respondents, is due to their satisfaction with the directions of the Ministry of Agriculture to restructure and organize the agricultural extension system on all administrative levels in the Kingdom, in addition to their conviction with the possible control of these administrative and organizational obstacles.
The key technical and production obstacles that encounter the extension workers in the area of the research, according to the arithmetic means, include: "farmers are not present in their farms during the official work hours", "it is the expatriate workers who assume the affairs of agriculture", "large number of farms under responsibility of the extension worker", "work conditions are not suitable to the job requirements" and "focus on the agricultural, not educational, services", by arithmetic means of 2.69, 2.67, 2.41, 2.33 and 2.33, respectively.
Moreover, the least important technical and production obstacles from the respondent extension workers' perspective are: "low attention to the evaluation and follow up of extension programs", "work out of the specialization", "there is no implementation plan to apply and achieve the strategy and purposes of agricultural extension", "unclear extension duties and tasks performed by the extension worker", "farmers' lack of appreciation to the extension worker", with arithmetic means of 2.10, 1.95, 1.89, 1.73 and 1.70, respectively. These results confirm the necessary attention to all obstacles without focusing on one obstacle. Importance of these obstacles may vary in accordance with the economic and psychological conditions of the extension workers who work in the agricultural extension system.

Suggested solutions for the obstacles that encounter the agricultural extension work:

The key solution suggested by the respondents to the obstacles that encounter the extension work include: support and supply of material incentives (mentioned by about 36% of them), followed by the increase of the number of extension workers (about 31%) and supply of material capacities, increase of the number of extension workers/ appointment of new extension workers (about 27% for each solution), coordination with research centers (25%), supply of the required work facilities, increase of the number of extension workers (about 23% for each), distribution and definition of the work and responsibilities, indication of the duties of every section and every employee (about 22% for each), supply of incentives and allowances, support of the extension staff with specialists,. Dedication of the extension worker to the extension work (about 20% for each).
The agricultural extension staff can be expected to reach satisfactory levels for those in charge of the Ministry of Agriculture whenever these solutions are considered in terms of the importance of implementing them in reality, and belief of the officials in the Ministry of agriculture with all its sectors that the extension services and agricultural extension work are the key works on which the Ministry shall focus, because it is the means for promotion of agriculture in the Kingdom of Saudi Arabia.

Based on the results of this study, some recommendations can be suggested to contribute alleviate or eradicate the obstacles that encounter the extension work in the Kingdom of Saudi Arabia as follows:

Holding training programs in the different fields of agricultural extension to bridge the knowledge and skill gap in the extension workers. It is preferable to hold these courses for the new entrants to the extension service and the extension workers who are actually in service.

The job description and definition of the duties and competences of workers in the agricultural extension agency in the way that guarantees the increase of efficiency and effectiveness of extension work.

Fixing and releasing suitable material allowances and incentives to extension workers who work in the field.

Creating the extension worker ‘s job within the jobs of those working in the agricultural extension agency because the title “extension worker” doesn’t exist in the Kingdom.

Observe the scientific and social properties of the extension worker such as the place of establishment, residency, qualification and specialization of agricultural extension on the appointment of the extension agency.

Increase the material and human capacities of the agricultural extension staff.

Increasing coordination and cooperation with the professors of agricultural extension in universities so that they assume the consulting role in relation to the extension work and its development.

BUSINESS NETWORKING - CONDITION TO INCREASE INNOVATION IN AGROSECTOR OF SERBIA

Biljana GRUJIĆ*, Vesna PARAUŠIĆ, Nataša KLJAJIĆ

Institute of Agricultural Economics, Belgrade, Serbia
*Corresponding author: biljana_g@iep.bg.ac.rs

Abstract

The paper emphasizes the importance of business networking agricultural enterprises, whereby creating favorable conditions for their business and achieve a positive operating result. By combining can create new resources which are difficult to copy, and so pooled funds contributions and creating greater value of the final product. The paper points to some forms of business networks (business incubators, cooperatives, clusters), noting and their characteristics. In Serbia, the largest number of clusters are formed in the area of agriculture and food industry. The paper analyzes the definition of business networks, the types of business networks and how they manifest in the agricultural sector, or whether the population is willing to accept changes or continue to believe that the problem is unsolvable nature. Then, provided definitions of forms of business networks of the respective authors and have been isolated associations that are important for agrosector of Serbia. The aim is to determine the degree of crosslinking of agriculture in theory and practice, a willingness distrustful population and businesses to come together to bring about change in agriculture, so that in the future time will improve better image of national agriculture and complete economy. Research methods are based on search literature and web sites that highlight the importance of innovation and business networking in agriculture.

Keywords: *business networking, clusters, innovations, agrosector.*

Introduction

Association of producers and their joint appearance in the market encourages innovations in the agricultural sector, because only joint forces could create a favorable business environment for the production, processing and marketing of agricultural products, with constant innovation of the whole production and manufacturing process.

Stefanović et al. (2012) point out that it is important to make a distinction between the concept of invention (scientific or technical discovery, and always are linked with creation) and innovation (a new way of putting old and new ideas to realization). You should then approach the planning opportunities to some innovative ideas are realized by pooling agricultural producers, because the formation of business networks can lead to financial support of the Government of Serbia. More specifically, the Ministry of Commerce in December 2006 has done the program for the development of business incubators and clusters in the Republic of Serbia 2007-2010 in order to allow all producers in Serbia stimulate the association.

Studies in developed countries show that for small and medium enterprises a key factor in improving innovative capacity of involvement in different types of networks, especially clusters. The efficiency of activities and processes that are implemented in the network increases the chance that the company successfully used the opportunity to acquire new knowledge and its transfer through the network. Business incubators, cooperatives and clusters are some forms of business networking companies and agricultural producers. The common characteristic of these business networks is cooperation and connection of all member states. The largest number of formed clusters is in agriculture and the food industry.

Materials and methods

Research paper analyzes the possibilities of increasing innovation of the agricultural sector in Serbia, which, among other things, can realize business networking and association of farmers. This paper consists three parts. The first part discusses the definition of business networks by many important authors, as well as possible reasons association of farmers in the group. The second section discusses the types of business networks of agricultural sector in Serbia, where appropriate: business incubators, cooperatives and clusters. The third part gives concrete examples of business networks in the agricultural sector in Serbia from all the above forms of association. In the study data were taken from the works of local authors, from the report of United States Agency for International Development (USAID), but also with sites of individual associations and organizations.

Forming of business networking

Changes in the market position of individual participants lead to substantial changes in the operations of many companies. For companies it is important connection (association), not only with consumers but also with the other participants. Accordingly, emphasizes the significance of networking companies in order to increase their own innovation. Networking should not be only within the company but also with participants from the region. Such networking contributes to achieving the common goal of all participants - making a profit.

Studies in developed countries show that for small and medium enterprises a key factor in improving innovative capacity of involvement in different types of networks, especially cluster. Innovations in all areas efficient use and transfer of knowledge are key to the successful development of innovation networks. The success of the connection is conditioned by: the efficiency of the process in the network, structure of the network, reputation and ability of companies to take advantage of networking *(Stanković et al., 2011).*

The efficiency of activities and processes that are implemented in the network increases the chance that the company successfully used the opportunity to acquire new knowledge and its transfer through the network. In this way, create new resources that are difficult to copy. Continuous integration of resources of various actors involved in the network, on the one hand, increases their value and on the other hand, makes it difficult to use the resources of entities that are outside the network. The degree of their interdependence determines the density of the network. Benefits arising from the density of the network based on the exchange of valuable information and knowledge that is difficult to obtain outside the network. However, it is necessary to point to certain restrictions imposed by the network density *(Stanković et al., 2011)*:

sharing information and knowledge involved subjects and groups can sometimes reduce the ability of rational response the company and its strategic adjustment;

if some of the information and knowledge not been use in the right way, can affect the competitive advantage of enterprises.

Koprivica et al. (2009) defines an association as a group of individuals who voluntarily unite in the organization in order to achieve common objectives and programs in creating agrarian policy of certain areas sharing the risks and the benefits. The voice of farmers, regardless of the length and nature of the membership, are equally valid and all have the same rights. In most cases, members of the group are also, and neighbors, friends, relatives, people who have built a relationship of mutual trust and respect, and have collaborated on business without the need for legal and statutory regulations.

Stanković et al. (2011) state that in modern economic *reputation* of the network is a significant source of competitive advantage. Her positive image contributes to the successful positioning of all participants in the network. *The ability* of the parties involved depends on

whether the benefit arising from connection, to be used in the right way. *Adjustment of goals* is a very important activity in the development of relations and networks.
Last few years significant research efforts are focused on studying the role and importance of innovation networks. According to *Stanković et al. (2011)* some of the benefits of innovation networks are: *the mobility of resources, creating conditions for the establishment of new businesses, stimulate innovation, efficient development and transfer of technology and knowledge, developing new business models and access to markets, the globalization of business, better strategic and operational adjustment of goals.*

Forms of business networks of agrarian sector in Serbia

Enterprises of agrarian sector problems production and placement of its products faster and more efficiently be overcome with business networking. Implementation of programs to support the development of business networks is realized in 2007 (*Programme for the development of business incubators and clusters in the Republic of Serbia 2007-2010*).
The goal of business networks is to join forces which networked actors bring greater benefits than individual performance in the market. *Mihailović et al. (2009)* point out some forms of business networks: business incubators, cooperatives and clusters.
Business incubators enable the provision of direct support to companies that are just starting business, because in this period the most exposed to failure. Services that provide business incubators are offered at subsidized prices, which provides a convenient location to companies in the incubator as compared to those outside it *(USAID report).* Business incubators in agrosector of Serbia are not so represented and are still in the development stage.
Cooperatives of agricultural producers are based on the principles of modern cooperative movement. This concept can be applied to forming of a whole production chain. Cooperatives of agricultural producers, built on the principles of modern cooperatives movement, can be seen as a business system - company, with all of its business functions which would be implemented through a service or employment of appropriate specialities. For example, the organizational model of cooperatives of agricultural producers should be designed so that the fruit producers are not transported to the buying centers, but it submitted directly from the plot. The final destination may be refrigerator, some processing facilities or shopping centers *(Mihailović et al., 2009).*
Paraušić, Cvijanović (2014) agricultural clusters defined as a geographic concentration of small and medium sized enterprises, specialized suppliers, related services companies, research institutions and government agencies in the agriculture and rural development. *Džanković-Jerebičanin, A. (2014)* points out that the strategy of clusters in Serbia must begin with mapping, to identify local and regional competitive advantages. In Serbia, the clusters in the agricultural sector formed more in the form of associations, at the initiative of the enterprise, much more because of better positioning in the market, and less for obtaining state incentives.
However, *Radojević (2007)* states that there are so-called **quasi clusters (associations)** which have the perspective in the future to become clusters. For Serbia and the agricultural sector is important to associate in any form, which leads to non-compliance of laws, programs, systems illogical and high capital costs.

Examples of business networks in the agrarian sector of Serbia

In this section are discussed concrete examples of agricultural business incubators, cooperatives and clusters which function on the territory of Serbia.
As an example of the **agricultural incubators** in Serbia is Municipality of Novi Bečej, which all registered farms and young farmers under 35 years of making available land, greenhouses, buildings, equipment, training and mentoring. Greenhouses are provided in cooperation with USAID. Farmers themselves are realizing their production, and the incubator helps them to find a buyer, placement and charging product. After an incubation period, farmers will have to

continue to work on an agricultural holding by starting their own businesses and investments in raising of greenhouse *(http://www.dnevnik.rs/ekonomija/poljoprivredni-inkubator-sansa-za-biznis)*. According to the USAID report, business incubators that have started or are only registered in Serbia are: Incubator of Technical Faculties – Belgrade , Business incubator - Knjaževac, Incubator center – Niš, Business incubator center – Prokuplje, Business incubator center Bor – Bor, Incubator center or the development of entrepreneurship Rača – Rača, Business incubator Subotica – Subotica, Business incubator Zrenjanin – Zrenjanin, Business incubator – Senta, Business incubator Beočin – Beočin, Business incubator – Pančevo, Business incubator – Kruševac, Business incubator – Užice (http://www.skgo.org/bz/data/8%20LER%20Koncept%20Brosure/SER/Business%20incubators.pdf).
Given that small farmers can not enter into competition with large agricultural producers, for them is the solution to collaborate with other producers to make **cooperatives** to be very innovative and thus add value to their products. As forms of cooperatives in the agricultural sector occur in association of raspberry and cherry fruit cooperatives in Arilje, apple producers of Vojvodina. Thus, for example, the national association of fruit and vegetable producers *Plodovi Srbije* established in order to improve the production, processing, placement and joint appearance on the domestic and foreign market (http://www.naslovi.net/2008-03-05/emportal/prva-nacionalna-asocijacija-vocara-i-povrtara/593940).
Mišić (2007) considers that the term cluster is still unknown to the territory of the countries in transition. Our business people are more aware of other terms of association in agriculture: cooperative society, cooperative association, farmers' association or the chamber. Accordingly, the previously mentioned forms of association (baking industry, meat industry) are distinguished by the fact that the cluster approach, only those who know their business interests through a clear objective. Some of the goals of association in clusters may be *(Mišić, 2007):*
increase the competitiveness of domestic products in the domestic and international markets with an increase in exports;
efficient use of resources (natural, productive and human);
cooperation between businesses, educational and development institutions;
connecting with funds to finance innovative projects;
training and education, which are in the interest of the region and the government.
Bošković and Kostadinović (2011) point out that the largest number of formed clusters is in agriculture and the food industry. These authors distinguish the following clusters: Cluster *BIPOM* - Balkan-Black Sea agricultural machinery industry; *Šumadijski cvet* - cluster of flowers; POLUKS - Cluster of Serbia food industry. Clusters zero phase, who have organized themselves and work without the support of the Government is *cluster for revitalization of old crafts* in Serbia and Cluster *Somborski salaši*. *Džanković-Jerebičanin, A. (2014)* stated some clusters in the field of agricultural production and processing: Cluster *Agroindustrija* - combines a network of agricultural producers and processors of primary agricultural products Northern Backa; Cluster *AGRO START UP* - a network of companies for production and processing of agricultural products and health food; Cluster *PEKOS* - networks of enterprises for the production of bakery products and educational institutions responsible for supporting the work and development of clusters (raw materials, transport, marketing, education).
In order to improve current practices and find solutions to specific problems farmers can voluntarily and independently to decide for different forms of organization. Some associations are specialized for solving only one kind of problem, such as associations of fruit producers, beekeepers, vegetable producers or associate in mechanical engineering community that achieves significantly better technical equipment and the rational use of mechanization *(Koprivica et al., 2009).*

Conclusion

In modern business conditions, innovation is one of the main sources of competitive advantage. In the long run the only reliable basis for the development of the agricultural enterprises to innovate faster, better and more in relation to its competitors. This applies not only to the product/service innovation, but also increasingly on innovation processes.

Agricultural population of Serbia is old and difficult to accept change. They have difficulties in making the aging population convince that the introduction of innovations in their pursuit of agricultural activities give positive results. Even harder to convince them that their inclusion in the network will bring better business conditions, better living standards and a better picture of the future. Also, innovations in agriculture could partially retain or recover a young population which migrates to the cities in the demand for a better life.

The development of business incubators, cooperatives and clusters in agriculture of Serbia would create the possibility of increasing the competitiveness of not only this sector but also the whole Serbian economy. Note also provide financial support to farmers with undeveloped and marginalized regions of Serbia.

Abstract

According to the motives for which tourists come to the rural areas, forms of rural tourism can be defined. It is estimated that today there are over 50 different forms of rural tourism. According to the Organization for Economic Cooperation and Development (OECD) agritourism is the most common form of rural tourism in the European Union. The aim of this paper is to present the current forms of rural tourism in the Republic of Serbia and to highlight opportunities for their development. The main hypothesis is that agritourism is most widely spread varieties form of rural tourism in the Republic of Serbia. In order to prove the thesis, survey was realized on the 104 subjects of rural tourism in 11 districts in the Republic of Serbia (North Bačka, South Banat, Kolubara, Mačva, Moravički, Pirot, NorthBačka, Srem, Šumadija, West Bačka and Zlatibor). The sample was formed by random sampling. Due to the fact that in Serbia there is no register of rural tourism households, in order to form the sample, it is used a database of the National Association "Rural tourism of Serbia" as the most comprehensive. The research which was carried out included 10.95% of the total number of providers of rural tourism in the Republic of Serbia, according to the specified database. The instrument used in the study was questionnaire. The questionnaire was administered by interview. The main groups of questions were related to the characteristics of rural tourism operators and determining whether there is a link in the development of tourism and agriculture, as well as complementary services.The paper used qualitative and quantitative research methods inherent in the social sciences.

Key words: *rural tourism, development, the Republic of Serbia*

Introduction

Rural tourism includes all tourist activities that can be implemented in rural areas. Rural tourism has started to intensively develop at the European area in the 70's of the twentieth century, as a part of the strategy of development of rural areas. The development of rural tourism was the result of reduced tourism demand for mass tourism and more prominent demands of tourists for differentiated tourism offer. According to the motives for which tourists come to the rural areas there are defined forms of rural tourism. It is estimated that today there are over 50 different forms of rural tourism. According to the OECD agritourism is the most common form of rural tourism on the territory of the European Union. The forms of rural tourism, the length of stay may be divided into residential and rural tourism excursion. The common characteristic of all forms of rural tourism is seasonal demand, which causes low occupancy at the annual level. The average occupancy rate in rural tourism in the territory of the European Union is 25% (Bartlet, 2006) and in the Republic of Serbia is only 4%.

The basic tourists' motive in agritourism is learning about the life and work in agricultural households. In addition to the agritourism in the area of the European Union, the most common are the following forms of rural tourism - ethno-tourism, eco-tourism and wine tourism. Ethno-tourism and "tourism based on heritage," as it is called (Brooks, 2000),

represents the trip due to natural, historical and cultural attractions, or because of a desire to study the past, but also looking for an answer how local and regional art, the natural environment and culture influence on the present. According to the cited author it is a form of rural tourism, which is based on heritage and an integral part of the new economic strategy that aims to focus on the development and promotion of cultural, historical, geographical and natural resources, community or region. Ecological tourism or ecotourism represents a trip to the protected natural areas "for enjoying nature and other cultural values" (Novković et al., 2012). The development of eco-tourism could be linked to the agritourism, which would create tourism product that would be interesting to both domestic and foreign tourists (Radovic et al., 2011).

Wine tourism is an extremely popular form of rural tourism, which is usually associated with gastronomy and is together called eno-gastronomy tourism. Wine tourism includes tourist trip with a visit to the vineyards, wineries, wine festivals and exhibitions of wine, with wine tasting and/or experience attraction vineyard region represents the primary motive for the trip. Wine tourism in Europe is mostly developed through the wine roads. "Wine Trail is a special form of selling wine, hospitality, tourism and agricultural products of a winemaking region, and the tourist offer includes wine trail and closer tourist attractions that are not directly on the route, but they increase the ethno-tourist offer" (Pivac, 2012). It is necessary that the wine path contains "scenarios for guests, as well as organizing various events" (Kušen, 1999). The aim of this paper is to present the current forms of rural tourism in the Republic of Serbia and to highlight opportunities for their development.

Materials and methods

The aim of the paper is to present the current forms of rural tourism in the Republic of Serbia and to highlight opportunities for their development. The main hypothesis states that: „agritourism is the most common form of rural tourism in the Republic of Serbia”. In order to prove the thesis, a survey was realized from June 2012 until October 2013, involving 104 subjects of rural tourism on 11 districts (North Bačka, South Banat, Kolubara, Mačva, Moravički, Pirot, NorthBačka, Srem, Šumadija, West Bačka and Zlatibor) and 31 municipalities in Serbia. Due to the fact that in Serbia there are no official data on the total number of entities engaged in rural tourism, data from the National Association "Rural tourism of Serbia" were used. The sample was formed by random sampling. The instrument used in the study is the semi-structured questionnaire. The questionnaire was administered by interview. The main groups of questions were related to the characteristics of rural tourism operators and determining whether there is a link in the development of tourism and agriculture, as well as complementary services.

Sources of data in the completion of the survey are the subjects of rural tourism: rural tourism households, handicrafts, ethno houses, ethno villages, farmsteads, hotels that are located in rural areas, as well as other service providers in rural tourism in the Republic of Serbia. The research used quantitative methods - statistical method. In statistical analysis, survey research was obtained by the methods of descriptive statistical analysis. The main obstacle in the study authors had in securing sources of data due to the fact that in Serbia there is no register of rural tourism households. A database of the National Association "Rural tourism of Serbia" is the most comprehensive and authors used it. The study included 10.95% of the total number of providers of rural tourism in the Republic of Serbia, according to the specified database.

Results and discussion

According to the results of the survey, in the Republic of Serbia are represented the following forms of rural tourism: agritourism, farmsteads, event, wine, eco-rural, beekeeping and bio-agro tourism. Entities engaged in rural tourism and rural tourism forms which are not mentioned in the literature, can be called: agro-ornithological and eco-agro tourism.

Agritourism is, according to the results of statistical analysis, the most common form of rural tourism in Serbia. According to the results, the most of respondents (72.1%) are engaged in rural tourism and agriculture together, or in agritourism. These data prove the main hypothesis that the most common form of rural tourism in Serbia is agritourism (Table 1; Figure 1). The Example of good practice is a rural tourist household "Gostoljublje" in the village Mionica, Municipality of Kosjerić (Radović, 2015).

Table 1. Relationship between tourism and agriculture

Industries:	Frequency (number of providers)	Percentage (%)
– only tourism	21	20.2
– tourism and agriculture	75	72.1
– tourism and other industries	8	7.7
Total:	**104**	**100.0**

Source:Elaboration based on the questionnaire results

According to the results obtained by statistical analysis, it can be concluded that the agritourism is represented in all districts. This form of rural tourism is the most common in Zlatibor, Moravičkom, Kolubara, Šumadija, Mačva, Pirot and South Bačka District (Table 2).

According to the results of qualitative research, it can be concluded that the farmstead tourism, as a special form of rural tourism, is characteristic for the area of the Autonomous Province of Vojvodina and is well developed, promoted and popular rural tourism product. On some farms are kept the classic Vojvodina's way of life, and many were renovated and adapted to the needs of modern tourists, and have swimming pools, sports fields, ponds and other recreational facilities (Pejanović et al., 2014). According survey results, the examples of good practice regarding the quality of rural tourism offer are: "Dida Hornjakov farm", near Sombor and Mother's and Flower farm in Palić. Event tourism is based on a number of ethnographic and gastronomy events that are implemented in rural areas. It is estimated that around 1,500 different touristevents are organized annually in the Republic of Serbia. Municipality with the highest number of ethnographic and gastronomy events that are held throughout the year in its territory, is Subotica - 15 ethnographic and gastronomy events. (Pejanović and Radović, 2012)

Wine tourism is a new form of rural tourism in the Republic of Serbia. Ministry of Economy of the Republic of Serbia initiated the project "Wine roads of Serbia," which aims to define a tourist offer of wine tourism. In the framework of this project nine wine routes are defined, which are located on the tourist map of Europe. Wine roads in the Republic of Serbia are: (a) wine route of Fruška Gora; (B) wine route of Vršac; (C) Palić wine route; (D) wine route of Smederevo; (E) wine route of Oplenac; (F) wine route of Negotin; (G) wine route of Knjaževac; (H) wine route of Župa; (I) wine route of Kosovo and Metohija (Radović and Pejanović, 2013). The motive in rural areas (in eco-rural tourism) is conected with visiting protected nature areas in order to observe or study rare plant and animal species. If the accommodation, which are located nearby, in rural tourist households is offered to tourists, such tourist offer can be called eco-agro-tourism due to the fact that it is the product of two forms of rural tourism: agritourism and eco-rural tourism. According to the results, good

example is Rokin farm, located in the area of the Special Nature Reserve "Lake Ludaš" (Radović, 2015).

Table 2. Connection between tourism and agriculture by district

District		Activity of the respondents			Total:
		Only tourism	Tourism and agriculture	Tourism and other industries	
North Bačka	Number	2	2	2	6
	%	1.9%	1.9%	1.9%	5.8%
West Bačka	Number	3	4	4	11
	%	2.9%	3.8%	3.8%	10.6%
South Bačka	Number	3	3	0	6
	%	2.9%	2.9%	0%	5.8%
South Banat	Number	0	7	0	7
	%	0%	6.7%	0%	6.7%
Srem	Number	4	1	0	5
	%	3.8%	1.0%	0%	4.8%

	%	3.8%	19.2%	1.0%	24.0%
Pirot	Number	2	4	0	6
	% u	1.9%	3.8%	0%	5.8%
Total:	Number	**21**	**75**	**8**	**104**
	%	**20.2%**	**72.1%**	**7.7%**	**100.0%**

Source: Elaboration based on the questionnaire results

According to the results, there are entities engaged in beekeeping, but also in rural tourism. Due to the fact that beekeeping can be one of primary interest for the arrival of tourists, beekeeping tourism can be considered a unique form of rural tourism. Bio-agri-tourism is a special form of rural tourism and has begun to develop in the Republic of Serbia. This term means the tourist industry within the households engaged in agriculture in the system of organic food production. The term "agro-ornithological" rural tourism does not exist in the literature. The existence of this type of rural tourism is confirmed by the results of the realized survey research. In the Republic of Serbia there are entities that, in addition to agricultural production, are dealing with rural tourism and a basic tourist facilities or motive for tourists is bird watching. Based on the results of the realized survey research, example of good practice – „Kuća na Orlovoj steni“ ("House at the Eagle Cliff") in the village Komarani in the municipality of Nova Varoš (Radović, 2015).

Conclusion

According to the results from the conducted survey, it can be concluded that the most common form of rural tourism in Serbia is agritourism, which verify the hypothesis. Most of the surveyed subjects (72.1%) is engaged in rural tourism and agriculture, which points to a high synergistic relationship between these activities in the Republic of Serbia. In order to develop agritourism in the Republic of Serbia, based on the example of the Republic of Slovenia, the operators of agritourism should offer a minimum of 30% of products from own agricultural production. This will enable the development of rural tourism, but also the agricultural development considering that the economic evaluation of agricultural production is the most appropriate implemented through rural tourism. Rural tourism is a "consumer" of agricultural products, which affects the intensification and stable development of agriculture. Revenues realized from the tourism sector could be invested in development and modernization of agricultural production.

In order to develop all forms of rural tourism in the Republic of Serbia investments are needed in: (a) the development of tourist facilities; (b) development of rural infrastruture; (c) the development and training of staff; (d) the development and promotion (e) the development of sales channels of the rural tourist products in the domestic and international tourism market.

Abstract

Tourism is the main source of foreign exchange earnings in almost 38% of countries and one of the five export categories in 83% of all countries. With a total number of 1,135 million tourists and income of $ 1,245 billion realized in 2014 and the expected number of 1.6 billion tourists in 2020, tourism represents one of economically most perspective activities. Tourism can have an important role in promoting rural areas as ecological oases with specific cultural and historic heritage. Rural tourism is most often identified with the "holiday village", but it also covers all other tourist activities in rural areas. Favorable natural and demographic conditions are the basic resources for the development of rural tourism. Around 9o% of European Union (EU) territory is considered a rural area on which more than 56% of population resides, therefore the politics of rural development is of vital importance for the further development of EU. Starting from characteristics of rural areas and European rural policy, the authors point out significant touristic potential that these areas have. In the paper is also analyzes the role and importance of tourism in preserving and promoting rural areas and fostering rural development at whole. Those analyses are based on contemporary national and international relevant sources and apply adequate methodologies such as: methods of analysis and synthesis, methods of induction and deduction as well as comparative method. Authors emphasis that the main positive effects of rural tourism development are: increasing the employment of the local population, the additional income for rural households, the development of production and services, prevention of migration at the level of rural-urban, protection and preservation of natural and cultural heritage and integrated development of rural areas.

Keywords: rural areas, tourism, rural tourism, rural development.

Introduction

From the very beginning of European integration of the fifties and sixties, were detected in significant economic and social disparities in the development of individual member countries. Today, after more than half a century of the EU, structural problems and problems of regional disparities are major problems of the European economy and society as a whole. The difference between the richest and poorest regions of Europe is 1:8, indicating that regional differences in Europe are not only still existing, but they are also very strong.

The effects of regional development are particularly sensitive rural areas. Although in the period 2000-2006 about 14 billion euros (7% of total assets) invested in rural development of the EU, however, the percentage of unemployment, especially youth, is very high in rural areas is as high as 17.6%. Besides the problems of unemployment, rural areas have a large demographic decline and aging of the population strongly (17% of the population are those over 65 years). It is therefore encouraging the development of small and medium-sized cities is crucial to the survival of rural areas inhabited by 5,000 to 100,000 people or 21% of European populations. In order to equalize economic development in countries and regions in the Union is defined by a common regional policy. The aim of the policy of balanced regional development policy is to achieve a harmonious, balanced and sustainable development and

strengthening of economic and social cohesion of the community, which is a common policy of balanced regional development and the EU called “cohesion policy” (Premović, Arsić, 2010).

Material and methods

Tourism is the main source of foreign exchange earnings in almost 38% of countries and one of the five export categories in 83% of all countries. At the same time, tourism participates with 9% of world GDP and about 30% of world trade in services. With a total number of 1,135 million tourists and income of $ 1,245 billion realized in 2014 and the expected number of 1.6 billion tourists in 2020, tourism represents one of economically most perspective activities (According to: UNWTO, Tourism Highlights, 2014; UNWTO, World Tourism Baromenter, 2015).

Actual results and projected future tourism growth, indicating that the need for strategic management of the tourism sector, primarily in the direction of control of further tourism growth. Changes in the contemporary world environment had its reflection in the field of tourism. Thus, after a period of domination of mass tourism at the end of the last century, the beginning of XXI century was marked tourist trips aimed at new destinations. The most interesting destinations for modern tourists are rural tourism destinations with untouched nature and specific anthropogenic values.

Rural development is a policy area which is vital for the EU because more than 56% of the population living in rural areas and 91% of the territory. By definition, the European Commission, the rural region is a territorial unit to economic and social structure of diversified activities. This entity can include villages, small towns and regional centers.

According to the OECD typology of rural regions are divided into three groups:

First regions where **over 50%** of the population lives in rural communities - **rural regions,**

Second regions in which **15 to 50%** of the population lives in rural communities - **significantly rural regions and transition regions**,

Third regions in which **less than 15%** of the population lives in rural communities - **mostly urban regions** (Network for Rural Development-Action Plan 2011-2015, 2010: 13).

Applying the OECD typology of EU regions in the example, we get the data by which rural regions make up about 55% of EU territory, significantly rural regions about 37% and 8% of EU territory can be considered semi-urban regions.

Contemporary politics of European Union moves to the center of local development for Rural Development, emphasizing rural areas, regions, and their coordination and harmonization.

In order to solve the problems of rural areas of the EU as a function of their development has an important role concept of SARD - Sustainable Agriculture and Rural Development. SARD includes the management and conservation of natural resources and direction of technological and institutional changes to achieve and continually meeting the needs of present and future generations. Thus, sustainable agriculture and rural development will enable the conservation of soil, water, plant and animal resources, without compromising the environment, with the technical and technological development (environmental) is applicable, socially acceptable and economically viable.

Analyzes of the role and importance of tourism in preserving and promoting rural areas and fostering rural development particularly in the European Union are based on contemporary national and international theoretical knowledge and relevant sources. Methods of analysis and synthesis, methods of induction and deduction as well as comparative method are used to explain the rural tourism and the main positive effects of rural tourism development.

Results and discussion

Rural tourism is often identified as “holiday village”, but it also includes all other activities in rural areas. The favorable natural conditions are the basic demographic resources for rural tourism. Positive effects of a rural development are: to increase employment of local people, extra income for rural households, development of manufacturing and service industries, preventing migration of the rural-urban level, the protection and preservation of natural and cultural heritage and integrated development of rural areas (Premović et al., 2011).
Rural tourism is comprised of more than nineteen different forms of tourism, such as the following: agro tourism/ farm tourism, residential tourism, heritage tourism, gastronomy and wine tourism, hunting and fishing tourism, cultural tourism, religious tourism, nautical tourism, continental tourism, school and educational tourism, medical tourism, sports recreational tourism, adventure tourism, camping tourism, transit tourism, nature and earth tourism, ecotourism, mixed and other forms of tourism.

Various possibilities for the development of rural areas depend on a number of factors, such as the following:
geographical location and accessibility of transport (rural areas in the proximity of urban regions, major public roads, processing capacities and the market itself have some developmental advantages);
natural conditions and potentials (the altitude, climate, land, forest cover, biodiversity, water resources, mining wealth);
human and material resources endowment (the infrastructure, industrial capacities, workforce qualification and selection, development of public services, size and morphological characteristics of settlements) and
social capital and interaction (cultural characteristics, attitudes towards tradition and modernization, horizontal and vertical cooperation, etc.) (Popović et al., 2011).

Tourism can play a significant role in promoting the rural areas as a kind of ecological oasis with specific cultural and historical heritage.

Tourism in rural areas, i.e. rural tourism is defined as tourism which provides a “rural environment” for visitors, by offering a combination of natural, cultural and human experiences which have typically rural character. The essence of rural life refers to the immersion of visitors in authentic, original and fundamental experiences. Rural tourism is what brings the visitor back to nature; back to the roots, back to basics, and embraces the return to the origins and originality. It is comprised of a spectrum of activities and services organized by rural population (Holland et al., 2003).
Therefore, various rural areas have significant comparative possibilities for environmentally sustainable tourism development. The main characteristic of rural tourism is to provide the visitors with the personal contact, a direct experience of physical, cultural and social natural settings for the purpose of their getting to know and understand the way of life of the local community, its tradition and values, so that they are eventually enabled to participate in one of its activities (UNWTO, Tourism & Leisure Advisory Services, 2011).

Tourism in rural areas is based on principles of sustainability and offers elements of country environment, nature, as well as presenting traditional hospitality and the values of life of the local population. It is the contact with nature and the personal human contact with the local people which makes rural tourism so unique. Rural accommodation combines different forms of tourism that showcase rural life, art, culture and heritage in rural locations. International

trends suggest that Rural Tourism is becoming an increasingly broader concept and that the needs and expectations of domestic and international demand are becoming ever more sophisticated.
Rural tourism, therefore, combines many different aspects of experiencing, sharing and showcasing rural life. These rural experiences can be defined in terms of rural activities and accommodation experience. It is the combination of the given forms that shapes the essence of rural tourism (UNWTO, Tourism & Leisure Advisory Services, 2011).

The main prevailing tendencies in tourist demand, particularly in Europe, are the following:
psychological and physical refreshment of urban people by traveling through the areas which differ geographically (tourist travels from low land to mountains, from towns to villages, from land to islands, etc.),
trend towards the experience in connection with cultural and historical heritage and preserved nature, "green" movement or tourism which is also called alternative and responsible, "soft", "good" or "new" tourism refers not only to tourism in the country but to tourism in cities as well as the littoral regions. Primarily, it implies pure water, clean and safe sea, healthy food and unpolluted air, i.e. it is not mass tourism but tourism which is environment friendly,
"blue" or nautical movement, i.e. demand, (cruise ship excursions by using marines, ports and harbors),
demand for the places, events and experience with prominent identity, integrity and differences,
demand for village (rural) and agro tourism, which implies stays in different accommodation types (not only in rural households) and performing activities (such as: sport, adventure, challenges, art, manual work, etc.),
demand for the health, spiritual and mental renewal and the identity renewal – refers to the new forms of medical, i.e. spa tourism: demand for a better condition (recreational activities, sport and exercises, diets, fitness) along with wishing to have a better health by means of reducing the levels of stress (www.cenort.rs. Downloaded to the site: 26.12.2013. Document: Village tourism, paper: The key questions of the rural tourism development).

When we talk about rural areas and opportunities for the launch of the tourist traffic, we must bear in mind that not all rural areas participate priori that market with its "tourist" offer. It is necessary that rural areas to first meet certain criteria. The basic criteria for the rural areas are given in the following chart.

Chart 1. The basic criteria for the rural tourist areas (Vuković et al., 2010).

CRITERIA	EXPLANATION
1. The location of households in their natural environment, a village or small town	Less than 5000 inhabitants in villages/towns or in very typical/traditional settlements
2. The rural area with emphasized characteristics of traditional agriculture and the outstanding natural values	Outstanding natural values (natural park, etc.). Traditional agriculture excluded industry
3. Tourism is not the main or predominant activity or source of income in the surrounding area	The ratio of the number of tourist beds and residents in rural areas should not exceed 1:1
4. A high level of environmental protection, a quiet and peaceful location, without any noise or pollution	Acceptable odors and noise which are characteristic of traditional agricultural production
5. Authentic accommodation and environment	_
6. Hospitality	The host takes personal care of his guests (tourists)
7. Small capacity units	The upper limit capacity is 40 beds, if not legally designated or prescribed by internal standardization by members
8. Compliance with the legal criteria for evaluation	Compliance with the standards adapted to evaluate quality
9. Social sustainability in the context of multifunctional activities in rural areas	The application of the criteria defined by “Agenda 21” for tourism
10. Connection with the local community and traditional culture	Minimum integration activities within the communities in the region, guests have the opportunity to make contact with local realities if they want to
11. Local products and gastronomy	Available in the environment
12. Culture (folklore, handicrafts, customs, heritage,...)	Available in the environment
13. Excluding criteria: - urban and industrial locality and their surroundings - areas of extreme mass and developed tourism - noise, - pollution and likewise	-

There have been approximately a million of registered rural households, providing “Farm and Village Tourism” services, by means of which 1.5 to 3 million job places are provided. The European continent is considered to be the leader in rural tourism with approximately 200.000 registered providers in rural tourism services and more than 2.000.000 tourist beds, whereas the number of direct and indirect employees in the European rural tourism industry is approximately 500.000. It has been estimated that the accommodation in farmhouses, private

village houses, small family boarding houses and hotels generate direct annual tourism expenditure of approximately 12 billion euros.
Taking into consideration the emphasized multiplicative character of tourist economy, it has been estimated that tourism has an indirect influence upon the additional 14 billion euros, which are achieved by means of the related industries, due to the rural tourism. Therefore, the contribution of rural tourism in the achieved outcome of the European industry amounts to approximately € 26 billion annually.

Conclusion

Tourism represents one of economically most perspective activities in world. The most interesting destinations for modern tourists are rural areas with untouched nature and specific anthropogenic values. Considered from the perspective of the modern business environment, rural areas are not only rounded agricultural areas intended solely primary production, but represent areas with significant potential for tourism development through meeting the various needs, such as environmental protection, preservation of traditional values, recreation, leisure, sports, different cultural and historical content, etc.
Based on previously findings, it can be concluded that tourism with its socio-economic effects and links to numerous economic and non-economic activities can be a significant factor in the promotion of rural areas as a function of encouraging rural development in general.

RED PEPPER PRODUCTION CHARACTERISTICS – COMPARATIVE ANALYSIS IN EU COUNTRIES AND SERBIA

Nebojša NOVKOVIĆ[1]*, Beba MUTAVDŽIĆ[1], Tomo KRASNIĆ[1],

[1]University of Novi Sad, Faculty of Agriculture, Serbia
*Corresponding author: nesann@polj.uns.ac.rs

Abstract

This paper analyses the production of the red paper of some important producers from EU countries. The analysis included six countries: Bulgaria, Greece, Spain, France, Italy, and Hungary. The following production characteristics were analysed and statistically processed: area of production, yields and total yearly production. Nominated countries encompassed about 80% of total production of red pepper in EU.

This research included official statistical data from EUROSTAT for the period of 13 years, 2000-2012. Descriptive statistical analysis included accountings of: average and extremes values of characteristics, coefficients of variations, and change rate. Furthermore, the results of analysis have been compared with the same data from Serbia.

The results of analysis have showed that:

- There has been tendency of decreasing the areas of red pepper in all observed countries (except Greece). The largest areas of red pepper were in Spain (21,000 ha), and Italy (13,000 ha). The average red pepper area in Serbia in observed period was 19,200 ha.
- Opposite to production areas, yields of red pepper had tendency of increasing (except in Italy). The highest yields were in Spain (48t/ha), Hungary (38.7t/ha) and France (31.5 t/ha). Average yield of red pepper in Serbia was 7.9 t/ha.
- Some of observed EU countries had tendencies of increasing production (Greece, change rate 4.1%, Hungary, 0.51%, and Spain, 0.20%), while some had tendencies of decreasing production (Bulgaria, -9.66%, Italy, -5.25%, and France, -1.67%). The largest producer of red pepper in EU was Spain, with more than one million tons. Next was Italy (318,000t). Average yearly production in Serbia was 152,000 tons.

Key words: red pepper, production analysis, EU countries, Serbia

Introduction

In this paper, the important producers of the red pepper production from the EU were analysed and compared with the data from Serbia. The analysis included six EU countries: Bulgaria, Greece, Spain, France, Italy, and Hungary. The area of production, yields, and harvested production were analysed, and statistically processed. Nominated countries consisted 80% of total production of red pepper in EU.

There are many papers about descriptive statistical analysis of vegetables (Mutavdzic et. al., 2011; Novkovic et. al., (2011, 2012, 2012a, 2014).

The goal of this research was to analyze the red pepper production parameters of the main producing countries in EU, and see comparative position of Serbia.

Materials and methods

In this research the quantitative methods were implemented. Observed period of analyzed data was 2000-2012. The data source was official publication of the Institute of Statistics of Serbia, and official statistical data from EUROSTAT for EU countries. The descriptive analysis included: average and extremes values of characteristics, coefficients of variations,

and change rate. The results of analysis of EU countries have been compared with the same data from Serbia.

Results and Discussion

The main results of descriptive statistical analysis of harvested area of red pepper are presented in table 1.

Table 1. Basic characteristics of red pepper harvested area (2000-12)

Country	Average (000ha)	Interval of variation		Coefficient of variation (%)	Change rate (%)
		Minimum	Maximum		
Bulgaria	7.55	3.00	13.90	52.79	-12.23
Greece	3.89	3.50	4.30	5.18	0.82
Spain	21.02	17.40	23.70	11.41	-2.37
France	0.65	0.50	0.80	13.92	-2.76
Italy	12.92	9.00	15.20	14.16	-3.90
Hungary	4.46	2.00	6.90	38.73	-9.47
Serbia[1]	19.20	18.47	20.02	2,60	-0.55
Republic of Srpska[1]	2.3	2.17	2.46	4.00	-0.52
Vojvodina[1]	4.6	4.10	4.92	6.60	-1.97

[1] 2001-10

According to the data presented in the table 1, it can be concluded that there has been tendency of decreasing the areas of red pepper in all observed countries (except Greece). Serbia ranks second in harvested area of red pepper (after Spain), and before Italy, on the third place. What is also positive, is a small coefficient of variation, and parctically, stable harvested area.

The changes of harvested area in EU countries in the obsereved period are presented in graph 1.

The results of descriptive analysis of yields of red pepper are presented in table 2. Opposite to harvested area, yields of red pepper have tendency of increasing (except in Italy). The highest yields were in Spain, Hungary and France. Average yield of red pepper in Serbia was far from maximal yields in EU, but there was a positive tendency.

Graph 1 Red pepper harvested area (2000-12)

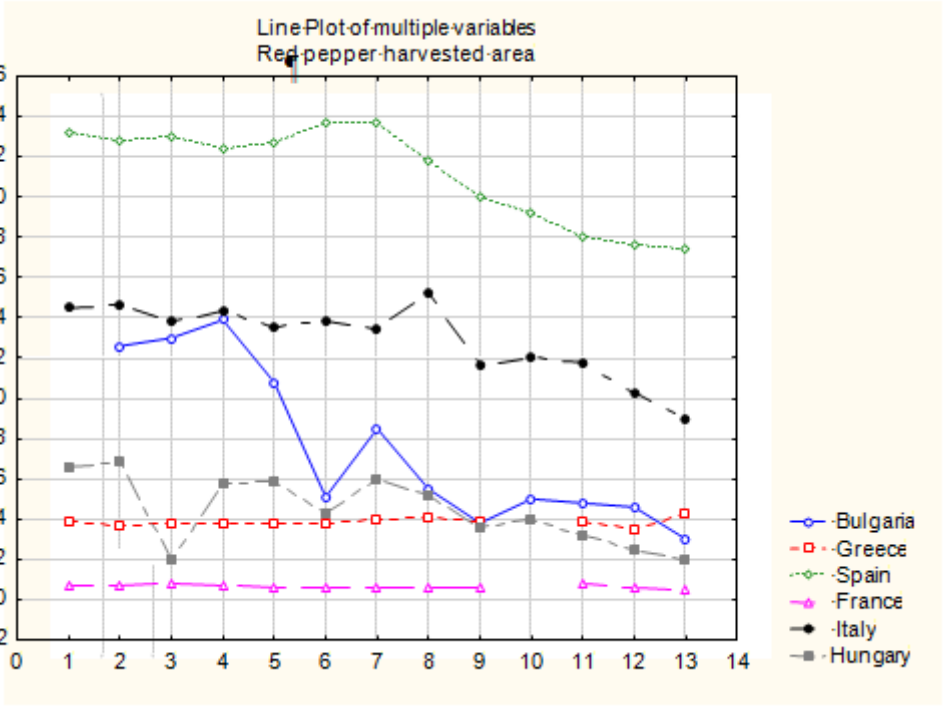

Table 2 Basic characteristics of red pepper yields (2000-12)

Country	Average (kg/ha)	Interval of variation		Coefficient of variation (%)	Change rate (%)
		Minimum	Maximum		
Bulgaria	14,419	11,430	18,400	13.30	2.93
Greece	29,353	21,130	39,410	19.29	3.33
Spain	48,049	40,810	55,630	8.38	2.62
France	31,509	10,100	42,170	26.05	1.68
Italy	24,449	19,060	27,840	10.15	-1.44
Hungary	38,709	18,900	72,000	45.93	11.03
Serbia[1]	7,900	6,800	9,200	10.31	2.32
Republic of Serpska[1]	9,900	5,800	12,200	21.07	7.90
Vojvodina[1]	11,053	9,130	14,339	18.62	5.01

[1] 2001-10

The changes of yield of red pepper in EU countries in the obsereved period are presented in graph 2.
The results of descriptive analysis of total year productions of red pepper are presented in table 3.
Some of observed EU countries have positive tendencies of total production (Greece, Hungary, and Spain), and some countries have tendencies of decreasing production (Bulgaria, Italy and France). The largest producer of red pepper in EU was Spain, with more than one million tons. Next was Italy with 1/3 production of Spain. Average yearly production in Serbia was half that of Italy.

Graph. 2 Red pepper yields (2000-12)

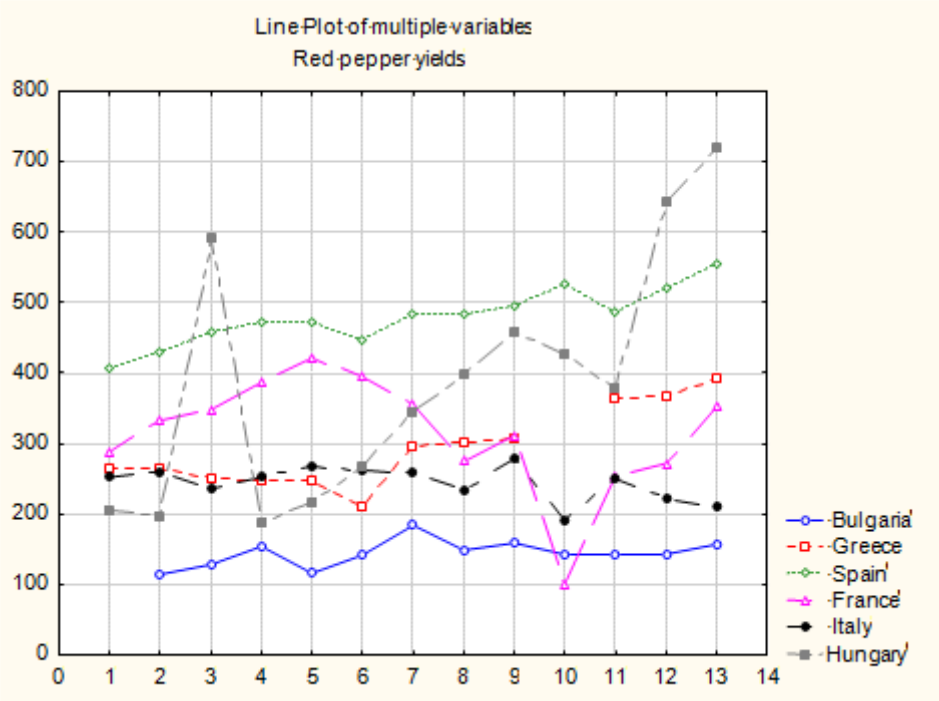

Table 3 Basic characteristics of red pepper yearly production (2000-12)

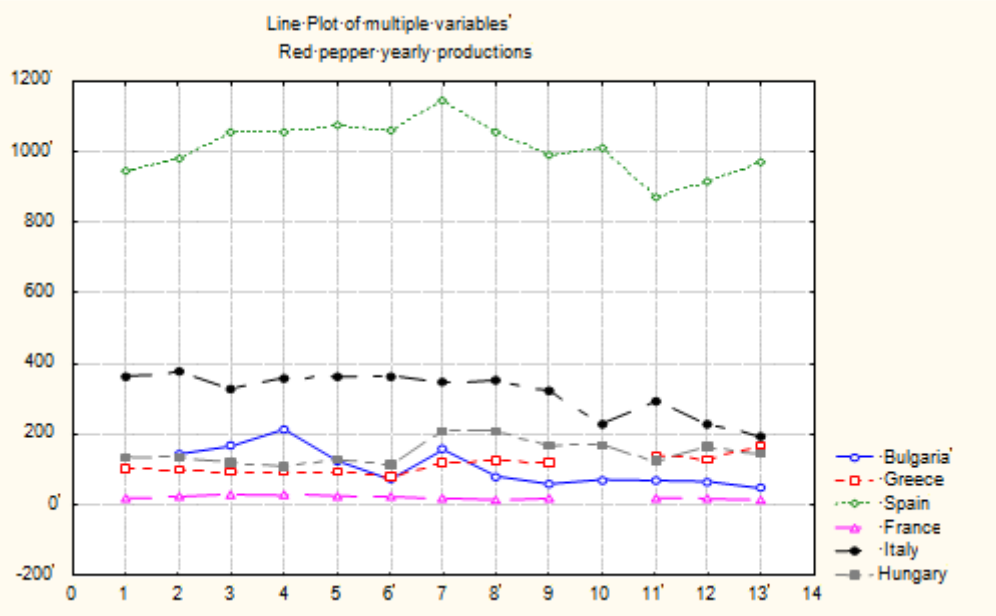
Country	Average (000t)	Interval of variation		Coefficient of variation (%)	Change rate (%)
		Minimum	Maximum		
Bulgaria	106.13	47.10	213.90	50.17	-9.66
Greece	113.98	80.30	167.90	21.60	4.10
Spain	1,011.20	873.00	1,147.80	7.35	0.20
France	21.43	16.50	27.80	18.64	-1.67
Italy	317.82	191.40	379.70	19.58	-5.25
Hungary	147.63	109.60	208.20	22.20	0.51
Serbia[1]	151.95	132.47	177.25	8.90	1.76
Republic of Serpska[1]	23.22	13.07	28.81	21.27	7.41
Vojvodina[1]	50.88	44.06	67.19	14.71	2.94

[1] 2001-10

The changes of year productions of red pepper in EU countries in the obsereved period are presented in graph 3.

Graph 3. Red pepper yearly productions (2000-12)



Conclusion

The results of analysis show that:

1. There is present tendency of decreasing the areas of red pepper in all observed countries (except Greece, where is present a slow increse). The largest areas of red pepper had Spain (about 21,000 ha), Italy (13,000 ha), and Bulgaria (7,500 ha).
2. Opposite of areas, yields of red pepper had tendency of incerease (except in Italy). The highest yields had Spain with 48 t/ha. Next were Hungary (39 t/ha) and France (32 t/ha).
3. Tendencies of total production depends of changes in area of production and yields. Tendency of increasing the production had only Greece. Spain showed tendency of stagnation, while in other countries were present tendency of decreasing. The largest producer of red pepper in EU was Spain, with about 1 million tons. The next were Italy (318,000 tons) and Hungary (148,000 tons).
4. Serbia ranks second in harvested area (19,200 ha), and had extremly small yield (7,900 kg/ha), which brough Serbia on the third place of red pepper producer in Europe (151,950 tons/year).

GROSS MARGIN OF STRAWBERRY PRODUCTION IN POMORAVLJE REGION IN SERBIA

Jasmina FILIPOVIĆ[1], Slađan STANKOVIĆ[2]*, Slavica ČOLIĆ[2], Dragan RAHOVIĆ[2], Vedran TOMIĆ[2], Nikola LJILJANIĆ[2], Robert RADIŠIĆ[2]

[1]Agricultural Advisory Service of Jagodina, Serbia
[2]Institute for Science Application in Agriculture, Belgrade, Serbia
*Corresponding author: sstankovic@ipn.bg.ac.rs

Abstract

According to the Census of Agriculture 2012, the area under strawberries in Serbia amounted to 1.801 ha and the yield per unit area was 14,7 tons. The total production of strawberries varied from 24.910 tons in 2000 to 37.924 tons in 2008. The assortment of strawberries in Serbia is heterogeneous. New, high-quality varieties almost invariably prevail on farms close to large consumer centers. It is important for farmers to be introduced to the economic effect of a certain production line. The gross margin (GM) is a quick and efficient indicator for comparing production lines within different conditions. GM was used as an indicator of economic effects of production. Data on GM calculations were collected from a questionnaire survey conducted on a representative strawberry farm in Jagodina (Kovačevac village, Pomoravlje region, Serbia) in the period 2012–2014. For calculating the basic GM elements, the following data were used: data on yield and price; product price; quantity and cost of fertilizers, pesticides, and fuel; and costs of contracted services. GM does not indicate profits and, therefore, does not include the size and value of fixed costs. It represents the total value of production, subtracted by direct costs of investments (purchased inputs). Within the period 2012–2014, GM varied from 7.085,28 EUR/ha (2013) to 20.432,37 EUR/ha (2012). At the same time, total variable costs varied from 2.723,03 (2014) to 3.226,71 EUR/ha (2013). High yields in 2012 (33,33 tons/ha) and a substantially higher price led to an outstanding GM.

Key words: *gross margin, strawberry, variable costs, yield, price.*

Introducton

The gross margin (GM) is a quite useful tool for assessing the economic importance of a certain production line. Comprising solely the production value and variable costs, it can be easily comprehended even by people with no special training in economics. This is especially the case in production lines such as strawberry production, with one product as an output, and no additional by-products. In this case, the value of the entire production can be calculated simply by multiplying the quantity of product with its selling price per unit. Contracted services are not included in calculations, regarding the technology of this production. Moreover, one has to bear in mind that GMs of different production lines should not be compared if they have different overhead costs (Kuhlman et al., 2012).

GM should be considered as an important tool, since it gives the result calculated only in relation to what has been invested to produce the quantity in question, thus giving us the best overview, possible to trace over time. GM became widespread in the UK in the 1960s, being used for the first time by farm management advisors for making analyses and planning purposes (Barnard and Nix, 1979).

GM is a fast and efficient indicator of profitability of a certain production line (Filipović et al., 2015). In this paper, GM was used as an indicator narrower than an analytic calculation. The gross margin shows the difference between the cost of production and direct costs, which makes it an important tool from the economic aspect (Janković et al., 2009, Anđelić et al.,

2010, Tomić et al., 2013). In order to analyze economic results in agriculture and the structure of farms more easily, we used the methodology for calculation a standard GM as a scientific tool to support technical and economic orientation of farms (Iurchevici and Chetroiu, 2011).

Materials and Methods

Along with standard descriptive statistic methods, authors used GM calculations as an indicator of economic effects of strawberry production. Production data were collected from a questionnaire survey conducted on a representative farm in Pomoravlje region (Kovačevac village) during a 3-year period (2012–2014). Some basic elements for gross margin calculation were used: yield and price; quantity and value of fertilizers, pesticides, and fuel, as well as costs of contracted services. All prices are given in EUR, but original data were collected in Serbian dinars (RSD). Prices were calculated based on Serbian National Bank average exchange rate against major world currencies for particular year (www.nbs.rs/internet/cirilica/scripts/kl_prosecni.html). Indicators of the value of production, total variable costs and gross margin were calculated according to the methodology provided by the website of the Serbian Agriculture Advisory Service (www.psss.rs). The authors used *Microsoft Excel* for processing data and calculating GM, and the program was set to calculate the average value of each element of the calculation. GM is the difference of total revenue and total variable costs (TVC), achieved in a line of agricultural production per unit of production area (in crop production). We also calculated the critical values with the aim of estimating results of production under conditions of uncertainty. Critical values are those values at which the GM equates to zero (Subić et al., 2015).

Results and discussion

GM is adequate analytical basis, used for efficient cost management and decision-making. Also, the complexity of the production of strawberries imposes farmer need daily decision making crucial to maintain or increase the profit. The authors cannot assess the performance of the farm, based on the data on the farm size and the acreage of the used agricultural land. The analysis requires data on what, when and how much of something is produced, so that one can compare the performance of individual production lines and make decisions on the future structure of production. One of the derived indicators that can be used as a criterion for determining this structure is GM. GM is not the only and the most important analytical model, but it is a good starting point that requires relative simple data and methodology. GM represents the total value of production, subtracted by the direct (variable) costs (purchased inputs).

Table 1. Gross margin calculation, 2012

	Category	**Quantity**	**Price** (EURO)	**Amount** (EURO)
1.	Fresh strawberries	33.333,33 kg	0,707	23.572,18
A.	**TOTAL INCOME**			**23.572,18**
	Variable costs			
1.	Fertilizers			437,56
2.	Pesticides			362,20
3.	Fuel			453,90
4.	Labor			1.803,27
5.	Other supplies (packaging, string, ...)			123,75
6.	Contracted services			
B.	**TOTAL VARIABLE COSTS**			**3.180,70**
C.	**GROSS MARGIN (A – B)**			**20.391,48**
	Critical cost = 0,0954			
	Critical yield = 4.497,81			

Due to substantially high yield, both GM and critical cost in 2012 were significantely different than in 2013 and 2014 (GM was 3 times higher and critical cost twice lower). The most important variable cost was labor (1.803,27 EUR/ha), but this is quite expected, primarily having in mind manual harvesting of strawberries. Critical yield was 7,4 fold lower that achieved.

Table 2. Gross margin calculation, 2013

	Category	**Quantity**	**Price** (EURO)	**Amount** (EURO)
1.	Fresh strawberries	16.666,67 kg	0,619	10.312,83
A.	**TOTAL INCOME**			**10.312,83**
	Variable costs			
1.	Fertilizers			503,86
2.	Pesticides			431,46
3.	Fuel			523,74
4.	Labor			1.675,10
5.	Other supplies (packaging, string, ...)			141,43
6.	Contracted services			
B.	**TOTAL VARIABLE COSTS**			**3.226,97**
C.	**GROSS MARGIN (A – B)**			**7.085,86**
	Critical cost = 0,194			
	Critical yield = 5.215,14			

In 2013, lower yield was expected, but still significantly lower comparing to 2013. Additional lower price of strawberries led to almost 3 fold lower GM, while total variable costs were quite similar in both years. Labor costs were the most important in cost structure, as expected. Critical yield, compared to achieved yield was 3,2 fold lower.

Table 3. Gross margin calculation, 2014

	Category	**Quantity**	**Price** (EURO)	**Amount** (EURO)
1.	Fresh strawberries	19.444,44 kg	0,600	11.603,08
A.	**TOTAL INCOME**			**11.603,08**
	Variable costs			
1.	Fertilizers			409,19
2.	Pesticides			422,91
3.	Fuel			488,25
4.	Labor			1.332,84
5.	Other supplies (packaging, string, ...)			119,35
6.	Contracted services			
B.	**TOTAL VARIABLE COSTS**			**2.772,54**
C.	**GROSS MARGIN (A – B)**			**8.879,56**
	Critical cost = 0,143			
	Critical yield = 4.646,21			

GM in 2014 was high, having in mind that strawberry production in 3rd year is expected to be more stagnant, even higher than in 2013. Variable costs were similar as in two previous years. Again, labor costs were the highest one. Critical yield was 4,2 times lower than achieved.

Labor costs, as seen from annual GM tables, were the most dominant item in the variable cost structure (48,07 – 56,69%, 51,97 on the average), followed by group of costs with similar values: fuel (15,96%), fertilizers (14,63%) and pesticides (13,27%) (Table 4.).

Table 4. Structure of variable costs in strawberry production, 2012-2014

	Variable costs	Amount (EURO/ha)	(%)	Amount (EURO/ha)	(%)	Amount (EURO/ha)	(%)	Average %
		2012		2013		2014		2012-2014
1.	**Fertilizers**	**437,56**	**13,76**	**503,86**	**15,38**	**409,19**	**14,76**	**14,63**
	NPK	220,99	6,95	220,99	6,85	170,49	6,26	6,69
	KAN	176,79	5,56	176,79	5,48	119,35	4,38	5,14
	Foliar	39,78	1,25	106,07	3,29	119,35	4,38	2,97
2.	**Pesticides**	**362,20**	**11,39**	**431,46**	**13,17**	**422,91**	**15,25**	**13,27**
	Fungicides	182,76	5,75	197,21	6,11	191,89	7,05	6,30
	Insecticides	86,63	2,72	101,66	3,15	103,15	3,79	3,22
	Herbicides	92,82	2,92	132,59	4,11	127,87	4,70	3,91
3.	**Fuel**	**453,90**	**14,27**	**523,74**	**15,99**	**488,25**	**17,61**	**15,96**
	Crop cultivation	57,46	1,81	66,30	2,05	61,80	2,27	2,04
	Crop tending	28,73	0,90	33,15	1,03	30,90	1,13	1,02
	Crop protection	57,46	1,81	66,30	2,05	61,80	2,27	2,04
	Shredding crop residues	11,49	0,36	13,26	0,41	12,36	0,45	0,41
	Transport	114,91	3,61	132,59	4,11	123,61	4,54	4,09
	Irrigation	172,37	5,42	198,89	6,16	185,41	6,81	6,13
	Harvesting	11,49	0,36	13,26	0,41	12,36	0,45	0,41
4.	**Labor**	**1.803,27**	**56,69**	**1.675,10**	**51,14**	**1.332,84**	**48,07**	**51,97**
	Winter pruning	119,33	3,75	159,11	4,93	153,44	5,63	4,77
	Summer pruning	92,82	2,92	123,75	3,83	119,35	4,38	3,71
	Irrigation	0,00	0,00	66,30	2,05	37,08	1,36	1,14
	Harvesting	1.591,12	50,02	1.325,94	41,09	1.022,97	37,56	42,89
5.	**Other supplies** (packaging, strings, ...)	**123,75**	**3,89**	**141,43**	**4,32**	**119,35**	**4,30**	**4,17**
6.	**Contracted services**							
B.	**TOTAL VARIABLE COSTS**	**3.180,70**	**100**	**3.226,97**	**100**	**2.772,54**	**100**	**100**

The most dominant single item within TVC was labor cost for harvesting (42,89%), followed by costs for fertilizers (6,69 and 5,14%), fungicides (6,30%) and fuel for irrigation (6,13%). Generally, such range of cost items within TVC was expected, due to standard strawberry production practice requirements.

Conclusion

Within the period 2012-2014, GM varied from 7.085,28 EUR/ha (2013), to 20.432,37 EUR/ha (2012). At the same time, total variable costs ranged from 2.723,54 (2014) to 3.226,97 EUR/ha (2013). High yields in 2012 (33,33 tons/ha) and higher price led to significantly higher GM.

Within the variable costs, the cost of labor was the most dominant item (48–56%), but the final result given in GM of strawberry production substantially depends on yield and price. It is well known that yields are highest in the first year of production (2012), so higher income was expected. Anyway, a higher price in 2012 (0,1 EUR/kg, comparing to 2013 and 2014) made the difference in GM.

Abstract

Extension service in Serbia is well defined under the set of laws and regulation, covering all important aspects of advisory works such as service provision, training and licencing. It also authorises the Institute for Science Application in Agriculture (ISAA/IPN) to perform such activities. ISAA has been preparing annual training plans (ATPs) and implementing the trainings since 2010. In this paper we will analyse training period 2010-2011 and increase in advisors' knowledge in economic and advisory/extension skills. The training of advisors is structured upon 3 axes: knowledge increase - knowledge not covered by academic education; knowledge update - innovative technologies and practices in the field of agriculture; and advisory skills acquisition, i.e. applied knowledge, advisory techniques and 'soft' skills.

Agricultural advisors in the period from 2010 to 2015, within the IPN's annual training programme, have been educated through more than 40 different modules. Trainings organized by ISAA/IPN were attended by more than 14,000 agricultural experts: mostly extension agents, but also experts from farmers' associations, local government, Rural Development Centres, non-governmental organizations (NGOs) as well as farmers. Educations have been performed by eminent experts and professors from various universities from the USA and the European Union (EU), as well as experts from different Serbian faculties and institutes.

More than 80% of the trainees have responded that the trainings did meet their needs, making it very useful for them. Meanwhile 53% of the trainees have identified the "Farm management" module as a module with the greatest impact/importance to their work, followed by the "EU Integration" module and "Extension Skills". A minimum level of knowledge after the trainings has been assessed as 'good'. About a half of participants (49%) said they could fully participate on all the important issues during the trainings.

Keywords: *Agricultural extension, training, Farm management, skills, module, knowledge*

Introduction

To be successful in an increasingly competitive EU aligned market economy, farmers need to improve their overall performance. Technical efficiency to increase yields and product quality while optimizing use of inputs will enable reduce production costs. Marketing skills ensuring good prices and farm management will increase net margin and enhance farm profitability and competitiveness. Extension workers must be able to explain with simple words, why some actions must be performed from an agro-ecological point of view and why these actions influence yields or product quality. Eventually, to make farming competitive, producers will need sound advice in farm management (World Bank. 2007, Jankovic et al., 2013).

Once increase of income from primary agriculture production is achieved, farmer might still enhance their income by different strategies and will need additional advice. On top of the services needed to improve their competitiveness and income, farmers will have to comply with EU framework and adopt environmentally-friendly agriculture (Lampietti et al., 2009, van Berkum and Bogdanov, 2012.). Extension services should be able to provide assistance in the areas of Good Farming Practices and organic agriculture. Extension workers and advisors

must establish good relations with their customers - to respect farmers, take into account their knowledge, their problems and understand their needs. This attitude must be reflected in the extension practice. To this end, a range of extension techniques exists and extension workers have to be acquainted with them. The agricultural extension service in Serbia is expected to provide wide range of services including advices on production, market information, production economics at farm level, trade, standardization and protocols, plant protection, environmental protection and animal welfare, business planning, etc. (World Bank. 2007).
Before 2010, Agriculture Stations in Serbia were insufficiently adapted to the emerging changes and processes of transition. Advisors activities should be focused on creating opportunities in order to service commercial producers and shift from production-oriented to market oriented agriculture, from quantity production to quality production. The extension service in Serbia was however in 2007 primarily focusing on the provision of non-economic advice. Such system of agricultural advisory service was out of date in information and usefulness to emerging farming enterprise.
Since 2010 Extension service in Serbia is defined by Law and following sets of regulations. This framework covers all important aspects of advisory work (service provision, training, licencing). Institute for Science Application in Agriculture (ISAA) is authorised by law to perform trainings. Since 2010, ISAA has been preparing annual training plans (ATPs) and implementing the trainings. In this paper we will analyse training period 2010-2011.
The training of advisors is structured upon 3 axes: **knowledge increase** - knowledge not covered by academic education of advisors; **knowledge update** – covering innovative technologies and practices in the field of agriculture; and **advisory skills acquisition**, i.e. extension/ advisory skills, ‘soft’ skills and applied knowledge.
Agricultural advisors in the period from 2010 to 2015, within the IPN’s annual training programme, have been educated through more than 40 different modules. Trainings organized by IPN were attended by more than 14,000 agricultural experts: mostly extension agents, but also experts from farmers' associations, local government, Rural Development Centres, non-governmental organizations (NGOs) as well as farmers. Educations have been performed by top experts and professors from various universities from the USA and the European Union (EU), as well as experts from different Serbian faculties and institutes (World Bank, 2013).
The Objective of the paper is to analyse and assess increase in advisors’ economic (Farm management, European integration) knowledge and advisory/extension skills for training period 2010-2011.

Materials and Methods

Evaluation approach: As a part of the evaluation a number of surveys have been conducted and carried out among the training participants, in order to assess the results and effects they as beneficiary think they have gained. There were developed the questionnaires - Survey among project holders for the extension service – training.

Table 1. Number of questionnaires and response rate

	No of submitted questionnaires	No of received questionnaires	Response rate (%)	Statistic uncertainty	Delivery Method
Extension survey: training	277	150	54	+/- 5,4	Postal

Source: [World Bank, 2012]

Survey contained 10 background questions and five questions/ tables regarding results and effects of the trainings. Of those who replied to the survey, 90% (131) are employed by a public extension service, whereas only 15 respondents (10%) are working for a private extension provider. Also most of the respondents, 96% (144), are working full-time. 4% (6) are working part-time.
In addition, we used other standard methods for this type of research (desk research, a method of deduction, descriptive statistics).

Results

Training in 2010

In 2010 the first training modules were organized and carried out by Institute for Science Application in Agriculture (ISAA). Eight modules were implemented: 1.1: Farm management, 1.2: The EU integrations, 2.1: Modern technologies in crop and vegetable production, 2.2: Modern technologies in plant protection, 2.3: Modern technologies in fruit production, 2.4: Modern technologies in livestock production, 3.1: Extension skills 1, 3.2: Diagnostic research methodology and Farmers Need Assessment. In addition hereto a workshop on Monitoring and evaluating extension projects and extension agents' work was conducted as well. Twelve foreign and eight local consultants carried out the modules. 27 training courses with the total of 1.153 participants were conducted. The training modules included all extension agents from the agricultural extension service of Serbia (22) and the agricultural extension service of Vojvodina (12), 13 private extension services, three NGOs, two local administrations and one association.

Twelve representatives of the Agency for Agricultural Expert Services from Republic of Srpska (BH) attended the training courses on the EU integrations and 6 extension agents from the Extension Service of Montenegro and 2 extension agents from the Livestock selection service of Montenegro attended the training courses on modern technologies.

The US Department of Agriculture (USDA) also participated in the training courses. The cooperation in providing experienced trainers was first arranged for the module on Farm management, and then for the modules on Extension skills and Modern technologies in plant protection. The USDA also provided the trainers for the workshop on monitoring and evaluation.

Trainings in 2011

The 2011, the annual training plan (ATP) was focused on expanding and enhancing knowledge acquired through the 2010 Trainings, with an emphasis on developing practical tools and techniques that extension agents can use in the field. Based on the proposal of the ISAA, the following training plan for 2011 was approved and implemented:

Axis 1: Expanding knowledge modules:

1.3: Farm Management 2,
1.4: Farm Management 3,
1.5: Marketing,
1.6: FADN.

Axis 2: Updating knowledge modules:
2.5: Modern Crop and Vegetable Production Technologies 2, Application of Plant Nutrients in Crops and Vegetable Nutrition,
2.6: Modern Plant Protection Technologies 2, Integrated Pest Management (IPM) in Crop and Vegetable Production 2,
2.7: Modern Plant Protection Technologies 3, IPM - Crop and Vegetable Production 3,
2.8: Modern Technologies in Fruit Production 2, Application of Plant Nutrients in Pommes, Stone Fruit and Berries Production 2,
2.9: Modern Livestock Production Technologies 2, Modern Technologies in Animal Nutrition - Non-ruminants.

Axis 3: Applying knowledge modules:
3.3: Extension Skills 2 - Working With Written Media,
3.4: Extension Skills 3 - Working With Audio-Visual Media,
3.5: Farmers Need Assessment 2 - Acquiring skills for assessing the needs of farmers.

Within the period May until December 2011, ten training modules and testing of assistant extension agents were carried out, these were: 1.3: Farm Management 2, 1.6: FADN, 1.7. Nitrates Directive – Preparation of the Action Plan, 2.6: Modern Plant Protection Technologies 2 - IPM in Crop and Vegetable Production 2, 2.7: Modern Plant Protection Technologies 3 - IPM in Crop and Vegetable Production 3, 3.3: Extension Skills 2 - Working With Written Media, 3.5: Farmers Need Assessment 2- Acquiring skills for assessing farmers' needs in the new regions according to the module 3.3, 4.1: Training of Trainers - Extension Skills, 4.2: Training of Trainers – Agricultural Incentives, 4.3: Training of Trainers - Assessment of Farmers' Needs -Testing of the assistant extension agents for their admission to the Extension Service.
The training courses included extension agents from the agricultural extension service of Central Serbia (22 services) and Vojvodina (12 services), 13 private extension services, three NGOs, 2 local administrations and two farmers' associations, as well as 2,085 assistant extension agents. Also 2 extension agents from the Extension Service of Montenegro attended the training. In order to educate the 2,000 assistant extension agents in extension work methods and to make them qualified for direct work with the farmers as soon as possible, three educations were organized based on the *Training of Trainers* model.
Approximately 140 extension service agents - one or two from each of 34 Agricultural extension services stations - attended the training for one of the three modules: 4.1: Training of Trainers - Extension Skills, 4.2: Agricultural Incentives and 4.3: Assessment of Farmers' Needs. After the four-day training held at the ISAA, extension agents were enabled to educate future colleagues - assistant extension agents.

Relevance: It is obvious that the participants had gained a lot from participating in the training and that the training themes are considered to be relevant (table below). More than 80% (101) have responded that the training programme did meet the current training needs of their clients, thus making it useful for them.

Table 2: Did the training meet the current training needs of your clients?

	Percentage
Largely corresponding to	26% (32)
Corresponds to a certain extent	56% (69)
Corresponds to a small extent	16% (20)
Does not correspond	2% (2)
Don't know	1% (1)
Total	**100% (124)**

Source: World Bank, 2012.

Impacts: Participants at the training modules have experienced an increase in their knowledge and capacity in relation to “farm management” (table 3). Everybody had a “good” knowledge level as minimum after attending the training modules and the number of participants with an “excellent” knowledge has increased from 7% till 39%. This is considered to be a very positive result. Attending different training modules for majority of participants was a positive experience, mainly because of being involved in the discussions during the training course. 49% found that they remarkably (“excellent”) could take part in all the important issues during the training course.

Table 3: Self - assessment of Farm management knowledge[#]**:**

	BEFORE the training	**AFTER** the training?	Participation on all important matters **DURING** the training
Poor	7 % (9)	0 % (0)	0 % (0)
Relatively good	14 % (17)	0 % (0)	1 % (1)
Good	41 % (51)	11 % (14)	14 % (20)
Very good	28 % (35)	48 % (58)	36 % (51)
Excellent	7 % (9)	39 % (48)	49 % (69)
Don’t know	2 % (2)	2 % (2)	0 % (0)
Total	**100 % (123)**	**100 % (122)**	**100 % (141)**

#Scale from 1 to 5 where 1 = Poor, 5 = Excellent
Source: World Bank, 2012.

“The relationship between theory and practical application” during the training modules is assessed to be “good” to “very good” for most participants (71%), and 14% found the balance to be “excellent”. The rating of “usefulness of group exercises” is more positive, only 2% did find the utility of group exercises to be “poor”. The “length of the training” received a positive evaluation as well.

Table 4: Assessment of training content and performance[#]:

	The ratio between theory and practical application	The usefulness of group exercises	The duration of the training
Poor	6 % (9)	2 % (3)	3 % (5)
Relatively good	8 % (12)	6 % (9)	7 % (10)
Good	26 % (38)	25 % (37)	27 % (39)

Total	**100 % (144)**	**100 % (146)**	**100 % (144)**

#Scale from 1 to 5 where 1 = Poor, 5 = Excellent
Source: World Bank, 2012.

It is interesting to see that the “communication skills and abilities” have been improved significantly due to the trainings. 51% found their “communication skills” to be “excellent” after the training, which is an increase of 34% compared to their own baseline assessment.

Table 5: Self - assessment of communication skills[#]:

	BEFORE the training	**AFTER** the training	Rate the training as a whole
Poor	4 % (6)	0 % (0)	0 % (0)
Relatively good	10 % (15)	1 % (1)	5 % (7)
Good	28 % (40)	7 % (10)	16 % (23)
Very good	41 % (60)	41 % (59)	43 % (62)
Excellent	17 % (24)	52 % (75)	35 % (51)

Total	**100 % (145)**	**100 % (145)**	**100 % (145)**

#Scale from 1 to 5 where 1 = Poor, 5 = Excellent
Source: World Bank, 2012.

Respectively 43% and 35% rated the training as a whole to be “very good” and “excellent”. Only very few of the respondents found that the training modules they have attended were not having any impacts on the factors listed below. On the contrary, the majority found that the training modules are contributing to: 1) improvement of the opportunities for the rural population to adapt to changes, 2) increase on focus and knowledge on farm management, 3) environmental protection and animal welfare, as well as 4) ecology and organic production.
In both years (2010 and 2011), most participants found the trainings to be very useful for their everyday work and to a large extent corresponded to the needs of their clients. The analysis of the tests in which participants anonymously rated their knowledge of key issues before and after each training course showed the improvement for all modules. Result from the training modules in 2011, ranging from 28% for the module 1.6 FADN to 38% for the module 1.7: Nitrates Directive- Preparation of an Action Plan.
The majority either „agree“ or „strongly agree“ that the trainings are contributing to increased focus and knowledge on sustainable agriculture, project work, getting through with ideas to the farmer and improvement the competitiveness of agriculture and understanding EU accession and IPARD.

Efficiency: 53% of the respondents found that the training module on “Farm management” had the greatest impact or importance to their work. This is followed by the “European Integration” (26%) and “Extension skills” (37%) as the third most important impact.

Table 6: Training with the greatest significance for work:

	The first response	The second response	The third response
Farm management	53 % (77)	0 % (0)	0 % (0)
European Integration	3 % (5)	26 % (18)	0 % (0)
FADN	0 % (0)	6 % (4)	20 % (7)
Modern technology: crop and vegetable production	10 % (14)	10 % (7)	11 % (4)
Modern technology: plant protection	8 % (11)	7 % (5)	0 % (0)
Modern technology: fruit production	5 % (7)	6 % (4)	9 % (3)

Total	**100 % (146)**	**100 % (68)**	**100 % (35)**

Source: World Bank, 2012.

Conclusion

Participants have gained a lot of knowledge from participating in the training, and training modules are considered to be relevant. More than 80% of the trainees have responded that the training did meet the current needs of their clients, thus making it very useful for them.
Participants have experienced an increase in their knowledge and capacity in relation to “Farm management”. Everybody has a “good” knowledge level as minimum after the training and the amount of participants with an “excellent” knowledge has increased from 7% till 39%. Majority of the participants had a positive experience in terms of being involved in the discussions during the trainings. The relationship between theory and practical application during the training is assessed to be “good” to “very good” for the majority of the participants (71%). “Farm management” module had the greatest impact or importance for their work (53%), followed by “European Integration” (26%) and “Extension skills” (37%). Feedback received during trainings confirms that the trainees are very much interested in acquiring knowledge and experiences. Training of advisors is generally needed to enhance the human capital and to facilitate the access to national support schemes, IPARD and other sources.

EXPERIENCES IN ESTABLISHING THE SERBIAN FARM ACCOUNTANCY DATA NETWORK – FADN

Vladimir JOVANOVIĆ*, Bojan ANĐELIĆ

FADN Project Office, Ministry of Agriculture and Environmental Protection, Belgrade, Serbia
*Corresponding author: vladimir.jovanovic@fadn.rs, vlada.f.jovanovic@gmail.com

Abstract

In this paper we have given the experiences in establishing the Serbian Farm Accountancy Data Network – FADN by the project of technical assistance, financed by European Union through the pre-accession funds. This system represents the instrument for monitoring microeconomic indicators of farm performance and evaluation of effects of agricultural policies.

Objective of the work is to point out Serbian experiences in establishing FADN and possibilities for improvement and use of the system. Methodology used for writing this paper consists of data analysis and description of experiences of the authors, who participated in establishing Serbian FADN system. Besides that, comparison with experiences of other countries has been used, based on desk research and information obtained from our colleagues, FADN experts from EU member states.

Reasons for establishing FADN in Serbia, organizational structure established within the project period, data collection and data analysis methodology, as well as the methodology for analyzing first results are presented in this paper. Also presented are the expectations and needs that the system should meet in the future, in order to achieve sustainability and establish the necessary capacity to perform its main tasks.

Keywords: *FADN, Serbia, experience, capacities, methodology*.

Introduction

In the period of accession to the EU, Serbia is facing the great challenge of harmonizing the agricultural and rural development policy to the Common Agricultural Policy of the EU (CAP).

One of the tasks in this process is to establish the network of microeconomic data from agricultural holdings – FADN (Farm Accountancy Data Network).

This system represents the instrument for monitoring microeconomic indicators of farm performance and evaluation of effects of agricultural and rural development policies.

Serbia is in process of establishing the system through the project of technical assistance, financed by European Union through the pre-accession funds of the IPA instrument[********].

The project is delivered by the international consortium and is to be finalized by the beginning of October 2015. Main activities of the project consist of capacity building, training and education, development of methodology, development of software and database. Beneficiary institution is the Ministry of Agriculture and Environmental Protection (later referred to as Ministry).

[********] Instrument for Pre-accession Assistance

Materials and methods

Data on economic size of farms in Serbia from database of Statistical Office of the Republic of Serbia are analyzed and compared with adopted Serbian FADN selection plan, in order to determine representativeness of Serbian FADN sample. Experiences of the authors, who participated in establishing Serbian FADN system, as well as experiences of other countries, based on desk research and information obtained from FADN experts from EU member states have also been used in this paper.

Results and discussion

Institutional Structure and Capacities

In order to establish sustainable network, totally harmonized with FADN system in EU member states, Ministry decided to form organizational structure of the system proposed by the project team.

Ministry is responsible for Serbian FADN and future liaison agency is to be formed within the Ministry. Besides the Ministry, which is the central institution in Serbian FADN, two regional bodies are responsible for organization and coordination of data collection and data validation – Institute for Science Application in Agriculture (IPN) and Provincial Secretariat for Agriculture, Water Management and Forestry in Autonomous Province of Vojvodina (PSAWMF) with their responsible persons – regional coordinators.

IPN is coordinating body for agricultural extension service in Central Serbia (including Belgrade), while PSAWMF is responsible for extension offices in Vojvodina. Insufficient communication between these two is noticeable. Hence, more cooperation between these bodies is essential.

Besides these, other institutions were also involved in establishing the system during the project period: Agricultural Faculty of the University in Belgrade, Agricultural Faculty of the University in Novi Sad and the Statistical Office of the Republic of Serbia.

Steering committee was established to take a role of the FADN committee, after the project period. This committee consists of the representatives of all institutions that participate to the FADN in Serbia. Even so, so far the responsibilities of steering committee do not seem to be clearly defined.

Immediate data collection and communication with the farmers is delegated to the agricultural advisors who work at the Agricultural Extension Service. At the moment, there are 100 agricultural advisors working as FADN data collectors. Their everyday tasks, however, are very time-consuming which influences their job within FADN.

Ministry also has to fully apply FADN methodology, in order to establish the data network which is totally harmonized and comparable with EU member states.

Field of survey

The system monitors microeconomic indicators of farm businesses, but it does not represent all agricultural holdings in one member state. FADN field of observation consists of commercial farms. These farms gain most of their income from agriculture. Field of survey includes farms that cover at least 80% of total agricultural area and 80% of total output (of all farms). In case of Serbia this figure is about 203.000[††††††††]

FADN provides data on economic size of the farms and their share in total output. Since these information were not available so far from the FADN database, data from agricultural census 2012 were used for determination of the field of survey and designing the sample through the selection plan.

[††††††††] Source: Statistical Office of the Republic of Serbia

Table 1. Farms grouped by the economic size and their share in total output

	Number of farms	**Total standard output (EUR)**	**Share (%)**
100,000 or more	1,902	803,541,678	21.42
50,000-100,000	4,825	327,469,428	8.73
25,000-50,000	11,221	385,335,130	10.27
15,000-25,000	18,261	346,286,320	9.23
8,000-15,000	52,949	563,169,693	15.01
4,000-8,000	113,194	636,383,661	16.97
2,000-4,000	140,641	404,571,557	10.79
less than 2,000	288,559	284,033,429	7.57
TOTAL	**631,552**	**3,750,790,895**	100.00

Source: Statistical Office of the Republic of Serbia

Farms in Serbia in 2012 reached the standard output (SO) of 3,750 million EUR, which makes an average of about 5,939 EUR per farm. Threshold of 4000 EUR standard output was taken since the farms with more than 4000 EUR output represent 81.64 % of total standard output of all agricultural households in Serbia.[‡‡‡‡‡‡‡‡]

Sampling

Aimed sample for Serbia, before the accession, is 2000 agricultural holdings. This number of farms will make a representative sample for Serbian agricultural sector, meaning it will represent farms that cover more than 80% of total agricultural land and more than 80% of total farming output. Due to insufficient capacities, sample was built gradually. At the very beginning in 2012, *pilot sample* had only 40 farms. Later, during 2013 it grew up to 172 farms. In 2014 Serbian FADN has collected data from 500 farms for accounting year 2013.
For the first time, farms were chosen by selection plan, following statistical rules on sampling and weighting data. In 2015 Serbian FADN has already nearly 1000 farms with the data collected for accounting year 2014.
It is decided that Serbian FADN sample consists of two regions, which match the two NUTS 1 regions in Serbia – Serbia North and South. Serbia North consists of Autonomous Province of Vojvodina and Belgrade region, and Serbia South represents the rest of the territory[§§§§§§§§].
Data collection
Dataset for the FADN purposes is defined by Commission Implementing Regulation (EU) 2015/220 of 3 February 2015 laying down rules for the application of Council Regulation (EC) No 1217/2009 setting up a network for the collection of accountancy data on the incomes and business operation of agricultural holdings in the European Union.
Regulated set of all data collected from farm is called *farm return*. This set consists of: general information related to farm location, labor, type of production, economic size, data on assets and liabilities, detailed technical data related to yields and farming activities, detailed financial data on costs and income.
Besides data defined by the Regulation, member states may define additional set of data to be collected. In case of Serbia, these are information on rental state, owned land and quantities of all inputs.
Since there is no accountancy on most of the agricultural holdings in Serbia, project team, in cooperation with national and regional coordinating bodies, developed methodology for data

[‡‡‡‡‡‡‡‡] Source: Statistical Office of the Republic of Serbia
[§§§§§§§§] Due to specific political status, Kosovo is not included in Serbian FADN system.

collection from farms, both with and without accountancy. Data are collected directly from farmer by using questionnaire.

During the first year of the project (pilot project), data were collected for accounting year 2011, by visiting farms at the beginning of 2012 and recording all required information from 2011, by interviewing the farmers. Data were recorded by using simple questionnaire that was designed to contain all necessary information on farm return. In 2012, data were collected by using Questionnaire, filled by the data collector and the Log Book, where the farmer kept records on farm activities. Later, in 2013 and 2014, single document - Questionnaire was used directly on farm level, filled together by the farmer and the data collector.

Benefits for Farmers

During the project period, it was a great challenge to motivate farmers to participate to the system. Participation in the FADN is on a voluntary basis, and farmers in Serbia do not get any direct financial benefit from the system.

Therefore, it is essential to provide farmers with some direct benefit that will motivate them to join the FADN and to remain in the system. There are several direct benefits that farmers in Serbia may enjoy by participating in FADN:

1. Feedback to farmers in Serbia consists of four sets of information on farming business. Most of the information presented in this document are based on FADN standard results. The first set consists of general information, such as area, labor, yields, and land use. Next group of information are presented as a balance sheet. All farms assets and liabilities are grouped and presented here. This gives a basis for calculation of indicators on farms liquidity and solvency. Following group consists of financial indicators including profit and loss statement. This gives an overview and the structure on farm costs and income. Finally, the last set of information is called *Additional indicators*. Unlike, previous three groups, these indicators are not based on standard results. These indicators are totally decided by Serbian FADN project team, and are meant to provide relevant and useful information on farm business results to the farmers. For results of accounting year 2014, it has been decided that these indicators include: farm net income per ha, farm net income without subsidies per ha, farm net income per hour of unpaid labor, output/input ratio, debt ratio, liquidity ratio, gross margin of crops and products, gross margin of livestock and products, and gross margin of other products and services.
2. Even though in Serbia, farmers have valuable opportunity to use agricultural advisory services for free, Agricultural extension service employs about 230 agricultural advisors, which leads us to the number of nearly 3000 farms per one agricultural advisor. Since 2014 FADN is an integral part of the Annual Program of Agricultural Extension Service in Serbia, which makes FADN activities an obligatory task for a number of agricultural advisors[*********]. This means that the farmers who participate to the system have at least four visits of an advisor, just for FADN purposes. Advisors are (or become) familiar with the farming activities at these farms, and are able to give more detailed advises on improving farm business.
3. Naturally, at the beginning, most of the farmers kept records for FADN purposes with significant assistance from the data collectors (agricultural extension advisors). Later on they started to record their farm activities and the farm situation more on their own. This way, farmers start (or continue) with the good practice of keeping records at farm level, which is a good starting point for planning of future farm business, as well as a valuable input for business plans and other essential elements for different applications for loans or use of public funds.

[*********] At the moment, 100 agricultural advisors work within the FADN network as the data collectors.

Use of FADN data

During the project period the Ministry and other beneficiary institutions were provided with sufficient expertise regarding data analysis for policy making and scientific purposes.

Several workshops on this topic with national coordinating bodies, universities and institutes were organized.

Still, there is no clear idea for efficient utilization of FADN data for policy making purposes. Until now, no official analysis based on Serbian FADN data was published, neither the Ministry has issued any publication based on FADN data. This way there are no sufficient information on microeconomic indicators of Serbian agricultural sector (especially since the agricultural census in 2012). So far, it looks like that the Serbian FADN data is only planned to be used to fulfill the requirements of European Union, as a part of the accession process.

Conclusion

As the FADN system was introduced in 1965, lots of experiences were gained until now. The methodology is fully regulated by the EU, and it still develops, following the development of EU CAP. Also, experiences from countries that joined the EU not long ago (such as Croatia), are available to Serbian team.

Experience gained tells us that if the clear and stable institutional and organizational structure is established, Serbia has real chances to have a sustainable FADN system, harmonized with EU member states. Among other things, this means that the FADN staff should only work on FADN, since it is the only way for them to keep focus and energy for this serious job. Also, the Ministry and other involved institutions should use all available expertise and experiences from other countries, of which many faced the same challenges. Indispensable part of this process is a political will for establishing such a network, since the FADN is mainly a state-operated system.

In order to gain the interest of all possible stakeholders to FADN, possibilities for use of FADN data analysis and possible benefits for agricultural sector should be clearly presented any time possible, since the FADN data are valuable as much as we use them.

THE GREEN INTEGRAL DEVELOPMENTAL MODEL CO-EVOLVED FROM GRASSROOTS INNOVATION MOVEMENT OF SLOVENIAN GOOD PRACTICES

Liliana VIŽINTIN

Biotechnical Centre Naklo, Naklo, Slovenia
*Corresponding author: lili.vizintin@gmail.com

Abstract

Grassroots innovations are community-led solutions for sustainability that respond to the local situations, interests and values of the communities involved. Integral green Slovenia model is a holistic model of sustainable development, started as a bottom up initiative of a group of people from social responsible and sustainable institutions and SMEs representing already established or emerging good practices. They connected their stories to the theories of Integral Economics and Integral Development developed by Ronnie Lessem and Alexander Schieffer from Trans4m's Institute for Integral Development in Geneva (Switzerland), internationally recognized models of integral economy and sustainable development as a part of socially responsible practice. Nowadays it could be considered as a grassroots innovation movement in Slovenia that supports sustainable farming, preservation of vital rural areas, social inclusion, green industry, social entrepreneurship, sustainable tourism and self-sufficiency.
This paper presented the essential elements, history and evolution of the Integral green Slovenia initiative. The case study of Biotechnical Centre Naklo (Slovenia) was in detail analyzed since the uniqueness of its model and vision called CARE (Catalysation, Activism, Research and Education) that incorporates many innovative aspects of education for sustainable development (ESD), nature protection, organic farming, research and activism. An evident impact on local/regional community was achieved, but the ambition of this initiative is to inspire, connect and upgrade good practices in a creative way and impact on various EU developmental policies.
Keywords: *Sustainability, grassroots innovations, Integral green Slovenia initiative*

Introduction

Grassroots innovations could be described as networks of activists and organizations generating novel bottom up solutions for sustainable development. These solutions are adapted to the local natural and socio-cultural context, the interest and values of the communities involved (Seyfang and Smith, 2007). Indeed, grassroots innovations are driven by social needs and ideology. Therefore, aspects of social economies, mutual exchanges, voluntary inputs, social responsibility, ethics and values are included. A review of grassroots actions for sustainability (Church and Elster, 2002) identified a range of direct environmental benefits and significant socio-economic impacts with benefits for sustainable communities.
Transition theorist (Geels and Schot, 2007; Seyfang and Smith, 2007; Lawhon and Murphy, 2012) have made important contributions to our knowledge of the challenges and possibilities for achieving more sustainable societies. Potential development, needs and challenges faced by mentioned grassroots initiatives, are better understood if these community-level-activities are analysed as *innovative niches*. Niche situations are open spaces for new ideas, good practices and social movements that initially are not enough robust to challenge *socio-technical regimes* as described by transition theorists. Niches need to be transposed to wider scale. It could be done by policy interventions, which bridge niches and mainstream situations and reformulate wider scale practices. Green niches explore problems as mobility, food supply, energy and entrepreneurship and propose solutions as short food supply chains and

innovative local food systems, removable energy services, social entrepreneurship and shared-use mobility. But socio-technical regimes are barriers for radical changes, causing lock out of sustainable alternatives. To seed wider changes, drivers for change that are able to put pressure on regimes, are needed (Sterrenberg et al., 2014). Some examples of drivers are: climate changes, population growth, increasing oil prices and financial crisis. Altogether are powerful drivers that require a radical change in thinking of humans, some kind of transition thinking toward a more sustainable society that would lead us out of our comfort zone and nearer to sustainable outcomes.

Sustainability must be an integrated concept, but it is radically insufficient if it addresses just economic, social and environmental dimension without ethics, values, culture heritage and social responsibility. The integral green economy model by Lessem and Shieffer (2010) is based on four pillars which integrated the world's diversity of nature, community, economics, culture and spirituality, science and technology with the central ethical core. Moreover, CARE (C+A+R+E) model (Lessem et al., 2014) is a holistic approach that covers and connects activities of Catalysation, Activism, Research and Education. The collaboration between Alexander Schieffer and Ronnie Lessem, TRANS4M Center for Integral Development, Geneva, Switzerland, Darja Piciga, founder of the initiative for Integral Green Slovenia (Piciga, 2012) and BC Naklo started in May 2013.

Biotechnical Centre (BC) Naklo (2014, 2015) is a Slovenian public educational and research institution, ecologically orientated. In the Vision of the Centre is written that the Centre is a truly sustainable institution with a positive attitude towards nature, a concern for production and processing of healthy food and a great care for the natural environment in cooperation with the green economy sector. The Centre property (organic farm) covers 4 hectares of build-up area and extra 22 hectares of ecological agricultural area. It is divided in 3 main units: Secondary school, Higher Vocational College with Research Unit, Enterprise Centre. The Centre's major contribution to raising the awareness of local population about the environmental situation and conditions is based on an active approach, cultural and natural heritage protection actions and projects.

The aim of this article is to present the above described theoretical models co-evolved by Slovenian good practices as Integral green Slovenia movement, a bottom up designed grassroots innovative niche. The potential benefits and implications of shifting from the current economic and developmental models toward models of integral economy are discussed. The case study is focused on the green integral model of BC Naklo as one of the leading cases of good practices involved in the movement.

Materials and methods

In the article we propose a qualitative case study that is used to study complex phenomena within their context (Baxter and Jack, 2008). The case study methodology can be applied not only in the social sciences, but also on interdisciplinary, education, business and environmental studies. There are different interpretations of the notion of "case study" (Yin, 1994; Gillham, 2001; Baxter and Jack, 2008), but in general the case study should have a "case" which is the object of the study that should be complex and contemporary and should be investigated in its natural context with a multitude of methods (Johansson, 2003). In our case, the aim of the used approach is to present a model that could be implemented also in different environments and in consideration of local situations, natural and cultural background of the communities.

Results and discussion

The Integral Green Slovenia movement

The beginning of the Integral Green Slovenia movement can be traced back to 2011 when cooperation between its three leading figures - Darja Piciga, Ronny Lessem and Alexander Schieffer – started, but the idea of Slovenia's development as a model of integral, low carbon economy and society was presented for the first time in 2012 (Piciga, 2012; Piciga et al., 2015). The attempt of the strategy for the transition to a low-carbon society included key elements of Integral Worlds approach by Lessem and Schieffer (2010), based on four realms and the central moral core. It is a promising new paradigm for sustainable social and economic innovation on different levels (Bečić et al., 2013). This holistic model presented the vision of Slovenia as a highly integrated and inclusive society with an excellent business sector and a high quality of life, space and natural environment. The policy planning processes started in 2013 and led to the inclusion of the integral economy approach into the guidelines for action of some draft policy documents (Piciga, 2013). According to this approach, every social system needs to find, in order to be and stay sustainable, a dynamic balance between its four mutually reinforcing and interdependent realms, balanced by the central moral core. To analyse this model in the Slovenian environment (Figure 1), already existing good practices (representing institutions or enterprises that are leading cases of any realm) are used. The four realms co-evolved in Slovenia (Piciga et al., 2015) were: (a) the ‘southern’ natural and communal realm (promotes the self-sufficient community-based economy) represented by Šentrupert Municipality, (b) the ‘eastern’ cultural and spiritual realm (promotes a developmental culture-based economy) represented by BC Naklo (Vižintin, 2015) and The Heart of Slovenia (Gradišek, 2015), (c) the ‘northern’ scientific and technological realm (promotes a social knowledge based economy) represented by Domel, Železniki (Rejec et al., 2015), (d) the ‘western’ realm (revising as “living” life-based economic realm with a strong focus on ecology and sustainability) represented by Pipistrel, Ajdovščina. Indeed, the moral central core (related to the innermost value base founded in each society) was represented by Kindergarten Oton Župančič, Slovenska Bistrica (Leskovar et al., 2015).

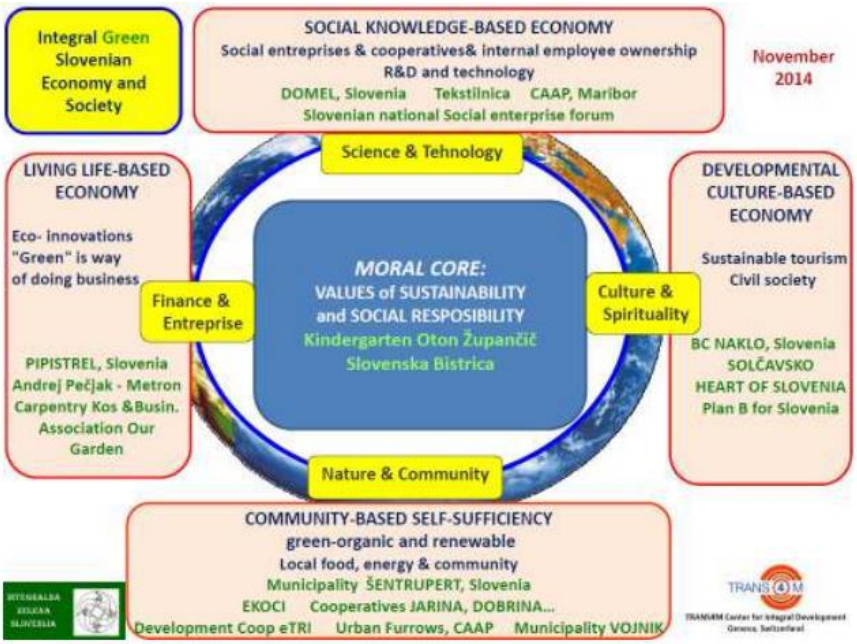

Figure 1: The model of Integral green Slovenia by Piciga et al. (2015).

The green integral model of BC Naklo

BC Naklo's adaptation called Green integral model of BC Naklo (Figure 2) is organised around a central ethical core defined through the positive social and environmental impact of the Centre (the emphases on the word "green" before "integral" is not casual). Great care is given to good interpersonal relationships, empowerment of the community, transparent administration, responsible entrepreneurship and the implementation of high-level certificated standards. Organic farming, low environmental impact of the estate, the use of renewable energy sources and ecological orientation are relevant indicators for the Centre's intense environmental engagement. The community of BC Naklo is growing continuously and has by now transcended national borders. Social responsible small and medium enterprises (SMEs) are supported by the Centre through joint efforts in education, production and services offered to the community and environment. Building on the integral green model, BC Naklo has set the following development and strategic objectives: (a) improving quality, (b) educating and training students and adult learners in the biotechnical field and related activities, (c) obtaining participants from the international environment, (d) becoming a Centre for sustainable rural development, (f) undertaking research and development activities to meet the needs of the economy at home and abroad, (g) implementing a wide range of projects, (h) development of green business ideas, (j) friendly working environment and employee development. To realize these purposes, the Centre has created good connection and solid collaboration with local authorities, communities, SMEs from green sector and non-governmental organizations (NGOs) in the fields of environmental protection, nature conservation and sustainable development. All these experiences of good collaboration practices are very important; together with values and cultural background they are the core of the success of the Centre. Nevertheless the Centre explores new ideas and innovative paths to give a more valuable contribution to strategies of local rural development and green economy. The goal is to obtain more relevant outcomes on the path of a sustainable lifestyle and responsible care for the environment.

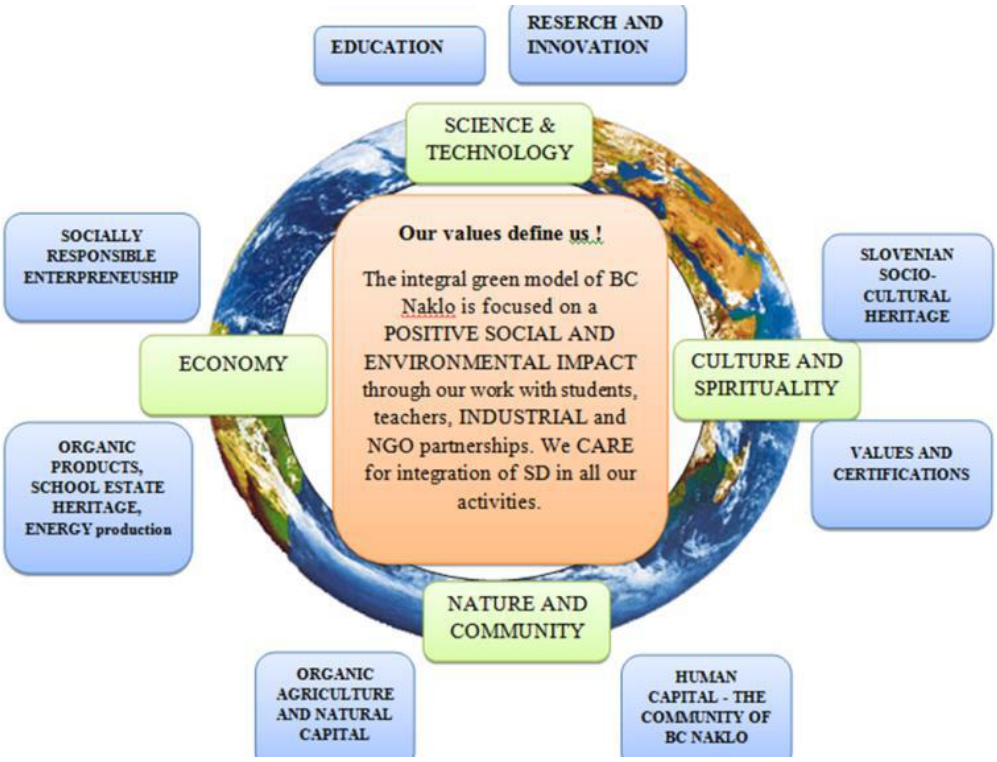

Figure 2: Green integral model of BC Naklo.

Central concepts as critical literacy, personal empowerment, mindfulness, human and nature well-being was promoted also by CARE (Catalysation + Activism + Research + Education) integration strategy that connect innovative education approaches like service learning and community-based-learning (CBL) with research, activism and the activation of consciousness of the community (Figure 3). The capacity for ethical reasoning present in human nature is the core of the future survival on this planet. Therefore new sustainable educational models are based on connection of nature protection, environmental and social sciences. CARE concept has different dimensions: (a) socio-cultural dimension that include caring for personal and professional development of students, employees and local community, (b) natural dimension that include caring for living organisms and for preservation of ecosystem dynamics and global ecosphere.

Figure 3: CARE model of BC Naklo (Modified from Lessem et al., 2014).

Regarding research, the integral framework for conceptualization was emphasized. Clarifying one's concepts with theory and practice (experiential learning) to understand the precise definitions could be a difficult step, but very useful since science aim to be explained and understood. It is a holistic approach that connects research and educational process to more affective domain (values, attitudes and behaviours). Indeed, “catalysation” is a process of activation of the consciousness of the community: we would like to create a community of BC Naklo that cultivates mindfulness of actions connected with protection of local cultural and natural capital. Mindfulness requires flexibility, openness, and the ability to break set (Hoy et al., 2006), which at the end could let to activism and pro-environmental behaviour. Environmental education that include CBL experiences as internships, volunteering, community service, out-of-the-class activities connects students’ theoretical work with their affective domain, values, interest and concern for the local community and nature. When students collaborate with local NGO, SMEs, organic farms and local community as activists, they are able to develop research projects, collect and analyse data, and share their results and conclusions, not just with their professors, but also with their outside tutors that can make use

of the information. The added values of these collaborations are much higher if outcomes are not just cognitive but also affective.

Conclusions

The theoretical framework of integral economics and development is being applied in an original and practical way in Slovenian natural and socio-cultural context. Starting from the moral core and introducing four economic paths (self-sufficient community-based economy, developmental culture-based economy, social knowledge based economy and “living” life-based economy) is an innovative and unique aspect of this approach. Slovenian integral green path is still considered as innovation niche that need to scale up. Evident impacts on local/regional community was already achieved, but the ambition of this initiative is to address global challenges, to develop sustainable economies and societies by inspiring, connecting and upgrading good practices at EU level and to weaving in a creative way various EU developmental policies.

Abstract

Tunisian agriculture is facing many challenges such as climate change, new pests and diseases, food safety, export requirements, etc. Farmers find it difficult to get new knowledge to deal with these problems on their own. Therefore, extension services have an important role to play in supporting them. This study aims to analyse the contribution of the public extension services, to agricultural and rural development in Tunisia. For that semi-structured interviews were conducted in March-April 2015 with farmers and extension managers and agents in the central, regional and local levels. The analysis shows that Tunisian farmers have a variety of needs and priorities that exceed the traditional new agricultural technologies demand. Extension services face a lack of human resources and logistics. Gender has an important place in the national extension strategies whether in terms of woman share in extension staff or attention paid to woman farmers. Extension approaches are numerous and their evaluation is not well reported at the central level. Most of the extension techniques are old but some new ones are introduced in integrated rural development projects. That being said, it is recommended to provide more training to extension staff at all levels; to establish a rigorous planning of extension activities; to strengthen linkages with the research system; to adapt themes and messages to target groups and to introduce new extension approaches specifically for rural women. For making the extension system more efficient it is also necessary to foster farmers' organizations involvement in extension activities and financing and to improve extension infrastructure and equipment.

Keywords: *Agricultural extension, Rural development, Farmer organizations, Tunisia*

Introduction

In Tunisia agriculture sector is a fundamental source of economic growth. Despite the change and diversification observed in the Tunisian economy (industrialization, growth of service sector and expansion of tourism), the agricultural sector remains economically and socially important for its contribution to the achievement of national objectives as regards to food security, employment, regional equilibrium and social cohesion (Chebbi and Lachall, 2007). The importance of agriculture to the country's economy is highlighted also by its contribution to supporting rural livelihoods and controlling urban migration as it employs about a quarter of the Tunisian workforce (Touayi, 2004)

Over the last two decades, Tunisian agricultural growth can be largely attributed to the use of output-enhancing technologies and the promotion of investments in agricultural projects. For technological change, the advances have mainly consisted of the introduction of new seeds, new varieties, improved breeds, water saving techniques, and the mechanization of farming.

These advances have gone hand-in-hand with the promotion of investment projects in agriculture and credit facilities, and with more technically trained and educated farmers. However, improvements in the agricultural sector have not been uniform. In fact, many farmers are still poor because they lack capital, experience, and knowledge to become

efficient producers (Aoun, 2004). Agricultural extension is indeed considered as one of the tools contributing in the evolution of the agricultural sector and in the mobilisation of all its potentials so as to stimulate production and cover the trade balance deficit in food products (Touayi, 2004). Nowadays, Tunisian agriculture is facing other new challenges such as climate change, emerging and re-emerging pests and diseases, food safety, export requirements, etc. Farmers find it difficult to get new knowledge to deal with these problems on their own. Tunisian government is aware of these problems and tried to face them by providing the right equipment and the adequate quantity of inputs, but these means are not effective as long as farmers do not know how to use them effectively.
The present paper attempts to provide a critical analysis of the contribution of public agricultural extension and advisory services to agricultural and rural development in Tunisia.

Material and Methods

The methodology adopted is based on a review of secondary data and semi-structured interviews performed in March-April 2015 with a selected gender-balanced sample of agricultural extension and training providers and beneficiaries representing various structures dealing with public extension services. More particularly, the sample comprises Agriculture Ministry officers and administrative staff, farmers and private agricultural entrepreneurs, agricultural technicians, practitioners, representatives of NGOs, researchers and professors (Table 1). The output of these semi-structured interviews has been exploited to evaluate and show the qualitative aspects characterizing device performance as well as suggestions for improvement of the extension services in Tunisia.

Table 1. Sample used for semi-structured interviews and some information about the interviewees.

Number of interviewees	Occupation and/or Affiliation
3	Extension coordinators at central and regional level
3	Administrative officers in the Agricultural Development Regional Commissions
5	Heads of Extension territorial cells or Agricultural radiance cells
4	Regional representatives of farmers' associations and agricultural development groups' members
1	President of a society of agricultural services
2	Specialists from technical centres (citrus, potatoes and artichokes)
2	Researchers from National Institute of Field Crops and National Research Institute
2	Engineers from general directorates in the Ministry of Agriculture (agricultural production and plant protection)
1	Engineer from Agricultural extension and training agency
3	Agricultural inputs suppliers (1 society and 2 shops)
1	Professor in a high agricultural school
2	Former development projects' coordinators (one of them was in charge of rural woman extension)
4	Engineers from the Office of Livestock and Pasture, Office of Cereals, Office of Olive Oil, and Olive Tree Institute

Results and Discussion

Tunisian extension services framework

Successive reforms gave the current framework of the Tunisian public extension services. The results of these reforms is that the present public extension system is based on a single three-

level system (central, regional and local). In fact, reforms made during the 7th 5-year plan (1986-90) and 5-year national agricultural extension development initiative started in 1991 as part of the 8th 5-year plan (1990-94) have produced a three-tier extension system (MetaMeta, 2013): Agricultural Training and Extension Agency (AETA) at central level, Agricultural Development Regional Commissions (CRDA) at regional level, and Extension Territorial Cells (CTV) and Agricultural Radiance Centres (CRA) at local level.

At the *central level*, AETA is in charge of mass agricultural, extension, support, follow-up and coordination of field extension. According to the Law No. 90-73, AETA's missions relate to the areas of extension and agricultural training. As for strategy and management of extension systems and training, the Agency: contributes to the design and implementation of the national agricultural extension and training policy; ensures the development, monitoring and evaluation of training programs; undertakes actions and studies for the promotion of extension and agricultural training; coordinates extension systems implemented by the Regional commissions and ensures didactic and logistical support; produces and disseminates technical written and audio-visual material; helps farmers and their organizations to undertake extension activities. As for training, the Agency ensures professional training of farmers and extension agents retraining.

In the central level also, attached to the agriculture minister office, there is the Central Unit for Women's Promotion which is in charge of the extension for rural women and is represented at the regional level by the regional rural women promotion cell in each commission consisting of only women extension agents. Actually there is no recent statistics available about gender but the interviewees are satisfied with the presentation of women in the extension work. As an example in the Zaghouan regional commission the three coordinators of the regional extension cell are women. This is to show that gender equity has an important place in the national extension strategies whether in terms of woman share in extension staff or attention paid to woman farmer. However, a more participatory extension system would involve a greater representation of women (MetaMeta, 2013).

At the *regional level*, the Agricultural Development Regional Commissions are in charge of field agricultural extension through Territorial Extension Cells and the Agricultural Radiance Cells. In every commission, there are the directory for Extension and the Promotion of Agricultural Production and the coordination cell mainly in charge of planning, organisation and follow-up of agricultural extension actions and training; coordination with the different districts in the commission, technical services, and regional subject matter specialists who ensure support to agricultural extension activities in addition of reporting all.

At the *local level*, the Territorial Extension Cells are in charge of helping extension agents by organising their programmed work and providing means to them in addition of the follow-up. Agricultural Radiance Cells are in charge of: making new technology, information and options available to farmers; participating in the selection of research topics related to the field problems met by farmers; awareness raising and training of farmers to form groups (cooperative society, association); helping farmers' groups; etc. (Touay, 2004).

In general extension activity is carried out by the regional commissions (about 40%), public technical centres and offices (about 40%), professional structures (about 15%) and private advisory structures (about 5%). So the bigger part of agricultural extension and advisory activities is ensured by the public structures (about 80%).

National extension strategy

In the absence of an official document that sets the national extension strategy for the coming period, are presented hereafter the only documents available that address this issue, namely: the axes of the XIth Plan (2007-2011) in extension services; and the main development issues planned for 2010-14 period and which were summarized in a document prepared by AETA in

September 2010, few months before the revolution. This document is out of date, but gives an idea about the reflections made in the development of the agricultural extension sector.
The orientations of the *XIth Plan* (2007-11) in extension are mainly:
• Fostering initiatives towards bigger private sector participation, within a progressive program to the multiplicity of extension forms, based on: a public extension service for small farmers; a farmers' associations, organizations, cooperatives and groups extension for their members; a private extension for large farms and agricultural societies.
• Improving the effectiveness of intervention of AETA to follow technological progress;
• Deep thinking on the establishment of a new extension system that will be based on "*the mandate extension*".
In terms of extension approaches, the main recommendations are:
• The development of new approaches to extension as the tour the researchers during the cereals campaign in the regions visiting and advising farmers or famer-to-farmer extension or "farmer field schools"; which are used in some regions, but are not yet widespread. In other areas extension agents have never heard of such an approach.
• The development of strong relationship between research and extension;
• Improving the identification of extension needs by the involvement of the farmers' associations;
• Start a deep reflection on the establishment of a new extension system that will be based on "*the mandate extension*" like what was done with the "*sanitary mandate*" for animal health.

These orientations and recommendations are in line with the key focus areas of agricultural extension listed by the representatives of AETA at a workshop organised by FAO in 2003 (Touayi, 2004) namely: conception and implementation of a programming, follow-up and assessment approach; launching of *computerisation* in the extension system at the central and regional levels; and updating and enhancement of the programming approach by including the qualitative aspect (*programming by objective*) particularly in intensive extension campaigns.
As for the 2014 *strategy*, the main stated objectives were: strengthening the number of extension agents according to the goal of 1 agent for 600 farms; doubling the number of private consultants; encouraging development of new approaches to extension (e.g. Farmer Field Schools); providing more means to extension agents (e.g. transport, computers, internet connection); and capacity building of extension agents by retraining sessions.
The mass extension is nowadays one of the main activities of AETA and concerns the organization of radio and TV broadcasts, preparation of TV spots, printing brochures and posters, preparation of printed and electronic (i.e. CD, DVD) technical guides...
A systemic challenge for agricultural research, extension and planning institutions, whether government or non-government, is to institutionalize approaches and structures that encourage learning (Pretty, 1995). But nowadays in Tunisia, the perception of the current extension system by farmers and other actors varies from one to another, and is often negative. But overall, the majority of interviewees claim that the extension effort is getting weaker from one year to another, with decrease of extension agents in the field. According to MetaMeta (2013), Tunisian Agriculture extension is still to a large extent envisaged as a unidirectional process of transferring scientific knowledge to farmers without emphasis on farmers' traditional knowledge and practices, farmer-to-scientist or framer-to-farmer learning.
The creation of technical centres as links between research institutions and extension services was to well identify the research needs and disseminate research findings. It was expected the involvement of the farmers' associations, represented mainly by Tunisian Farming and Fishing Union, in the extension work by as a first step the preparation of annual extension programs but actually the involvement of the union is not effective. Many good attempts on extension are done by the Farmers' Syndicate, which is less important than the Farmers'

Union (e.g. information days on cereals crops). The material resources available to the extension agents of the Regional commissions are very poor. Thus in some extension cells, there is only one vehicle available for extension services (for both territorial extension cells and agricultural radiance cells attached to it). In addition, several vehicles dedicated to the extension are old (aged twenty years and more).
Touayi (2004) reported that in spite of the significant evolution in the agricultural extension sector in the past few years, agricultural extension faces many constraints, mainly: multiplicity of decision-making levels; number of topics to be extended is not proportional to the means made available to extension agents; lack of material and human resources at the central and regional levels (at the regional level, extension agents are called on to undertake many tasks beside agricultural extension activities); weak involvement of farmers and their organisations in extension system; and weak links between research and extension. Weak linkages between agricultural researchers, extension agents and farmers can be due also to the weak performance of the Agricultural Research and Higher Education Institute (IRESA) as one of the missions of IRESA is establishing linkages, on the one hand, between agricultural research and higher education institutions and, on the other hand, agricultural extension and farmers.

New technologies in extension

Regarding the use of the web and communication technology tools in extension almost all the territorial extension cells and agricultural radiance cells do not have Internet access or adequate didactic materials such as projectors, camera, etc. However, the National institute of field crops adopted since few years warning and exhortation mobile short messages from database that it has implemented and gathers farmers and extension agents. The messages concern irrigation based on the water deficit of each region, but also cereals disease. The majority of commissions, centres, general administrations, institutes, agencies have their own Facebook pages in which they publish information and sometimes in certain websites there are online software dealing with supporting farmers in some tasks like calculating irrigation amount. The AETA has a good database on its website with a lot of extension documents and videos available online.
A new information system for extension was set up. It provides for automatic processing of information and direct communication between AETA and the extension cells in the regions. For the implementation of this system, 11 governorates have been involved in the project, have been equipped with computer means and received specific training on the use of this system. But this system is out of use for the moment.
Audio-visual and printed material of AETA is un-optimized although it has its own audio-visual equipment used for the realization of extension materials. These devices are suitable for audio-visual production in accordance with professional standards, but AETA has a lack of internal skills required for such activity, which affects the ability of the agency to produce materials in sufficient quantity and quality.

Financing

The extension services are mostly public so the financing of extension projects comes mainly from public funds. The other structures dealing with extension, like farmers' organisations and some non-governmental organisations, are providing outputs and equipment (renting) in addition of extension free services or included in the final fees. Some of these societies have cooperation with external organization (*e.g.* IFAD - International Fund for Agricultural Development, etc.) or universities.
Budgets allocated for extension services in regional commissions are low and sometimes not effectively used. It is about of 50 thousand of Tunisian dinars (TD) (23000€) a year per

Regional commission, which means a budget from 5 (2300€) to 10 thousand of dinars (4600€) per territorial extension cell. Taking into account the many extension activities to be conducted by a territorial extension cell (information days, demonstration plots, visits to pilot farms, etc.), it turns out that such a budget is a major constraint for the implementation of the planned extension programs.

Examples of cooperation projects dealing with extension services

Integrated Agricultural Development Projects are carried out in some governorates and are controlled by the Regional commissions. We take here the example of two projects led in the governorates of Siliana and Kairouan.

The *Siliana's integrated project* lasted 10 years (2003-2013) aimed to improve the living conditions of local populations. The project is funded by IFAD, AFD (French Development Agency) and the GEF (Global Environment Fund). It includes an infrastructure component (development of irrigated area, water supply, rural roads, etc.) and an agricultural development component (tree plantations, creation of small and medium enterprise, etc.). Regarding extension, the project has planned an intervention by private extension among 500 farms spread over 17 sectors and over a period of 3 years.

Two private consultant societies were commissioned to carry out this project for a total budget of around 800,000 TD (350,000€). Each society has mobilized 4 or 5 extension agents that are supported when needed by experts or specialists in certain topics. Extension mission started by carrying out a participatory diagnostic with approximately 3000 farmers in order to identify their needs for extension and to choose later 500 to have the extension support. The choice of farmers was mainly related to the potential of development they can express and which fit with the objectives of agricultural development in the governorate (improve intensification and exploitation of irrigation, livestock development, etc.). It is expected that the 500 supported farmers will spread the knowledge to more or less 12000 surrounding farms. For each of 500 selected farms, a technical-economic profile was set up with the description of the starting situation (methods, tools, etc.) and performance (income, production, etc.), and the expected objectives at the end of the coaching period. Every three months an evaluation of the situation was held. According to the project team, the extension mandate experience was positive, since it has targeted farms in disadvantaged areas which were not well covered by the public extension services (because of lack of human and material resources), introduced into the region, participatory identification of extension needs approach and a method of defining objectives and evaluation of the impact of extension, succeeded in improving production in the majority of supported farms. This progress may be limited to the introduction of new techniques like the introduction of crop rotation and fodder crops, or the improvement of performance like lower livestock mortality rates and better yields.

The *Kairouan's integrated project* (8 years) was called "*Integrated Agricultural Development for Kairouan Hills*" covers more than 200000 ha (44% of the total area of arable land in the governorate) and includes 50% of the total population and 50000 households. The budget was 54 million dinars (25 million €), and includes an extension component. The project extension approach was an innovation in the region. In fact, the extension activity was subcontracted to private societies which recruited young engineers and planned for them complementary training according to specific project needs in the region. The contract with private societies was for 48 months and the total amount of compensation was around 1.2 million dinars (550 thousands €). A staff of 12 engineers, trained as "extension advisors", was divided into three teams called extension cells. Each cell is in charge of 250 to 400 farmers. In collaboration with the head of the Extension Territorial Cells concerned. It is expected that 5000 to 15000 farmers in the project area would benefit from good quality extension services.

The future of extension services in Tunisia: what role for private sector?

The private extension in Tunisia remains largely undeveloped and is limited either to specific interventions in big farms or some extension activities conducted under projects financed by public structures (AETA, Office of Livestock and Pasture, etc.) or external donors' funds. Thus, with the lack of a sustainable funding mechanism, private extension will remain very uncertain. It is expected that the farmers' associations, represented mainly by Tunisian Farming and Fishing Union, will be more associated to the extension efforts but actually the involvement of the union is not effective. National Agriculture and Fishing Union was occasionally involved in conducting extension activities through projects funded by donors. The aim was to test the transfer of the extension tasks from public structures to the farmers' associations. Upon completion of these projects, and given the absence of adequate resources (e.g. management, transport), many regional branch of National Agriculture and Fishing Union that were involved in these projects have had their extension activity annihilated and engineers recruited to extension stations are now managing administrative tasks. Other trials are led by some farmers' groups but the experiences ended with the end of projects.

Many good attempts on extension are done by the Farmers' Syndicate (*e.g.* information days on cereals crops).In addition, a successful agricultural services society provides extension, equipment and inputs for cereals' cultivators in a small area and the results are very encouraging. This syndicate has a cooperation with Emilia-Romagna Region in Italy.

Some pilot projects have been led with the "extension mandate" but these projects are few. *Extension mandate* was adopted as a sub-contracting approach by some organizations such as the Office of Livestock and Pasture and certain integrated rural development projects. These mandates are the subject of fixed-term contracts of around 3 to 5 years. The use of *extension mandate* remains, however, limited and the number of private consultants involved in projects would be about fifty.

One can mention as a successful experience that of the Office of Livestock and Pasture which use private advisors. Agreements have been signed with 22 private consultants to support groups of farmers in a 10 governorates (in the proportion of 1 to 3 consultants per governorate), over a period of 3 years. Funding for this program is provided by the budget of the Office. In addition to its positive impact on improving the technical knowledge and performance in livestock operations, this extension program has encouraged many private consultants to engage in this business. However, the sustainability of this program is not guaranteed in terms of financing, since there is no specific budget dedicated to it in the annual budget of the Office. With the absence of continued financing, the sustainability of private adviser jobs is not assured, and many consultants are looking to integrate the technical services of the Ministry of Agriculture.

The National Institute of Agronomic Studies, which is the most important and the oldest educational institution in Tunisia, has introduced a 5-year agricultural advisory diploma whose first promotion graduated in 2012 consisting of 40 persons (engineers in agricultural advisory). The first problem facing these young advisers was the fact that they have no experience in extension and that was a big constraint to be operational since the beginning.

According to the 2011 activity report of AETA, there are 177 private agricultural advisors but only a hundred are actually active.

The main obstacle to the development of this sector is the financing commonalities. Indeed, farmers, who are mostly small and the agricultural structures (Agricultural Development Groups, service societies, etc.) experiencing financial hardship are unable to use paid services of a private consultant. In addition to funding problems, other obstacles are to mention as competition with free extension agents as inputs suppliers, public extension, researchers and

lack of experience of some young private consultants, so that in some cases they could not win against the farmers who have extensive field experience.
However, private extension has several advantages compared to the public extension: flexibility and pragmatism in the contact with farmers, new extension tools, and looking for best results in efficient way and at the lowest price.
However, the farmers, especially small ones are not used to pay money for extension services. For this reasons, the private extension still very undeveloped and limited only for very specialized operations or complicated procedures or carried out under projects funded by public structures (e.g. AETA, Office of Livestock and Pasture) or foreign donors.

Conclusions

Tunisian agricultural extension is since many years in a continuous change and reforms to face new challenges. To support this dynamism, it is recommended to provide more training to public extension staff; to have extension activities better planned to be well supervised and improve efficiency; to strengthen linkages with the research institutions through contracts and agreements; to adapt themes and messages to target groups (including small-scale farmers) and to introduce new extension approaches specifically for rural women. For making the extension system more efficient it is also necessary to foster the involvement of other institutions in extension activities - like farmers' organizations and the private sector, which is largely undeveloped - get well planned budgets to be effectively used, optimize the extension resources in order to invest more in new technologies (*e.g.* ICTs) and to facilitate dissemination of research outputs/findings through more functional linkages between agricultural Research and Extension. It is also crucial to foster Public-Private Partnerships (PPP) related to extension work in order to create and strengthen synergies between the public and the private sectors. It is as well important to develop channels of knowledge transfer that facilitate learning from and among farmers.

ADOPTION AND DIFFUSION OF GRASS SILAGE IN TRABZON PROVINCE OF TURKEY

İsmet BOZ*, Çağatay YILDIRIM, Hatice TÜRKTEN

Ondokuz Mayıs University Faculty of Agriculture Department of Agricultural Economics Samsun, Turkey
*Corresponding author: ismet.boz@omu.edu.tr

Abstract

Developments in agricultural sector largely depend on the application of advanced agricultural technologies. These technologies sometimes consist of very complex issues but sometimes include very simple practices. Use of these technologies especially in disadvantaged regions enables farmers to increase their income and welfare level, as well as, makes contributions to a reduction of developmental gaps among regions. Depending in the area where they are being used, the new technologies have one of the effects of decreasing production costs, increasing productivity, easing the work being done, and reducing labor requirement. Grass silage for small holder cattle owners is considered as one of these technologies for Trabzon Province of Turkey since it has not been commonly used in the region. The main objectives of this research were to determine socioeconomic characteristics and communication behavior of small holder cattle owners, to determine what practices are being applied by the farmers in the present farming system, to determine problems encountered by farmers, and to determine the awareness level of grass silage in the region and possible contributions that grass silage will make to the farmers in the region. It is aimed also to develop recommendations for the region to accelerate the adoption and diffusion process of this technology. Descriptive statistics were used for data analyses. Research findings showed that small holder cattle farmers are mostly older people and operate in conventional ways. They face serious problems with drying their grass and lack information about grass silage. In order to adopt grass silage, farmers must be aware of its benefits, and extension work is needed for this purpose.

Introduction

The use of advanced technology in agriculture, particularly in disadvantaged areas and regions make remarkable contributions to the income and welfare of farmers. Advanced technologies, depending on the area they are used, make it possible for farmers to reduce production costs, save labor, and play a role on increasing the quality and quantity of agricultural production. While contributing to the prosperity of the people of a region for the first time, any use of a technology can be considered as an innovation for the region. In this context, grass silage technology is an innovation for the Eastern Black Sea region, while the region is considered as a disadvantaged region due to a lack of sunny days during the harvest season. Grass silage is not a common technology that is being applied by farmers in the region. Even in Turkey, corn is the first crop that comes to mind in silage making. Although grass silage is used widely in developed countries, it is not common in Turkey, even in areas where the most intensive farming structures prevail. In order to understand the benefits of grass silage and promote it to the farmers of Trabzon province it is important to describe the existing unique farming systems of the region.

Trabzon is located on the Black Sea Coastal region of Turkey with a population of 766.782 and surface area of 4,685 square kilometers. It is bordered by the provinces of Rize from the east, Giresun from the west, and Gümüşhane and Bayburt from the south. The total area is

22.4% plateau and 77.6% hills (Wikipedia, 2015).

Agriculture is one of the main occupations providing livelihood to thousands of rural families in Trabzon. Majority of farms are specialized in hazelnut and tea production, particularly in coastal area. The eastern neighbor province, Rize is popular with tea plantations while the western neighbors of Giresun and Ordu provinces with hazelnut production in their coastal lands. Trabzon can to some extend economically grow both commodities. As we move to 40-50 kilometers inland from the coast the altitude goes up to 800-1200 meters and it becomes almost impossible to economically grow hazelnut and tea. However, geographical and climatic conditions in these altitudes allow farmers to grow maize, beans, potatoes, cabbage, and various fruits and vegetables. There are forests, pastures and meadows areas starting from these altitudes and going up to 2500 meters from sea level. Because the landscape is shaped by natural forces, it is almost impossible to use farm machinery in sloppy and fragmented parcels of lands, therefore farming activities largely depend of labor. These conditions create a different farming system producing mainly annual maize and beans in the operated fields and perennial grass for livestock. In addition, in the higher uphill and mountainous areas public rangelands are available for grazing livestock, mainly caws and sheep, from early June to late September, depending on the altitude.

Climate in Trabzon is considered suitable for livestock. Due to abundant rainfall grasslands (pasture and meadows) are always covered with lush grass. Particularly native breeds and Jersey for cattle, sheep and goats can graze at least 5 mounts in public rangelands. Grazing period can be extended to 8-10 months for sheep and goats but due to uphill and mountainous areas are covered by snow in the winter season, lower lands which are private properties must be utilized. During the winter season, hazelnut gardens can also provide grazing opportunities for sheep and goats. However, in order to utilize these lands for grazing purposes there must be an agreement between the land owner and the herd owner. Caws, on the other hand, kept in barns and fed by roughage and concentrate feeds which must be prepared from the summer season or purchased from feed marked. Many farmers have to purchase concentrate feeds but to be economically viable they must prepare their own roughage feeds from their own field. Therefore, they keep some part of grass land away of animal grazing and harvest it in early August for winter feeding.

Grass silage is expected to make two important contributions to animal husbandry in the region. The first one is it will provide sustainable roughage feed production which cannot be provided by the current farming system. This is because during the harvest season the weather is quite rainy in the research area and therefore, it is quite difficult- some seasons impossible because of continuing rainy days- to dry harvested grass for winter feeding. If grass is harvested in a sunny morning and it begins raining in the afternoon, grass cannot be dried. Some farmers collect and cover it by nylon until the sun appears again. But this time it is necessary to spread harvested grass in sun and let it completely dry. This procedure requires too much hard work and labor, and therefore, grass silage making will make another contribution to farmers which is labor save. In some years rainy days take so long that (a couple of weeks) and it becomes impossible for farmers to get dried grass form their own field. This lack of roughage feed results in selling the animals or purchasing roughage feed from other regions.

The primary purpose of this study was to investigate possible adoption and diffusion of grass silage making in Trabzon province of Turkey. The specific objectives were to determine socioeconomic characteristics and communication behavior of small holder cattle owners, to determine what practices are being applied by the farmers in the present farming system, to determine problems encountered by farmers, and to determine the awareness level of grass silage in the region and possible contributions that grass silage will make to the farmers in the region.

It is aimed also to develop recommendations for the region to accelerate the adoption and diffusion process of this technology. Research findings are intended to make contributions to the public in the region, researchers, extension personnel of the Ministry of Food Agriculture and Livestock, and other stakeholders.

Materials and Methods

Target population for this study was defined as small holder cattle owners in Trabzon province of Turkey. Two districts from this province, namely Çaykara and Maçka districts and three villages from each district (total six villages) were selected based on their agricultural potential, distinct from the city center, socioeconomic characteristics of rural communities, and potential of livestock production. From each village a list of small holder cattle owners showing their number of cattle was obtained from the District Agricultural Office. Lists of farmers and their cattle sizes from six selected villages made the accessible population of the study. Considering frequency distributions of the number of animals, accessible population was divided in three strata with 1-5 animals, 6-10 animals, and more than 10 animals. Yamane's (2001) stratified sample size determination formula was used to determine sample size. The equation for this formula is:

$$n = \frac{N\sum N_h S_h^2}{N^2 D^2 + \sum N_h S_h^2}$$

Where
n = sample size,
N = accessible population,
Nh = number of farmers in a stratum,
Sh = standard deviation within a stratum,
D^2 = desired variance,
e = accepted error from the mean, and
t = t value corresponding the accepted confidence interval.

Accepting 5 percent error from the mean (e) and 95 percent confidence interval (t = 1.645), the sample size was calculated as 52 farmers. This number was proportionally distributed to three strata, and respondents from each stratum were randomly selected.

Data were collected by conducting face to face interviews with farmers during which a questionnaire was administered. It included three sections. The first section included questions related to socioeconomic characteristics of respondents while the second section communication behaviors. Finally the third section included questions related to present farming systems in the region and possible adoption of grass silage making. Technically the questionnaire included both open ended and closed ended questions. Respondents' opinions and comments were noted for the open ended questions. Genever (2013), Budak et al., (2012), Güven (2011), Castro et al., (2010), Carvalho et al., (2010), Arslan and Dinç (2009), Bilal (2009), Bingöl et al., (2009), and Gebremedhin (2003) were utilized for preparing the questionnaire. Data were collected in March and April 2015. It was needed approximately half an hour to complete a questionnaire.

Descriptive statistics including frequencies, percentages, means, and standard deviations were used to analyze quantitative variables. For the items collected in a five point Likert scale, an interpretive scale was developed by the researchers. During data collection process many notes were taken by the researchers from respondents' comments in a given issue related to their farming system. If many farmers concerned about similar problems and made comments accordingly, these were also considered in data analysis process.

Results and discussion

Socioeconomic characteristics of respondents are presented in Table 1.

Communication behaviors of farmers are presented in Table 2. From the table it can be seen that 44.2% read newspaper every day. But during the interviews it was observed that most of the farmers read newspaper in tea-houses located in the center of the villages. Approximately half of the respondents listened to radio almost never while 96.2% watched television 2-3 hours a day. Approximately one-third of the respondents were aware of the internet but 71.2% almost newer used the Internet. Majority of the respondents traveled to district center at least once a week or more often while majority of the respondents traveled to province center at least once a month or more often. More than two-third of the respondent never met with extension personnel while almost half of them sought advise related to farming problems. More than three-fourth of the respondents never participated any farming events such as meeting, seminar, field day etc.

Source: Author’s elaboration based on the questionnaire survey results.

Average small holder cattle farmer in the region owns 4.77 hybrid breeds, 1.21 native breeds, and 0.35 improved breeds. Selected farming practices applied by small holder cattle owners in the region are presented in Table 3. From the table 94.2% of the respondents provided their cattle by their own production, 57.7% provided dry grass from their own production, 69.2% provided concentrated feeds by purchasing from the market. Almost two-third of the respondents sold their cattle to butchers or for ritual slaughter every year. More than half of

the respondents yearly observed their cattle for diseases and other problems, almost half of the respondents considered live weight of the animals as a criteria when decided selling time, 92.3% used private veterinarians as information source about animal diseases, more than three-third reported that meadows were grazed properly, almost all respondent used manure in their own land, 84.6% experienced a decrease in their cattle size. Almost two-third of the respondents could properly dried 80% or less of their grass, 40.4% believed that grass can be turned in silage without drying, 69.9% didn't consider roughage to concentrated feed ratio in feeding their animals, 78.8% never heart of protein content of the feeds while the same percent of the respondents never heart of metabolic energy content of feeds. Research finding of this study showed that 84.6 percent of farmers reported that their number of cattle decreased (Table 3). Reasons for this decrease was investigated in a five point Likert scale from 1 = Not important at all, 2 = Not important, 3 = Neutral, 4 = Important, 5 = Very important. An interpretive scale considering the means was developed. According to this scale means were evaluated as 0.00-1.46 = Not important at all, 1.50-2.49 = Not important, 2.50-3.49 = Neutral, 3.50-4.49 = Important, and 4.50-5.00 = Very important. Considering this interpretive scale, the only item in the important category was lack of family members dealing with animals (Table 4). This was because young people in the region want to change occupation other than farming.

Providing roughage feeds is one of the most important problems in the area because of climatic conditions. Farmers were asked what kind of problems they encountered during providing their roughage feeds in a five point Likert scale and results are presented in Table 5. Considering the above interpretive scale drying of roughage feeds was the only item in the very important category. Harvesting, transportation, temporary storage in the field were in the important category. This finding verifies that providing roughage feed from own land is quite difficult in the region. Findings of this study showed that majority of farmers in the research area had no information about grass silage (Table 6). When the question "what can grass silage provide for you?" was asked on a five point Likert scale, respondents remained neutral in four of the five items and disagreed with the item "livestock would be better occupation". This finding showed that farmers lack information about grass silage and they need to be informed. They don't believe that grass silage will make livestock a better livelihood in the region.

Table 4. Reasons for decreasing cattle size

Awareness of grass silage	n	Mean	Standard deviation
Lack of family members dealing with animals	52	3.60	1.963
Feed prices high	52	3.23	1.967
Low income	52	3.19	2.010
Lack of governmental support	52	3.06	1.984
Lack of capital to purchase live animals	52	2.75	1.714
Illegal animal entries	52	2.42	1.913
Low meat prices	52	2.19	1.663
Lack of pasture and meadows	52	2.12	1.700
Low milk prices	52	1.71	1.446

Table 5. Problems encountered with roughage feeds

Problems encountered with roughage feeds	n	Mean	Standard deviation
Drying	52	4.62	0.599
Harvesting	52	4.08	1.186
Transportation	52	3.88	1.199
Temporary Storage in the field	52	3.87	1.299
Storage in the farm building	52	3.08	1.480

Table 6. Farmers' awareness of grass silage

Awareness of grass silage	n	%
I have never hearth about this practice	32	61.5
I have hearth it but have not enough information to apply it	10	19.8
I have heart it but my farm conditions do not provide adequate possibilities to practice it.	8	15.4
I have hearth it but I do not believe that it will be useful	2	3.8
TOTAL	52	100.0

Table 7. What grass silage can provide for farmers

What grass silage can provide	N	Mean	Standard deviation
Drying problem will disappear	52	2.90	2.070
It will provide more nutritious feeding	52	2.65	1.877
Reduces feed wastes	52	2.60	1.871
Labor save	52	2.50	1.863
Livestock would be better occupation	52	2.42	1.851

Conclusion

This study investigated the adoption and diffusion possibilities of grass silage among small holder cattle farmers in Trabzon province of Turkey. A socioeconomic profile of small holder cattle farmer in the region is an old man, elementary school graduate, has no membership in cooperatives, participated in village administration, own approximately 5 decares of land, had social security, doesn't use credit and bank loans, owns a yearly income about 20 thousand liras, doesn't have a tractor and has farming experience of more than 30 years. In terms of communication behavior he read newspaper mostly in tea-house of the village, doesn't listen radio too much but watch television every day. Although he is aware of the Internet he doesn't use it. He has regular travels to district and province centers but doesn't meet with extension personnel. Although he sometimes seeks farming advice from different people he doesn't participate in in farming events.

Farming in the region mostly carried out by conventional practices. Farmers are mostly older people and they have no option to switch profession. They must try to earn income as much as they can with their limited opportunities. Within the present farming system providing roughage feeds is quite problematic due to rainy season. It is also very much labor intensive. Grass silage will probably make it possible for farmers to produce cheaper and healthier died for livestock. This may increase the profit margins and attract younger farmers to stay in their villages.

Abstract

In this study, it is aimed to examine which level marketing communicating tools the businesses operating in the food industry in Çukurova Region, Turkey. For this purpose a survey was conducted with 92 enterprises in Adana and Mersin which operate in milk and dairy products, meat and meat products, fruit juice industry and 400 households living in Adana provinces determined by simple random sampling. As a result of the survey with enterprises; it was determined that they used the marketing communication tools (sales promotion, advertisement etc.) to increase sales, reduce inventory and so on, even though they aren't mostly aware of the concept of marketing communications and they indicate that they don't practice marketing communication programs. The mostly used tools by the enterprises are personal sales, direct marketing, sales promotions and advertisement. Also, as a result of the analysis, a correlation is determined between the enterprises' usage of marketing communication tools and brand and market performance. As a result of the survey with consumers, it is determined that the sales promotions are the most effective marketing communication tool when buying food products and changing the brand they use. When the consumers mainly buy food products they buy products which they decide in the market. In this case, advertisement, promotion and how natural the content of the product is the most important factors. Also it was determined that while buying different food products, consumers which have different gender, age, education and income levels, have different attitudes to marketing communication tools; such as young people mostly affected by media and primary and secondary school graduates mostly influenced by gifts.

Keywords: Marketing communication, marketing communication tools, consumer behaviour, food products, Çukurova Region.

Introduction

Economic and technological developments in the world create an intensively competitive environment. Particularly marketing with these developments, business structures, consumers and the buying behavior of consumers have changed. Today the changing customer profile, business information and communications technologies emphasizes the necessity to integrate to approach and strategies for sales and marketing (Babacan ve ark., 2008). Products on the market do not have very different properties with each other that is why there is an intense competition in the market. Since consumers prefer products of businesses from among these similar products, communication are becoming a major market power and businesses are forced to make changes to their marketing strategies. According to Mihart (2012), the survival of businesses in a competitive economic system and the development requires the existence of accurate and detailed information about customer behavior, motivation, the attitudes and behaviors. In order to meet consumer demand and their needs, enterprises should reveal appropriate products and services. To do this, they have to use appropriate marketing communication tools which are also help their profit (Uçak, 2004).

Marketing communications are a respond to their audience needs with changing existing business message and establishing a new communication channels with the creation

of new communication opportunities (Durmaz, 2001; Uçak, 2004; Ebren, 2006). Marketing communications are the means by which firms attempt to inform, persuade and remind consumers –directly or indirectly- about the products and brands they sell (Keller, 2001; Keller, 2009). A prerequisite for effective marketing communications is the consistency of sended messages through various channels of communications (Zavrsnik ve Jerman, 2011).

Marketing communications; to inform target consumers about products or services, if this is strengthening of their attitude and behavior in the desired direction, in the opposite direction change it or aims to create intended to a new attitude and behavior (Uçak, 2004; Durmaz, 2001; Ebren, 2006; Tuğrul, 2009). In the minds of consumers of messages transmitted with marketing communications to remain as the information and therefore, it is desirable to influence the purchasing decisions of future (Odabaşı ve Oyman, 2012; Uçak, 2004). Effective marketing communications contribute in brand awareness and the creation of a positive image (Erpelit, 2010). The instruments of marketing communications are regarded as advertising, sales promotion, public relations, direct marketing and personal selling (Jerman ve Zarvrsnik, 2013). Marketing communications; specifically in support promotion functions but in scope to, encompasses in all actions and components of the marketing (Özgül, 2008).

Consumers are having a hard time to choose between products and brands in the markets as their number is increasing and diversifying every day. In agricultural products, like others, various new brands are emerging to compete in market. So it is necessary to use marketing communication tools to affect consumer purchase behavior.

In this study, it is aimed to determine what percentage and how marketing communication tools that used by the food companies and its' affect on their business performance. Also marketing communication tools affect has been analyzed on consumer purchase behavior.

Materials and methods

Primary data for this study was obtained with face to face interview. The list of food companies in Adana and Mersin was gathered from Provincial Directorate of Food, Agriculture and Livestock. During the survey time 334 meat and meat products, milk and dairy products, fruit juice (soft drinks) companies were registered at Adana and Mersin Directorates (GTHB, 2014). Researchers are connected with all enterprises but only 92 companies from the population were willing to participate to the study and give information about their marketing communication tools. To select consumers "Based on Population Ratio Probability Simple Random Sampling" is used and calculated as 384 with 95% confidence interval and an error of 5% margin. However, 400 questionnaries were completed to prevent unusuable questionnaire. The questionnaire was related about consumer behavior in terms of choice of agro-industrial products.

Results and discussion

Out of 92 companies, milk and dairy products consist of 50%. Meat and meat products and fruit juice (beverage) companies consist of 29.35% and 20.65%, respectively. The average working time of the companies were 20 years and majority of them doing business at micro level. Companies of all three sectors were mainly trying to keep their position in business. Unfortunately, companies did not aware of the concept of marketing communications tools and their application in their companies. Juice companies implement marketing communications programs higher than others. In our study, it was found out that 79 company was classified as small, 12 company was medium and only one company was large. Mainly medium-sized companies had been applying marketing communications programs.

Although the vast majority of companies stated that they were unaware of the concept of marketing, it has been found out that many of them were using at least one marketing

communication tool (MCT) when they needed. The most widely used MCT by companies were direct selling, sales promotion, personal selling and ads. Fairs and sponsorship were the MCTs uncommon in these companies.

The tools used for advertising may have different effects on the consumers. The most widely used tool by companies for advertising were billboards and radio because of low cost. Esposito (2013), indicated that television is expensive and is considered not to be very effective to achieve specific goals. In this study it is found out that the companies do not use television as an advertisement tool because of high cost. Majority of companies (61.54%) used sale promotions such as advantageous packages, free trial, discounts and sales quota. Companies mainly used marketing communication tools to remind products (44.57%); to introduce new product (22.83%); and to maintain their position and to increase their sales (13.04%).

Scale, consisting of three dimensions prepared by Reid (2005), to measure brand performance -including performance related to sales, brand advantage, customer satisfaction- is used. In general enterprises assessed their level as intermediate in terms of brand performance. Correlation Analysis conducted in order to investigate whether a relationship between brand performance evaluation with marketing communication tools used. But Spearman were calculated because data did not normally distributed, in terms of communication tools variables. Spearman correlation coefficient was found 0.252 and p(0.015) which was lower than 0.05 that appears to be a linear relationship in a positive direction between brand performance evaluation with marketing communication tools used by companies. If the use of marketing communications tools are increased, also brand performance evaluation are also increased as a certain extent.

Changes in the specific topics of the last three years in order to measure the operating performance of the company were asked to evaluate. According to these assessments; companies stated that 52.17% had increased their market share, 56.52 % had increased of awareness gain on the market, 58.70% had increased to acquire of new customers, 51.09% had increased the consumer retention success and 51.09% has not unchanged the communication budget. Correlation analysis was performed to see whether there was a relationship between business performance with the use of marketing communications tools and whether there was a impact of brand performance on the market performance. Results indicated a positive linear relationship between the variables in both cases. This relationship showed that increasing use of marketing communication tools of company had increased of business performance and increasing the brand performance had increased market performance.

Multifactor analysis of variance was performed to investigate whether the companies showed a significant difference according to field of activity of business, company size and the type of company of brand performance, market performance and communication tools profitability impact assessments. When the data were analyzed, it was found that companies did not show a significant difference according to the business scope of the brand performance, market performance, communication tools profitability impact assessments ($p > 0.05$). In contrast, it was observed that no significant difference between the company size with market performance and communication tools profitability impact assessments profitability, which showed a significant difference between company size and brand performance ($p < 0.05$). In addition, it is observed that there was no found significant difference between types of companies with brand performance and market performance, which showed a significant difference between company type with communication tools profitability impact assessments profitability ($p < 0.05$).

According to the consumer survey results; respondents were 60% male and 40% women. The average age of consumers was 33 and 42% had a high school diploma and only

20% had a university degree. Majority of consumers were 36% craftsmen/artisans while 18% housewives, 14% workers/employees, 13% qualified experts, 11% students and 5% unemployed or retired. The average income was £ 1773 and about one-third of the income devoted to food expenditures. Food purchase was done mainly by mother (46.4%).

While consumers purchased food products and changed the brand they use, most affected tool of them was price reductions, the least affected the tool was advertising. It has been argued that this is because consumers often base their purchase decisions not on what they can explicitly remember about an advertisement but on what they know about the product (Zavrsnik ve Jerman, 2011). Roux and Zyl (2013) stated that more than 80% of consumer have a positive attitude towards sales promotional techniques and consumer have less disposable income were pleased from the extra products and low price that presented to them by companies using sales promotion techniques. Yılmaz et al. (2007), the vast majority of consumer groups (57%) reported that they received food according to advertisement. The research results showed that approximately 37% of the consumers had affected by advertisement before shopping, but the effect seems to be small compared to other tools. Although the effect while changing the brand was 29%, it is seen to be less effective than other tools. In granting purchase decision a product and replace new brand, sale promotions were more effective than other tools.

According to the research results, men had more affected from the sales efforts than women. Consumer behaviour was changing depend on gender. In this study, it was found that majority of men (63.01%) influenced by advertisement while women were most influenced by price reduction. While changing the brands that they used, the tool that the men were most influenced were free trial (61.03%), the tool that the women were most influenced were advantageous packages (42.05%). Overall, consumers who purchased products least affected from sales efforts were consumers aged 45 and above. Yılmaz et al. (2007), found that young people with 41% of group that most affected from the media. Our finding was also support this finding. When buying a certain product, younger consumers were also affected from other tools, which was advertisement. In changing of brand that used, while young group most affected from advertisement, other consumers were affected mainly from sale promotions. While literate, primary and secondary school graduates were influenced mostly by gifts buying a product, high school graduates were influenced by advertisement, college graduates were influenced by the price reductions. While product purchased, group who were least influenced from sales efforts were literate people. Consumers who have different levels of education had purchased products to influence from the different sales promotion techniques. While education level decreases, consumers seem to be more effected by tools such as gift, free trial. The group who had purchased products with the influence of marketing communication tools had income between £ 1000-1499. Consumers who had different income levels were affected from the different sales promotion techniques. Consumers with high income level had more affected from the ads when buying a particular product.

Product groups which purchase the most affected from advertisement were beverages (28.6%) and meat and meat products (25.1%). The product groups which purchase the most influenced from price reduction were milk and dairy products and meat and meat products. The product groups which purchase the most influenced from advantageous package were meat and meat products (45.9%) and beverages (45.1%). The product groups which purchase the most influenced from free trial were legumes (53.4%) and beverages (52.6%). The product groups which purchase the most influenced from gifts were beverages (46.6%), meat and meat products (43.4%). While the product groups which purchase the most influenced from the coupon were beverages (34.1%), the product groups which purchase the most influenced from awards were beverages (35.8%) and meat and meat products (32.3%). While consumers often purchased general food, milk and dairy products, meat and meat products, and the fruit

juices, they expressed not a particular brand that prefer. However, they spesifically pointed out the brands when it comes to milk and dairy products 43.1% and meat and meat products 42.1%.

When consumers purchased food products, the most important reason to prefer the brand was mainly reliability, taking into account the complaints and suggestions and ease of refund. Consumers were predominantly informed by seeing on sales area for the first time from products such as overall food (45.4%), milk and dairy products (43.1%), meat and meat products (41.1%) and fruit juices (40.9%). The product group which conducts mainly research were milk and dairy products and meat and meat products. Fruit juices were predominantly taken without any research. While the price was the most important reason when buying the product at the first time for general food (49.37%), meat and meat products (20:55%), fruit juices (18:55%) but the expiration date was important in milk and milk products (22.81%).

Decisions depend on advertisement, promotion and naturalness of the product had rated highly by consumers when it comes to milk and milk products. When buying the meat and meat products decisions were made mainly at the stores. When purchasing meat and meat products consumer were affected mainly by advertisement and promotions and the naturalness of the content was pointed out greatly important. While consumer purchased different product groups, Chi-square test was conducted to see whether a differences among attitudes toward marketing communications tools and among assessment of attitude against marketing communication tools according to product groups with consumer characteristics. There were differences among attitudes at 0.01 significance level ($p < 0.01$) while consumer purchased general foods, milk and dairy products, meat and meat products and juice. Consumers exhibited different attitudes toward marketing communication tools when buying different product groups. There are differences among attitudes at 0.01 significance level ($p < 0.01$) while consumer purchased general foods, milk and dairy products, meat and meat products and juice according to gender, age, education level, occupation and income. Consumers who had different features demonstrated different attitudes against marketing communication tools when buying different product groups.

Conclusion

Consequently, in order to create awareness for a product or brand in the consumers, informations of product or brand are required to present continuously to consumers of through variety communication tools because consumers mainly made their choices according to brand name coming to their mind when they have to choose among so many brands. In that sense, marketing communication tools are essential for creating awareness and ensuring the consistency of the messages delivered to consumers. In this study, although companies were not aware of the concept of marketing communications, marketing communications tools were used by one for specific purposes. While milk and milk products companies were mainly using direct sale, personal sale and sale promotions; meat and meat products companies were using direct sale and sale promotions and juice companies were mainly using marketing sale promotions and direct sale. With the use of marketing communication tools of businesses, there was a linear relationship between the brand and market performance. Also the companies were increasing market performance with increased brand's performance. Consumers were also affected by marketing communications tools when they purchased food products and replaced the brands they used.

Abstract

Berry fruits, which are quite liked and consumed much by consumers, can be assessed in variable ways. Antioxidants, minerals and vitamins included in berry fruits make them one of the indispensable choices of conscious consumers for healthy diet. Hence, berry fruits can be desired continuously in dmestic and foreign trade, and can be sold with high prices. Sale potential of berry fruits continuously increases more with the usage of these fruits along with in beverages, fruit yogurt/milk, dessert and consumption with alcohol more densely. Even though berry fruits have a great number of type and kind of commercial importance in the world, the vital berry fruit types in terms of commercial in Turkey are mulberries, strawberries, raspberries, and cranberries. According to data of Turkish Statistical Institute in 2014; 62.9 thousand tonnes of mulberries, 4.6 thousand tonnes of raspberries, 376.1 thousand tonnes of strawberries, and 10.9 thousand tonnes of cranberries were yielded in Turkey. In this study, evaluations will be made by analysing structure of berry fruits, which are commercially grown in Turkey, in terms of agricultural marketing components such as product, price, distribution and promotion. In this study, some researches, articles, presentations, thesis, and statistics were searched by considering relevant subject.

Keywords: *Mulberry, strawberry, raspberry, cranberry, agricultural marketing.*

Introduction

Berry fruits are significant agricultural products with respect to their relatively high demand elasticity against the change of their prices. Berry fruits are able to take place in the list of consumers in direct proportion to the recognition of their importance in terms of health. In other words, consumers demanding berry fruits are the ones having high health consciousness. Because the demand they have created allows these products to be sold in high prices (Ertürk and Geçer, 2012). Berry fruits are continuously demanded regarding domestic and foreign trade and can be sold with high prices (Onur, 1996). Sales potential of berry fruits increases in parallel to spread of fresh and processed product range. Sales potential of these fruits have increased more as a result of starting to be intensely used in production of beverages, fruit yogurt/milk, corn flakes, desert, and alcoholic drinks. This increase is also considerably supported with the image of health usefulness of berry fruits (Agaoglu, 2006). Within the rapid flow of modern life, women increasingly involved in business life and in parallel to the increase of consuming frozen foods have enhanced the importance of berry fruits which is source of these products. Additionally, another significant area of utilization of these fruits in both industry and homes is making jam and jelly. Due to the variation of berry fruits increased in terms of their use as fresh or frozen in food industry and especially their increasing importance in terms of dairy products industry, ice cream producers, confectioners and pastry cooks; these fruits are regularly processed in food sector as fresh, mashed, jam, molasses, syrup, or fruit juice (Yetgin, 2009). Big food producers use these products in large amounts. There is also a wide demand for berry fruits in alcoholic drink industry, as well. The fact that different natural herbal teas have become asked by consumers in recent years have brought the use of berry fruits into the forefront for this purpose

(Agaoglu, 2003). Types of cola and fizzy drinks constitute almost half of beverage industry abroad. Concentrated fruit juices constitute approximately the other half market of this amount. Share of berry fruits in this group is large. Rate of berry fruits increases within group of the fizzy drink. In this group; raspberry, strawberry, and black currants are regarded among products to increase the market share in future (Agaoglu, 2003).
According to data of Turkish statistical institute for the year 2014 in Turkey, total agricultural area is 23.943 thousand hectares and orchards with the rate of 13.52% constitute 3.237 thousand hectares of this. Rate of berry fruits among the total agricultural area is 2.15% and its rate among horticultural crops is 16.7%. Berry fruits constitute 27.73% of the total fruit production (Anonim, 2015a). For this reason, berry fruits are an agricultural activity with a different significance in economy of Turkey. They are also important because they allow assessing agricultural areas inappropriate to be utilized especially for growing other products (Yayar et al., 2006). In this study, assessments were performed by investigating the structure of marketing of berry fruits (mulberry, strawberry, raspberry and cranberry) in Turkey.

Raspberry

Since Turkey is among the native lands of raspberry, it has a profoundly suitable location in terms of raspberry cultivation. In addition to its consumption freshly; raspberry with its types of consumption regarding industry such as fruit juice, ice cream, pastry, deep freezing is on course of being a candidate fruit species to be an important cultivation branch in Turkey (Göktaş, 2011). Data have been started to be collected by Turkish Statistical Institute as from 1995 along with the establishment of commercial collective orchard lands for raspberry. Table 1 illustrates production areas, production amount, and yield levels for raspberry between 2004 and 2014. Production areas, being 3.5 thousand decares in 2004, started a downtrend trend beginning from this year. This downtrend has changed from 2011 towards the increasing trend. It was observed that raspberry production areas increased more than twice in 2012 compared to the previous year; despite a period of recession experienced in 2013, an increase of 4.14% was observed in 2014 compared to the previous year. Collective plant areas of raspberry increased to 4.8 thousands da in 2014 with an increase of 39.51% compared to 2004. Raspberry production, which was 2.2 tonnes in 2004, has shown a continuous increase in parallel with the increase of yield. By the influence of the increase in yield per decare up to 939 kg, a production of 4.6 thousand tonnes occurred in 2014 (Table 1)

Table 1. Production area, production amount, and yield of Raspberry (Anonymus, 2015a)

Year	Area (da)	Production (ton)	Mean yield (kg/da)
2004	3.500	2.200	629
2005	3.410	2.200	645
2006	3.387	1.997	590
2007	3.388	2.103	621
2008	3.397	2.050	603
2009	3.419	1.976	578
2010	2.198	1.980	901
2011	2.211	2.059	931
2012	4.675	4.080	873
2013	4.674	3.942	843
2014	4.883	4.587	939

Figure 1 illustrate 2003-based Agricultural Sector Producer Price Index and reformed Raspberry producer prices by months. According to this data, it was observed that producer prices were higher in June and July when Raspberry was relatively low in supply, lower in August when the product was abundant, and the prices started to increase by harvesting completely the product. Means of eight years indicated that the price showed stability in the rest periods of year. When the Figure 2 showing 2003-based Agricultural Sector Producer Price Index and corrected annual average take-home pays of the raspberry farmer between

2006-2014 was examined, it was observed that raspberry price being 3.46 TL/kg in 2006 fell to the lowest price level of the eight-year period by decreasing to 2.55 TL/kg in 2009 and raised to the highest price level of the same period by increasing to 4.39 TL/Kg in 2011. Producer prices of raspberry were 2.76 TL/Kg in 2012, 3.06 TL/Kg in 2013, and 2.91 TL/Kg in 2014. The fact that raspberry supply increase occurred in parallel with the increase in production areas and yield was higher than the demand for raspberry could be asserted to be effective in low level price formation in recent years.

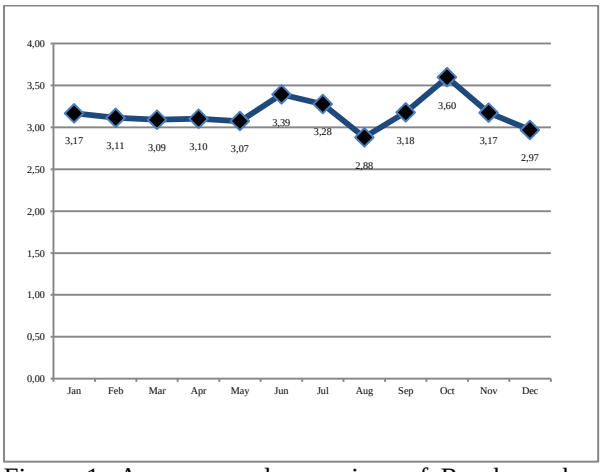

Figure 1. Average producer prices of Raspberry by months (2006-2014)

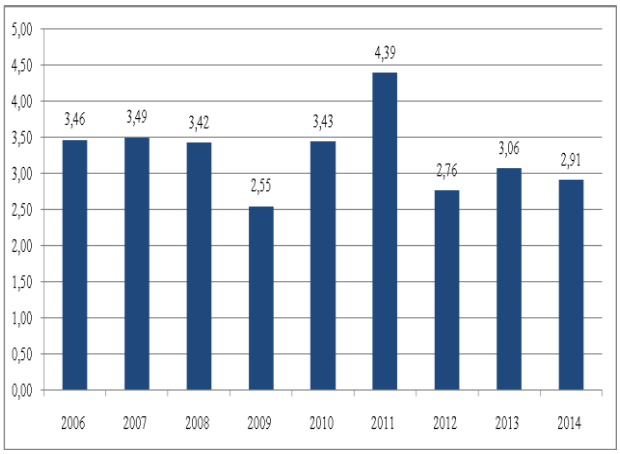

Figure 2. Average producer prices of Raspberry by years (2006-2014)

Strawberry

Strawberry, whose native land is expressed as South America (Chili), is a species which is appropriate for forced growing, has good export and domestic sales possibilities, is herbaceous but a perennial fruit type and also has an increasing spreading in the world with each passing day thanks to numerous rehabilitation studies. USA, Turkey, Canada, Europe, South and East African countries, New Zealand, Australia, and Japan are the countries where strawberry is grown mostly (Anonymus, 2015b). Strawberry cultivation, which started in 1300s A.D. in Europe, contemporarily begun in 1970s in Turkey (Gunduz and Ozdemir, 2008; Ertürk and Geçer, 2012). Turkey plays an important role for strawberry production in the world and takes the 2nd place after USA (Anonymus, 2015b).

A large portion of its production is supplied from Mediterranean, Marmara, and Aegean regions. Mersin is the leading province with the most strawberry production and meets 47% of the total production. Other strawberry producing provinces are Antalya (11%), Aydın (11%), Bursa (9%), and Manisa (6%), respectively (Anonymus, 2015a). Table 2 illustrates strawberry production areas, production amount, and yield levels between 2004 and 2014. Strawberry production areas, which were 97.5 thousand decares in 2004, are generally observed in an increasing trend along with decreases in very small rates by years. Strawberry production area reached 134.2 thousands of da with an increase of 37.68% in 2014 compared to 2004.

Table 2. Strawberry production area, production amount, and yield (Anonymus, 2015a)

Year	Area (decare)	Production(ton)	Mean yield (kg/da)
2004	97.500	155.000	1.590
2005	100.000	200.000	2.000
2006	99.851	211.127	2.114
2007	109.545	250.916	2.291
2008	112.785	261.078	2.315
2009	121.500	291.996	2.403
2010	116.792	299.940	2.568
2011	119.670	302.416	2.527
2012	127.928	351.834	2.750

2013	135.494	372.498	2.749
2014	134.234	376.070	2.802

Production of strawberry, which was 155.000 tonnes in 2004, showed a continuous increase with the influence of increase in the yield in addition to the increase in production areas and reached 376 thousands of tonnes in 2014 with an increase of 142.6% compared to 2004. Owing to use of new technologies and types with high yield in the production, mean yield, which was 1.590 Kg/da in 2004, increased to 2.802 kg/da in 2014 with an increase of 76.23% compared to 2004 (Table 2).

Figure 3 illustrate Agricultural Sector Producer Price Index and corrected strawberry producer prices by months. According to this data, it was observed that producer prices were formed in the period between April and September when strawberry was presented into the market. Accordingly, it was observed that prices were higher in April when the product was relatively lower, lower in June when the product was abundant, and the prices increased again in August by harvesting completely the product. When Figure 4 illustrating 2003-based Agricultural Sector Producer Price Index and annual average take-home pays of the strawberry farmer was examined, it was observed that strawberry prices in this period of ten years were the highest in 2007, the lowest in 2010, and showed increase or decrease depending on export.

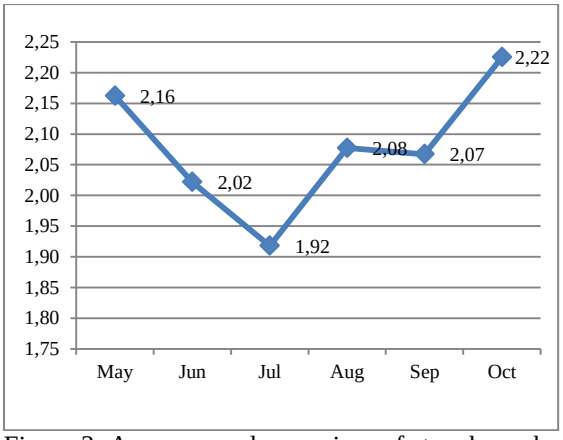

Figure 3. Average producer prices of strawberry by months (2006-2011)

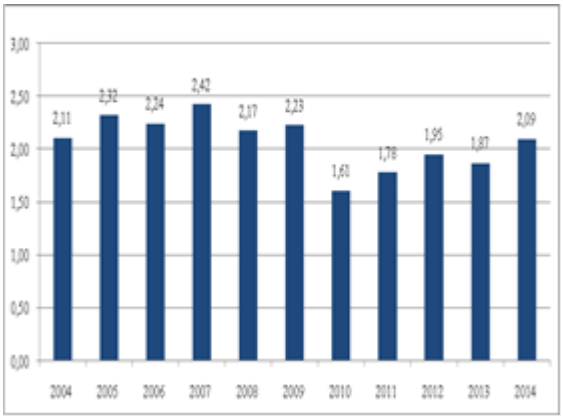

Figure 4. Average producer prices of strawberry by years (TL/Kg) (2004-2014)

In accordance with data of Turkish Statistical Institute, it was observed that 22.360 tonnes of strawberry was exported in 2004-2005 market year, this export increased to 33.000 tonnes as from 2006-2007 market year, reached the highest export level with 37.6 thousands of tonnes in 2009-2010 market year, and 30.3 thousands of tonnes of strawberry was exported in 2013-2014 market year (Table 3).

Table 3. Import, export, and consumption per capita by market years (Anonymus, 2015a)

Marketing year	Imports (Tonne)	Imports-EU 27-28 (Tonne)	Exports (Tonne)	Exports-EU 27-28 (Tonne)	Human consumption per capita (Kg)
2013/'14	492	84	30 279	12 791	4.00
2012/'13	1 401	130	31 926	14 687	3.80
2011/'12	433	48	34 131	16 383	3.20
2010/'11	92	59	34.925	20.477	3.20
2009/'10	167	164	37.627	22.561	3.12
2008/'09	347	148	30.380	18.512	2.88
2007/'08	183	78	35.508	20.212	2.71
2006/'07	161	...	33.011	...	...
2005/'06	303	...	22.158	...	...
2004/'05	-	...	22.360	...	1.67

The exported strawberry changed year by year in small rates by 2007-2008, 56-60% were exported to 27 EU countries, this rate was in tendency to decline as from 2011-2012 market

year, and decreased to 42.2% by 2013-2014 market year. According to data of Turkish Statistical Institute, strawberry consumption was 1.67 kg per capita in 2004-2005 market year in Turkey, increased year by year and reached to 4 kg in 2013-2014 market year (Table 3).

Mulberry

Mulberry grown generally in temperate and subtropical regions of north hemisphere is widely grown in Turkey. White mulberry (97%), black mulberry or red or purple mulberry are common species of mulberry in Turkey. China, India, Turkey, Russia and Middle East countries are known as native land of mulberry (Islam et al., 2006). At the present time, mulberry has an important market potential due to nutritious characteristics of its processed products in addition to consuming it freshly. Tens of products such as molasses, jam, dried fruit roll-up, mulberry paste, dried mulberry, fruit ice cream, fruit leather, vinegar, fruit juice concentrate, spirit are made of its fruit. Especially juice of black mulberry has become a popular drink and a demanded fruit in recent years. In Turkey, mulberry fruits are traditionally used for making molasses and for dry food production by drying. In addition, black mulberry and red mulberry species are used traditionally and at the least commercially for jam industry (Akbulut et al., 2006).

According to 2004 data of Turkish Statistical Institute for areas of collective orchards produced commercially in the direction of industrial demands of mulberry; while 50.000 tonnes of mulberry yielded from 2.130 fruit bearing trees in the area of 11.700 da, areas of collective orchards raised to 20.7 thousand decares by increasing at the rate of 77.55% and the number of fruit bearing trees raised to 2.383 thousand with an increase of 11.90%. The amount of production for the same period reached to 62.879 tonnes in 2014 with an increase of 25.76%. While the lowest production amount within this period of 10 years was observed in 2010, the highest production was observed in 2011(Table 4). While the mean yield per tree was 23 kg in 2004, it raised to 26 kg with an increase of 13.04% in 2014 (Table 4).

Table 4 – Production area, production amount, and yield of mulberry (Anonymus, 2015a)

Year	Area of collective orchards (decare)	Production(tons)	Mean yield per tree (kg)	Number of trees in fruit bearing age	Number of fruitless trees	Total number of trees
2004	11.700	50.000	23	2.130.000	365.000	2.495.000
2005	12.000	55.000	26	2.120.000	366.000	2.486.000
2006	12.797	51.558	25	2.029.207	353.078	2.382.285
2007	13.127	61.665	29	2.094.715	560.426	2.655.141
2008	17.628	65.140	28	2.300.689	539.122	2.839.811
2009	17.029	67.986	28	2.392.609	537.264	2.929.873
2010	18.662	75.096	30	2.479.192	507.465	2.986.657
2011	18.864	76.643	31	2.453.440	359.740	2.813.180
2012	20.500	74.170	30	2.446.907	379.146	2.826.053
2013	21.143	74.600	31	2.422.729	380.047	2.802.776
2014	20.773	62.879	26	2.383.522	379.894	2.763.416

Figure 5 illustrate 2003-based Agricultural Sector Producer Price Index and corrected annual average take-home pays of mulberry producers by months. According to this data, it was observed producer prices formed in the period between May and October when product came on the market. Accordingly, it was observed that the prices were higher in May in which the product was relatively lower, lower in June when the product was abundant, and increased again in July and August as a result of harvesting completely the product, and decreased as from September.

As the Figure 6 illustrating 2003-based Agricultural Sector Producer Price Index and corrected annual average take-home pays of mulberry farmers was examined, it was observed that mulberry prices in this period of ten years were the lowest in 2004 and the highest in 2014.

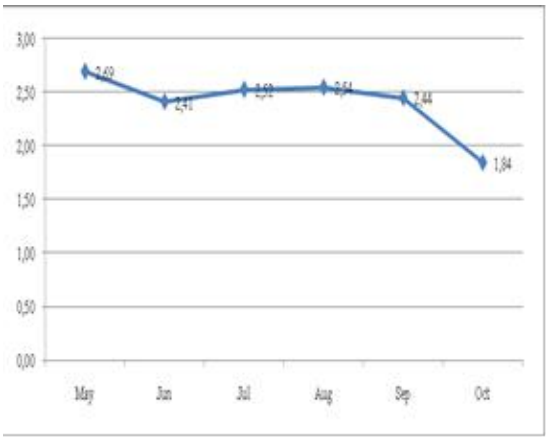

Figure 5. Average producer prices of Mulberry by months (TL/Kg) (2004-2014)

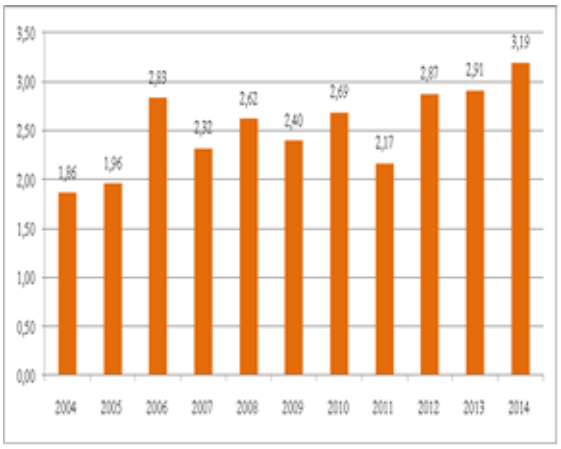

Figure 6. Average producer prices of mulberry by years (TL/Kg) (2004-2014)

In accordance with data of Turkish Statistical Institute stated in Table 5, it was observed that while 258 tonnes of mulberry was exported in 2004-2005 market year, it was 3.751 tonnes in 2013-2014 market year with an increase of 14.54 % compared to 2003-2004 market year. The exported mulberry changed year after year by 2007-2008, and 47-64 % of it was exported 27 - EU countries. Import of mulberry is also performed in order to supply the black mulberry demand of food and drink industry in particular. According to data of Turkish Statistical Institute, mulberry consumption, which was 0.60 kg per capita in 2004-2005 market year, reached 0.77 kg with an increase of 29.35% in 2013-2014 market year in Turkey.

Table 5. Mulberry import, export, and consumption per capita by market years (Anonymus, 2015a)

Market year	Imports (Tonne)	Imports-EU 27-28 (Tonne)	Exports (Tonne)	Exports-EU 27-28 (Tonne)	Human consumption per capita (Kg)
2013/'14	630	79	3.751	2.067	0.77
2012/'13	886	117	1.924	1.238	0.82

Cranberry

Cranberry, whose native lands are Anatolia, Caucasia, and Europe, is found generally in wild types as single or groups in coastal and higher parts, mountain sides, and stream beds in Black Sea, Marmara, Aegean, and Mediterranean Regions. Cultivation of graft cranberry is performed in limited amounts in Malatya, Bursa, Yalova, Karabük, and İstanbul provinces (Yalçınkaya et al., 2001). Cultivation of this fruit species, most of which is grown naturally in Turkey, has not been attached importance by the present day (Guleryuz and Pirlak, 1996).

Cranberry is an important source in terms of human health and nutrition. Cranberry fruits are quite much rich in terms of content of vitamin C. Tea and coffee are made of its seeds and leaves. Cranberry is not consumed as fresh fruit much because of its sour and harsh taste and its fruits are utilized for producing gel, compote, jam, marmalade, syrup, alcoholic drink and fruit juice (Kalyoncu and Ecevit, 2005). Essence and drug against dysentery are produced from its fresh peels. It is utilized in numerous forms as dried and table fruit in food industry, as flavouring and aroma giving substance for food and by making compote. Fruits can be conserved for a very long time with the addition of sugar (Ertürk and Geçer, 2012).

According to the data of Turkish Statistical Institute; regarding cultivation area of cranberry commercially produced to supply demands of food industry, 12.000 tonnes of cranberry was

obtained from 1 million trees in fruit bearing age planted in the area of 2.300 da in 2004; whereas, a decreasing trend started by 2006 and 10.982 tonnes of product was obtained from 787.7 thousands of fruit bearing trees planted in 1.522 da area in 2014. Within this period of ten years, the decrease was -34,30% in collective orchard areas, -21,23% in number of trees in fruit bearing age was and -8,48 % in the amount of production compared to 2004. On the contrary of this decrease, there was an increase of 16.67% observed in mean yield per tree; while the mean yield per tree was 12 kg in 2004, 15-16 kg levels were reached in some years and it was 14 kg in 2014 (Table 6).

Table 6. Production area, production amount, and yields of cranberry (Anonymus, 2015a)

Year	Area of collective orchards (decare)	Production(tonnes)	Mean yield per tree (kg)	Number of trees in fruit bearing age	Number of fruitless trees	Total number of trees
2004	2.300	12.000	12	1.000.000	230.000	1.230.000
2005	2.480	11.500	12	981.000	223.000	1.204.000
2006	2.206	9.303	11	878.834	211.773	1.090.607
2007	1.754	9.722	10	947.077	208.088	1.155.165
2008	1.740	11.010	12	942.281	185.967	1.128.248
2009	1.764	14.472	16	889.944	189.085	1.079.029
2010	1.535	12.517	15	820.927	160.130	981.057
2011	1.549	12.427	15	824.118	153.591	977.709
2012	1.873	12.368	15	828.269	150.807	979.076
2013	1.675	11.838	15	810.769	146.747	957.516
2014	1.511	10.982	14	787.709	80.422	868.131

Figure 7 illustrate 2003-based Agricultural Sector Producer Price Index and corrected annual average take-home pays of cranberry farmer. According to these data, it was observed that producer prices formed in the period between April and November when product was in the market. According to means of ten years, it was observed that prices started to increase by the demand of industry beginning from May when the product was abundant and continued to increase in June, this increase was balanced with a relative decrease by July, prices increased again along with the decrease of product amount by October, and reached the highest level in November. When 2003-based Agricultural Sector Producer Price Index and corrected annual average take-home pays of the cranberry farmer (Figure 8) were examined, it was observed that the lowest level of price in period of ten years was 1.72 TL/Kg, as from 2004 producer prices tended to increase along with the changes year by year, reached to the highest level twice with 3.15 TL/kg in 2011 and 2012, it was 2.23 TL/Kg in the following year 2013 and 2.54 TL/Kg in 2014.

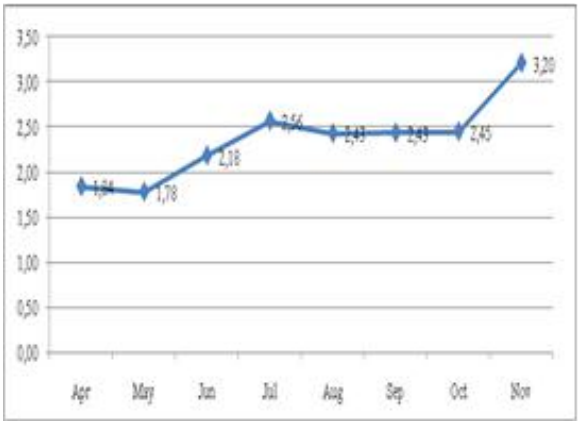

Figure 7. Average producer prices of cranberry by months (2004-2011)

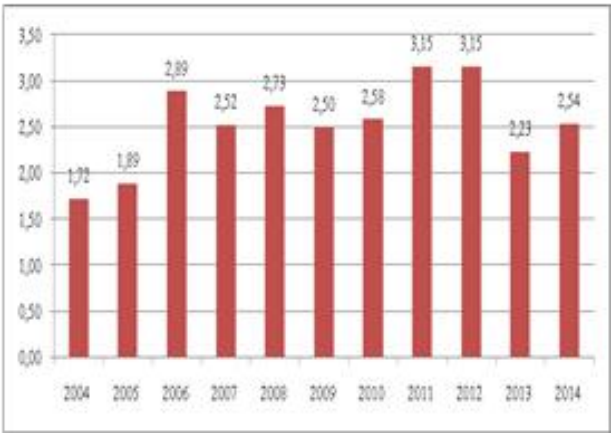

Figure 8. Average producer prices of cranberry by years (2004-2014)

Marketing channels of berry fruits

The process in which property of products is passed into other hands and which includes the steps between producer and consumer is called as marketing channel. Structural development of the sector affects the marketing system, as well. Thus, small-sized enterprises with limited marketing opportunities are generally dominant in agriculture. This situation causes enterprises to carry out insufficiently or never numerous marketing functions such as price formation, standardisation, storage, packaging (Albayrak, 2013). In case that large yield loss and high expenses are observed because of problems resulted from physical processes such as classification, packaging, storage performed for marketing, distribution irregularities and overflow hand-over until agricultural products reach consumer market (Anonymus, 2011). In agricultural product markets; producers, middlemen, brokers, merchants, broker merchants, forwarder merchants, private firms, public agents, commodity exchanges, wholesale food markets, wholesalers, retailers, cooperatives, and producer unions carry on business (Anonymus, 2011; Albayrak, 2013). Major actors playing a role in marketing channels of berry fruits and relationships between them are shown in Figure 9. Sale of products growth by berry fruit producers using organic/traditional methods is performed by themselves or their family members in producer markets, district markets, roadsides through making sale. Another method of sale for the products they grown as with or without a contract is sales they make with local brokers, merchants, farmer associations /cooperatives, manufacturers, and exporters (Figure 9). Local wholesale food market brokers sell the product they buy from producer or producer associations/cooperatives to local retailers, local merchants or directly to brokers in marketplaces of consumption area (Figure 9). Merchants carrying on a business in production area commercialise the products they buy by supplying from producers, producer association /cooperatives, brokers operating in market places of production area to brokers of consumption area, to retailers in production or consumption area (Figure 9).

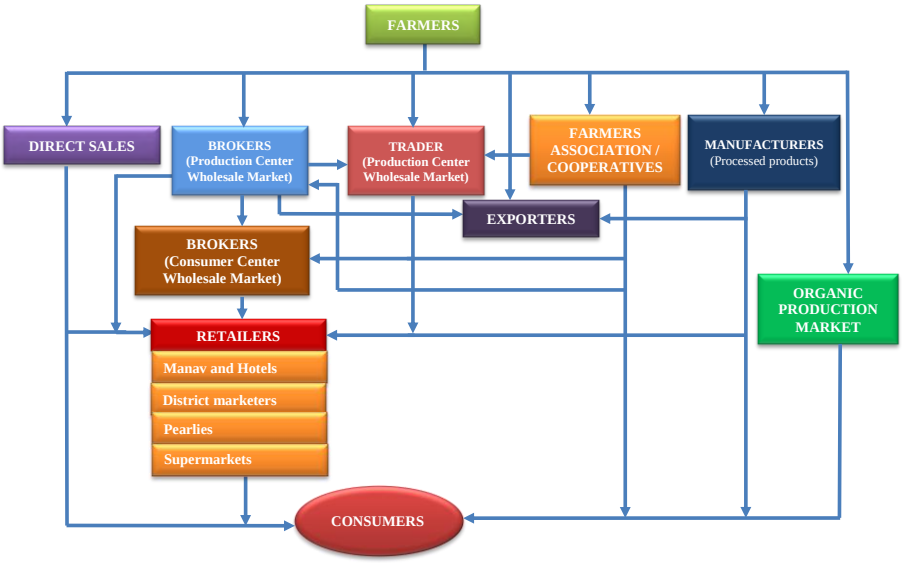

Figure 9. Marketing channels of berry fruits

Exporters supply the raw products they procure from producers and marketplace brokers of production area and the processed products they procure from manufacturers to international market (Figure 9). Producer associations/cooperatives market the product they grow to producers, either directly to consumers or brokers and merchants acting in marketplaces of production area or to retailers (Figure 9). Manufacturers either export products by themselves or transfer them to exporters, after they transform them they supply via contracted production, to finished or semi-finished products by processing. They also make sales via wholesalers or

directly via retailers. Products marketed in market of organic products are directly exported in general or reached to consumers via retailers (Figure 9).

Conclusion and recommendations

When the data of Turkish Statistical Institute is evaluated, it is important to promote increase production of raspberry, strawberry, mulberry, and cranberry species from berry fruits and to establish surrounded gardens in terms of health and welfare of the community. To increase the consumption of these fruits, each of which is virtually a healing capsule, is significant in terms of economy not only by considering health aspects but also because of the added value they create/will create. From production of seedling/sapling to establishment of garden, from establishment of garden to harvesting, labour is heavy, that is, numerous economic activities creating employment are required. It is necessary to pay special attention for the production of these products since they are raw material of many products produced either traditionally or industrially, they are the most interested products in both domestic market and foreign markets, they are the products to have high prices because of high demand. Promoting the production and consumption of these products will considerably increase incomes of small and medium sized enterprises, accordingly be able to embank to migration phenomenon by providing social welfare and peace, enable product diversification to be demanded by consumers, and provide opportunity to fruit processing industry to meet raw material demands.

Abstract

Livestock is essential for both human nutrition and agricultural industries. Hence, governments often apply some support policies in order to develop profitable livestock husbandry and better life. Although the governments applied some statist support policies until 1980, some public support policies have started to be applied after this year. A Supporting Animal Decree numbered as 2000/467 was applied under titles of artificial insemination, calf, equipment, stud heifer, beekeeping and honey, meat and milk, forage, and fisheries in 2000. After this decree, another decree numbered as 2005/8053 was applied for A five-year period in 2005. This decree was cancelled in the following year and it was decided that supports should be decided every year. In this content, "supporting farm animals for each head" policy was preferred and also support of artificial insemination was cancelled. In 2005 a Strategy of Agricultural Policies was applied for agricultural policies between 2006 and 2010. The titles of certified forage seed production, clarifying artificial insemination regions, equipment support for milking hygiene, vaccine, pedigree and conservation native animal genetic resources were determined in this strategy document. Decrees of "Supporting Milk Cows in Southeast Anatolia Region" and "Supporting Beef and Combine Cows in East Anatolia Region" were applied in 2011. Livestock supports in whole supports were 3.4%, 4.4%, 9.2%, 22.3%, 24.4%, 28.5%, 31.7%, 30.5%, and 29% in years of 2000, 2002, 2005, 2010, 2011, 2012, 2013, 2014, and 2015 respectively. In this study legislation based on relavant support policies was investigated by using other researches, articles, thesis, and statistics.

Key words: *Livestock, support, subsidy, agricultural policy.*

Introduction

Livestock has a significant place in Turkish agriculture. The share which value of animal production received from total agricultural production value has gradually increased between 2000 and 2014. According to data of Turkish Statistical Institute; the share of animal production in agricultural production was 44.17% in 2000 and reached to 51.50% in 2009. Value of livestock production continued above fifty percent constantly by receiving a share of 51.50% in 2010, 53.57% in 2011, 56.21% in 2012, 51.49% in 2013 and 52.16% according to provisional data of 2014. The share received by livestock production value within total agricultural production value is accepted as an important indicator along with the other criteria used for determination of development levels of countries (Peşmen and Yardımcı, 2008; Saçlı, 2007). While an investment of at least 80 thousand dollars is required in order to provide employment opportunity for an individual in the industry at the present time, a source which is one fifth of this investment is adequate for livestock. As it is compared to industrial area, employment opportunity can be provided for 5 times more people by livestock with the same amount of investment. Rate of agricultural employment among the total employment in Turkey is a high level like approximately 35% (Demir, 2012). Therefore, livestock also has a vital socio-economic task like preventing the population migration from the rural to urban (Akpınar et al., 2012). Of the area of total 184.329.490 decares in Turkey, 72.38% is in the

possession of enterprises performing both herbal production and livestock, 27.38% is in the possession of enterprises making only herbal production, and 23% is in the possession of enterprises making only livestock (Demir, 2012). All these reasons listed here reveal place and the importance of livestock in the economy of the country. In addition, it makes essential to support livestock when considering the unique importance of animal products in nutrition, mental and physical development of humans. This study investigated support policies carried out for livestock between 2000 and 2015 in Turkey.

Livestock support policies

Livestock sector having considerably high added-value, have been tried to be supported via various policies from 1923 to the present time. Subsidy focused on genetic improvement of native herds, control of diseases, and veterinary services until 1950s (Demir and Yavuz, 2010). When compared to vegetative production industry in the past, desired goals for livestock could not be achieved because livestock supports are not continuous, do not have adequate infrastructure for applying supply policies and accordingly problems of livestock could not be eliminated (Yavuz, 1999, Yavuz et al., 2006, Sayin, 2002).

Livestock policies, which were mainly the public until 1980s in Turkey, were thereafter in tendency to liberalisation, and then came to a state of mostly looking after the interests of parties. Stand-by Treaty concluded with IMF within this scope in 1999 has become the beginning of a new age for agriculture of Turkey (Saçlı, 2007). “The Project of Supporting and Improving Livestock” was initiated in order to eliminate the problems. Within this scope, Decree of Supporting Livestock No.2000/467 was entered into force in 2000 in order to develop livestock and increase animal production. The implementation is a five year decree and involved the years between 2000 and 2004. Along with this decree, incentives were brought for artificial insemination, calfs born by artificial insemination, equipments to use for artificial insemination, animals with breeding certificate, and keeping the stud book records in order to bring the genetic breeding more efficient and common. Furthermore, supports such as breeding heifer support, beekeeping and honey support, support of incentive pay for meat and milk, forage crops support, and fisheries were implemented (Anonymous, 2000). Also, Decision of Partnership Council, which is a milestone for livestock in this period and was concluded in 1998, was also put into force. However, any kind of development has not occurred by 2005 regarding importation of livestock and meat promised to EU within the scope of this decision (Saçlı, 2007). Council of ministers no 2005/8503 with the same content, prepared as a result of studies performed instead of the Decree no 2000/467 expired in 2005, was enacted for a 6 year period. But after one year, this decree was cancelled by Council of Ministers’ Decision no 2008/13489. Thus, it was passed on one-year execution in which supports would be determined again every year, quality and content were changed. A support method as “payment per animal” was preferred within this scope and artificial insemination supports were cancelled (Saçlı, 2012).

In 2005, “Agricultural Strategy Certificate” implemented between 2006 and 2010 as a follow-up version of the decision applied in 2000 was brought to agenda through a council of ministers’ decision. In this policy to be applied, it was aimed for livestock to have a share of 12% among the all supports in 2010. Within this scope, applications regarding the production of certified forage crop seeds, determination of the areas of artificial insemination, equipment support concerning milking hygiene, vaccine support considering animal health, animal identification support, and conservation of gene resources were at the top of the agenda. Supports for sheep and goat breeding took place among the supporting items in which almost all were applied for stock farming in following years (Saçlı, 2007).

In 2006, a legal framework was formed for supports via The Law of Agriculture entered into force by being published in Official Gazette dated 25.04.2006 and numbered 26148. The Law of Agriculture aims the determination of policies and making regulations required for

advancement and support of agricultural sector and rural area in accordance with development plans and strategies. According to the Law of Agriculture, support measures are taken with the aim of race breeding, increasing the production of coarse fodder, increasing the efficiency, specialisation of establishments, providing hygiene conditions in establishments, animal health and welfare, encouragement of animal identification system, processing and marketing animal products, and improvement of related controls, follow-up, and standards and supporting fisheries. Council of Ministers was authorized upon the offer of Council to apply supports and determine the amounts of payments on the basis of regions and provinces in livestock supports (Anonymous, 2006).

Livestock was not imported because Ministry of Agriculture and Rural Affairs did not issue the control certificate for livestock and meat import since 26.8.1996 on the account of the fact that "foot and mouth disease existed in Turkey and health of imported animals could not be protected because of the illness in our country" (Kandemir, 2010). Along with the emergence of Bovinge Spongiform Encephalopathy (BSE) in 1996 in international arena, butchery animal and red meat were not imported from 1997 to 2010 in Turkey (Aydın et al., 2010). However, while gradually increase of the population against the decrease in number of animals reduced the meat production per capita, meat prices considerably rose. However, a reel increase in red meat prices firstly appeared for sheep-goat meat as it came to the 2nd half of 2008, which was followed by the cattle meat in the 2nd half of 2009. Ministry of Agriculture and Rural Affairs (TKB) wanted to balance the reel price increase of red meat (Aydın et al., 2010). The task for butchery animal import was assigned to General Directorate of Meat and Fish Authority, in 2010 in the first step to decrease red meat prices having a tendency to a continuous increase from the second half of 2009. Import permit for stock material and carcass meat was given to private sector by deducting custom duties after then because a decrease was not observed in prices (Anonymous, 2011). In this period, import of livestock, meat and breeding animal was started in Turkey and both custom duties and reference prices and import countries and technique specifications of animals to import have been changed for several times from 28 April 2010, when the first tender bid was announced, to 2014 (Akman, 2011). The last change made in custom tariff entered into force by being published on Official Gazette dated 30 October 2012 and numbered 28452. Proportions of custom duty for cattle carcass meat increased from 75% to 100%, for butchery male calf from 15% for other cattle from 0%, for lamp and sheep from 20% to 40%, by Council of Ministers' Decision No 2012/3758 (Anonymous, 2014).

When it came to 2011; livestock supports started in 2000s considering various issues in bovine and ovine breeding were continued by "Council of Ministers' Decision Regarding Agricultural Supports to be performed in 2011" Numbered 2011/1430. With the given decision; support payments were made in the subjects of brood cattle-buffalo, sheep-goat, calf born via artificial insemination, hybrid born via artificial insemination, raw milk, raw milk assessment, sheep-goat breeding project, feeder male cattle, protection of gene resources, angora, silk worm, beekeeping and fisheries, coarse fodder production, returned animal disease, disease free establishment, struggling with animal disease, programmed vaccine practices. In addition, several political tools were enabled such as "Decision Regarding Supports of Dairy Cattle Breeding Investments in Provinces within the Scope of Action Plan of Southeastern Anatolia Project " and "Decision Regarding Supporting the Investments of Breeding Cattle Establishment to Built with Beef and Combined Cattle Breeds in Provinces within the Scope of Eastern Anatolia Project " (Saçlı, 2012).

Payments regarding certified breeding heifer support, incentives of artificial insemination, incentives of artificial insemination calf, incentives of artificial insemination equipments, silk worm cocoon support, angora support, hatched chick support, avian influenza disposal compensation, beekeeping and honey support, meat incentive pay, milk incentive pay,

disease-free establishment support, forage crops, machinery support, seed support for certified forage crops, milking hygiene and milk quality, animal gene resources, animal identification system, struggling with disease (vaccine), food safety, ovine breeding association support, fisheries support, and bovine support has been provided to breeders since 2000 within the scope of livestock supports (Demir and Yavuz, 2010).

Support payments of livestock

Table 1 illustrates that agricultural supports between 2000 and 2015 reached to 4 billion dollars from 1.48 billon dollars by increasing 4 times in 2000. At the same period, livestock supports increased to 1.16 billon dollars from 19 million dollars by increasing 60 times. When it came to share of livestock supports among the total supports by years, the share was 1.29% in 2000 and reached to 21.8% in 2015 with an approximately increase of 22.5 times. While rate of increase of livestock supports compared to the previous year was examined, we can assert that it increased with higher rates compared to total agricultural supports (Table 1).

Table 1- Total agricultural support payments and livestock supports * (Anonymous, 2015a)

Years	Total agricultural supports (Million TL)**	Total agricultural supports (Million $)	Livestock supports (Million TL)**	Livestock supports (Million $)	Share of Livestock supports in Total agricultural supports (%)	Increase rate of agricultural supports compared to previous year (%)	Increase rate of livestock supports compared to previous year (%)

Figure 1 illustrates payments of agricultural and livestock supports. It was observed that supports were in increasing trend despite decreases in 2009 and 2014.

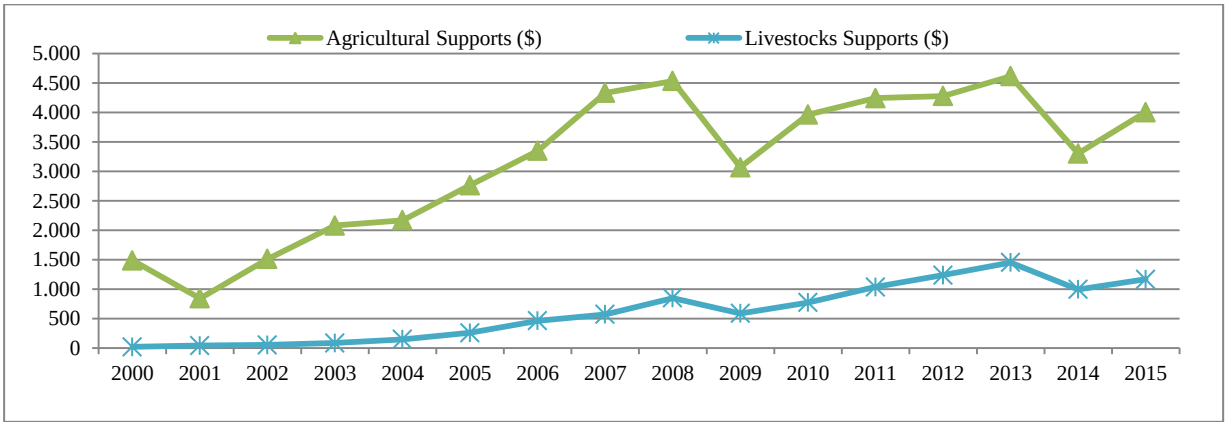

Figure 1 – Total agricultural supports and livestock supports (Anonymous, 2015)

Figure 2 illustrates the share of livestock supports within total agricultural supports. Whilst it was observed that share of livestock supports within total agricultural supports was increasing

gradually, reached to the highest level in 2013 with an increase of 31.41%, went back to 30.08% in 2014, and it is estimated to decrease to 29.12% in 2015 (Figure 2).

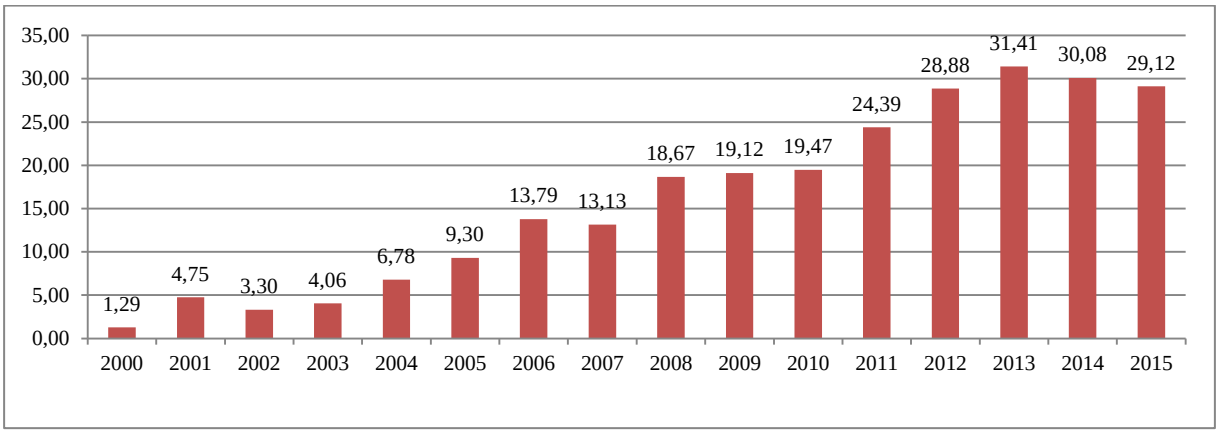

Figure 2 – Share of livestock supports within agricultural supports (%),(Anonymous, 2015a)

Annual increase rates for total agricultural supports and livestock supports from these supports were compared at Figure 3. Annual increase rate for livestock supports increased in a higher level compared to total agricultural supports. But, it can be asserted that I has followed a parallel trend since 2009 when a negative increase was observed compared the previous year. Although share of livestock supports increased to 30% after 2010, rate of increase has shown a gradually decreasing structure as from 2011.

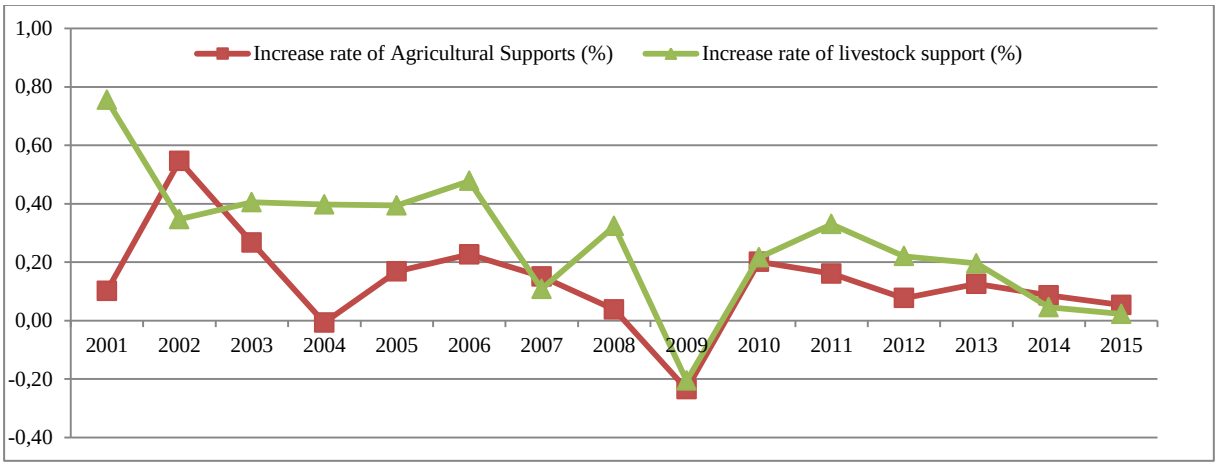

Figure 3 – increase rate of agricultural and livestock supports compared to the previous year

Changes in presence of main livestock and major animal products in turkey between 2000 and 2014

This section examined the changes occurred in number of livestock in return for the increase of share of livestock supports within total supports. Giving permission for livestock import in 2010 and providing agricultural credit with interest of 0% for animal production activities via Ziraat Bank and Agricultural Credit Cooperatives (TCC) as from 2011 have caused increase of animal number and animal prdocution. (Hatunoğlu and Eldeniz, 2012).

It was observed that while the number of cattle was 10.7 million heads in 2000, it reached to 14.1 million heads with an increase of 23.8% compared to 2000 due to the positive effect of increasing supports as from 2010 (Table 2). The number of buffalos, which was, 146.000 in 2000 decreased dramatically because buffalo breeding was underestimated. Even though it showed an increasing trend again after 2010, 2014 was entered with 121.8 thousand heads of buffalo with a decrease of -19.4% compared to the number of buffalo in 2000 (Table 2). The

number of heads of sheep, which was 28.4 millions in 2000 in Turkey, decreased to 25.1 millions in 2002. The number of sheep, which was almost 25 million heads until 2008, reduced to 21.7 million heads in 2009 by showing a decreasing trend. The effect of supports increasing as from 2009 was started to be observed and the number of sheep in Turkey reached to 31.1 million heads with an increase of 8.43% in 2014 compared to 2000. The number of goats, which was 7.2 millon heads in 2000, entered to a decreasing trend ongoing until 2009 and reduced to 5.1 millon heads. With the effect of supports given as from 2009, an increasing trend started again. Thus, the number of goats in 2014 reached to 10.3 million heads with an increase of 30.41% compared to 2000.

Table 2 – The number of major Livestock in Turkey between 2000 and 2014 (Anonymous, 2015b)

	Cattle	Buffalo	Sheep	Goat
2000	10.761.000	146.000	28.492.000	7.201.000
2001	10.548.000	138.000	26.972.000	7.022.000
2002	9.803.498	121.077	25.173.706	6.780.094
2003	9.788.102	113.356	25.431.539	6.771.675
2004	10.069.346	103.900	25.201.155	6.609.937
2005	10.526.440	104.965	25.304.325	6.517.464
2006	10.871.364	100.516	25.616.912	6.643.294
2007	11.036.753	84.705	25.462.293	6.286.358
2008	10.859.942	86.297	23.974.591	5.593.561
2009	10.723.958	87.207	21.749.508	5.128.285
2010	11.369.800	84.726	23.089.691	6.293.233
2011	12.386.337	97.632	25.031.565	7.277.953
2012	13.914.912	107.435	27.425.233	8.357.286
2013	14.415.257	117.591	29.284.247	9.225.548
2014	14.122.847	121.826	31.115.190	10.347.159

Figure 4 illustrates increase rates in number of cattle, buffalo, sheep, and goat between 2000 and 2014 compared to the previous year. When the figure was examined, supports given at Figure 3 changed in parallel to annual increase rate. It can be asserted that the lowest rate of increase was seen as a negative growth in 2007 for buffalo breeding, in 2008 for cattle and goat and in 2009 for sheep. It was observed that livestock supports increasing as from 2009 affected the increase in the number of goats at the most and a decreasing trend started in increase rates after 2012 (Figure 4).

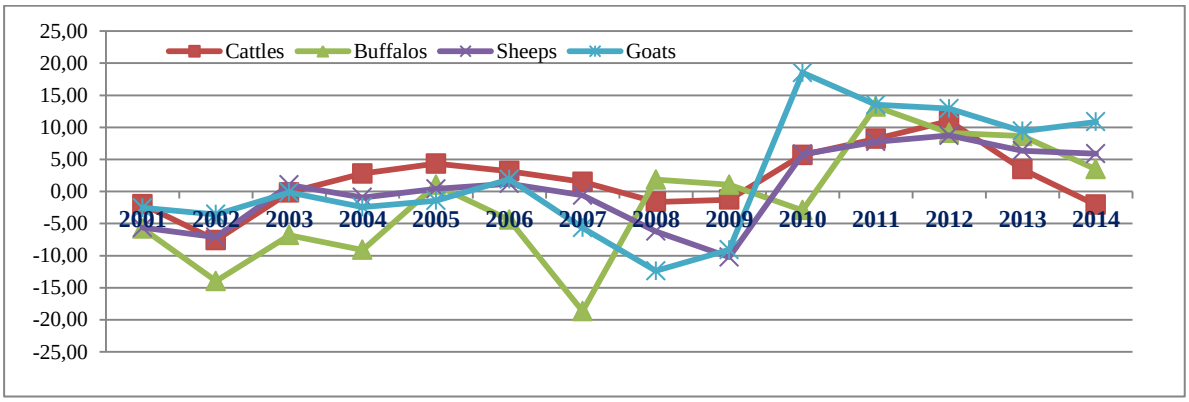

Figure 4 – Increase rate in number of major livestock compared to the previous year

Table 3 illustrates changes of some animal products between 2000 and 2014. It was observed that there was a considerable increase in animal production as a result of policies implemented for decreasing the price increase observed in the market of meat products sector after 2009 (Hatunoğlu and Eldeniz, 2012).

Red meat production, which was 491.5 thousand tons in 2000, increased more than 1 million tonnes with an increase of 49.29% in 2014 compared to 2000 (Table 3). Milk production,

which was 9.79 million tonnes in 2000, increased to 18.49 million tonnes with an increase of 45.5% compared to 2000 in parallel to supports increasing as from 2009 (Table 3). Chicken production, which was 643.45 thousand tonnes in 2000, and reached to 1.89 millon tonnes with an increase of 68.5% in 2000 by replacing red meat with chicken meat upon high red meat prices (Table 3). Chicken egg production which was 13.5 billion in 2000, reached to 17.14 billion in number with an increase of 17.82% in 2014 compared to 2000 (Table 3). When honey production was examined, honey production, which was 61 thousand tonnes in 2000, showed an increasing trend at lower levels for long years and reached to 102 thousand tonnes with an increase of 34.37% in 2014 compared to 2000 (Table 3).

Table 3- Main Animal products in Turkey between 2000 and 2014 (Anonymous, 2015b)

	Red meat (Ton)	Milk (Ton)	Chicken (Tonnes)	Chicken egg (1000)	Honey (Tonnes)
2000	491.499	9.793.962	643.457	13.508.586	61.091
2001	435.778	9.495.550	614.745	10.575.046	60.190
2002	420.595	8.408.568	696.187	11.554.910	74.554
2003	366.962	10.611.011	872.419	12.666.782	69.540
2004	447.154	10.679.406	876.774	11.055.557	73.929
2005	409.423	11.107.897	936.697	12.052.455	82.336
2006	438.530	11.952.099	917.659	11.733.572	83.842
2007	575.622	12.329.789	1.068.454	12.724.959	73.935
2008	482.458	12.243.040	1.087.682	13.190.696	81.364
2009	412.621	12.542.186	1.293.315	13.832.726	82.003
2010	780.718	13.543.674	1.444.059	11.840.396	81.115
2011	776.915	15.056.211	1.613.309	12.954.686	94.245
2012	915.844	17.401.262	1.723.919	14.910.774	89.162
2013	996.125	18.223.712	1.758.363	16.496.751	94.694
2014	1.008.272	18.498.630	1.894.669	17.145.389	102.486

Figure 5 illustrates the increase rates in production amounts of animal products between 2000 and 2014 in comparison with the previous year. It was observed in case that there was a change in parallel to annual increase rate of supports given in Figure 3. We can tell that the of highest production level of animal products decreased in 2010 by reacting to 2009 when share of livestock supports started to increase and as from this year it entered into a decreasing trend (Figure 5).

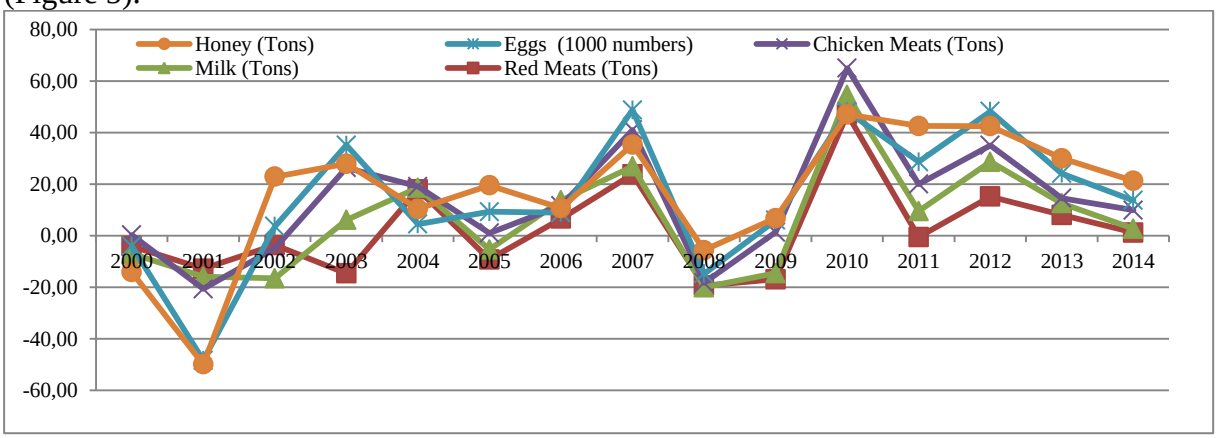

Figure 5 – Increase rate of main animal products compared to the previous year

Conclusion and recommendations

Through livestock supports implemented from 2000 to the present day; measures for environmental precautions have been put into practice along supports regarding meat premium, marketing support, modernisation of livestock enterprises in addition to current support instruments for the purpose of improvement of race breeding, improvement of coarse fodder production, increase of yield, specialisation of establishments, providing hygiene conditions at establishments, animal health and welfare, incentive of animal identification

system, processing and marketing animal products supports and improvement of related controls, follow-up, and standards.

It was aimed to increase the number of livestock establishments specialized in the sub-sector of livestock through new supports. Share of livestock supports in agricultural support budget increased to 30% as a result of growing within the scope of implementation.

According to 2000-2014 data from Turkish Statistical Institute, number of livestock and production of animal products responded to support policies and thus increased and policies were successful even though they were not sufficient enough to meet the demand of increasing population. But, the fact that changes in production are supersensitive to changes in supports indicates structural problems of livestock establishments have continued. Livestock supports need to turn to construction and improvement of permanent end sustainable-sized enterprises.

Abstract

Nitrogen pollution of river water due to agricultural activities was concerned in the Tokachi River basin in the eastern Hokkaido, Japan. Meanwhile, the riparian forests and windbreak forests in agricultural area exists as a buffer zone of nitrogen export and a migratory path and breeding site for wild animals. Here, we examined the relationships between the forestland in the watershed and the nitrate nitrogen (NO_3-N) concentration in the river water. Also, we discussed the importance of forestry management for the implementation of sustainable agriculture and the biodiversity conservation.

The main stream and the tributaries of the Tokachi River basin were monitored in 2007-2011 and the NO_3-N concentrations in the river water were measured. The proportion of forestland and connectivity of forestland (the spatial continuity (*SC*) of forestland) were analyzed by the GIS. NO_3-N concentrations were negatively correlated with the proportions and *SC* of forestland. It was considered that the agricultural land runoff, which contained a lot of nitrogen was diluted by the forestland runoff which had low nitrogen concentration. In particular, the correlation coefficients between the *SC* of forestland and the NO_3-N concentrations were high.

There is a possibility that the NO_3-N concentrations decreased by not only the large forestland in upper stream but also by the windbreak forests or riparian forests, which have high connectivity in the agricultural area. It is important to manage the forestlands properly for suppression the nitrogen export from the agricultural land in the Tokachi River basin.

Keywords: *Forestry management, River water quality, NO_3-N concentration, The Tokachi River basin*

Introduction

Forests serve multiple functions including provision of timber products, land conservation, watershed protection and ecosystem service such as conservation of biodiversity (Erwin, 2000; Pistorius et al., 2012). The Tokachi River basin in eastern Hokkaido, Japan has an important role as a food base of Japan. Forestland accounts for 60% of the watershed area in this basin as well. The native and mountain forests in the upper stream of the Tokachi River are conserved areas. However, the riparian and windbreak forests in the lowland areas have reduced in the last couple of decades because of their conversion to agricultural land and the decrease in wood prices (Tsuji et al., 2005). Forests in the lowland area represent a valuable habitat and serve as a migratory path for the wild animals in an agricultural area (Strasser and Lang, 2015). Riparian forests are expected to remove some nutrient salts from the groundwater and river water (Hubbard et al., 1997).

In addition, the Tokachi River basin has been assessed as one of the basins with the highest nitrogen load from agricultural activities in Hokkaido, Japan (Woli et al., 2004; Yamazaki et al., 2013, 2014). Forest ecosystem functions such as water quality conservation have attracted attention in recent years. Enrich (1996) and Moore and Allen (1999) suggested that

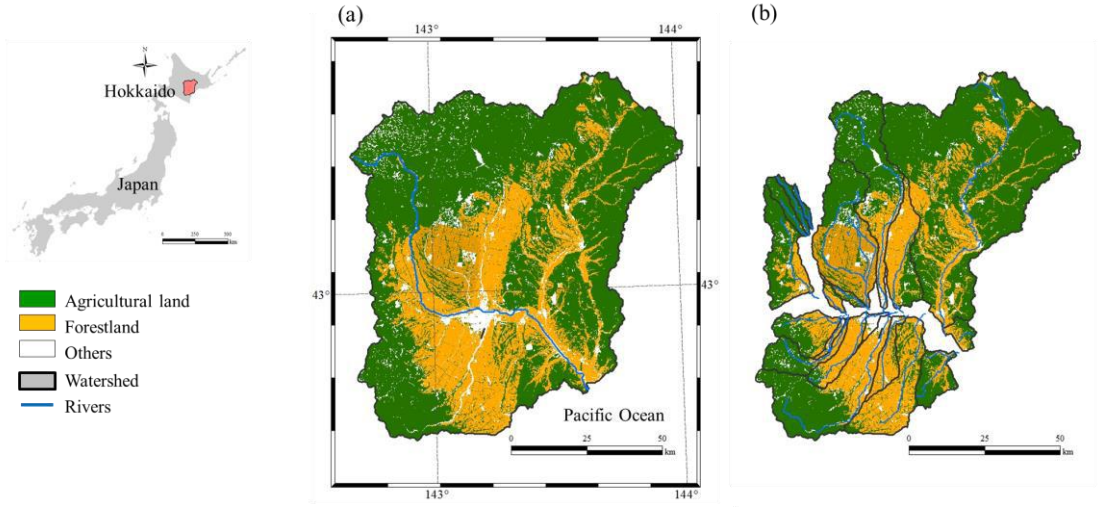

Fig. 1 The Tokachi River basin: (a) Land use andwatershed boundaries of the main stream; (b) Land use and watershed boundaries of the tributaries

biodiversity conservation in forests is strongly related to ecosystem function and stability.
To identify ecosystem functions, it is necessary to evaluate not only the area but also the distribution of forestland. For example, connectivity (agglomeration) of forestland is emphasized in forest ecosystems (Forman, 1995; Schumaker, 1996).
In this study, we evaluated the impact of forestland on nitrate-nitrogen (NO_3-N) concentrations in the river water of the Tokachi River basin. We also focused on the proportions and agglomeration of forestland. We discussed the importance of forestry management for the implementation of sustainable agriculture and ecosystem services.

Material and methods

Study area

An outline of the study area in the Tokachi River basin (142.68–144.02°N, 42.55–43.65°E, 0–2,077 m altitude) in eastern Hokkaido, Japan is shown in Fig. 1. The basin consists of the main stream and approximately 20 tributaries. The main land uses in this river basin are agriculture and forests. Of the agricultural land, 70% is used as cropland and the remaining 30% as pasture. The low-lying areas around the tributaries are used as croplands. The crop cultivation period is from May to November. Chemical fertilizers and compost are used in the agricultural land.
The headstream of the Tokachi River is designated as a nature conservation area, and a virgin habitat is maintained for rare species. Mixed forests of conifers and broad-leaved trees comprise the native forests of this basin. Riparian and windbreak forests have been planted in the low-lying areas of this basin to prevent soil and wind erosion of the agricultural land. *Salix pet-susu*, *S. rorida*, *S. gracilistyla* and *Chosenia arbutifolia* are the main tree species in the riparian forests. In particular, *C. arbutifolia* has a disjunct distribution limited to Hokkaido and Nagano prefectures. The main tree species in the windbreak forests in the Tokachi River basin are *Larix kaempferi*, *Betula platyphylla sukachev* var. *japonica*, *Abies sachalinensis* and *Picea glehnii* (Tsuji et al., 2005). The meteorological environment in the Tokachi River basin is classified as a warm summer continental climate type (Dfb) according to the Köppen–Geiger climate classification (Peel et al., 2007). The annual mean air temperature and precipitation, measured at Obihiro city from 1981 to 2010, were 6.8 °C (minimum −7.5 °C in January; maximum 20.2 °C in August) and 887.8 mm/y, respectively.

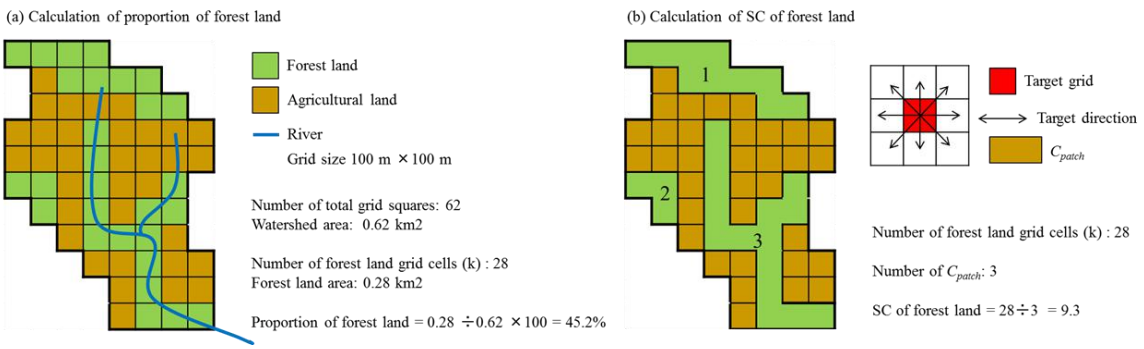

Fig. 2 Calculation methods for (a) proportion and (b) spatial continuity (SC) of agricultural land

Water quality investigation

Sampling points were located on the main stream (points 1–17) and downstream of each tributary (A–T). Thirty-seven sampling points were monitored in June, August or September and October from 2007 to 2011 under base flow conditions. NO_3-N was analysed by the chromotropic acid or cadmium methods.

Land use analysis

The GIS software application ArcGIS Desktop (ver.10, ESRI) was used for land use analysis. ‘River line’, ‘watershed boundary’ and ‘land use raster (100 m grid size)’ data provided by the National Digital Information were used to construct a land use map of the Tokachi River basin. The proportions and the spatial continuity (SC) of agricultural land were used for land use analysis. The proportion of agricultural land is the area of agricultural land in a watershed divided by the watershed area (Fig. 2a). SC was proposed by Tsunekawa et al., 1991. Okazawa et al (2011) investigated the relationship between SC of agricultural land and forestland in the Tokachi River basin and T-N concentration on a trial basis. To calculate the *SC* index, the land use grid squares that were vertically, horizontally and diagonally connected were grouped into a patch (Fig. 2b). *SC* values in the watershed were obtained by Eq. (1).

$$SC = k/C_{\text{patch}} \qquad (1)$$

Where k is the total number of grid squares of agricultural land in the watershed, C_{patch} is the number of patches in the watershed. SC evaluates the area of connected identical land use grid squares in the watershed.

Results and discussion

The relationships between the proportion or SC of forestland in the watershed and the NO_3-N concentrations in the river water are shown in Fig. 3 (a) and (b). NO_3-N concentrations are average values during the study period. The proportion of forestland in the watershed and the NO_3-N concentrations in the river water showed a negative correlation (r = 0.87) (Fig. 3 (a)). The NO_3-N concentrations tended to be low in watersheds with high proportions of forestland. However, NO_3-N concentrations varied from 1.9 to 5.7 mg/L in watersheds with ≤40% proportions of forestland.

NO_3-N concentrations in the river water showed a negative correlation (r = 0.92) with the SC of forestland (Fig. 3(b)). The correlation coefficients of SC of forestland were higher than those of the proportion of forestland. This result suggested that the NO_3-N concentrations tended to be low in the watersheds with high connectivity of forestland even if the proportion of forestland was the same.

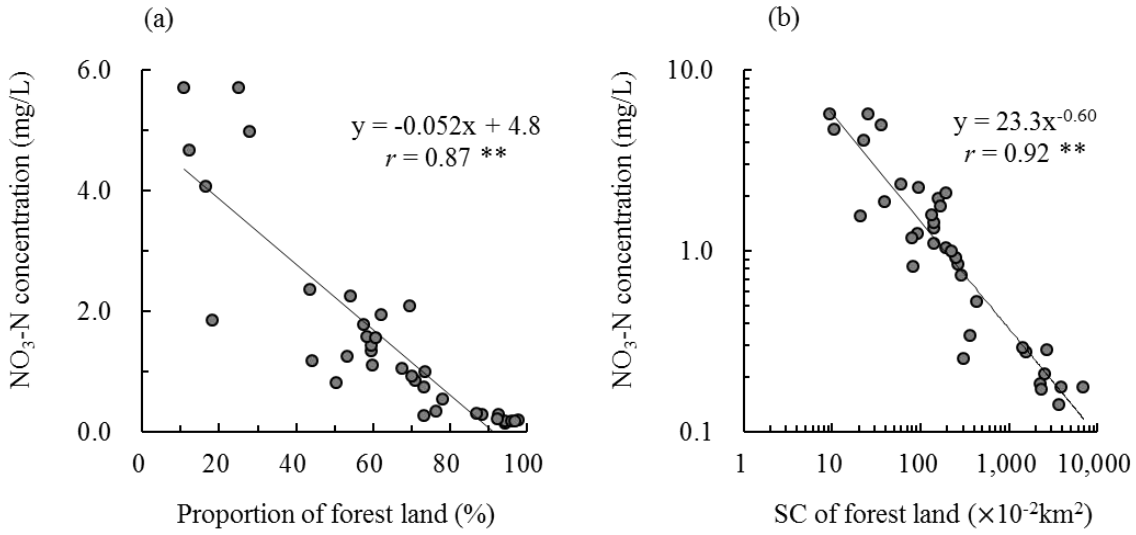

Fig. 3 (a) and (b) Relationship between the Proportion and SC of forestland and the NO_3-N concentrations in the Tokachi River basin. ** shows significance level ($p < 0.01$)

Generally, NO_3-N concentrations in mountain streams were low. Consequently, a dilution effect on the river water NO_3-N concentrations, by mountain streams, was found as a function of forestland in agricultural watershed. The NO_3-N concentrations in upper streams of the Tokachi River with forestland of ≥90% showed very low values (≤0.2 mg/L).

It was inferred that the connectivity of forestland was extended by the riparian and windbreak forests in lowlands of the Tokachi River basin. Riparian forests have abundant soil moisture and relatively nutrient reducing conditions (Robert et al., 2009). Denitrification and plant uptake in the riparian forest are thus thought to remove nitrogen from shallow groundwater (Nakamura et al., 2005). On the other hand, there are few studies on control of nitrogen runoff from agricultural land by windbreak forests. However, we speculate that the biodiversity in the windbreak forests has the potential to consume or remove surplus nitrogen from agricultural land.

Conclusion

There was an effect of decreasing the NO_3-N concentrations in the river water by forestlands in the Tokachi River basin. The results suggested that increasing the connectivity of forestlands, especially the forests in lowland area was effective to remove the nitrogen loads from agricultural activities and also to conserve the biodiversity.

From these results, we should preserve not only mountain and native forests but also forests in agricultural land such as riparian and windbreak forests to bring out the multi functions of forests in agricultural watershed. It is necessary to investigate the ecosystem function and effects on environments of forestlands in detail to preserve forestlands in agricultural watershed with sustainable agricultural productivity.

Abstract

Eroded material in torrential watercourses moves in waves of maximum discharge. The paper deals with studies related to the impact of geological type of stream bed in a drainage basin on the rate of rock erodibility, fragmentation and hydraulic transport through the catchment hydrographic network. The study was performed in the area of the Teaching Base of the Faculty of Forestry from Belgrade, on the river Gvozdacka Reka on Mt. Goc, in the Zapadna Morava River basin. A reservoir was created at the profile of the Gvozdacka Reka tributary. Water was released from the storage to simulate floodwave discharge in the watercourse. The experiments were repeated by successive releases of water from the storage and suspended sediment concentrations were calculated. Maximum discharges were measured at the overflow, at the beginning of the experimental stream reach. The characteristics of eroded material along the riverbed were defined, based on the geomechanical and granulometrical analysis of sediment from the profile and banks of the riverbed at the experimental stream reach. Using standard methods related to the conditions for the initiation of motion of bedload and suspended load, critical tractive forces for each sediment fraction from the structure of the stream profile were calculated.

Key words: *sediment particle-size composition, bedload, tractive forces.*

Introduction

River sediment is composed of particles of different sizes, from dust to bpulders. Depending on boundary shear stress, energy gradient, flow velocity and particle-size, river sediment moves in the form of:

Bedload, usually 5-15%, though it can vary from 100% to less than 0.1% (Galy and France-Lanord, 2001; Babinski, 2005; Kazemi et al., 2012);

Suspended sediment, 85-95%, (Jovanovic, 2008).

The characteristics of eroded material (fraction sizes and roundness) in drainage basins of hill and mountain streams primarily depend on bedrock type and rock resistance to weathering. Rounding of sediment particles depends on the rock composition and hardness and the distance travelled from the source the depositional area (Letic, 1981). The movement of eroded material is a continuous process with varying intensity and it is directly related to flow and water level variations in the stream cross section. (Bakker, 2005) Sediment movement is a very complex natural process and its study requires the application of almost all modern scientific methods in the fields of fluid mechanics, water and sediment turbulent movement, stochastic analysis of peak flows and sediment transport through the drainage pattern (Globevnik, et al, 1998).

Although the study of bedload entrainment and movement has been the subject of scientific interest for a long time, the adequate results in the professional practice are still insufficient for the solution of current engineering issues (Jovanovic, 2002; Martha et al, 2005).

The transport of suspended sediment is commonly monitored at the selected sites by standard procedures. While bed material moves beyond a given shera stress threshold during flood waves, suspended sediment, and especially its wash load component, is transported also during the lower flows of the flood hydrograph (Lamakin, 1950).
Bedload moves sporadically and randomly on the river bed in response to local flow conditions which can be investigated at selected sites (Kondolf et al, 2002).
There is not a strictly defined threshold between bedload and suspended sediment grain size. The same particle sizes that, in the given hydrological-hydraulic conditions, move as bedload can become suspended sediment, depending on hydraulic forces, increased discharge and tractive forces (Karasaev, 1975; Ortigosa and Ruiz Flano, 1995).
Sediment management relies on the quantitative data measured in the field as sediment transport equations predict transport rates which are commonly even a few orders of magnitude far from the actual ones. The necessary data should be measured in natural streams as input data for contour conditions (Keesstra et al, 2003).
To give a contribution to the solution of particle entrainment conditions in natural streams, this study was carried out on the the main stem of the Gvozdacka Reka ("*reka*" means river in Serbian language) (Fig. 3 and 5) and its tributaries in the experimental reach about 250m long (Kantoush and Sumi, 2010), in the area of the Faculty of Forestry Teaching Base of Belgrade on Mt. Goc (Serbia).
The Gvozdacka Reka tributaries, Bela Reka and Prerovska Reka, deliver great quantities of eroded material from the catchment to the zone of the Teaching Base on Mt. Goc and silt up the check dams constructed in the streams (Fig. 2). The vegetation of the study drainage basins is characterised by good canopy and coverage (>95%), so there is no visible evidence of runoff erosion, except for gravel roads and the input of sediment of organic origin. However, fluvial erosion processes are present, witnessed by bank scouring and bank collapse (Rogers & Schumm, 1991). The organo-mineral sediment moves permanently and periodically through the stream network and it is transported as suspended load and bedload, respectively (Fig. 4) (Ortigosa and Ruiz Flano, 1995).
The entrained sediment is deposited upstream of natural obstacles or the check dams. The essential function of the dams in the catchment is to control the bedload movement and also to protect the storage intended for trout fishpools, which belongs to the Teaching Base, and to conserve water quality for downstream users. (Suresh Kumar et al, 2012).

Material and methods

The study was carried out on the Gvozdacka Reka, which is located in the Zapadna Morava River basin (Fig. 1).
The bedrock underlaing the Gvozdacka Reka catchment consists of dacites and andesites, mainly from the Tertiary, Mesozoic porphyries and porphyrites, with the following distribution:
Serpentines, serpentinites 11.02%;
Harzburgites, granodiorites, 35.00%;
Sandstones, dacites and andesites, alevrolites, marbles 8.75%;
Schists, mixed serpentinites and metabasalts, 45.23%.

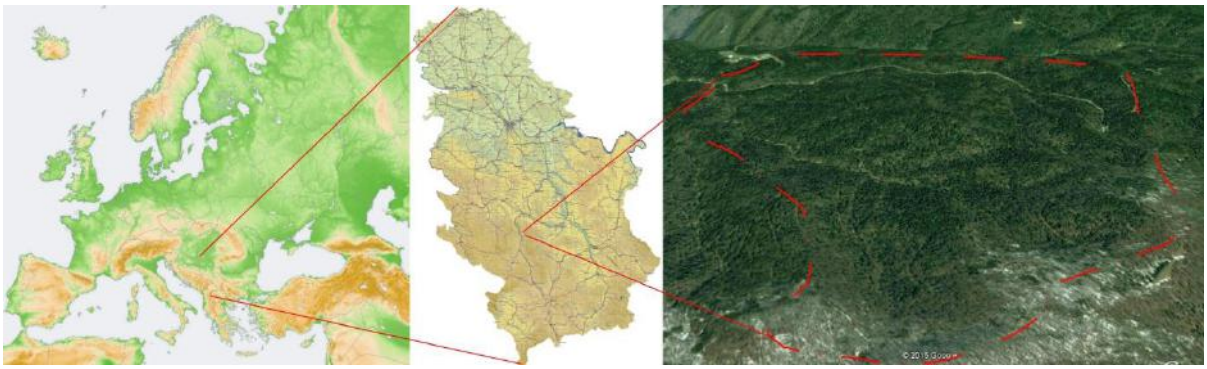

Figure 1. The study area of the Teaching Base of the Faculty of Forestry from Belgrade, the river Gvozdacka Reka on Mt. Goc, the Zapadna Morava River basin.

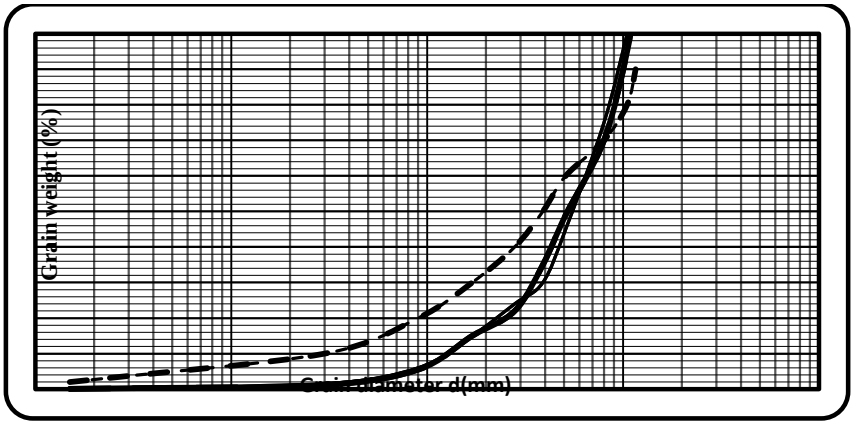
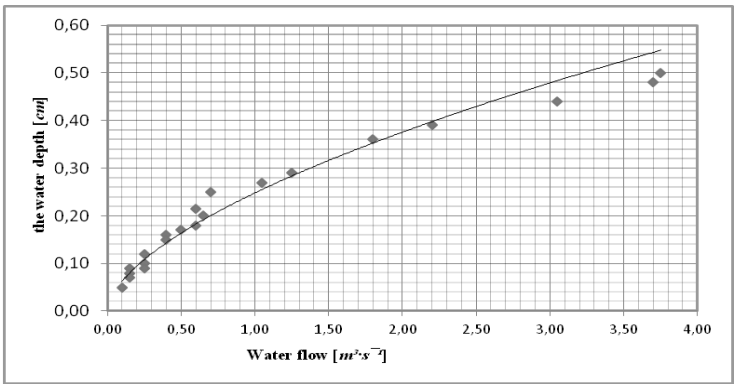
The rocks of groups 2) and 4) account for 80.23% of the catchment area and play the decisive role in the supply of river sediment in the upper, middle and downstream parts of the stream and river valley. In the downstream reaches, bed material consists of coarse gravel and sand fractions which are are transported as bedload and partly as suspended load during floods.
In norder to measure particle size distribution, bulk density, and specific weight of sediment, samples were taken from the river bed and banks (Fig. 5.)
The particle size distribution for fraction sizes > 0.1mm was obtained through standard sieving method and the results are graphically reported in Equation 1. and in Table 1. presenting the analysis of sediment movement at different discharge rates.
Further analysis consists in the calculation of a few characteristic diameters such as D_{10}, D_{50} and D_{90}, i.e. the dimeter by which 10, 50 and 90% of the distribution is finer. The sampled sediment grain diameters and weights were subject of hydraulic analysis.



Equation 1. Diagram of the particle size distribution of the sediment from the river Gvozdacka Reka. (Source: original)

To determine the discharge at the selected cross section (Fig. 4), the following measurements were made: cross section area and flow velocity, by using a current meter along different verticals, to obtain mean cross-section discharge. Based on several measurements in different hydrological conditions, we defined the flow rating curve (Fig. 2).



Equation 2. The Gvozdacka Reka discharge curve at the intake for fishpool. (Source: original)

The river discharge was measured in different seasons and weather conditions over the period 1993 - 2006 (Fig. 2). During the same interval, flood waters were sampled for the measurement of suspended sediment concentration.

The threshold conditions for bedload entrainment were calculated using Meyer-Peter Muller's formula; i.e. for the calculation of critical tractive forces. For different sizes of eroded material, the calculation of different phases of initiation of motion and also the definition of the method of transport through the catchment was performed using the comparison of tractive forces with critical tractive forces.

In this sense, the following methods were applied:

Modelling the complete physical process of eroded material movement under the effect of the river hydro-dynamic forces;

Field methods, including the survey of water discharge in the main stem and the tributaries;

Sediment sampling for the measurement of particle size distribution, bulk density, and specific weight;

The samples were analysed for other geomechanical characteristics, the angle of internal friction of sediment and cohesion;

The morphology of natural channel, cross sections, stream bed slope, and the slope of the water surface were defined based on field geodetic surveys;

Hydrometric measurement of water discharge at the sampling point;

Samples of torrential water for psammological research and estimation of suspended sediment concentration.

Particle movement (suspended sediment and bedload) is directly related to sediment grain sizes and particle specific weight and also to the stream turbulent regime and tractive forces in the stream. Critical tractive forces, according to Shields' criterion (1936) are defined depending on sediment specific weight, water density and median particle diameter.

$$\tau_{cr} = 0.047 \cdot g \cdot (\rho_s - \rho) d_{sr} \, [\mathrm{kN/m^2}] \qquad (1)$$

where:

τ_{cr}, critical tangential stress;

g, acceleration of gravity;

ρ_s, sediment density;

ρ, water density;

d_{sr} (design) of particle diameter

In eq. (1) the dimensionless Shields' parameter was take as 0.047, rather than the original value of 0.056, au suggested by Andrews (1983), because of the coarsenees of bed material.

In this study, attention was focused on the conditions of particles entrainment from river bed and banks, i.e. on the assessment of the conditions under which some sediment fractions start moving as bedload.
Tractive force is defined by the equation:

$$\tau_0 = \rho_v \cdot g \cdot R \cdot J \text{ [kN/m}^2 \tag{2}$$

where:

τ_0, tangential stress;

g, acceleration of gravity;

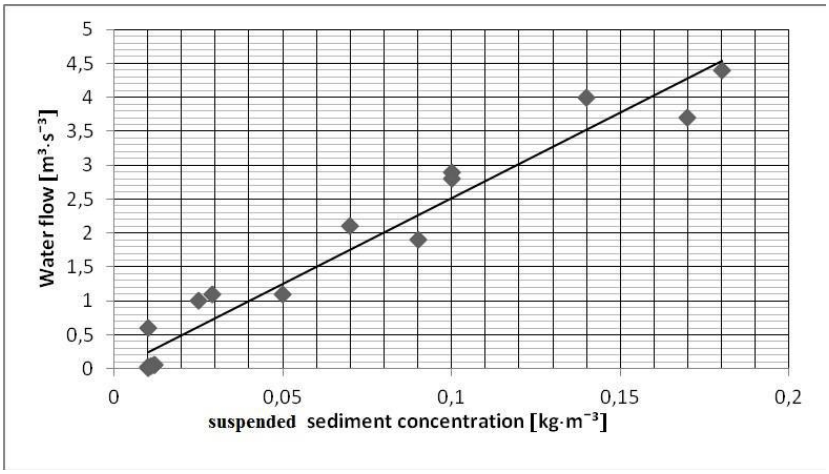
ρ_v, fluid density;

R, hydraulic radius;

J, slope of the water surface.

Results and Discussion

Suspended load



Equation 3. Suspended sediment concentration in the function of discharge. (Source: original)

Equation 2 shows the variation of suspended sediement concentration with discharge. The correlation between these two variables is rather high since flow discharge explains 95% of suspended load conscentration.
Maximum oncentrations, as high as 0.193kg·m^{-3} were measured with a discharge (Q) of 4.4m^3·s^{-1}. During 2006, some considerably higher concentrations of suspended sediment were recorded in coincidence with particular hydrological conditions (Fig. 5). These conditions were caused artificially by water releasing from the reservoir on the Prerovska Reka and, on such occasion, part of the infilled sediment was moved from the storage (Fig. 5).

Bedload transport

The transport of large fractions of bed material occurs periodically, that is mainly during floods. Depending on the mode of transport, river sediment is classified as bedload in the form of sliding and rolling grains and suspended load. Tangential stresses occur throughout the stream wetted perimeter, and the highest tangential stresses occur at the deepest places in the stream (Lajczak, 1996).

Table 1. Measured discharges in the main stream and its tributaries (10-12). 05.2010

Prerovska Reka	**Bela Reka**	**Gvozdacka Reka**
Q (m^3sec^{-1})	**Q (m^3sec^{-1})**	**Q (m^3sec^{-1})**
0.110	0.120	0.230
0.219	0.198	0.417
0.215	0.235	0.450
0.215	0.785	1.000
0.215	1.785	2.000
0.215	2.285	2.500

It is known that the rate of flow next to the stream bed equals zero, due to water viscosity and boundary roughness, but it changes rapidly at a small distances from the stream bed. As the rate of flow next to the stream bed is the rate of flow which occurs at the distance of *0.04h* from the stream bed, the rate of flow next to the stream bed is calculated in relation to the mean flow rate.

$$V_0 = V_p \cdot \eta^k = 1.20 \cdot V_{sr} \cdot 0.04^{0,20} = 0.63 \cdot V_{sr}(m^3 \cdot s^{-1}) \quad (3)$$

where:

V_0, velocity near the bottom (0,04h);

V_p, speed on the water surface;

V_{sr}, the mean flow velocity profile;

η^k, the ratio of the surface velocity and the velocity near the bottom.

Threshold force is the force, at which sediment grains of certain sizes and bulk density are on the brink of being entrained. The larger the sediment, the greater force is necessary to entrain the sediment. As tangential stress is related to flow depth and the energy slope, assumed equivalent to the water surface slope (and consequently to streambed gradient) for very low gradients, and as these parametrs depend on discharge, it is not only sediment transport competence of the stream that can be determined at each discharge in the river channel, but also the grain sizes which can be entrained in such conditions.

In the study reach, as bedload is moved mainly in flood waves and he study was based on Shields' criterion defined by Eq (1). This equation was derived from flume experimental measurements entarinment of particles with a given mean diameter. Eq. (1) was used to calculate the critical tractive force for grain diameters spanning from D_{10} to D_{90} of the study

site bed material. The comparison of tangential stresses with critical stresses can be applied in the determination of the phases of the initiation of motion of individual grain sizes in different hydrological conditions. A straight, 250 m long study reach (Fig. 6.) was selected downstream of the storage intended for fishpool (Fig. 6).

Morphological analyses included topographic surveying of the study reach consisting in the measurement of cross sections and longitudinal profile. The cross sections areas are uniform throughout the reach, with depth ranging from 21 - 77 cm, while the width of water surface at maximum discharge amounted to about 3.80 m. The streambed gradient was found to be J = 0.0229 (Billi, P., 2011) equal to the slope of the water surface. Graduated rods were used for water depth measuring during floods.

To ensure the general stability of the watercourse, the banks are protected with large stone blocks D=500-1000 mm, which could not be move by dicharges much higher than the largest flow measured. The field data indicate that the size and the bed slope did not change and other hydraulic parameters, such as sediment sizes and the resistance coefficient, remained constant. The discharge during water release form the storage was determined using the flow rating curve obtained for the study cross sections.

As the simulation of flood wave discharges in this stream reach can be repeated several times per day by releasing water from the storage, the experiments are very significant for the region of hill and mountain streams. Based on the grain-size distribution of bed material in the Gvozdacka Reka, the calculated sediment bulk density is as follows:

$$\rho_s = 2.054\ t.m^{-3}$$
$$\tau_0 = 0.047 \cdot g \cdot (\rho_s - \rho) d_{sr}$$
$$(\rho_s - \rho) = 1.054 N \cdot m^{-3} \quad (5)$$

The tractive force in the stream is defined by the equation:

$$\tau_0 = \rho_v \cdot g \cdot h_{\max} \cdot J \quad (6)$$

Table 2. Thresholds of sediment entrainment in the Gvozdacka Reka

Discharge (Q) ***l·sec***	**Design sediment grain diameter in [mm]**									τ_{cr}	τ_o	**Water depth**
	d10	***d20***	***d30***	***d40***	***d50***	***d60***	***d70***	***d80***	***d90***	kN/m^2	kN/m^2	***M***
125	0.09-3									0.0000437-0.0015	0.0472	0.21
216		5.5-9								0.0026-0.0043	0.0539	0.24
230			15-17							0.0073-0.0083	0.0564	0.25
417				22-28						0.0107-0.0136	0.0808	0.36
450					30-39					0.0146-0.0189	0.0819	0.36
1000						45-51				0.0219-0.0249	0.1213	0.54
2000							70-80			0.034-0.0389	0.1582	0.70
2490								95-105		0.0462-0.0510	0.1703	0.76
2500									116	0.0563	0.1724	0.77

Based on the above analysis, Table 2, at the discharge Q=2.5m$^3 \cdot$s^{-1}, all fractions of sediment from the channel of the river Gvozdacka Reka will be moved and only coarse particles larger than 116 mm will remain. By comparison of true tractive forces with critical tractive forces, it can be observed that tractive forces are higher than critical forces within the analysed discharge range in thestudy reach. Therefore, conditions for the entrainment ofa large

proportion of bed material are expected to occur commonly, resulting in the morphological changes in the stream cross section. Sediment grain diameters d<116 mm are transported under the discharge rates Q>0.230 $m^3 \cdot s^{-1}$, mainly as bedload. In such conditions, water depth ranges from 210 to 250 mm.

The total volume of the reservoir after the construction of the dam was W = 2730 m^3. After 10 years' of filling the reservoir, reservoir volume was decreased by 70% and amounted to W = 820 m^3; of which 1910m^3 of organo-mineral deposits.

Morphological analysis of the river channel

Figure 6. The reservoir from which water was released, on the experimental stream reach (*Photo: A. Andjelkovic)*

Conclusions

Sediment transport in the experimental stream reach of the Gvozdacka Reka, as well as the changes in morphology of the stream profile, were measured by successive releases of water from the storage (Fig. 5). The following conclusions were made based on the above research:

Based on the above research, by implementing the same methodology, it is possible to define the type of material for the revetment and the construction of the specific types of river improvement structures. Also, it is possible to calculate the entrainment thresholdsfor different particle sizes, as well as the phases when and under which conditions it is necessary to protect the stream channel against erosion processes caused by river water.

This research is unique because it is done on a natural model, filling and emptying the reservoir during the day. This is achieved by simulation of flood wave downstream from the reservoir. Maximum flows were to 2.49 $m^3 s^{-1}$, and the maximum water flow of samples was taken by the flood waters, by the laboratory methods it was identified the concentration of suspended sediment load transport.

The results of these studies have pointed to the importance of the impact of land use patterns, as well as the impact of anthropogenic factors on the intensity of ssoil erosion. Although the river basin is covered with the 95% of beech-fir forests, accumulation was feeded with 70% sediment of organomineral origin, for a period of 10 years.

INFLUENCE OF DIFFERENT PLANTING CONDITIONS ON THE GROWTH OF SPRUCE FOREST CULTURES (CASE STUDY: SIVINSKII FOREST DISTRICT, PERMSKII KRAI)

Aleksandr ROMANOV, Mariia IAKOVLEVA, Artem PEPELIAEV

Perm State Agricultural Academy 23 Petropavlovskaya, Perm 614990 Russia
*Corresponding author: moraposh@mail.ru

Abstract

This article is discussion of research results of spruce forest cultures carried out in summer 2014. Investigations were carried out in western part of Permskii krai (Russia). Forest cultures were planted on cutover areas of spruce shamrock and herbaceous forests in 2008, 2011 and 2014. Soils of cut over areas are damp (C3) and normal (C2) loam. The influence of soil treatments by two kinds of forest ploughs (PL-1 and PLP-135, made in 2013) on growth of four-year seedlings was studied. The width of planting place profiles after using forest ploughs was measured. The soil density at furrow and ridges of planting places was measured. A planting place ramping was defined. The annual growth of spruce forest cultures and their conservation was measured. Also, the growth of spruce forest cultures planted after soil treatment by forest plough “PL-1” on cutover areas on different forest site was studied. The two- and four-year seedlings were planted. The width of planting places created by ploughs “PL-1” and “PLP-135” differ from literature data. The practical width of furrow after soil treatment by “PLP-135” is 105 cm instead of 135 cm. The practical width of furrow after soil treatment by “PL-1” is 54 cm instead of 1 meter. The density of furrow soil (1.9-2.0 g/cm3) exceeds optimal data for spruce. The use of the forest plough “PL-1” does not provide furrow clearness from grasses in planting year. The annual growth of spruce cultures did not depend on the height of seedlings in 2014. Two-year seedlings planted into furrow have the better growth and conservation than four-year seedlings. On damp cutover area, the forest cultures must be planted into ridges. The plough “PLP-135” is the best for ridge creating.

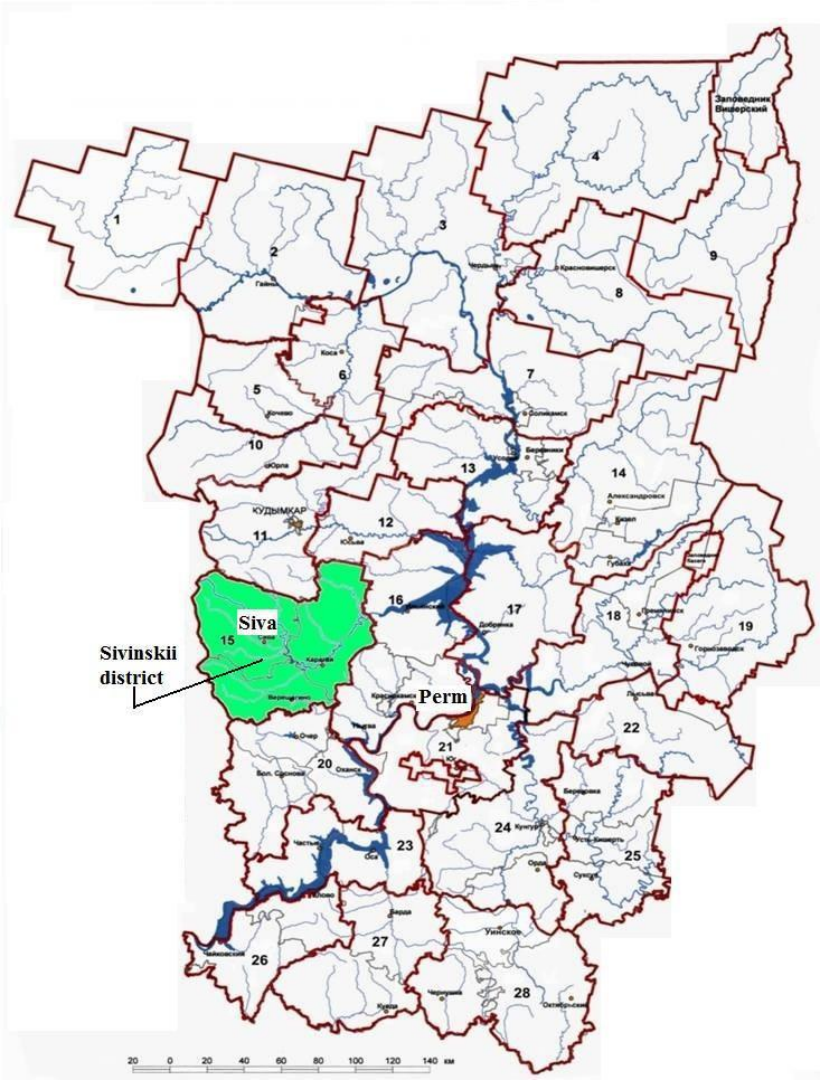
Introduction

Percentage of Permskii krai forest land is about 62 %. Annual deforestation area is 25000 ha. The Forest Code of the Russian Federation provides the forest inexhaustible using and up to date reforestation with valuable wood species. These are coniferous species for Permskii krai. Quantity of annual precipitations changes are from 500 to 1000 mm. Such conditions promote natural reforestation. Also these conditions are favorable for growth and development of vegetation layer. Grass crowd out stand or does not let grow of self-seed crop on plots with rich soil. In this case we use artificial reforestation. The artificial reforestation in Permskii krai is about 5500 ha per year. It is 20 % of entire area of reforestation (Indicators, 2014). Forest ploughs are the main soil cultivation tools for artificial crops. They are cheap and easy for exploitation than tools with active work details. The soil cultivation by rip dozer is effective on the clearance of big quantity stamps, but it reduces soil fertility. In the seventies of the 20th century perm forest scientists (as other scientists of USSR) studied different ways of soil cultivation for artificial crops. They discovered the soil structure differences after cultivation. They used forest ploughs (PKL-70-1, PKL-70-2, PLP-135) and rip dozers (D-210 V, D-259). Also our forest scientists studied spruce planting into furrow and ridge created by forest plough. But those works were not finished. Now our foresters continue to create forest

crops using the worst way (in most cases). They usually plant spruce and pine seedlings into plough furrow. Our work is showing negativity of this practice.

Material and methods

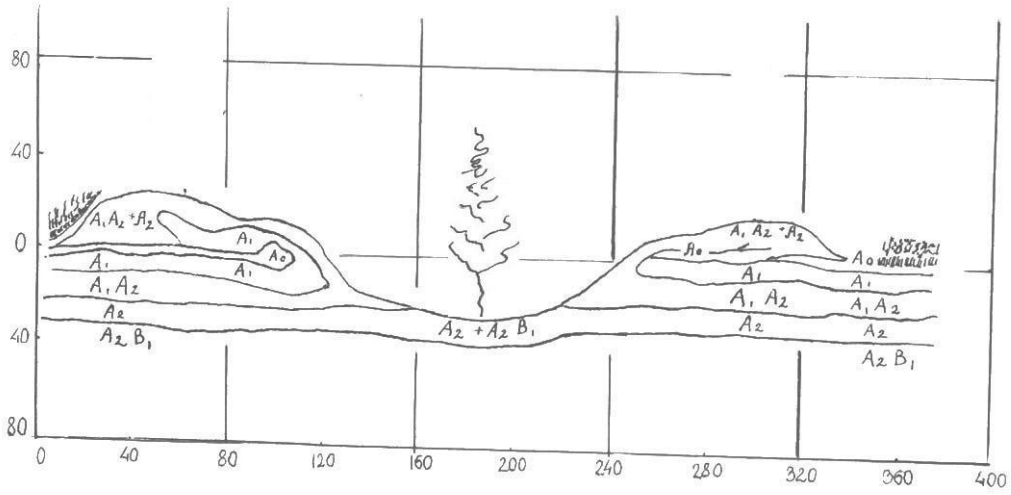
Research was made on the territory of Sivinskii forest in Permskii krai (pic. 1) in summer 2014. The forest district is in the plain part of Permskii krai. The territory has plain-mountain relief. Forest crops on cutover areas in spruce shamrock and herbaceous forests were analyzed. These forests were felled in 2008, 2011 and 2014. Soils of cutover areas have a high fertility (the soil is loamy), but differ in moisture conditions. The spruce shamrock forest has a normal moisture condition. This forest is C2 of forest site type by Pogrebniak classification (Sennov S.N.,2011). The spruce herbaceous forest has a high moisturization. This spruce herbaceous forest responds to C3 of forest type by Pogrebniak classification. The aim of the research is developing recommendations for forest crop creating under the condition of Sivinskii district. The program of the research includes three parts. The first is influence of soil cultivation with different forest ploughs on growth and development of spruce forest crops. The second is influence of different forest site type on growth and development of spruce forest crops. The third is age influence of spruce seedling on growth and development of spruce forest crops.



Picture 1. – Placement of forestry districts on Permskii Krai territory

The tillage was carried out by forest ploughs PL-1 (forest plough, 1 m of width) and PLP-135 (). The plough PL-1 was aggregated with tractor «LHT-55» (forestry tractor, power is 55 h.p.). Such aggregate cannot root out stamps and should route away them making ruptures in furrows. The plough PLP-135 was aggregated with tractor T-130. This aggregate has grubber and make unbroken furrows for forest crop planting. The comparison of different ploughs was carried out on cutover area of spruce shamrock forest. Spruce artificial crops were planted into furrow as four-year seedlings. The efficacy of artificial reforestation of different type of forest site was carried out on forest crop plots planted after plough PL-1 using. Planted seedlings were two-year and four-year. Seedlings were planted into furrow with spacing 0.7-0.9 m.

The research program consisted of four sections. The first is the measurement of the cross section of planting space created with forest ploughs. The second is defining soil density of furrow and ridges (pic. 2). The soil density was measured by Nekrasov's soil borer. The third is the measurement of occlusion with herbaceous vegetation at planting places. The fourth is the measurement of the spruce forest crop growth. Full heights of spruce forest crops, annual apical growth, stipes thickness and placement of spruce crop relative to each other were measured. The capacity for survival of artificial crop was defined.



Picture 2. - Cross section of planting space created by PLP-135

Results and discussion

The plough PLP-135 makes unbroken planting furrow. Ruptures in planting places after using plough PL-1 are 13 % at their length (table 1). The depth of furrow is equal. The furrow soil density is equal, too. The density of furrow soil (1.9-2.0 g/cm3) exceeds optimal data for spruce. The width of planting places created with ploughs "PL-1" and "PLP-135" differs from literature data. The practical width of furrow after soil treatment with "PLP-135" is 105 cm instead of 135 cm. The practical width of furrow after soil treatment by "PL-1" is 54 cm instead of 1 meter.

Table 1. – The description of planting places for spruce artificial crop (cultivating – June 2013, planting – May 2014, study – August 2014)

Plough	Percentage of furrow ruptures, %	Width of cultivated stripe, cm	Width of furrow, cm	Depth of furrow, cm	Furrow soil density, g/cm^3
PL-1	13	194±9	54±4	14±1	2.0±0.3
PLP-135	0	302±13	105±3	16±3	1.9±0.3

Cutover areas (forest type “spruce shamrock forest”) were overgrown actively with ashweed (*Aegopodium podagraria* L.), blackberry (*Rubus caesius* L.), wild strawberry (*Fragaria vesca* L.) and starwort (*Stellaria holostea* L.). Orobus (*Orobus vernus* L.) and tufted vetch (*Vicia cracca* L.) were less than the others.

On the plot with cultivating with plough PLP-135 there are Adam's-rod (*Verbascum thapsus* L.), bottlebrush (*Equisetum sylvaticum* L.) and yellow bedstraw (*Galium verum* L.). On the plot cultivated with plough PL-1 there are Canadian thistle (*Cirsium arvense* L.), dog nettle (*Galeopsis ladanum* L.), white dead-nettle (*Lamium album* L.). The planting furrow was overgrown with forest grasses more intensive after cultivating with plough PL-1. The projective cover of grasses on furrow was from 30 to 60 %. The most part of the overgrown land was made by annual meadow grass (*Poa annua* L.) and blackberry. Often we saw sprouts of Canada fleabane (*Erigeron canadiensis* L.), germander speedwell (*Veronica chamaedrys* L.) and Canadian thistle. Seldom there was bottlebrush on the furrow. At the same time the ridges were overgrown more intensive (the projective cover of grasses was from 40 to 100 %). Ashweed occupied the most part of ridges.

Three years later after tree cutting in forest type “spruce shamrock forest” the living ground cover was accompanied with bush grass (*Calamagrostis epigejos* L.) and rosebay willow-herb (*Chamaenerion angustifolium* Scop.). At the same time the cutover area in forest type “spruce herbaceous forests” was overgrown with European aspen (*Populus tremula* L.).

Created with plough PLP-135 furrow was overgrown with blackberry and bottlebrush. Adam's-rod sprouts appeared less often. The projective cover of herbaceous vegetation was less than or equal to 5 %. At the same time the projective cover of herbaceous vegetation was from 10 to 70 % on ridges. Ridges were overgrown with Adam's-rod, starwort and blackberry. Sometime there were strawberry, ashweed and sparrow-tongue (*Poligonum aviculare* L.).

Planted in 2014 spruce seedlings had a planting stress. However, annual apical growth of spruce forest crop planted after plough PL-1 was more at 1.2 time than after plough PLP-135 (table 2). The conservation of spruce artificial crop created after plough PL-1 was 10 % lower than the second variant. The espacement of seedling into furrow created with plough PL-1 did not allow realizing a plan for optimal planting density (2652 instead 3500-4000 off/ha). At the same time, planting density was 3580 off/ha after using PLP-135. The annual growth of spruce cultures did not depend on the height of seedlings in 2014.

Table 2. – Consistence of spruce artificial crop (cultivating – July 2013, planting – May 2014, study – August 2014)

Tool	Width of inter-row spacing, m	Planting spacing, m	Planting density, off/100 long meter	Conservation of forest crop in 1 year, %	Apical growth, cm
PL-1	5-7	0.59	156	81	3.1±0.3
PLP-135	4-6	0.57	179	91	2.6±0.2

Also, we studied spruce artificial crop growth in different forest type (spruce shamrock and spruce herbaceous forests). Soil cultivating was made with plough PL-1. Study results of artificial crop planted as 4-year seedlings are in table 3. The consistence of artificial crop planted as 2-year seedlings are in table 4. Two-year seedlings planted into furrow have the better growth and conservation than four-year seedlings.

Table 3. – Annual apical growth of spruce artificial crop in different forest type (cultivating – July 2011, planting – May 2012, study – August 2014)

Forest type (type of forest site)	Apical growth, cm			Conservation of forest crop, %
	in 2012	in 2013	in 2014	
Spruce shamrock forest (C2)	4.9	6.9	8.1	37.6
Spruce herbaceous forest (C3)	4.5	6.9	6.4	28.6

Table 4. – Consistence of spruce artificial crop planted by 2-year seedlings (cultivating – July 2007, planting – May 2008, study – August 2014)

Forest type (type of forest site)	Conservation of forest crop, %	Butt diameter, mm	Height, cm
Spruce shamrock forest (C2)	94	11.1±0.5	61±2
Spruce herbaceous forest (C3)	85	9.6±0.7	49±3

Many authors believe artificial crop must planted into ridges as in condition C3 as in condition C2 (Merzlenko, M.D., 2002, Redko G.I., 2008, Shutov I.V., 2007). Study results of ridges created by ploughs PL-1 and PLP-135 are in table 5. Data of table show ridges after PL-1 do not provide optimal width of ridge. The ridge can dry. Other authors wrote about it.

Table 5. – Characteristics of ridges created forest ploughs (cultivating – July 2013, study – August 2014)

Tool	Width of ridge top, cm	Height of ridge, cm	Soil density of ridge, g/cm^3	Soil density of raw piece of land, g/cm^3
ПЛ-1	30±4	12.6±1.6	1.15±0.2	1.1±0.2
ПЛП-135	53±8	9.0±2.6	1.6±0.2	1.2±0.3

The ridge after PLP-135 is better for artificial crop planting than ridge created by PL-1. However, acceptable width of ridge is in evidence about 54 % of cultivated places and soil density of such ridge is not optimal for spruce growth (1.6 instead 1.3 g/cm^3, this is maximal acceptable value (Merzlenko M.D, 2002).

Conclusions

Forest ploughs are used extensively for the soil cultivating as to plant artificial crop in many forestry districts of Permskii Krai.

Planting furrows created with forest plough PL-1 are overgrown living ground cover to 60 % of surface in planting year. The furrow soil density is 2 g/cm^3. This is more optimal value in 1.7 time.

Planting furrows after cultivating with forest plough PLP-135 are overgrown living ground cover to 5 % of surface. Furrow soil density is unsuitable for spruce growing too and one is 1.9 g/cm^3.

The apical growth spruce planted after plough PL-1 is 1.2 times more than after cultivating with plough PLP-135.

The growing of spruce artificial crop in condition forest type “spruce shamrock forest” is more from 1.1 to 1.2 times than such data for condition “spruce herbaceous forest”.

Abstract

The structure of high beech stand in the Eastern Serbia was quantified using different structural indices, in order to assess the ecosystem alpha diversity. For quantification of the simple structure, applied were the Lorenz index, and for the spatial structure applied were the aggregation index, while for description of the structure on small areas - the indices of individual trees based on the relations of neighbouring trees - uniform angle index, mean directional index, diameter differentiation index, and dominance index were used. Lorenz index and diameter differentiation index show that it is well structured stand, both over a small area and at the level of the whole stand. Aggregation index, uniform angle index and mean directional index provide random arrangement of tree positions within the stand with a mild tendency to regular tree pattern. Dominance index shows that 53 % of the nearest neighbours of an observed tree have a larger diameter. The greatest advantage of the application of modern indices for structural quantification is that the different aspects of stand structure can be expressed numerically, which is opposing to classical descriptive structure presentations. Due to the pronounced structural diversity of beech forests in Serbia application of these indices is necessary in order to objectively analyze the structural changes over a longer time.

Keywords: *simple structure, spatial structure, ecosystem diversity, beech, index.*

Introduction

Structure refers to a specific arrangement of elements in a system. Accordingly, forest structure, describes the distribution of tree attributes (characteristics) within a forest (von Gadow, 2005). The description of forest structure defines the percentage of certain attributes within a population, e.g. the percentage of tree species or the percentage of different tree dimensions (Vanclay, 1998).

In the widest sense, forest structure is described as simple and spatial. Simple structure denotes the frequency distribution of individual tree attributes, without knowing the spatial position of trees. Spatial structure describes the distribution of tree attributes taking into account the inter-neighbour relations between individual trees.

In the management of natural (primarily structured and mixed) forests, the study of forest structure has decisive significance in the assessment of forest condition, analysis of the previous management and definition of future management methods.

Also, in natural forests, structure is the main and most often the only measurable indicator in the determination of species and ecosystem diversity (Pommerening, 2002). Species diversity has become a very important aspect of forest management and conservation. It can be described using numerous parameters (Aquirre et al., 2003). At the spatial level, ecosystem diversity is divided into alpha, beta, gamma and delta diversity (MacArthur, 1965). In forest ecosystems, alpha diversity represents the diversity within a forest stand, beta diversity refers to the differences between forest stands, and gamma and delta diversities refer to wider

contexts (Lähde et al., 1999). Nowadays, it is especially relevant to know alpha diversity. Its determination requires the study of spatial distribution of trees and their attributes (Ferris, Humphrey, 1999).

Previous researches were mostly devoted to simple or basic stand structure. Simple structure consists of: diameter structure, height structure, species diversity, coefficient of homogeneity, distribution of basal area, volume, volume increment, crown length, etc.

Compared to simple structure, the study of spatial stand structure is a more complex problem. The quantification of spatial structure is based on a number of indices (parameters).

Firstly, the aim of this study was to quantify the structural diversity of a beech stands, using various structural indices, aiming at an objective definition of the ecosystem alpha diversity. Secondly, to show the possibilities of practical application of these indices in beech forests in Serbia.

Materials and methods

Study area and data collection

The study area is a high stand of beech in Eastern Serbia (stand 33a, management unit “Majdan-Kučajna“). Stand area is 22.7 hectares. Its latitude 44°24'05", longitude 21° 36'32", altitude is 410-520 m, slope 7-28 degrees. The prevailing aspect is north-west. Parent rock consists of dense limestones, and the soil is cambisol eutric, depth 40-80 cm. The stand is classified as a submontane forest of beech (*Fagenion moesiacae submontanum* B.Jov.1976). By silvicultural and structural form, it is a high group-selection uneven-aged stand of beech, with virgin forest characteristics. Site class is II, conopy closure is 0.90, percentage of beech in the volume 97%, stand quadratic mean diameter is 39.4 cm, and Lorey’s mean height 31.0 m. There are 274 trees per hectare, basal area is 33.4 m^2/ha, volume is 522.5 m^3/ha, and current annual volume increment is 8.6 m^3/ha. (Koprivica et al., 2008; Matović, 2012).

Simple circular sample plots of 500 m^2 (radius 12.62 m) were established (total 23), distributed in square grid network design, spacing 100 m (a circle represents a hectare). Diameter and height of all trees above taxation limit (>10 cm) on sample plots in the stand were measured. Also, to research the spatial structure, the data recorded for every stem on each plot included the azimuth and the distance from plot centre.

Indices for quantification of stand structure

The quantification of simple structure was performed using the Lorenz index (Lee et al., 1999). The aggregation index was used for the quantification of spatial structure (Clark, Evans, 1954). Indices of individual trees based on inter-neighbour relations between individual trees were used for the description of structure on small areas (uniform angle index, von Gadow et al., 1998; mean directional index, Corral Rivas, 2006; diameter differentiation index, Füldner, 1995; dominance index, Hui et al., 1998). The Lorenz index was calculated from the field data in Excel and Statgraphics, and the indices of spatial structure were computed using an especially developed software package Crancod (Pommerening, 2006).

The Lorenz index. The Lorenz index *L* numerically defines the plot or stand simple structure. A measure of stand homogeneity can be the tree diameter, basal area, volume, etc.

Lee et al. (1999) calculated the Lorenz index from the basal area percentage and the percentage of tree number. Trees are first ordered from the thinnest diameter in the increasing order, then basal area is calculated for each tree. The basal area percentage pg_i is calculated from the thinnest-diameter tree to the i^{th} tree using equation (1). Percentage of tree number pn_i to the i^{th} tree is calculated using equation (2).

$$pg_i = \frac{1}{G}\sum_{j=i}^{i} g_j \text{ , } G \text{ - total basal area} \qquad \text{(Eq.1)}$$

$pn_i = \frac{i}{n}$, n - total number of trees (Eq.2)

Lorenz curve is graphically best represented as a power function $pg_i = pn_i^{\beta}$. β can be equal to or greater than 1. When β =1, the stand is fully homogeneous, and with the increase in the coefficient β, the stand structure heterogeneity also increases.
The Lorenz index of sample plot structure is calculated using equation (3).

$L = 1 - \frac{1}{\beta}$, $0 \leq L < 1$ (Eq.3)

From the aspect of basal area, fully homogeneous stand is when L = 0, but with the increase in L value, the stand becomes structurally heterogeneous.
The Lorenz index of stand structure is calculated as an arithmetical mean of sample plot indices (4).

$\bar{L} = \frac{1}{n}\sum_{i=1}^{n} L_i$, i = index of a sample plot (i=1..n) (Eq.4)

Aggregation index. Aggregation index *CE* describes the spatial structure and represents the relation between the average measured distance between a tree and its nearest neighbour $\bar{r}_{obs}$ and the average distance when the trees are randomly distributed $\bar{r}_{\exp}$ in a sample plot or stand (5).

$CE = \frac{\bar{r}_{obs}}{\bar{r}_{\exp}}$ (Eq.5)

The average distance between a tree and its nearest neighbour $\bar{r}_{\text{obs}}$ in a sample plot is calculated as the ratio of a sum of distances between all trees and their nearest neighbours and the number of trees N (6). The average distance when the trees in the stand are randomly distributed $\bar{r}_{\exp}$ is calculated using equation (7).

$\bar{r}_{obs} = \frac{\sum_{i=1}^{N} r_i}{N}$ (Eq.6)

$\bar{r}_{\exp} = \frac{1}{2\sqrt{\frac{N}{A}}}$, where A is the sample plot or stand area. (Eq.7)

Theoretically, *CE* ranges from 0 (when the trees are clumped) to 2.1491 (when the tree pattern is regular in the hexagonal grid). *CE* = 1, represents a random arrangement of tree positions (Poisson distribution) in the sample plot or stand.
One of the problems occurring in the research of spatial structure is the estimation of distances between edge trees in the sample plot or stand and their nearest neighbours. This problem is solved using edge-correction. In the study stand, the spatial structure was studied based on the of edge correction method *NN1* (Pommerening, 2006).
Indices of individual trees based on the relations of neighbouring trees for the description of the structure on small areas. These indices describe the spatial structure using the structural groups of 4 neighbours in relation to reference tree *i* (*Figure1*).

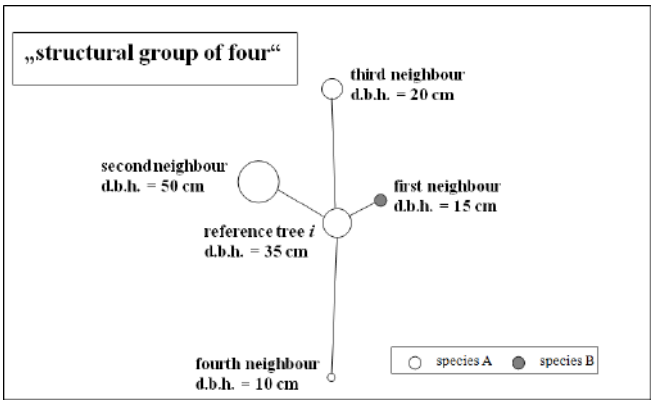

Figure 1. *Structural group of 4 neighbours in relation to the reference tree i (Pommerening, 2002)*

The uniform angle index W describes the degree of regularity of spatial distribution of four nearest trees in relation to the reference tree *i*. *W* is calculated from the ratio of true values of angles between 4 neighbouring trees α_j and a predefined standard angle α_o. Binary random variables v_J are calculated by comparing each value of α_j with standard angle α_o. Uniform angle index is defined as the ratio of angles α_j between four neighbouring trees which are greater or lower than the standard angle α_o (8).

$$W = \frac{1}{4}\sum_{j=1}^{4} v_j \text{, where } v_j = \begin{cases} 1, & \alpha_j < \alpha_o \\ 0, & \alpha_o < \alpha_j \end{cases}, \; 0 \le W \le 1 \qquad \text{(Eq.8)}$$

The uniform angle index of sample plot $\overline{W}$ is calculated as the arithmetical mean of individual values of *W* for all trees in the sample plot.
Hui, von Gadow (2002) determined 72° as the optimal standard angle, when the trees are randomly distributed at the value $\overline{W}$=0.5. When $\overline{W}$<0.4815, the neighbouring trees tend to regular distribution, and when $\overline{W}$>0.5130 the trees are clumped in relation to the reference tree.
Mean directional index R is defined as the sum of the unit vectors from the reference tree *i* to its *n* nearest neighbours (9).

$$R = \sqrt{\left(\sum_{j=1}^{n} \cos\alpha_{ij}\right)^2 + \left(\sum_{j=1}^{n} \sin\alpha_{ij}\right)^2}, \qquad \alpha_{ij} \text{ is the angle between trees } i \text{ and } j \text{ and a reference direction} \qquad \text{(Eq.9)}$$

Mean directional index of a sample plot $\overline{R}$ is calculated as the arithmetical mean of individual values of *R* of all trees in sample plot.
When $\overline{R}$=1.799, the neighbouring trees are randomly distributed, if $\overline{R}$=0 trees are regularly distributed in square grid, and if $\overline{R}$>1.799 trees are clumped in relation to the reference tree.
Differentiation index T describes the spatial distribution of tree dimensions (diameter at breast height, height, etc.). Diameter differentiation index, when the structural group of 4 neighbours is applied, is calculated using equation (10).

$$T = 1 - \frac{1}{4}\sum_{j=1}^{n} \frac{\min\left(DBH_i, DBH_j\right)}{\max\left(DBH_i, DBH_j\right)}, \qquad j = 1 \ldots n \text{ (4) neighbour trees, DBH – diameter at breast height} \qquad \text{(Eq.10)}$$

Diameter differentiation index of sample plot $\overline{T}$ is calculated as the arithmetical mean of individual values of *T* for all trees in the sample plot.

Low differentiation is when $0.0 \le \overline{T} \le 0.3$, medium $0.3 \le \overline{T} \le 0.5$ strong $0.5 \le \overline{T} \le 0.7$, and very strong $0.7 \le \overline{T} \le 1.0$.

Dominance index U quantifies the percentage of neighbouring trees having larger dimensions (diameter at breast height, height, etc.) than the reference tree *i*. When applied to a structural group of 4 neighbours, diameter dominance index is calculated using equation (11).

$$U = \frac{1}{4}\sum_{j=1}^{n} v_j \ , \ v_j = \begin{cases} 1, & DBH_j \ge DBH_i \\ 0, & DBH_i \ge DBH_j \end{cases} \qquad \text{(Eq.11)}$$

When *U*=0, it means that all neighbouring trees have a smaller diameter, when *U*=0.5 three neighbours have smaller diameter and three neighbours have larger diameter, and when *U*=1.0 all neighbouring trees have larger diameter than the reference tree.

Diameter dominance index in the sample plot $\overline{U}$ is calculated as the arithmetical mean of individual values of *U* for all trees in sample plots.

Results and discussion

In the study stand, the Lorenz index per sample plots ranges 0.38 – 0.73. In the majority of sample plots, the Lorenz index ranges between 0.50 and 0.70, while only in four sample plots, the index is below 0.50 (*Figure 2*). The above values clearly point to a high structural heterogeneity at the plot level.

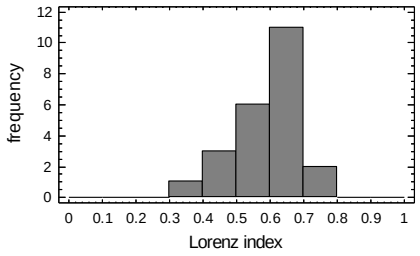

Figure 2. *Distribution of the Lorenz index value by sample plots in the stand 33a*

Lorenz index in the stand is 0.60, standard error 0.02, coefficient of variation 15.40%. The index values reported by Lee et al., (1999) amounted to 0.26 in a relatively homogeneous stand, 0.50 in a clearly structured stand, and 0.58 in a relatively non-homogeneous stand. The Lorenz index points to a high structural heterogeneity in the study stand and at the stand level.

Aggregation index per sample plots was 0.68 – 1.75. On 14 sample plots, aggregation index ranged from 0.80 to 1.20, on 2 plots it was below 0.80, and on 7 plots it was above 1.20. The above values of aggregation index show that the majority of sample plots show random arrangement of tree positions or there is a mild tendency towards a regular tree pattern. In a small number of sample plots, aggregation index shows that se trees are more clumped or have a regular tree pattern.

Aggregation index of the stand amounts to 1.12, standard error 0.05, coefficient of variation 21.69%. At the stand level, the calculated value shows the random arrangement of tree positions with a mild tendency towards a regular tree pattern. Bilek, et al. (2011) established the Aggregation index for the beech stands in the Czech Republic. Virgin stands had values between 0.97 to 1.08, while in managed even-aged stands it went from 1.21 to 1.33.

Aggregation index quantifies rather objectively the spatial structure in the sample plot and stand, but it cannot be applied when a tree position is observed in relation to its neighbours.

This problem can be solved using the indices of individual trees based on the relations of neighbouring trees for the description of the structure on small areas.
Uniform angle index in sample plots is 0.25 – 0.69. In 11 sample plots $\overline{W}$<0.4815, on 3 plots 0.4815<$\overline{W}$<0.5130, and on 9 plots $\overline{W}$>0.5130. Value $\overline{W}$ shows a high heterogeneity of spatial structure per sample plots.
Uniform angle index in the stand is 0.44, standard error 0.03, coefficient of variation 32.17%. The calculated values show that the trees are relatively randomly distributed at the stand level, with a tendency to regular tree pattern.
In the study stand, the mean directional index per sample plots ranges from 0.68 to 2.82. In 17 sample plots $\overline{R}$<1.799, and in 6 sample plots $\overline{R}$>1.799. Just as the uniform angle index, the mean directional index also shows a high heterogeneity of spatial structure per sample plots.
Mean directional index of a stand is 1.55, standard error 0.12, coefficient of variation 36.31%. At the stand level, the calculated value shows the random arrangement of tree positions in space with a tendency to a regular tree pattern.
Diameter differentiation index per sample plots ranges from 0.20 to 0.62. In 7 sample plots $0.0 \le \overline{T} \le 0.3$, in 11 sample plots $0.3 \le \overline{T} \le 0.5$, and in 5 sample plots $0.5 \le \overline{T} \le 0.7$. Diameter differentiation index shows that the differentiation is medium category in the greatest number of sample plots.
Diameter differentiation index of the stand is 0.38, standard error 0.03, coefficient of variation 32.39%. At the stand level, the calculated value shows that the diameter differentiation is medium, i.e. the thinnest-diameter trees in the stand account for 62% of the diameter value of the thickest-diameter trees. Bilek, et al. (2011) found in virgin beech stands in the Czech Republic that diameter differentiation index values were going from 0.76 to 0.78, while in managed even-aged stands it was 0.34 on average.
In the study stand, diameter dominance index per sample plots ranges between 0.25 and 0.86. On 12 sample plots $\overline{U}$<0.5, and on 11 sample plots $\overline{U}$>0.5.
Diameter dominance index of the stand is 0.53, standard error 0.04, coefficient of variation 33.41%. The calculated value shows that, at the stand level, neighbouring trees have a somewhat larger diameter at breast height than the reference trees.
The greatest advantage of the application of modern indices for the quantification of stand structure is that the aspects of stand structure can be expressed numerically as opposed to classical descriptive presentations of structure. Also, a great advantage of structure quantification is that the changes in stand structure can be monitored over a long time period. Since it is established that the beech forests in Serbia are structurally very diversified (Matović, 2012) using these indices can objectively quantify any changes in structure over a longer period of time.
The Lorenz index can be obtained from the data collected for forest stand during the regular forest inventory. The disadvantage is the fact that Lorenz index describes the stand homogeneity, without taking into account the spatial distribution of trees. Aggregation index requires the measurement of positions of all trees on the sample plot. It describes the spatial structure at the plot level. However, it cannot present the changes in spatial structure on a small area (Zenner, Hibbs, 2000). This weakness is especially pronounced in uneven-aged forests where the structure on a small patch is highly variable (Albert, 1999). The indices of individual trees based on the relations of neighbouring trees successfully describe the changes in spatial structure on small patches. These parameters can be assessed at the level of the entire plot when it is necessary to determine the positions of each tree in the sample plot. However, Hui, Albert (2004) proposed the calculation of indices of four reference trees nearest to the sample plot centre. Each reference tree with its four nearest neighbours makes the structural group of 4 neighbours, for which it is necessary to find the positions in relation to the plot centre. Such an approach is called Plus-sampling (Stoyan, Stoyan, 1994) and it

makes it possible to avoid the use of edge correction, which can have a significant impact on the accuracy of index estimation on small plots. Generally, collecting data in the field was simplified due to the modern technologies and tools such as Field-Map technology (IFER-Monitoring and Mapping Solutions Ltd.) and PosTex (HAGLOF).
In common forest practice, e.g. in forest inventory (especially for rapid assessment of spatial structure) uniform angle index, differentiation index and dominance index can be directly calculated in the field without measuring azimuth and distances from the plot centre. Consequently, the above indices are the most simple solutions in practice.

Conclusion

The Lorenz index and diameter differentiation index show that it is the case of a structured stand, both at the plot level and at the stand level. However, the diameter differentiation index shows a somewhat lower value compared to the Lorenz index, which results from the structure which characterises group-selection uneven-aged stands, i.e. such stands are more homogeneous on a small patch than at the plot level or at the stand level. The aggregation index, uniform angle index and mean directional index show random arrangement of tree positions in the stand with a mild tendency towards a regular tree pattern. The diameter dominance index shows that 53 % of the nearest neighbours have larger diameters than the reference tree. The dominance index, in the concrete stand is not a sufficiently indicative measure for the description of spatial structure, however in mixed stands, it is a very good indicator of the relations between different tree species.
All structural changes occurring in the stand as a consequence of management operations and the effects of biotic and abiotic factors can be assessed by the quantification of stand structure using structural indices.

INTEGRAL EVALUATION OF BELGRADE FOREST RESOURCES FUNCTIONALITY

Dragana DRAZIC*, Ljiljana BRASANAC, Djordje JOVIC, Milorad VESELINOVIC, Nevena CULE, Suzana MITROVIC

Institute of Forestry - Belgrade, Serbia
*Corresponding author: drazicd@yubc.net

Abstract

Until the middle of the past century, forests were treated as natural raw-material resources for wood production intended for mechanical and chemical processing, for civil engineering and thermal energy. Today, we are facing the increasing hazards to the environment and natural ecosystems in general, as the consequence of profit-making, disregarding the ecological consequences. The previous method of "wasting the nature" endangers the human survival and life in general on our Planet. In the past period, especially in the larger and industrial towns in Serbia, forests were not focused sufficient attention to, and there was not sufficient interest of the professional as well as the general social community in the evaluation of forest ecological functions. Taking into account the actual state of the environment of the two-million Belgrade city, and starting from the fact that forest ecosystems are among the most stable terrestrial ecosystems, they should get a much higher significance both in the narrower and in the wider city zone. The common attitude that forest is exclusively for production should be changed, and forest ecosystems near large towns should get new functional priorities in harmony with the principles of sustainable development, protection and enhancement of environmental quality. The paper presents some results of the researching project “Integrated valorization of forest resources in Belgrade” in the light of some of the most significant international regulations of environmental protection, the necessity of biodiversity conservation and sustainable development. The paper also discusses the multifunctional values and significance of urban forests from the aspect of environmental protection and social benefits.

Keywords: *urban forests, functionality, integral evaluation, Belgrade*

Introduction

With intensive development of industry, traffic and other human activity, natural balance on Earth is disturbed. The fact is that we are today faced up with the increasingly excessive endangerment of all elements of the environment and nature ecosystems as a whole, which is the consequence of race with profit, regardless of the ecological consequences. The problems are numerous: environmental degradation and pollution, global melting and climate changes, radiations, water disturbance, impoverishment of biodiversity, etc.

State of environment and significance of forest ecosystems

The sources of pollution in Belgrade and its surroundings are more and more numerous. Increasing amounts of poisonous gases accumulate in the atmosphere, resulting from the combustion of fossil fuels in transport and industry. Agriculture - pesticides and mineral fertilisers are also significant polluters of the environment. Radioactive pollution is a permanent hazard. Demographic growth and many other factors also disturb the ecological balance. The task of modern society is to detect and implement the methods which will not harm the nature. In addition to different technical-technological aspects of environmental protection, the conservation primarily of forest ecosystems as the most powerful and stable systems of maintaining the ecological balance, is very significant. The establishment of forest

cultures and establishment of new spaces of urban greenery of different categories is an irreplaceable form of enhancing the quality of life in general.

In the past period, especially in the larger and industrial towns in Serbia, forests were not focused sufficient attention to, and there was not sufficient interest of the professional as well as the general social community in the evaluation of forest ecological functions. Taking into account the actual state of the environment of the two-million Belgrade city, and starting from the fact that forest ecosystems are among the most stable terrestrial ecosystems, they should get a much higher significance both in the narrower and in the wider city zone (Drazic D., Drazic M., 2001). As the result of the immediate surrounding of concrete, asphalt and metal, concentration of the transport systems and industrial activity within and around the urban areas, the mean temperature values are higher (effect of the "heated island"), the air is drier and polluted, rainfaill are less effectively apsorbed, and noise is significantly higher than in the rural regions.

The aim of paper is to point out that the common attitude that forest is exclusively for production should be changed, and that forest ecosystems near large towns should get new functional priorities in harmony with the principles of sustainable development, protection and enhancement of environmental quality.

Material and Methods

Extensive research in last five years has included the following activities:

Preparatory works (collection of cartographic, literature review, analysis of foreign and domestic experiences in the field of multifunctional evaluation of forest resources in urban spaces)

Field works (vegetation and floristic research, research of vegetation health condition, research of the state of forest resources, research of fauna, soil and floristic sampling) have included the followef forest complexes: Košutnjak with Topčider, Forests and park of Beli and Stari Dvor at Dedinje, Miljakovačka forest, Banjička forest, Zvezdarska forest, Stepin Lug–Baba Velka–Torlak–Jajinci, Makiš and Ada Ciganlija

Laboratory analyses were conducted in the accredited laboratory of the Institute for forestry Belgrade (SRPS ISO/IEC 17025: 2006, LOB 510.01): analysis of soil samples, analysis of heavy metal contents and other hazardous substances in soil and plant samples, determination of agents of phytopathological diseases and insect pests).

The standard soil analyzes and the preparation of samples was applied, by the following methods:

Table1. Applied laboratory methods for the analysis of soil

Analysis	Method
Active and substitutional acidity	Electrometrically LUP504.07
Total humus	Method by Tjurin LUP504.04
Total nitrogen (N)	Method by Kjeldlahlu LUP 504.33
Easily accessible phosphorus and potassium	AL method LUP504.03
The content of free carbonate	Volumetric method LUP504.05
The textural composition of soil	Sedimentation method LUP504.02
Preparation of samples for the analysis of heavy metals	Destruction in nitric acid and H_2O_2

Cabinet processing of field data, documents and results of laboratory analyses (state and classification of Belgrade urban forest resources – age, structure, productivity, degree of conservation, results of comparative research of individual autochthonous species and exotic species development, health condition of forest resources),

Evaluation of the actual functionality (protection, functions of forests and forest soils, conservation of biodiversity and gene pool, base for generative and vegetative reproduction, site-habitat of different flora and fauna species, protection of springs and watercourses, socio-

cultural function, aesthetic function, picnic-recreation function, production function, other functions).
In the aim of assessment of relative value of the main functions of urban state forest in Belgrade administrative region, the modified classifications by Papanek and Vlatković has been applied.

Results and Discussion

Main data on Belgrade forest resources

Total forest area in Belgrade region (with suburban municipalities) is 35.980 ha, of which state forests 20.064 ha and private forests 15.823 ha. Percentage of forest cover in Belgrade region is 11.2% and forest area per capita 0.025 ha. In the municipalities, forest area per capita is very different and ranges from 0.0 ha at Savski Venac to 0.23 ha in Barajevo and Sopot.

Photo 1. Mountain Kosmaj with monastery in the vicinity of Belgrade

Photo 2. Quercetum frainetto cerris Rud. on mt. Kosmaj

As the "minimal optimal value" of forests per a citizen is about 0.33 ha, it is obvious that Belgrade has insufficient land under forest. The situation is moderate by existing different category of urban open green spaces.

Table 2. Open green urban spaces in Belgrade

Category	Hectares
Parks and squares	393
Greenery of the residental parts	1.078
Greenery of the trafficroads	175
Banks, riparian areas, islands	226
Protection zones	36
Greenery of the special categories	350
Total:	**2.258**
Trees in the tree lines	67.063 pieces

The research included the following urban forests in the city of Belgrade administrative region:

Table 3. Objects of research

Locality	Area (ha)
Košutnjak with Topčider	262.71
Forests and park of Beli and Stari Dvor at Dedinje	100.00
Miljakovačka forest	155.95

Banjička forest	41.59
Zvezdarska forest	129.00
Stepin Lug–Baba Velka–Torlak–Jajinci	491.72
Makiš	380.22
Ada Ciganlija	92.65
Forests along motor-way Belgrade–Zagreb to Surčin	159.74
Total:	**1.813.58**

Natural boundaries of Belgrade occur at the borders of two large and different natural entities with three basic biomes: (1) steppe and forest-steppe, (2) broadleaf forests of floodplain and lowland type, and (3) forests with Hungarian oak and Turkey oak. These natural landscapes have been modified by human impact, so that today the prevailing landscapes are urban, suburban and cultivated landscapes.

Forest ecosystems are the most developed form of living-being organisation and the greatest treasury of biodiversity. For this reason, special attention is devoted to the research of forest resources. Major forest types of Belgrade region are represented by the complexes: alluvial-hydrophilous forest types, xero-thermophilous Hungarian oak-Turkey oak forest types, xero-mesophilous sessile oak, Turkey oak and hornbeam forest types and mesophilous beech and beech-conifer forest types. In Belgrade region there are several forest ecosystems: forest of Hungarian oak and Turkey oak, forest of pedunculate oak, forest of silver lime and oaks, forest of pedunculate oak, forest of poplars and willows, forest of sessile oak and hornbeam, forest of pedunculate oak and hornbeam, montane forest of beech and forest of sessile oak. In addition to forest ecosystems, there are also steppe ecosystems of Pontic-South Siberian region and forest-steppes on loess plateaux and hills along the Danube.

Thirty-five tree species have been identified in the region, of which 22 are autochthonous. The most represented species are Turkey oak 18.00%, pedunculate oak 15.40% and Hungarian oak 5.32%. Other species of hard broadleaves have individual percentage of 5%. The most represented soft broadleaf is poplar clone I-214. The percentage of willow, white and black poplar, as autochthonous species, is less than 3.50%. Grey poplar occurs individually at some localities. There are also a great number of alochtonous species which are very well adapted to the existing environmental conditions and achieved very good growth, vitality and decorativeness in adequate locations. To mention a few: *Cedrus atlantica* Man., *Quercus rubra* Du Roi non L., *Liriodendron tulipifera* L., *Taxodium distichum* L. etc. (Drazic D., 1998).

Functions of Belgrade urban forests and other open green spaces

It is necessary to specify some of the most important functions of urban forests in general, in order to access the evaluation of urban forests Belgrade. These are:

Air filtering. Trees very effectively absorb gas pollutants, including CO_2, SO_2, NO_x, etc. The dust is deposed on the trees. It was determined that the tree belt about 30 m wide contains almost the whole dust from air; *Keller* (1979) proved the reduction of Pb for almost 85% behind the protective zone of the trees; Trees also neutralize and almost completely absorb unpleasant smell, replacing them by much more pleasant ones; Helps the increase of the relative air humidity.

Modification of the temperature extremes. Trees, bushes and other vegetation help the regulation of the temperature extremes (Chen, A. et al., 2014); The shade of a big tree can reduce the temperature of the building as 15 air-conditioners (4.220 кJ) on the similar building which is not protected by shade; Energy which is saved by tree planting around the building accounts for 10-50% for cooling and 2-22% for heating (NAA/ISA, 1991).

Noise reduction. Excessive levels of the noise of the majority of the big cities contribute towards the physical and psychological damages. Trees also help by absorbing the noise which is produced by the intensive traffic circulation and numerous activities.

Use of water, re-use and preservation. In the system of parks and forests, stabilisation pools for the treatment of the waste waters can be integrated. Protection of the suburban and rural areas which serve as the water wells for cities must be integrated in the urban plans.
Land protection. Trees and forests are the means of land protection, they protect the sensitive ecocystems on steep inclinations with the sparse vegetation and abundant season rains, and in this way protect human life and their homes.
Biodiversity of the green areas has a vital role for the urban biodiversity.
Green belts and green corridors can serve as the biological corridors, and the connection of the green areas in the network ensured the biological preservation and biodiversity.

Photo 3. Lake on Tresnja surrounded with forests

Photo 4. Recreative zone of Ada Ciganlija with lake in the central zone of Belgrade

Social benefits. Improvement of the esthetic quality of the urban areas - refers to the esthetic and recreation values of the trees, forests and parks; Well-selected and planted trees shelter inevitable visions and provides the privacy, at the same time giving the free view on the remaining part of the landscape; Trees fulfils numerous psychological, social and cultural needs of the population (*Dweyer et al.*, 1991). It has a very important role in release of tension and improvement of the psychological health; The improvement of air quality has a great influence on health, mainly on the decrease of the respiratory diseases.
Health. Urban forests, parks and other green areas provide possibilities for the health physical activities and recreation; The benefits for the physical and mental health of the urban landscapes with trees are proved in the industrialized countries (*Ulrich*, 1984). The studies showed that the patients in the hospitals with a view of the trees recover faster and need the shorter health treatment (*Ulrich,* 1990). Urban forests contribute towards the safety and quality of food.
Employment. Reforestation, landscape arrangement and care of the different categories of the green areas, and particularly agroforest systems, intensify the employment, which is important for the poor cities.
Education and scientific research. In the urban forests, botanical gardens, zoological gardens and other facilities of nature the information centers should be established. They also serve for the scientific research.
Increase of the economic force of the cities and values of the estates. The values of the apartments and houses increase if they are located in the vicinity of trees, for instance by 5% in Hong Kong (*Webb*, 1998), in Finland (*Tyrvainen*, 1999) and even 18% in the USA (*Morales, Micha and Weber*, 1983). In Singapur and Kuala Lumpur the urban area rich in the

forests and trees is an important attraction for the new business and investors (*Kuchelmeister*, 1991).

Urban forests and other categories of the urban greenery unite the people on the work for the welfare of the community and improvement of the environmental quality at the local and global levels (NUFU, 1998).

Integral evaluation of Belgrade forest resources

10	-	-	-	**10**	5	5	50	**60**	10	15	5	**30**	100

Note: Main forest functions expressed as a percentage (%).

*The production function “Game rearing and hunting“ in Belgrade urban forests does not anticipate. Game rearing and other fauna is presented through the socio-cultural function “nature protection and spatial management“, and it was treated also by the proposal of photo-safari, “Game park“, etc. at the suitable sites.

Conclusion

Taking into account the actual state of the environment condition of the Belgrade, and starting from the fact that forest ecosystems are among the most stable terrestrial ecosystems, they should get a much higher significance and the new universal benefical functional priorities in accordance with the principles of the sustainable development, biodiversity protection, improvement and protection of the enviromental quality were determined.

In the aim of biodiversity conservation and multifunctional utilization of urban forests in the region of Belgrade, besides the higher goals that imply implementation of strategies and measures in the fields of environmental protection, protection of nature, forestry, protection of water and the system of city green spaces defined by the Regional Spatial Plan of Belgrade administrative region and Belgrade Master Plan, the following should be realised in the following years:

conservation of natural forest ecosystems in the direct urban surroundings and protection of ecosystem and species components of biodiversity;

protection and improvement of all water ecosystems;

establishment of new forest stands established on the principles of coenotic diversity;

maintenance and establishment of green area within the urban cores including parks, squares,

tree rows and gardens;
protection of landscape diversity;
evaluation of landscape quality (according to European Landscape Convention) by the establishment of a system of green corridors by integrative model;
increase of total forest area and percentage of forest cover.
In addition to the aforementioned higher goals, it is necessary to realize the following individual goals:
integral evaluation of urban forests functions from the aspect of actual state of environment and demands of the citizens;
identification the priority multiple benefit functions of Belgrade forest resources;
for each forest complex, to determine the percentage of each function ranked by priorities;
by the evaluation of their beneficial ecological functions, contribute to the healthier environment;
to define forest management on the principles that guarantee the conservation and enhancement of optimal forest ecosystem values.

ADAPTIVE MEASURES IN FOREST ECOSYSTEMS VULNERABLE TO CLIMATE CHANGE

Mihailo RATKNIC*, Tatjana RATKNIC, Ljubinko RAKONJAC, Sonja BRAUNOVIC

Institute of forestry, Kneza Višeslava 3, 11000 Belgrade, Serbia
*Corresponding author: mihailoratknic@yahoo.com

Abstract

The paper presents the concept of sustainable use of renewable natural resources through: adaptive activities focused on maintaining genetic variability and resistance of species to climatic changes; a change of technique and technology of forest planting; protecting natural areas; improve forest fire protection; improvement of forest resilience to insects and diseases; protection against erosion and floods; improved forest regeneration and sylviculture. Additionally, an alternative use of natural resources through inclusion of the eco-centric approach into adaptive measures has been proposed. The idea of applying adaptive measures is to maintain and build connections between habitats that will allow the movement of insertion and resistance to climate change. However, the consequences can be excessively diverting resources that could undermine the effectiveness of its conservation.

Key words: *adaptive measures, forest ecosystems, climatic change, models, Serbia*

Introduction

Previously recorded changes of climatic parameters and examination of various climate change scenarios (global, regional) indicate that the Serbian territory belongs to a group of regions in which climatic changes endangers sustainable use of natural resources and, consequently, threaten the state of the environment. The most serious problem related to adaptation of forest communities to climate change is the rate of the change. The intensity of change of climate parameters is higher than the natural capacity of many species to adapt to newly-created conditions.

The impact of climate change on forest ecosystems in Serbia

Expected maximal change of temperatures in 21st century could be up to 5. 6°C, so Ratknić et al. (2010) designed modeling experiment with five temperature increase scenarios (for 1, 2, 3, 4 and 5 °C).. Based on the designed model and scenarios, it can be concluded that a drastic change in number and structure of forest ecosystems in Serbia is about to occur in a relatively short period. In addition to the above-stated, it is important that a higher level of risk, related to the expected adverse effects, is associated to relict, rare and endangered forest communities and tree species, which make them distinctive. Considered cumulatively, the above-mentioned effects will have a direct impact on the possibility of preservation of biological diversity and viability of appropriate management of these resources.

The total number of forest habitats in Serbia is 210. An increase of temperature by 1° reduces the number of habitats to 198, whereas a 2° increase reduces the number to 192. An increase of temperature by 3° reduces the number of habitats to 159, whereas a 4° increase reduces the number to 131. A 5° temperature increase reduces the number of habitats to 116, which is a decrease of 44.8%. Number of broadleaf deciduous forest habitats in Serbia is 160. An increase of temperature by 5° reduces the number of habitats by 40%. Of the 32 habitats under conifer forests increase in air temperature of 5°C number of habitats will be reduced by 68.7%, and 18 habitats under the mixed deciduous and coniferous forests of 83.3%.

As the two thirds of the Serbian territory are comprised of mountain terrains, there are species the population of which is limited to mountain peaks, where there are no natural corridors for

their migration. Those species will be among those worst hit by climatic changes, since they are already sensitive, on account of a low population and isolation.
A change of climate creates favourable conditions for arrival and acclimatisation of new alien and invasive plant species. Invasive species drive out autochthonous species from their habitats, change the structure and composition of plant communities and reduce the entire richness of species.

Adaptive activities in forestry

Adaptation ought to reduce sensitivity of forest ecosystems towards climatic changes. Despite the fact that forest ecosystems will adapt to climatic changes on their own, bearing in mind the importance of forests for the society, it is necessary to influence the course and dynamics of adaptation in certain fields. Activities related to a process of adaptation of forest ecosystems must be accomplished now, in order to obtain their full effect in future. Researches in forestry must estimate a long-term impact of climatic changes and determine how and in which habitats should be reacted to this threat. A sustainable forest management must include built-in elements of forest ecosystem adaptation, where it should be emphasized that the inclusion of adaptation to climate change, as a part of sustainable management of forest ecosystems, does not require large financial investments into an unknown future. However, the applied adaptation measures must not have an adverse effect on the present state of forest ecosystems, therefore, an effective adaptation policy must provide a response to a broad spectrum of economic, political and ecological circumstances (Spittlehouse et al., 2003). Adaptation requires:
establishing objectives for future forests, which will be under the influence of climatic changes
raising awareness of the importance of adaptation to climatic changes
determining a vulnerability level of forest ecosystems and forest communities
development of present and future cost-effective flexible activities
forest management aimed at mitigating vulnerability and improving conditions for rehabilitation
monitoring the state of changes and identification of a critical threshold for survival
a successful impact reduction, shortening of a rehabilitation period and reduction of vulnerability towards future climatic changes.
The change of climatic characteristics will cause a shift of species areals towards higher altitudes, along with a shift towards the north. Therefore, it is necessary to guide adaptive activities in afforestation towards maintaining genetic variability and resistance of species with respect to adaptation to these changes, as well as towards changing techniques and technology of planting:
determine the adaptability of species and genotypes in relevant climatic conditions, the boundaries of their transferability, and the development of climate-related characteristics of seed in the zones which are to be changed in the course of time. Provenances should be tested at the boundaries of their ecological range, with understanding of relevant physiological processes (Tyree, 2003).
planting of specific genotypes resistant to pests and showing a higher tolerance to climatic extremes.
planting of forest fruit trees. With the change of climatic conditions, certain forest fruit trees will disappear from some forest ecosystems. As they represent the basis for a regular functioning of ecosystems, genotypes resistant to changes ought to be discovered (Ratknic, 2005).
in selection of species and planting type, forest stands of mixed provenances ought to be established.
change the principle of preservation and re-introduction of rare and endangered plant species.

Rare and endangered plant species usually have specialised ecological needs and low genetic variability (Hansen et al., 2001). A long-term preservation of certain rare species is easier to accomplish in archives (Ratknić, 2005), artificially established stands or arboreta, than in natural stands (Parker et al., 2000).

develop an afforestation technique and technology that will enable survival of seedlings in first years of life in newly-created conditions (mulching, use of polymers, etc) (Ratknić et al., 2010).

By means of adaptation to climatic changes, spreading of genotypes or species adapted to new climatic conditions ought to be enabled. Spreading of non-commercial trees and vegetation will present a particular economic problem. Adaptive activities in the field of forest regeneration involve:

identification of genotypes tolerant to drought (Ratknić, 2007)

aiding migration of commercial tree species from their present to future habitats by means of artificial regeneration (Parker et al. 2000). Shift of species towards the north or higher altitudes may be hindered by inadequate soil conditions, such as lack of nutrient matter, the depth, deficiency of mycorrhizal fungi, etc.

plantation of provenance growing in a broader spectrum of conditions as compared to current habitat provenances

control of undesired plant species, which become competitive species in conditions of changed climate (Parker et al. 2000)

In near future, climatic changes may increase productivity of forests (Cohen, Miller, 2001). However, in long-term, the availability of nutrient matter and adaptation of tree species to a higher content of carbon dioxide may limit productivity. In warmer habitats, stabilisation of productivity at the present level can be expected. Changes may also be expected in forest distribution border areas in the zone of scrub and grass habitats. Based on these changes in forest ecosystems, a change of positions and procedures in the field of forest sylviculture is essential. Adaptive activities aimed at responding to changes are the following:

non-commercial thinning or selective removal of individually driven out, damaged or trees of poor quality, with a view to increasing light, water regime and nutrient matter, which would all be more accessible to remaining trees (Papadopol, 2000). This adaptive measure, however, if applied on larger areas may have an impact on a current regular functioning of ecosystem.

reducing endangerment, with a view to decreasing disturbances in future, by controlling a stand thickness, type and structure of a forest (for instance, supplemental planting, planting of species from subsequent successive phases, etc) (Ratknić et al., 2010).

planting of other species or genotypes, in cases which natural regeneration is not acceptable from the perspective of forest ecosystems in future.

decrease of rotation period and plantation of adaptive species with a view to a more rapid establishment of resistant forest ecosystems.

Rapid changes of forest age structure and changes of terrains can be caused by more frequent and intensive disturbances such as fire, stormy winds and outbreak of pests. There is a high possibility of occurrence of interaction between climatic changes (warmer and drier climate), pest outbreak and forest fires (Fleming et al., 2002).

Adaptive activities must be concerned with changes in the regime of forest fires, which involve:

focusing on protection of regions of high economic and social value (Ratknic et al., 2009).

changing a forest structure (distance between trees, stand thickness, removal of dry upright trees, removal of dead trees) aimed at decreasing a risk and a degree of ecosystem disturbance (Dale et al., 2001). In the process of reduction and removal of dry trees, it should be borne in mind that this material has a particular ecological importance for functioning and preservation of ecosystems, therefore it is necessary to reconcile a threat of fire with the ecological

component (Ratknić, 2011).
development of a ‘smart’ fire landscape. By means of cut, regeneration, stand activities as systems of management of the amount of combustible material in the process of control of fire occurrence and spreading. For instance, an aspen stand, a species resistant to fire, can be planted in several localities in coniferous cultures or in natural forests, with the aim of mitigating vulnerability of ecosystems in large fires. This is an example of an adaptive activity, a positive effect of which will be felt for several decades (Spittlehouse et al., 2003).
increase of a rate of recovery of forest ecosystems after fires (Ratknić, 2011).
Climate change will increase warmth and humidity in present forest ecosystems, create conditions for increased occurrence of insects and diseases. Adaptive activities in protection of forests against insects and diseases may involve:
partial cut or thinning aimed at increasing stability and lowering sensitivity to attacks (Gottschalk, 1995).
sanitation cut of infected trees, where it should bear in mind that this practice may increase the sensitivity of ecosystems to other pests.
shortening of a rotation period with a view to decreasing the period of vulnerability of a stand to harmful insects and diseases (Gottschalk, 1995), aimed at effecting a more rapid transition to more suitable species (Lindner et al., 2000).
use of insecticides and fungicides in situations where other activities are ineffective of inappropriate (Parker et al., 2000).
use of genotypes grown for the purpose of increasing resistance to pests.
Biological and climatic changes will also have implications on use of forests and forest ecosystems. An increased amount of precipitation during winter and a decrease in the summer period may have an impact on water resources in forest ecosystems, increase the risk from erosive processes and endanger fish habitats and hatcheries. Adaptive activities in the field of use of forest ecosystem resources are the following:
an increased amount of wood from sanitation cuts, which are carried out after fires and damage of stands inflicted by insects, along with a reduction of treatment in natural stands left to natural adaptation.
maintenance and rehabilitation of roads, damaged as a result of erosive processes due to an increased amount of precipitation and abrupt snow melt.
mitigation of the impact upon infrastructure, fishery and reserves of potable water.
inclusion of adaptive planning measures into forest certification, as a part of the risk management strategy.
mitigation of climatic changes through carbon management (Ratknić, 2008).
an increased use of biomass as an energy generating product.
development of policy aimed at facilitating creation and implementation of an adaptive response to climate change (Parker et al., 2000).

In order to reduce the drawbacks of the existing global climatic projections, it is essential, for the purpose of quantification of reliability and uncertainty of forecasts, to use regional climatic and impact models.

Conclusions

For forest ecosystems to adapt to climatic changes, it is necessary to preserve forests in their most natural form, with avoiding mono-cultures together with promotion of mixed forests, with respect to both type and age. Maintaining natural or close-to-nature regeneration is recommended, as the method of maintaining genetic diversity and, consequently, reducing sensitivity of forest ecosystems. It is also essential to strategically increase the size and number of protected areas, particularly in exceptionally valuable habitats, create artificial reserves or arboreta, with the aim of preserving rare species and providing multiple protection

to climatic refugia, and to include climatic parameters into the models of forest growth and yield. In artificially established forests and mixed cultures, natural genetic diversity should be fostered, the structure of surrounding forests should be imitated and a direct substitution of a natural ecosystem should be avoided. In order to increase the potential of an ecosystem to respond to climatic changes, it is essential to reduce stress factors that are not related to climatic conditions. With a view to preventing adverse changes in distribution of plant and animal communities, it is necessary to maintain seed sources (seed banks and seed facilities) and increase genetic diversity of trees that are used for establishment of plantation. With regard to seedling nursery production, seedling nurseries should be prepared for potential extension of their capacities, while intensifying experimentation with various plant species and production, growth and plantation of genotypes resistant to drought and other climatic extremes, insects and diseases. It is necessary to build-in the results of regional climatic and impact models into activities that enable timely adaptation to climatic changes, or their mitigation (if possible).

Abstract

Scolytid ambrosia beetles present xylophagous group of insects which decrease economic and aesthetical value and technical properties of wood. Damages are highly expressed within high quality veneer wood trunks of Common oak (*Quercus robur* L.) where even minimal damage decreases price significantly. Most threatened are new harvested logs on forest storages which protection is necessary from March till November. In previous decades this problem was solved with application of Lindane (Hexachlorocyclohexane HCH) insecticide, but contemporary regulations excluded its use. Therefore, experiments with use of alpha-cypermethrin insecticide for protection of oak timber was performed.

On June 28th 2012, four experiments were established at Forest estate Sremska Mitrovica of Public Enterprise „Vojvodinašume“ Serbia on two spatially divided localities MU Blata-Malovanci and MU Neprečava Varoš Lazarica. On each locality experiments were divided to Fastac® Forst application with 1% concentration for 1 month period of protection and 2% for 3 month protection period. From each experiment, 4 logs were used for treatment and 4 logs for control. Pesticide consumption was 4 liters per cubic meter of wood. Treatment was performed with backpack blower and assessment was performed 1 and 3 months after application . Efficacy was calculated by Abott′s formula.

Fastac® Forst application in concentration of 1% for protection period of 30 days showed 87.3% and 94.7% efficacy, while application of 2% concentration for 90 days protection period showed 61.6% and 90.23% efficacy. Obtained results indicate good efficacy of application of 1% concentration of Fastac® Forst for oak wood protection for 30 days period.

Key words: scolytid ambrosia beetles, insecticide, protection

Introduction

Scolytid ambrosia beetles (Coleoptera: Curculionidae: Scolytinae) represent very important technical pests of felled logs of oak wood oak at the forest storages. In addition to harvested wood they attack weak oak trees under process of drying, often makes holes in places where trees were mechanical injured. Scolytid ambrosia beetles mostly present secondary even tertiary pests (Mihajlović, 2008). By the construction of the hall in the wood reduces the technical, aesthetic and economic value of oak wood. According to Weidner (1953) technical value of the wood can be lowered by 50 – 90%, while Mirić and Petrović (2005) claim that high quality logs attacked by scolytid ambrosia beetles can decrease its class for 2 ranks what causes lowering of price of timber. Economical value loss of the wood is especially high on damages made on most valuable veneer logs which can be no longer used for veneer production. Scolytid damages can be alleviated by felling of trees during winter and transporting them out of the forest before vegetation started, but in praxis such situations are rare. Also demand for wood in most situations is in collision with working conditions in forest. As alternative a sinking trunks in to the water or permanent water spraying exists, but

those protection measurement are expensive and not to practical in forest conditions. For many decades protection of oak logs were carried out with insecticides based on HCH, but it was prohibited in Serbia in year 2006. After that protection of oak logs became a problem due to the lack of registered insecticides for that purpose. Meanwhile damages and losses were rapidly increased on trunk stocks in forest.

Purpose of this paper was to determine possibility of application of insecticide Fastac® Forst for protection of oak logs on forest log storages and to start registration process for that purpose in Serbia. Significant help during research we had by FE Sremska Mitrovica (PE Vojvodinašume).

Materials and methods

All experiments for protection of english oak logs against Scolytid ambrosia beetles were established on 28.06.2012. at a temporary forest timber stock in FE Sremska Mitrovica (PE Vojvodinašume). In total four experiments were established at Forest estate Sremska Mitrovica on two spatially divided localities MU Blata-Malovanci and MU Neprečava Varoš Lazarica. On each locality experiments were divided to Fastac® Forst application with 1% concentration for 1 month period of protection and 2% for 3 month protection period. From each experiment, 4 logs were used for treatment and 4 logs for control. Insecticide Fastac® Forst content active ingredient alpha-cypermethrin in quantity of 15 ± 2,25 g/l produced by BASF Agro. In all experiments treatment and contol consissts of 4 logs (repetition). Logs in control were not treated. Pesticide consumption was 4 liters per cubic meter of wood, and treatment was performed by backpack blower. Assessment of experiments with 1% concentracion applied insecticide was performed 27.07.2012. Assessment of experiments with 2% concentracion of applied insecticide was performed 09.10.2012. by bark peeling and counting of entrance holes on bark. Efficacy was calculated by Abott′s formula (Abbott, 1925).

Results and discussion

Results of the efficacy of Fastac® Forst for 30-day protection period are presented in tables 1 and 2.

Table 1. Results of the investigation of the efficacy of Fastac® Forst in 1% concentration for log protection from scolytid ambrosia beetles in experiment established in MU Blata-Malovanci

Tretments	Total number of entrance holes	Average number of entrance holes per m^2 of bark	Efficacy (%)
Fastac® Forst	14	1.36	87.3
Control	138	10.72	-

Table 2. Results of the investigation of the efficacy of Fastac® Forst in 1% concentration for log protection from scolytid ambrosia beetles in experiment established in MU Neprečava – Varoš – Lazarica

Tretments	Total number of entrance holes	Average number of entrance holes per m^2 of bark	Efficacy (%)
Fastac® Forst	3	0.3	94.7
Control	59	5.70	-

Results of experiments with 1% concentration showed good efficacy of 87.3% and 94.7% respectively after one month period. Experiments with 2% concentration after 3 months showed only 61.6% in experiment located at Blata-Malovanci (Table 3), while experiment at

second locality (Table 4) showed high efficacy of 90.2%. Obtained results indicate decreased reliability of long period protection suggests 1% concentration with one month protection period. Further research should investigate efficacy of application of 2% concentration for 60-day period what could decrease costs of protection if results show positive results.

Table 3. Results of the investigation of the efficacy of Fastac® Forst in 2% concentration for log protection from scolytid ambrosia beetles in experiment established in MU Blata-Malovanci

Tretments	Total number of entrance holes	Average number of entrance holes per m^2 of bark	Efficacy (%)
Fastac® Forst	23	2.25	61.6
Control	98	5.86	-

Table 4. Results of the investigation of the efficacy of Fastac® Forst in 2% concentration for log protection from scolytid ambrosia beetles in experiment established in MU Neprečava – Varoš – Lazarica

Tretments	Total number of entrance holes	Average number of entrance holes per m^2 of bark	Efficacy (%)
Fastac® Forst	25	2.13	90.2
Control	210	21.8	-

During assessment of experiments more frequent damages of logs were recorded in areas with mosses what probably presented barrier for pesticide. In order to increase protection, mosses should be removed prior to pesticide application.

Due to bark roughness, logs should be treated individually right after the felling in order to evenly distribute pesticide to entire surface of logs. In wood industry, logs stored for longer period can also be damaged by scolytid ambrosia beetles (Maksimović, 1959) and therefore should be also treated with pesticides in order to protect them from insects.

Investigations of efficacy of Fastac® Forst enabled registration and commercialization of this pesticide for common oak logs protection against scolytid ambrosia beetles in the Republic of Serbia. Problem related with use of this pesticide is that active matter alpha – cypermethrin is listed on FSC certificate list of forbidden pesticides (Anonymous, 2015) and therefore Public Enterprise “Vojvodinašume” applied for its derogation of restriction and the process is still ongoing. Derogation permission will enable use of this pesticide for oak logs protection.

Conclusions

Conducted research of investigation of possibility of protection of common oak logs against Scolytid ambrosia beetles showed following:

Experiments showed that application of Fastac® Forst in concentration of 1% with amount of 4 liters per m^3 presents good protection of common oak logs for 30-day period.

Application of 2% concentration can not secure adequate protection of logs for 3 month period of protection.

During vegetation, treatment of oak logs must be conducted immediately after felling and should be continued throughout entire vegetation period.

IMPACT OF FUNGUS DAEDALEOPSIS CONFRAGOSA (Bolt.: Fr.) J. Schröt. MYCELIUM ON THE LOSS OF WILD CHERRY (Prunus avium L.) WOOD MASS

Miroslav MARKOVIĆ*, Predrag PAP, Vladislava GALOVIĆ, Srđan STOJNIĆ, Andrej PILIPOVIĆ, Marina KATANIĆ

Abstract

The paper presents the results of the impact of *Daedaleopsis confragosa* (Bolt.: Fr.) J. Schröt. mycelium on the loss of wood mass in wild cherry (*Prunus avium* L.). This phenomenon was examined on the wooden material (dimensions 4 × 15 × 25 mm) that is taken 20 cm above and below tree breast height, separately from sapwood and heartwood. The fungus *Trametes versicolor* (L.) Lloyd was used as control fungus. The observations were performed on 20 samples in three replications, for each fungus and period of incubation (15 days, 1, 2 and 3 months), separately for sapwood and heartwood. Loss of wood mass was determined as the difference in absolutely dry mass of the sample before and after the fungal treatmant. Statisticaly significant loss of sapwood and heartwood mass was observed immediately after the beginning of the experiment, in the samples infected by *D. confragosa*. In the case of *T. versicolor*, statisticaly significant loss of sapwood and heartwood mass was observed two months after beginning of the experiment. The highest impact on the wood mass loss had duration of wood exposure to fungus ($\beta = 0.696$, $p = 0{,}000$), part of the wood ($\beta = -0.419$, $p = 0.000$) and fungal species ($\beta = -0.237$, $p = 0.000$). During this experiment it was demonstrated that fungus *Daedaleopsis confragosa* caused different types of decay in different tree species. White layered rot was obseved on the wood of wild cherry, linden, willow, alder and Norway spruce, while the white mosaic rot was found on the wood of crab apple and hornbeam.

Keywords: decay, fungi, *Daedaleopsis confragosa, Trametes versicolor*, white rot

Introduction

The fact that the fungi can cause wood decay was accepted after the works of Hartig (1874) who discovered that the fungi actually cause destruction of wood tissue instead of being a consequence of its decomposition. Wood decay develops in dead parts of tree and except for fungi that cause root decay, do not directly endanger life of trees. However, indirectly, wood decay leads to tree breaks and throws under the influence of stormy winds and snow, and make substantial economic damages because usually attacks the most valuable part of the tree (heart), and often starts from the base of the tree which destroys the first most valuable log. According to research of Krstić (1950) in the forests of Istočna Boranja in the fifth diameter degree of beech stands percentage of trees infected by rot fungi ranged from 50 to 85% and the loss of wood mass was above 20%.

Epixylic fungi have an irreplaceable role in the carbon cycling on the Earth, returning into the atmosphere every year, billions of tons of carbon. It is believed, according to Lazarev (2005), that if decay process stopped and the process of photosynthesis continued life on the Earth would be terminated in less than 40 years due to the absence of carbon dioxide. In addition, decay fungi have crucial role in getting rid of wood waste in the soil and make it more fertile. Also, they affect natural pruning and can be applied in medicine *(Fomes fomentarius, Piptoporus betulinus, Ganoderma lucidum, Fomitopsis pinicola, Laetiporus sulphureus,*

Schizophyllum commune, *Trametes versicolor* etc.), some are used for human consumption (*Laetiporus sulphureus*, *Flammulina velutipes*, *Pleurotus ostreatus* etc.) and so on.

Causers of white rot, in the later stage of wood decomposition, cause brighter color of wood in comparison to the color of a normal, healthy wood and are more common in deciduous tree species. This decay is primarily result of lignin degradation, although in a later stage of decomposition, cellulose and hemicellulose are decomposed as well. White nod is never completely white, but there are many types, for example white-yellow, pale ocher, black layered, white ring, white freckled, white mosaic and so on.

A difference in the kind (appearance) of rot caused by *Daedaleopsis confragosa* on different tree species was observed during this research. On wild cherry, linden, willow, alder and spruce it caused layered white rot while on the wild apple and hornbeam caused white mosaic rot. Causers of dark rot in an advanced stage of wood decomposition make wood darker in comparison to a normal, healthy wood and are more common in coniferous tree species. Rot causing fungi firstly break down cellulose and hemicellulose (degradation of the carbohydrate components) but not the lignin. This is a real destructive rot because the structure of wood is destroyed in the final stage, in some species, the whole heartwood is decomposed so that cavities occur, which can be seen after tree falling (Karadžić, 2010).

Material and methods

The mass loss and chemical changes in wood of wild cherry - *Prunus avium* L. (syn. *Cerasus avium* Moench.) was studied on wood samples (tubes) of 4 x 15 x 25 mm dimension, taken from healthy 48 years old trees (age was determined by counting the growth rings on a tree stump), with chest diameter of 37 cm and height of 19 m originating from the National park "Fruska gora". For the analysis was taken the first chuck with the length of 2.0 m and tubes were made from the part of the chuck at breast height (20 cm above and below), particularly in the sapwood and heartwood.

The mycelium of the fungus *Daedaleopsis confragosa* (Bolt .: Fr.) J. Schroet. used in this work, was isolated by standard methods from the piece of wood near the fruit body of the fungus, which was sampled on wild cherry tree from Crni vrh (coordinates N 44^0 08^I $39{,}70^{II}$, E 21^0 58^I $23{,}60^{II}$), at an altitude of 749 m a. s. l. The isolate was stored in mycotheka of Institute of Lowland Forestry and Environment in Novi Sad. Isolate of fungus *Trametes versicolor* (Fr.) Pil., which was used as a test - fungus, was obtained from mycotheka of Department for forest protection, timber and ornamental plants, the Faculty of Forestry in Belgrade.

For test were used tubes (dimensions 25 x 15 x 5 mm) with proper flow of fibers, smooth surface and free of knots and defects. 40 tubes (20 + 20) constituted a control and 20 tubes were used for each fungus and each intended incubation period (15 days, 1, 2 and 3 months), especially for the hardwood and the sapwood. Three replicates were performed so that the number of samples (test tubes) was sufficient for a statistical analysis (Soskic, B. 1994).

After drying and measuring, all specimens were conditioned by the standard method at approximately 12% moisture. The tubes were exposed to the influence of fungus according to the method proposed by Miric (pers. com., 2010).

The experiment was set up in the way that on the fungus was first layed the ring and then on the ring were slowly layed 4 tubes. Ring was enabled fungus to comes in contact with the wood (specimen) and also represented the isolation between the substrate and wood. For each incubation period 5 petri dishes were used, for the hardwood and the sapwood and for each fungus as well. Petri dishes of the same incubation period were then placed in aquariums and on them was put petri dish without the lid in which was 5% aqueous solution of boric acid. After closing, aquariums were placed in a climate chamber General Electronik Modernlab mode. 560, and in total darkness at 25 ± 2^0C. After expiration of the incubation period, the

tubes were taken out from the petri dishes, cleaned from the surface mycelium and dried in a classic oven at 103 $\pm 1^0$C and then measured.
To obtain the difference in mass of healthy wood and wood that has been exposed to the fungus for 15 days, 1, 2 and 3 months. Mass loss of wild cherry wood under the influence of the tested fungi was determined according to the formula:

$$\mathbf{Gm = \frac{m1-m2}{m1} \times 100}$$

Where is:
Gm - loss of wood weight
m1 - mass of absolutely dry wood before exposure to a fungus (expressed in grams)
m2 - mass of absolutely dry wood after exposure to a fungus (expressed in grams).

Results and discussion

For the fungus *D. sonfragosa*, a statistically significant mass loss of sapwood and heartwood was recorded with increasing time (Figure 1). For *T. versicolor* fungus statistically significant mass loss of sapwood and heartwood was recorded in the second and third month (Figure 2).

Figure 1. Mass loss of sapwood and heartwood under the influence of fungus *Daedaleopsis confragosa*

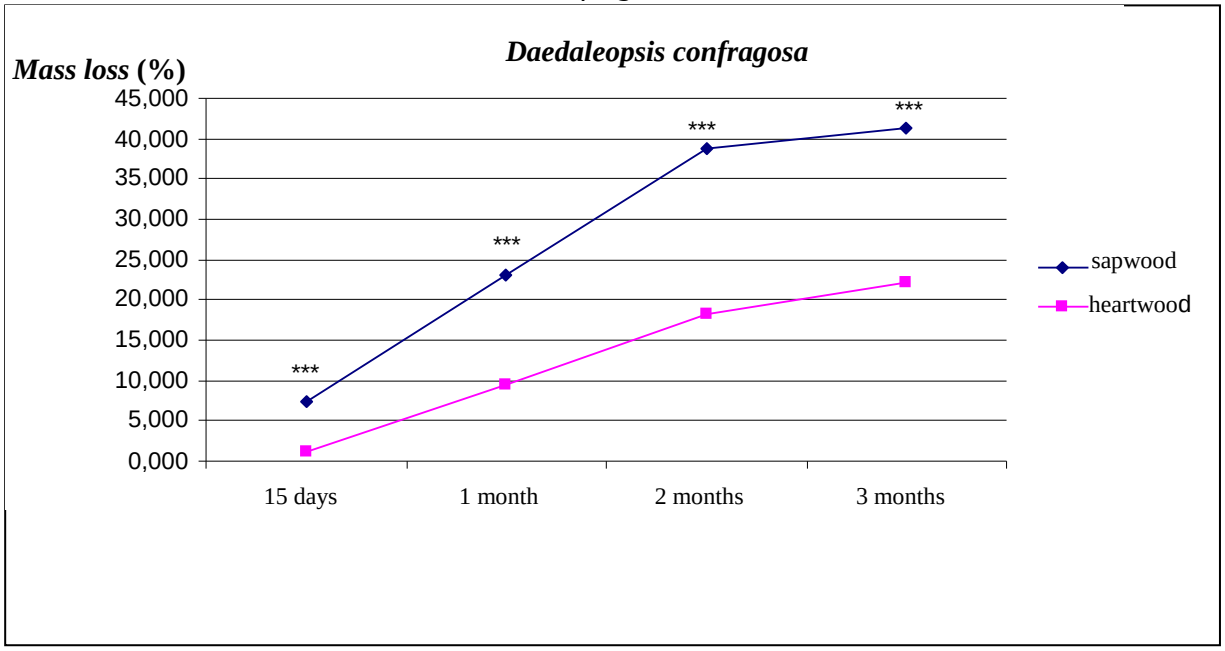

Figure 2. Mass loss of heartwood and sapwood under the influence of fungus *Trametes versicolor*

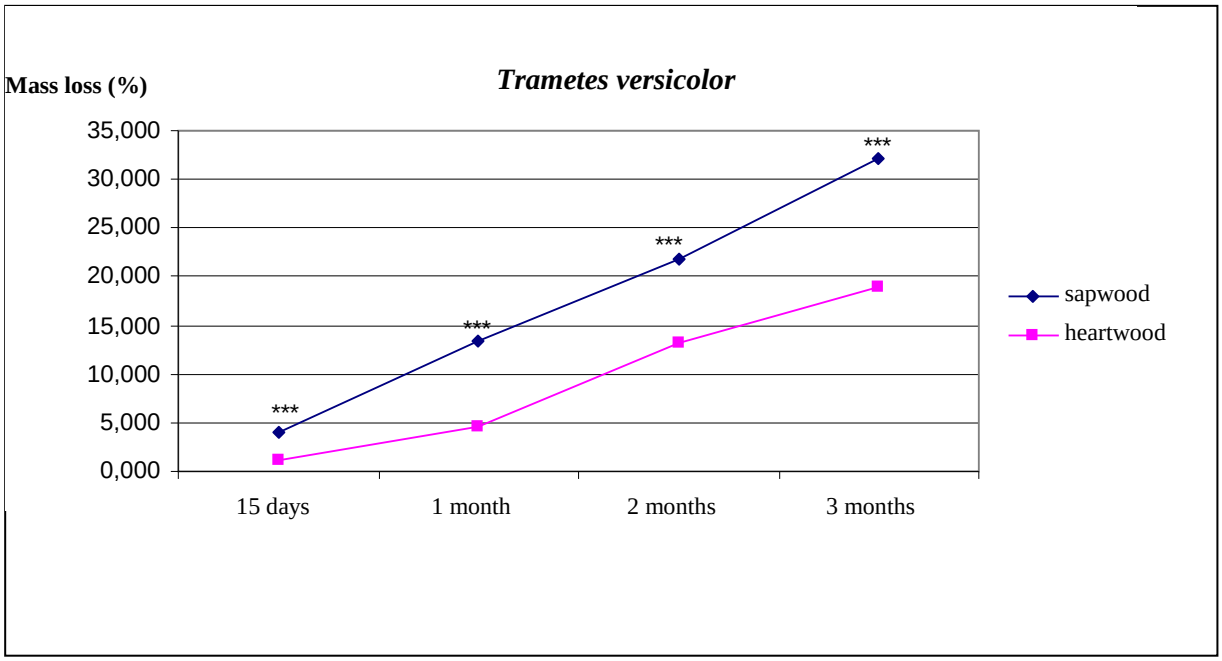

If the mass loss of sapwood was compared in examined fungi, significantly higher mass loss was caused by *D. sonfragosa* compared to *T. versicolor* in all tested periods (Figure 3.) Although fungus *D. sonfragosa* decomposed more heartwood than *T. versicolor* in all periods, the mass loss was significantly higher only in the first month (Figure 4). The mass loss under the influence of the tested fungi was significantly higher for sapwood in relation to heartwood in all investigated periods.

Figure 3. Mass loss of sapwood under the influence of fungi *Daedaleopsis confragosa* and *Trametes versicolor*

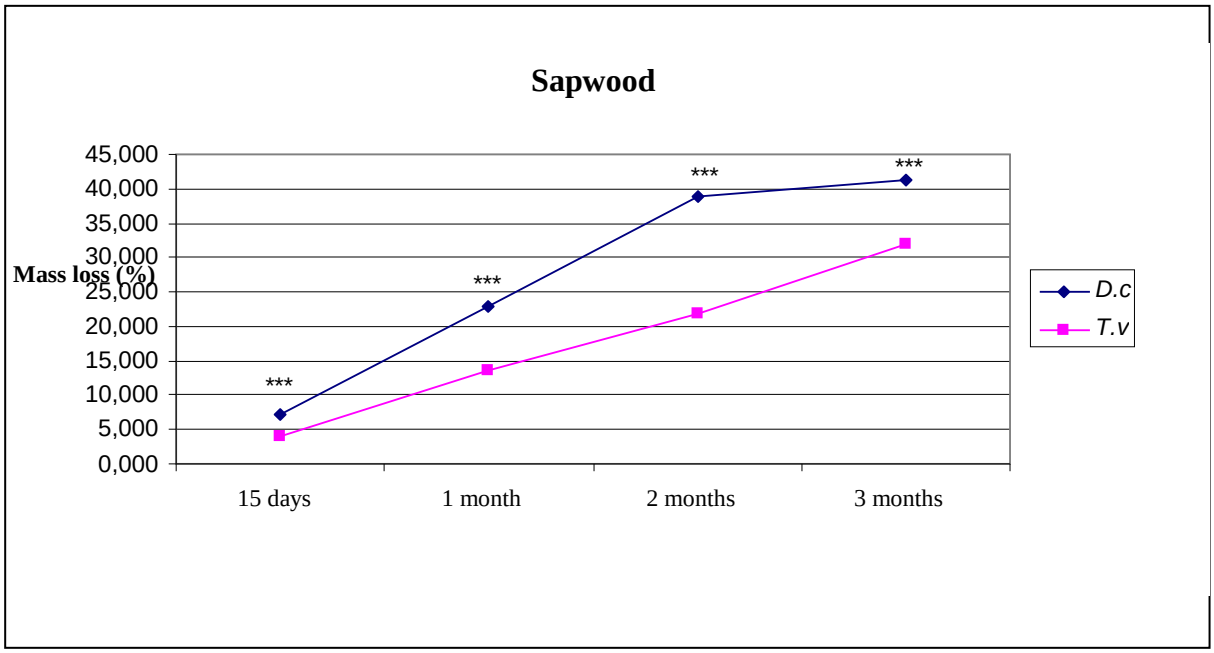

Figure 4. Mass loss of heartwood under the influence of fungi *Daedaleopsis confragosa and Trametes versicolor*

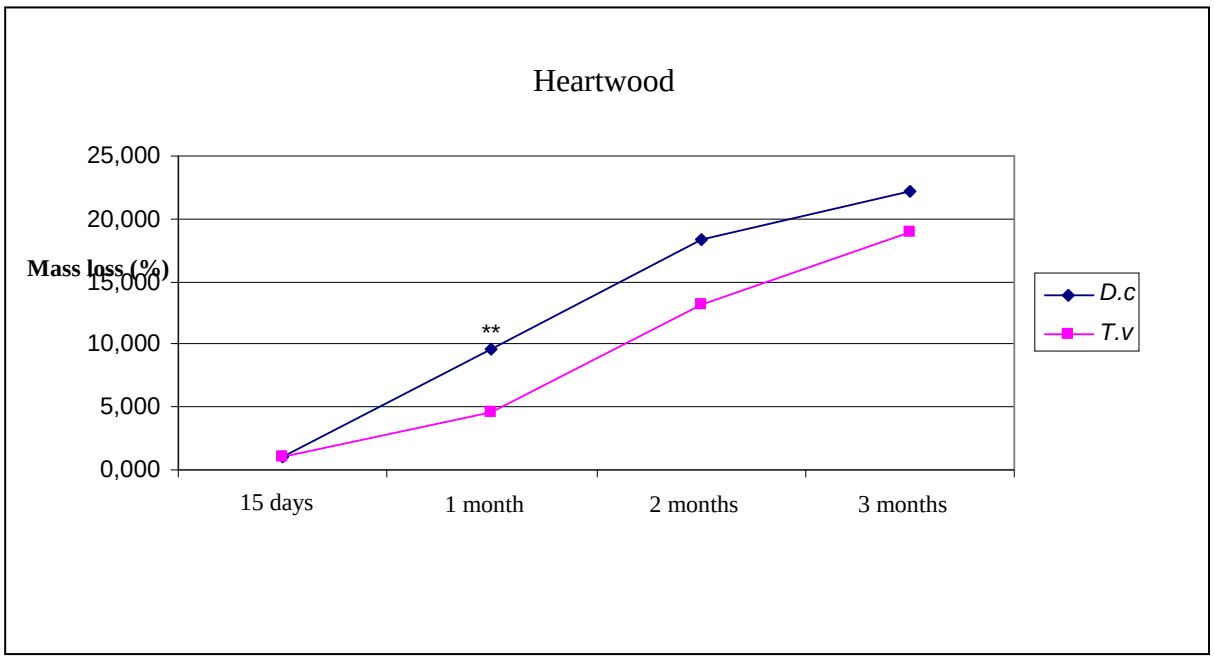

The link between mass loss and joint and partial impact of fungus, type of wood and exposure time to fungus was determined by linear regression analysis. Mass loss is in high correlation ($r = 0.846$, $F = 265.990$, $p = 0.000$) with the joint influence of species of fungus, type of wood and time of exposure (data not shown).

ANOVA analysis showed that mass loss was significantly affected by all studied parameters. The biggest partial influence on the mass loss is the time of exposure to the fungus ($\beta = 0.696$, $p = 0.000$), followed by part of wood ($\beta = -0.419$, $p = 0.000$), and types of fungi ($\beta = -0.237$, $p = 0.000$) (data not shown).

Conclusion

Fungus *D. confragosa*, as a weakness parasite or saprophyte was registered during our studies on wild cherry, alder, willow, linden, hazel, hornbeam, wild apple and spruce. Based on investigation of the effect of *D. confragosa* mycelium on the mass loss of wild cherry wood can be concluded that the tested fungus decomposed much more sapwood and heartwood compared to the control fungus (*T. versicolor*). For the fungus *D. sonfragosa*, with increasing time, a statistically significant mass loss of sapwood and heartwood was recorded. For *T. versicolor* was observed statistically significant mass loss in sapwood and heartwood but only after two and three months. Mass loss was significantly affected by all investigated parameters. The biggest partial influence on the mass loss had the time of exposure to the fungus, followed by part of wood and species of fungi.

Abstract

The paper shows the variation of heavy metals level in underground water in the middle Danube basin. Underground water was analyzed in following hydromorphic soils: fluvisol, humofluvisol, humogley and eugley. Level of following heavy metals: arsenic, cobalt, chromium, copper, iron, manganese, nickel, lead and zinc was determined for a period of two years in three seasons: spring, summer and autumn. Maximum allowable concentration was applied from two sources: Official Gazette of RS 23/1994 and Food and Agriculture Organization (FAO) classification. The results showed levels of manganese above the maximum allowable concentration in all four soil types in all studied seasons, and increased level of arsenic in groundwater of humofluvisol in the summer of 2006, and eugley during the summer of 2007 and copper in groundwater of eugley in summer and autumn of 2006 and in spring in 2007. The level of manganese was below the maximum allowable concentration in certain seasons, in the piezometers which were closer to the stream of the Danube. According to the pollution index (C_d) of the area, heavy metals content varied depending on the underground water level. Thus, at a lower level of underground water, contamination by heavy metals was lower.

Key words: *Maximum allowable concentration, pollution, season*

Introduction

Quality of precipitation water, as well as the presence of harmful substances including heavy metals, gives insight into the overall pollution in a region, which is important for a variety of industries as well as for planning and implementation of environmental policy at national and international level (Špirić et al., 2009).

In order to protect the groundwater is necessary to know the spatial distribution of pollution and the impact of anthropogenic factors (Zahn and Grim 1993). Anthropogenic impact on groundwater quality is primarily influenced by agricultural activity, industry, waste water, settlements and waste disposal (Vlahović, 2004). The consequences of anthropogenic influence are manifested mainly by increased content of nitrates, phenols, total fat, mineral oil and heavy metals which represent a growing problem.

Among all the chemical pollutants, heavy metals are considered as substances with special ecological, biological and clinical significance (Kadović and Knežević 2002, 2004). Presence of one or more of these elements can be significantly increased under the influence of anthropogenic factors at site and remote transport of pollutants. Their concentrations may exceed the critical or toxic levels for the ecosystem or ecosystem component (Kadović et al., 2005). The presence of a compound in a certain amount, might not cause a disturbance in the plant production on one soil type, while on the other type might reduce quality and quantity of yield. If the adsorption capacity of soil or sediments becomes exhausted, the concentration of metal ions in water increases. The accumulation of heavy metals is mostly related to soil clastic, especially to the clay fraction of sediments (Appello and Postma 1994). Heavy metals

reduce the intensity of photosynthesis. As a result the production of plant organic matter is reduced. They also affect the water regime of plants, reducing absorption of water and its transport into the aboveground organs, increase the diffusion resistance of stoma and thereby reduce transpiration (Borišev, 2010). For a more extensive study of hydropedological properties in the Middle Danube region, it was important to determine the level of heavy metals in groundwater as a very significant agent of area pollution. Contamination of groundwater by heavy metals adversely affects the quality of soil and consequently the vegetation at site.

Therefore the aim of our study was to determine the influence of season on heavy metals concentration in groundwater of hydromorphic soil from protected area in the middle part of river Danube basin in Vojvodina, Serbia.

Materials and methods

An area in a protected part of the alluvial plain of the Middle Danube basin in Vojvodina, northern province of Serbia was examined in 2006 and 2007. Groundwater in the area of Vojvodina is situated in the Quaternary sediments and the alluvial deposits and diluvial formations, which are fluvial and eolian deposits, gravel, sands, and loess-like sediments. In the alluvial plain of the Danube the groundwater level oscillations are directly related to the water level of Danube, which feeds groundwater depending on the distance of the riverbed and texture of the soil. The research was done on the terrain which altitude varied from 72.50 to 78.20 m.a.s.l.

This research covered the area of about 14000 ha. On the site samples of groundwater were taken from piezometers to determine the content of heavy metals in different soils of hydromorphic order: fluvisol, humofluvisol, humoglej and eugley. Distance of piezometers from the bank of the Danube ranged from 226 m to 4161 m. The study was carried out on the left bank of the Danube, in a protected part of the alluvial plain. Ten samples of groundwater were taken for chemical analysis from these soils in three seasons: spring, summer and fall, throughout the study period in 2006 and 2007. In total, 60 samples of groundwater were taken. The content of heavy metals was determined by standardized atomic absorption spectrometry procedures, using atomic absorption spectrometer - "Varian 600". The limit values of heavy metal content i.e. Maximum Allowable Concentration (MAC) were applied from two sources: the Official Gazette of RS 23/1994 and the classification of FAO (Ayers and Westcot, 1985). For purpose of statistical analysis arithmetic mean was calculated, as a measure of central tendency, and the results of repeated measurements analysis of variance and the least significant difference test (LSD-test) at the risk level of 5%. On the basis of analytical data, the level of heavy metals exceeding the MAC in all types of soil was determined by the index of pollution (C_d) for examined area. The index of pollution (C_d) quantifies the pollution of groundwater with heavy metals, and combines water quality parameters that exceed the MAC (Nakić et al., 2007). According to Nakić et al., (2007), Backman et al. (1998) gave the following formula for calculating the pollution:

$$C_d = \sum_{i=1}^{n} C_{fi}$$

$$C_{fi} = C_{ai} / C_{ni} - 1,$$

where C_{fi} stands for pollution factor for the i-component, C_{ai} for analytical value of the i-component and C_{ni} for MAC value of the i-component.

Results and discussion

For determination of heavy metals level in groundwater in the area where hydromorphic soils are distributed, sampling was conducted in three seasons during 2006 and 2007. It is important to note that in 2006 level of groundwater was high, while in 2007 the groundwater level was low, i.e. in both years the groundwater level was in correlation with the water level of the Danube (Pekeč, 2010).

Table 1. Repeated measures analysis of variance for levels of heavy metals in groundwater of hydromorphic soils

	Soil (A)	Error $_{(A)}$	Time of measurement[1)] (R)	Interaction A x R	Error $_{(A \times R)}$

[1)] Times of measurement within a heavy metal when the values for all measurements were zero did not entered the analysis of variance

[2)] df – degree of freedom

Analysis of variance indicates that variations in levels of examined heavy metals were under significant influence of time of measurement, except for iron and lead (Table 1). However, there was no significant statistical difference in the variation of any heavy metal concentrations in the underground water depending on the soil type. Only in the case of arsenic, chromium and lead the effect of interaction: time of measurements x soil was statistically significant, indicating a significant contribution to the difference between soil types in a deviation from the trend formed under the influence of differences in the times of measurements.

Table 2. Mean levels of heavy metals in groundwater of hydromorphic soils - results of Repeated measures analysis of variance and LSD test at the level of risk of 5%.

1sp, 1su, 1au – 2006 spring,summer and autumn , 2sp, 2su, 2au – 2007 spring,summer and autumn

Analyzing the mean values of heavy metals concentrations for years and times of measurement (Table 2) a certain tendency could be noticed: in the summer measured values were the highest, in fall the lowest, and in the spring values were mainly in the middle. This phenomenon is obvious for arsenic and zinc in both years, and for cobalt and nickel in 2007. It was only for the concentration of copper in the first year where the reverse sequence of values was found.

Pollution index of groundwater

According to analyzed pollution index (C_d) can be concluded that in the year with higher level of ground water (2006) higher level of heavy metals were found in groundwater, in all tested soils.

Table 3. Pollution index of groundwater

Piezometer	S3	S6	S10	S16	S12	S13	S14	S4	S15	S18

Bold - high value pollution index of groundwater in 2007 compared to 2006

Only in certain periods in year with lower level of groundwater (2007) the index of its pollution by heavy metals in some soils was relatively high: in the fluvisol (S3) and humofluvisol (S16) in the fall, in humogley (S13) in the spring and in humogley (S14) and eugley (S18) in the summer.

Analysis of the variations of heavy metals in groundwater of hydromorphic soils in different seasons during two years brought the next results. During 2006, with high level of

groundwater in the spring, above the MAC was the level of manganese in all tested soils, except for fluvisol (S10) and humogley (S14). In the summer the contents of arsenic in groundwater on humofluvisol (S10) and the content of copper (Cu) in groundwater on eugley (S18) were above the MAC. The content of manganese exceeded the MAC level in the groundwater of all types of soil. During the autumn values for Cu were still above the MAC for groundwater on eugley (S18), a values of Mn concentration were above the MAC in the groundwater of all types of soil, except for site S10 (fluvisol). In 2007, when the level of groundwater was lower, contamination by heavy metals was lower. In the spring there was higher level of Cu then MAC in groundwater at eugley (S18), and the content of manganese was above the MAC in the groundwater of all types of soil. The number of samples with higher content of manganese than the MAC was lower than in 2006. In the summer concentration of arsenic was higher than the MAC in groundwater at eugley (S4 and S18). Also, manganese concentration was above the MAC within a small number of samples in relation to the summer of last year, but present in the groundwater of all types of soil. In the autumn the level of manganese was also higher compared to the MAC, except for groundwater in humogley,..The level of manganese on sites closer to the Danube was usually below the MAC during low groundwater levels.

Conclusion

In this study was explored area of the Middle Danube Region in the Republic of Serbia, which extends in a protected part of the alluvial plain. In the investigated area groundwater composition was studied to determine the content of heavy metals in ground water in the soil of hidromorphic order: fluvisol, humofluvisol, humogley and eugley. It can be noticed that the manganese content in groundwater at all investigated soils during all investigated seasons in both years was greater than the MAC. However, oncentration of arsenic was above the MAC in the summer and fall of 2006 in the groundwater of humofluvisols and 2007 in groundwater of eugley and the concentration of copper in the summer and fall of 2006 and spring 2007 in groundwater eugley. The pollution index (C_d), in the year with higher level of groundwater (2006) was higher than in 2007 for all types of hydromorphic soil, except for a small number of samples of groundwater where increased only in certain periods.

Abstract

Investigations were carried out in a two-storey culture of Euro-American poplar clone Pannonia, and black locust on the sandy form of fluvisol soil in the area of the upper Danube region (Serbia). In the studied culture, which was established with planting space of 5 × 5 m, and inter-row planted black locust, two experimental plots (EP-1 and EP-2), size of 0.12 ha, were established at close distance.

In the 10 years old culture on each experimental plots was found approximately the same number of trees per hectare, poplar 330-340, which are located in the upper storey, and black locust 2760-2800, which are located in the lower storey. On the EP-1 dominant height of poplar trees amounted 18.7 m, while on the EP-2 amounted 22.4 m. The average diameter of poplar trees on the EP-1 amounted 15.5 cm, and on the EP-2 20.4 cm, and the volume was 52 $m^3 \cdot ha^{-1}$ and 104 $m^3 \cdot ha^{-1}$, respectively. Dominant height of black locust trees amounted 13.0-15.2 m, the mean diameter was 5.2-5.8 cm, and wood volume 44-54 $m^3 \cdot ha^{-1}$, respectively.

In order to foster the growth of black locust trees on experimental plots, the selective thinning were carried out, at which 204 (EP-1) and 169 (EP-2) trees for tending per hectare have been selected and their 482 (EP-1) and 829 (EP-2) direct competitors felled. Thinning coefficient (q_d) was 1.08 (EP-2) and 1.39 (EP-1), indicating thinning from above. Thinning volume on the EP-1 was 14.4 $m^3 \cdot ha^{-1}$ and on the EP-2 was 17.7 $m^3 \cdot ha^{-1}$.

Key words: *mixed culture, poplar, black locust, elements of growth, selective thinning*.

Introduction

Mixed forests are presently on the advance as they are widely held to provide many ecosystem functions and services better than pure stands. The higher resistance and resilience of mixed forests to natural and anthropogenic disturbances combined with the higher biodiversity and carbon storage capacity which result in a higher potential for mitigation substantiate this timely research (Bravo-Oviedo et al, 2014). Mixing has mainly ecological and biological advantages, but in a narrower sense it may also have a strong positive effect on yield and economic efficiency (Redei, 2002).

Two basic principles of species interactions in mixed stands are: (1) „complementarity“, in which two dominant species exhibit reduced competition in mixture compared to that in monoculture, thereby utilising resources more efficiently – also called „the competitive production principle“, „competitive reduction“ or „resource partitioning“; (2) „facilitation“, in which one species positively affects the growth od another in mixture (Kelty and Cameron, 1995)

However, all tree species do not naturally form mixed stands and their establishment and maintenance is often not successful and requires high costs.

In Hungary there are the great interest to establish mixed stands of black locust and white poplar because of their fast initial growth rate and a similar rotation age and have mutual advantages. Planting (mixing) schemes have to be chosen in such a way that they increase the compatibility of the two or more species in the stand (Redei et al, 2012).

Mixed natural stands of white and black poplar with admixture of pedunculate oak and narrow-leaved ash, formerly widely represented in the alluvial zone of the Danube River in its middle course, due to changes of hydrological conditions and vegetation succession, and Euro-American poplar plantation production in the previous decades-long period, today there are only in fragments (Herpka, 1979).

In the former wetland habitats forestry practices in Serbia in the previous work more or less successfully, was established mixed stands of poplar and other tree species in minor areas. However, adequate scientific research that documented and verified the importance of such work, and tending measures in these stands, are left out.

The aim of this study is to highlights the elements of growth in a mixed, two-storey culture of Euro-American poplar clone Pannonia, with planting space of 5 × 5 m, and the inter-row planted black locust on the fluvisol soil and the characteristics of the first thinning in black locust.

Material and methods

Investigations were carried out in a mixed culture of Euro-American poplar (*Populus* × *euramericana* Dode Guinier), clone Pannonia (working title M-1) and black locust (*Robinia pseudoacacia* L.), 10 years old, which is located in the upper Danube region of Serbia (MJ „Apatin protected forest“, section 27, subdivision a). Culture is located on alluvial soil type fluvisol, sandy form, with very variable characteristics in a small area (Živanov 1982). It was established after the clear-cutting of poplar plantations of clone I-214 and complete preparation of the site. So called. „deep“ planting was used for planting seedlings of poplar clone Pannonia at a distance of 5 × 5 m (400 trees·ha^{-1}), while black locust seedlings were planted with so called. „normal“ planting at a distance of 1 m between poplar trees and in inter-row (3600 trees·ha^{-1}).

Two experimental plots (EP-1 and EP-2), with an area of 0.12 ha, a rectangular (aproximately square) shape and a distance of 100 m, were formed in a culture in the autumn of 2014. All poplar and black locust trees on the experimental plots had two cross diameters at breast height measured, with an accuracy of 1 mm. The heights were measured using Vertex III hypsometer on all poplar trees and on a certain number of black locust trees in all diameter degrees, with a width of 5 cm, in order to construct height curves.

In the experimental plots was performed nomination of black locust trees for tending in a number which with poplar trees should be definitive at the end of the production cycle of 25-30 years. Each tree for tending were primarily eliminated main competitors, defined as obstructionist (Klädke, 1990). The intensity of thinning is represented as a percentage of the reduction of the number of trees (N), basal area (G) and volume (V) per hectare before felling (Jovanović, 1988). The numerical definition of the thinning is expressed as the ratio of the quadratic mean diameter of the felled trees to the quadratic mean diameter of the remaining trees, as coefficient q_d (Pretzsch, 2005).

Data analysis included standard procedure for processing the experimental plots in order to obtain the quadratic mean diameters (d_g), the dominant diameters (mean diameter of the 100 thickest trees per hectare, D_{100}), mean height by Lorey (h_L) and dominant (top) height (mean height which corresponds to the diameter of the 100 thickest trees per hectare in the plantation, H_{100}) for each studied tree species. The function of Mihajlov was used for the construction of height curves ($h=a\cdot e^{-b/dbh}+1.3$). Stand volume was obtained using the volume tables for poplar clone Pannonia (Pantić et al, 2013), and for black locust (Cestar and Kovačić, 1982).

Results and disscussion

In the investigated two-storey culture up to 10 years, on the experimental plots, the survival rate of poplar trees was 82-86%, and of black locust trees was 77-78% (Table 1).

Growth elements of the mean and dominant tree of poplar clone Pannonia are smaller in EP-1 compared to EP-2. The difference between the dominant heights of poplar trees on experimental plots of 3.7 m (20%) indicate differences in site index of the stands. Differences in mean Lorey's heigh are even larger and amounts to 4.3 m (25%). The mean and dominant diameter of poplar clone Pannonia in EP-2 are higher by 4.8-4.9 cm (26-32%), i.e. for the entire diameter degree, compared to EP-1. Although there are approximately the same number of poplar trees on both experimental plots, basal area and volume per hectare are lower in EP-1. Basal area per hectare of poplar clone Pannonia in the experimental plot EP-2 are higher by 65% and volume by 99% compared to the EP-1 (Table 1, Figure 1).

Table 1. Basic growth elements in the experimental plots.

Experimental plot	Species	d_g [cm]	D_{100} [cm]	h_L [m]	H_{100} [m]	N [trees·ha^{-1}]	G [m^2·ha^{-1}]	V [m^3·ha^{-1}]
	Poplar	15,5	18,5	17,35	18,72	343	6,50	52,26
	Black locust	5,2	10,3	10,13	13,03	2802	6,03	44,09
EP-1	Total					3145	12,53	96,35
	Poplar	20,4	23,3	21,68	22,41	330	10,74	103,82
	Black locust	5,8	11,4	11,62	15,20	2759	7,21	54,16
EP-2	Total					3089	17,95	157,98

Mean and dominant height of black locust trees on the EP-2 were higher by 1.5-2.2 m (15-17%) compared to the EP-1, while the mean and dominant diameters were higher by 0.6-1.1 cm (11-12%). On both experimental plots was found approximately the same number of 2760-2800 black locust trees per hectare. Basal area of black locust trees on the EP-1 amounted 6.0 m^2·ha^{-1}, and volume 44.1 m^3·ha^{-1}, while those on the EP-2 were greater by 20-23% (Table 1).

The total volume of poplar and black locust trees on the EP-1 amounted 96 m^3·ha^{-1}, and on the EP-2 was 158 m^3·ha^{-1}.

Mean and dominant diameters of black locust trees amounted 0.28-0.34 and 0.49-0.56 of the diameter of poplar trees, respectively. Mean heights of black locust trees amount 0.54-0.58, and dominant heights 0.68-0.70 of poplar tree heights. The relative share of mean and dominant diameters and heights of black locust in relation to the poplar were greater on the EP-1, or on the experimental plot with the lower site index. Similar to heights and diameters, and relative share of basal area and volume per hectare of the black locust in relation to the poplar were greater on the plots with lower site index in which amounted to 0.93 and 0.84, respectively (Table 2).

Table 2. The ratio between growth elements of black locust and poplar trees in the experimental plots.

Experimental plot	Ratio	d_g	D_{100}	h_L	H_{100}	N	G	V
EP-1	Black locust / Poplar	0,34	0,56	0,58	0,70	8,17	0,93	0,84
EP-2	Black locust / Poplar	0,28	0,49	0,54	0,68	8,36	0,67	0,52

Height curves, obtained by the function of Mihailov, show good agreement for both tree species. The coefficient of determination is slightly higher, and the standard error of regression is lower in poplar compared to black locust and indicates a better fit of empirical values with the model (Table 3, Figure 1).

Height curves of black locust have a greater curvature in thin diameters and indicate the presence of trees with smaller diameters and heights. Higher site index (EP-2), causes more pronounced separation of height curves in both, poplar and black locust (Figure 1).

Table 3. The parameters of the height curve model and the elements of the model assessment.

Species	Experimental plot	Model: $h = a \cdot e^{-b/dbh} + 1.3$		Model assessment		
		a	b	R^2	s_e [m]	n
Poplar	EP-1	25.82272	7.587266	0.8651	0.6036	42
	EP-2	28.47813	6.891195	0.8946	0.4581	41
Black locust	EP-1	16.85545	3.933335	0.7563	1.1609	35
	EP-2	19.39680	4.141521	0.8614	1.0832	31

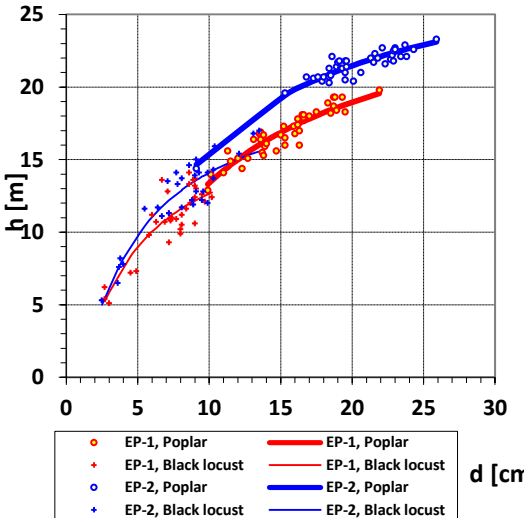

Figure 1. Heigth curves in experimental plots

On the experimental plots nominated 169 (EP-2) and 204 (EP-1) black locust trees for tending per hectare. Mean diameters of black locust trees for tending amounted 8.2-9.6 cm, mean heights 12-14.2 m, and the total volume 8.27-10.16 $m^3 \cdot ha^{-1}$ (Table 4).

Direct competitors of nominated black locust trees for tending were removed in the lower storey, a total of 507 trees per hectare in the EP-1 and 829 trees per hectare in the EP-2. The mean diameters of the felled black locust trees amounted 6.1-6.8 cm and the mean height amounted 11.2-11.5 m. Total of 25 non-perspective poplar trees with a volume of 1.66 $m^3 \cdot ha^{-1}$ were removed on the EP-1. Total basal area and volume, which were removed by the thinning operation, were 1,97-2,39 $m^2 \cdot ha^{-1}$ and 14,43-17,74 $m^3 \cdot ha^{-1}$, respectively (Table 4).

The total number of black locust trees, which were removed by the thinning, was 17% on EP-1 and 30% on EP-2 in relation to a total number of black locust trees on experimental plots. The removed volume amounted 29% (EP-1) and 33% (EP-2) in relation to the total volume of the black locust trees. The thinning coefficient (q_d) was 1.08 in EP-2 and 1.39 in EP-1 and thinning can be described as heavy thinning from above.

Significant variability of the growth elements of trees was found in the mixed two-storey culture of Euro-American poplar clone Pannonia, and black locust on the transect 100 m long, in the coastal part of the Danube, on the soil type fluvisol with very variable characteristics in a small area (Živanov 1982),

The differences of 3.7 m and 4.3 m, which were found between the top and the mean heights of poplar trees, respectively, indicate differences of the one site index class (Marković et al, 1987; Andrašev, 2008). The above is confirmed by the double higher volumes per hectare of poplar on a higher site index (EP-2) compared to a lower site index (EP-1), with a close number of trees, 330-340 trees per hectare.

According to previous research, poplar plantations of Euro-American clones, with spacing of 5 × 5 m, or 400 trees per hectare, provide the greatest amount of wood volume per hectare at a medium and favorable sites (Marković et al, 1997). In the poplar plantations established with a distance of 5 × 5 m, as well as in plantations with a distance of 6 × 6 m, by the age of 10-11 the canopy had been closed by the crowns of trees (Andrašev et al, 2012). In the experimental two-storey culture, despite the high percentage of survival of poplar trees up to 10 years (over

80%), there was no closing canopy on both experimental plots which favored to high percentage of survival of black locust trees on both experimental plots (about 78%) in the lower storey. In addition, black locust trees influenced to the cleaning of the lower branches of poplar trees, and thus to lower costs of tending measures in plantation due to the absence of pruning operation of lower branches that are regularly used in monocultures of poplars.
The growth elements of poplar and black locust trees and the previously mentioned indicates that the mixed cultures of poplar and black locust achieve greater wood volume per hectare compared to the pure cultures (plantations) of poplar at the age of 10 years.

Table 4. The main growth elements of trees for tending and felled trees.

Collective of trees	Experimental plot	Species	d_g [cm]	h_L [m]	N [trees·ha^{-1}]	G [m^2·ha^{-1}]	V [m^3·ha^{-1}]
Trees for tending	EP-1	Black locust	8,2	12,02	204	1,09	8,27
	EP-2	Black locust	9,6	14,24	169	1,21	10,16
Trees for cutting	EP-1	Poplar	11,3	14,21	25	0,24	1,66
		Black locust	6,8	11,22	482	1,73	12,77
		Total			507	1,97	14,43
	EP-2	Poplar			-	-	-
		Black locust	6,1	11,50	829	2,39	17,74
		Total			829	2,39	17,74

On the EP-1, which represents the lower site index class, black locust achieves smaller growth elements of trees and stand in relation to the experimental plot EP-2 on higher site index class. However, the growth elements of black locust trees and stands in relation to the growth elements of poplar is higher in lower site index class in relation to a higher site index class. This could be explained by shading of black locust by poplars, which on a higher site achieve greater heights, diameters and crown, and thus more overshadows black locust in the lower storey. On the lower site index, which represent EP-1, due to the smaller size of poplar trees, black locust trees get larger amount of light, and their dimensions are determined primarily by site characteristics (site class).
On lower site index class trees reach smaller dimensions of diameter, height and crowns volume which causes the higher number of trees per hectare (Assmann, 1970). Given this fact, it can be concluded that maintaining a similar number of black locust trees up to 10 years on experimental plots with different site index classes is caused by favorable lighting conditions in the lower storey. A total number of poplar trees and black locust trees for tending is 499-547 per hectare, which is 25-37% higher than the initial number of poplar trees at the establishment of culture. Direct competitors of nominated black locust trees for tending were removed in the area of crown with the aim of intensifying their growth. Conducted thinning had the character of thinning from above (q_d = 1.08 to 1.39), whereby in the stand at a lower site index class (EP-1) two competitors of each tree for tending of black locust were removed, on average, while in the stand on a higher site index class (EP -2) on average, at least 4 direct competitors were removed.

Conclusion

Based on the number of trees and growth elements of two light-demanding tree species in the two-storey culture, at the age of 10 years, it can be concluded that the black locust trees had enough light for their growth. Growth elements of both tree species are determined by the influence of habitat (site index classes), and the growth of black locust, in great extent, is slowed on the experimental plot with higher site index class. The first thinning was performed

in order to allow more space for growth of selected black locust trees for tending, and heavier intensity is proposed on the experimental plot with higher site index class.

Acknoledgement

This paper was realized as a part of the project "Studying climate change and its influence on the environment: impacts, adaptation and mitigation" (43007) financed by the Ministry of Education and Science of the Republic of Serbia within the framework of integrated and interdisciplinary research for the period 2011-2014.

Abstract

Induced visible injury by ozone (O3) is that many plant species respond to ambient levels of ozone pollution with distinct visible foliar symptoms that can be diagnosed in the field. The results attributed to LEVEL II Serbia – Mokra Gora sites will be documented in maps covering Europe, characterizing areas of increased ozone risk for European forest ecosystems. Many plant species respond to elevated ambient levels of tropospheric ozone (O3) with distinct specific foliar symptoms. Harmonization of procedures is essential to ensure spatial and temporal data comparability. For the injury data being accepted for the international database and evaluations, National Focal Centers and their scientific partners that are participating in the UN/ECE ICP Forests program must follow the methods and apply the manual described herein. The assessment for visible ozone injury on main tree species is conducted on the leaves from the same branches where foliar analysis is carried out. The samples for foliar injury are collected every second year from the upper sun exposed crown. Methodologies, including quality assurance, such as data harmonization, completeness and plausibility tests have been applied according to the ICP Forests Manual, Parts VIII - Assessment of Ozone Injury. Specific targets are set as follows: quantification of injuries ozone on the selected parcel level II in Europe; detection of temporal trends in the selected plot level II in Europe (significant changes within 10 years with a 95% level of significance of individual plots).

Keywords: *foliar injury, experimental plot, ozone.*

Introduction

The essential basis for choosing ozone (O3) induced visible injury is that many plant species respond to ambient levels of ozone pollution withdistinct visible foliar symptoms that can be diagnosed in the field. The results attributed to LEVEL II sites will be documented in maps covering Europe, characterizing areas of increased ozone risk for European forest ecosystems. However, the development of ozone-induced injury is inter-and intra-species specific, and depends apart from local ambient ozone concentrationson other environmental such asbiotic and climatic factors. Due to the complex nature of the diagnosis and the given restrictions of the investment, results from the tree and vegetation assessment should be considered as semi quantitative.

From July to September, many plant species that are sensitive to elevated ozone concentrations, show visible injuries on the upper surface of the leaf mass. In addition to the apparent symptoms, the leaves of plants damaged ozone is smaller, and the plant may produce a smaller amount of healthy seed. Moreover, injuries may result in depletion of the sensitivity of plants to other damaging agents, such as harmful insects and fungi. In our climate, the best time to observe violations of ozone is from mid-July to mid-September. At higher altitudes, however, a violation of the ozone can be masked by staining the leaves in early fall.

Since the 1980s there are higher concentrations of tropospheric ozone, especially in the warmer half of the year, when the value of the ozone increase depending on weather

conditions and increased anthropogenic activities. While at humans ozone irritates the mucous membranes and restricts lung capacity, in plants attacks and destroys the cell walls or individual cells in the leaves. Over the past 50 years, a large volume of literature has documented O3 impacts on forest trees (see reviews by Kickert and Krupa, 1990; Miller, 1993; Skelly et al., 1997; Chappelka and Samuelson, 1998; McLaughlin and Percy, 1999; Krupa et al., 2000; Bytnerowicz et al., 2003; Percy et al., 2003).

Depending on the sensitivity of plant species and the concentration of ozone, depends and the visibility of damage to leaves or needles. The harmful effects of ozone is difficult to prove, because there is no chemical residues that can be analyzed and measured. Visibility damage on the leaves or needles is the only effect that professionals can easily detect. Tropospheric ozone background concentrations have increased 36% since pre-industrial times (IPCC, 2001). Ozone is known to impact forest trees in many ways including inducing visible foliar symptoms (Chappelka et al., 1999a; Schaub et al., 2005).

The aim of this study was to investigate the long-term, cumulative ozone concentrations in relation to the occurrence and development of visible foliar injury to leaf mass. In addition, in order to assess the impact of environmental factors (abiotic and biotic) that modify the information on air quality in a given forest ecosystems is evaluated experimentally established symptoms in the field, in order to develop a regional risk assessment based on monitoring of ozone and data modeling. So, are evaluated visible ozone depletion in the selected area (Level II) and evaluated the effect of tropospheric ozone at locations where monitors of ozone injury, as well as risk assessment of ozone effects on forest ecosystems. Methodologies, including quality assurance, such as data harmonization, completeness and plausibility tests have been applied according to the ICP Forests Manual, Parts VIII - Assessment of Ozone Injury. Specific targets are set as follows: quantification of injuries ozone on the selected parcel level II in Europe; Detection of temporal trends in the selected plot level II in Europe (significant changes within 10 years with a 95% level of significance of individual plots).

Results from a Stage II will be documented in maps covering Europe, characterized by an area of increased risk of ozone to European forest ecosystems.

Material and methods

The locality on which is a measuring station for monitoring the meteorogical data, within the IPCC project, is located in 20 department, GJ "Mokra Gora - Panjak" in the logging camp "Užice".

Basic features of forest ecosystems on this site are as follows: elevation of 600 m; exposure is northwestern; the locality belongs to the type of white pine forest (*Pinus sylvestris* L.) on clay soil. The culture are 35 years old.

The goal is to collect needles from trees representative of the experimental plot from which the sampling is performed again, twice during the growing season. Sampled needles should then be divided by categories, the one-year and two years.

Score of experimental samples for the presence of damage of ozone is carried out at certain chemical reactions, and the special equipment, by laboratory methodology. For sample preparation is necessary related equipment and a certain amount of dedicated substances. The analytical techniques are used because on the narrow vegetation or tree needles it is difficult to determine damage by ocular methode. In the tables damages are grouped according to the degree of damage and the manner in which recorded occurrence was shown (Tables 2).

The main objective of assessing ozone visible injury on a selected number of Level II plots is to assess the effect of tropospheric ozone at the sites where ozone monitoring is performed, and to contribute to an ozone risk assessment for European forest ecosystems.

For the in-plot assessment, the following variables are measured: Symptomatic leaves or needles, reported as frequency classes (% score of symptomatic leaves for each sampled branch per IM plot).
Ozone visible injury on conifer species is expressed at the upper parts of the crown, in the upper side of branches and needles. For identification follow the criteria below:

- Chlorotic mottling is the most common ozone-induced symptom described for conifer needles; it is the result of chronic exposure to ozone and can be described as yellow or light green areas of similar size without sharp borders between green and yellow zones. However, not all needles in a fascicle may be uniformly affected.
- Chlorotic mottling frequently appears only in needles older than 1 year (second-year needles and older). That is, the observed symptom seems to increase with increasing needle age (age effect).
- Chlorotic mottling is more distinct on light-exposed needle areas in comparison to shaded ones (shade effect).
- It is easier to observe the mottling, if several needles are held close to each other, forming a “plane” of needles.

Results and discussion

Ozone visible injury on conifer species is expressed at the upper parts of the crown, in the upper side of branches and needles. A minimum of 3 branches per tree and 5 trees per plot are assessed. For off-Plot are measured variable, and they are shown in Table 1.

Tabele 1. Scoring and definition for the percentage of symptomatic leaves on a branch with approximately 30 leaves

Score	Frequency class (%)	Definition
0	No injury	None of the leaves are injured
1	1 - 5 %	1 – 5% of the leaves per branch show ozone symptoms
2	6 - 50 %	6 – 50% of the leaves per branch show ozone symptoms
3	51 - 100 %	51 – 100% of the leaves per branch show ozone symptoms

Samples were taken for laboratory analysis from 3 branches for all five trees on which were done evaluation of damage (trees numbered 153, 157, 283, 322 and 350). Also, samples were taken (three branches) from five trees from the edges of the stand. Needles are cut to length by 3 mm and placed in an Eppendorf cuvettes, in which are prepared solution (2.5% glutaraldehyde in Sorrensenovom buffer pH 7.0). Samples are immediately di pinto Eppendorf vials with accurate labels. In lab fixative solution were renew,remove the air in samples by vacum evacuation using an excicator connected to vacuum pump. Then we were done microscopical analysis.
Results are presented in Tables 2 and Table 3. In Table 2 are showen ozone injury of the trees within stands (trees numbered 153, 157, 283, 322 and 350).

Tabela 2. Assessment of damage from ozone on the assimilation organs of ***Pinus sylvestris* L**

No	**153**			**157**			**283**			**322**			**350**

0	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+
1															
2															
3															

The results presented in Table 2 show that damages are the same even it depends of possition of the tree in the stands, or from their exposure.
The bole and other crown variables that are associated with growth and overall tree vigor can respond to elevated ozone exposures. Branch mortality in the lowest portion of the crown has been observed in southern California (Parmeter, 1968.) leading to a decrease in vertical crown length, as measured by percent live crown (Stark, 1968.). A reduction in the vertical and radial growth of stems has been documented for ozone-stressed trees in southern California and southern Sierras (McBride, 1975.).

Picture 1, 2and 3 – Level II - Mokra Gora

Conclusion

- Negative operation of photo oxidants with ozone as the main compound was observed on vegetation in Europe since the 80s of the last century. The problems caused by these influences in more detail have been studied over the last decade.
- There is evidence that ambient concentrations of ozone can cause different effects on vegetation including visible lesions on the leaves, reducing growth and yield, and increased sensitivity to biotic and abiotic stresses further. It was concluded that the increase in the concentration of ozone not only has a negative effect on the production of wood (reducing to 10 %), but can also lead to unstable conditions in the forest ecosystem.
- Determining the symptoms of ozone damage to the main tree species in the ICP Forests in bio-indicating points level II subject to ongoing monitoring of the last few years in Europe. Minimum 3 brances by tree and 5 trees by parceles are controled. Experiment were made on red fir and locality Mokra Gora. Based on results, there were no damage by ozone on our experimental plot.

Acknowledgments

The study was carried out within the Project TP-31070: “The development of technological methods in forestry in order to attain optimal forest cover “, financed by the Ministry of Education, Science and Technological Development, Republic of Serbia.

Abstract

This paper shows the analysis results of morphometric characteristics of Turkish hazel (*Corylus colurna* L.) one-year-old seedlings, their inter-connection and the relation of morphological indicators of the planting material quality that all have been observed in repetitions in three successive years of research. Except the height and the root collar diameter the following morphometric characteristics have been measured: root length, weight of aboveground part of plant (shoot) in absolutely dry condition and weight of underground part of plant (root) in absolutely dry condition. Also, the ratio of diameter and height as well as the quality index of seedlings were calculated. The quality index which includes the height, root collar diameter and their relationship, as well as the weight of aboveground and underground part of the plant in absolutely dry condition and their relationship can be considered the most comprehensive morphological indicator of quality. Beside the quality index the height and the diameter are the good quality indicators, too – especially the diameter due to stronger correlation with the quality index. Both the weight of aboveground and the weight of underground part of the seedlings in absolutely dry condition have the strongest positive dependence with the quality index. The advantage of height and diameter for the assessment of quality is in the method of quantifying these characteristics, because the measurement of the weight is a “destructive” method.

Keywords: *Turkish hazel (Corylus colurna L.), morphometric characteristics of seedlings, quality index*

Introduction

World Wildlife Fund announced in 1999 that the natural biological wealth of the Earth in the period from 1970 to 1995 decreased by 30% (Loh et al., 1999). Therefore, in recent years special attention has been paid to forest fruit trees whose introduction into existing forests and use for afforestation of non-stocked forest land contribute to improvement of the existing status of biodiversity and natural biological wealth.

Turkish hazel (*Corylus colurna* L.) due to its morpho-physiological, anatomical, ecological and technological characteristics has a special place in the forest communities. This fruit tree is a tertiary species which is widespread in the Balkans since the Oligocene (Tucović, 1970). Experience has shown that in afforestation, beside a proper selection of species, the characteristics of the planting material have to be taken into account because that is very important for the success of afforestation. Using of poor-quality planting material can reduce the percentage of acceptance, survival and growth of seedlings in the field and increase the costs for maintenance of forested areas (Oliet et al., 2009).

Determination of planting material quality is mostly based on relatively simple measurement of morphological characteristics (Thompson 1985; Pinto et al 2011) and their good correlation with the success of survival after transplanting (Dey and Parker 1997; Rose et al., 1997). Among the most-used morphological characteristics are the root collar diameter and the height of seedlings. However, these two directly measured characteristics are not individually sufficient to assess the quality (Haase, 2008). Therefore, the derived indicators are commonly

used, such as Dickson's quality index (Dickson, 1960) which connects the height, diameter and weight of seedlings in dry condition; Roller's sturdiness quotient (Roller, 1977), which is the ratio of the height and the root collar diameter.
Calculation of the quality index is an "aggressive" method because it requires to "destroy" a certain number of seedlings for measuring dry mass of shoot and root and to have more measured characteristics. In this research it was separately analyzed the correlation of quality index with directly measured parameters height and diameter.

Material and method

Seed of Turkish hazel was collected from the same tree and planted in three successive years. It was collected from the tree located in the Arboretum of the Forestry Faculty in Belgrade, at 44° 46' 59" N latitude and 20° 25' 29" E longitude, at an elevation of 97 m. Seed was stratified with cold moist stratification (temperature 0-5 °C) in sand for 5 months and thus prepared for spring sowing. 50-100 fruits per meter were sown in early April at a depth of about 5-6 cm. The seed was sown in the substrate *Tref PS fine brown*. The substrate is in the fraction of <8 mm and has a pH of 5.8 (± 0.3) and it is a mixture of peat and perlite in the ratio of 9:1, and peat mixture is 70% white and 30% black peat (Ćirković-Mitrović, 2014).
At the end of the vegetation period on a sample of 90 seedlings were measured height, root collar diameter, root length, oven-dry mass (weight) of aboveground part of plant and of oven-dry weight of root. The weight in absolute dry condition was measured after plant drying in a dryer type *Binder*, at a temperature of 105 °C for a period of 48 hours. It was also determined Roller's sturdiness quotient (Roller, 1977), weight ratio SW/RW and Dickson's quality index (Dickson, 1960).
Basic statistical indicators of morphometric characteristics, as well as the linear correlation between them (Pearson's correlation coefficient) were obtained using software package Statistica 7.

Results and discussion

The average height of measured seedlings in all three years of research is 21.3 cm, ranging from 12.5 to 36.5 cm (amplitude is 24 cm). Most of tested seedlings, 95.6%, were higher than 30 cm. The root collar diameter is 4.58 mm in average, varying from 2.99 to 6.87 mm. The diameter of most plants (43.3%) is between 4 and 5 mm. The average root length is 216 cm; the shortest root length is 107 cm and the longest 420 cm. The average root weight in dry condition is 1.57 g and it is greater than the average weight of aboveground part of seedling, which is 1.43 g. Root weight ranging from 0.75 g to 2.98 g, and the shoot weight ranging from 0.84 to 2.50 g. The ratio of height and root collar diameter is 4.68 and the ratio of weight of aboveground and underground plant part (shoot weight and root weight) in absolutely dry condition is 0.92 in average. The average value of the quality index for all three years of research is 0.54 (Table 1).

Table 1. Basic indicators of descriptive statistics for average values of morphological characteristics of Turkish hazel one-year-old seedlings in three successive years of research

	Mean	Minimum	Maximum	Variance	Std. dev.	Standard error
H (cm)	21.3	12.5	36.5	18.26	4.273	0.260
D (mm)	4.58	2.99	6.87	0.60	0.776	0.047
RL (cm)	216	107	420	4247.14	65.170	3.966
RW (g)	1.57	0.75	2.98	0.14	0.378	0.023
SW (g)	1.43	0.84	2.50	0.13	0.362	0.022
H/D	4.68	2.90	6.83	0.36	0.603	0.037
SW/RW	0.92	0.44	1.64	0.02	0.143	0.009
QI	0.54	0.30	0.90	0.01	0.124	0.008

H – average height, D – diameter, RL – root length, RW – root weight, SW – shoot weight, H/D – height/diameter ratio, SW/RW – shoot weight/root weight ratio, QI – quality index

The statistical analysis of the height of the seedlings showed that there were no significant differences in the size of this morphometric characteristic between three examined years of research (Table 2). The analysis of the root collar diameter of one-year-old seedlings in three years of research showed that in the first and the third year were achieved the significantly greater root collar diameters with respect to the second year (Table 3).

Table 2. Basic indicators of descriptive statistics for the height of Turkish hazel one-year-old seedlings in three successive years of research (2011, 2012 and 2013)

Year	Height (cm)	Minimum	Maximum	Variance	Std. dev.	Standard. error	Coefficient of variation
2011	21.6[a]	12.5	36.5	19.32	4.39	0.46	20.32
2012	21.1[a]	14.1	34.1	21.33	4.62	0.49	21.89
2013	21.4[a]	13.8	30.8	14.44	3.80	0.40	17.76
average	21.3	12.5	36.5	18.26	4.27	0.26	20.05

Mean values in the same column followed by different letter are statistically different for $p<0.05$ (Post hoc Tukey's HSD test)

Table 3. Basic indicators of descriptive statistics for the root collar diameter of Turkish hazel one-year-old seedlings in three successive years of research (2011, 2012 and 2013)

Year	Diameter (mm)	Minimum	Maximum	Variance	Std. dev.	Standard. error	Coefficient of variation
2011	4.84[a]	3.09	6.87	0.72	0.85	0.09	17.56
2012	4.17[b]	2.99	5.38	0.39	0.62	0.07	14.87
2013	4.71[a]	3.16	6.41	0.46	0.68	0.07	14.44
average	4.58	2.99	6.87	0.60	0.78	0.047	17.03

Mean values in the same column followed by different letter are statistically different for $p<0.05$ (Post hoc Tukey's HSD test)

The results of these researches are similar to the results that have been obtained by Ninić-Todorović et al. (2007) that showed that the height of Turkish hazel one-year-old seedlings of different genotypes ranged from 26.77 to 49.27 cm and the root collar diameter ranged from 5.76 to 12.22 mm. However, Ninić-Todorović et al. (2012) in their subsequent researches have found the average height of Turkish hazel seedlings from 13.48 to 17.82 cm, the average root collar diameter of 5.66 to 5.89 mm, the average root weight of 2.93 to 4.18 g and the average shoot weight of 1.80 to 2.81 g depending on the genotype of these seedlings. Considerably higher dimensions in the previous research authors attributed to favorable environmental conditions and intensified tending in the nursery with the aim of forcing Turkish hazel seedlings for successful grafting in the first year of development.

Table 4. Correlation of the studied indicators of quality of Turkish hazel one-year-old seedlings

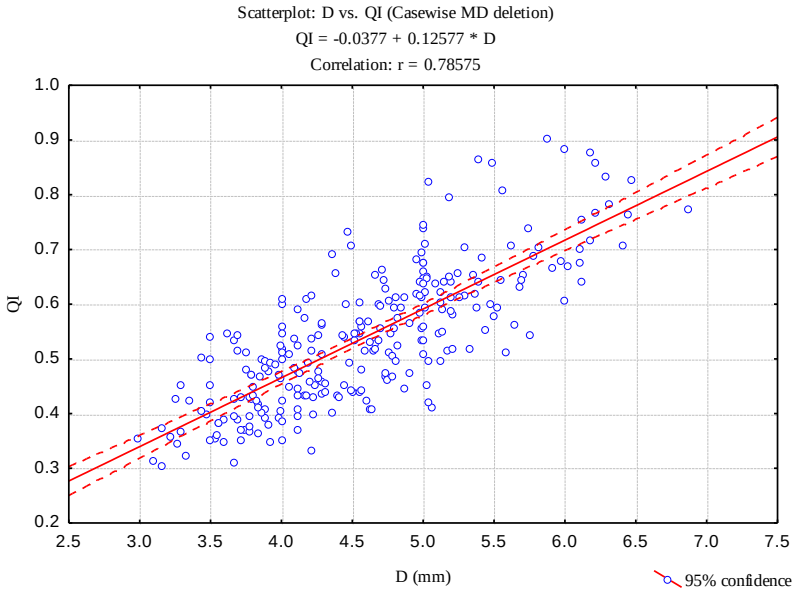
	H (cm)	D (mm)	RL (cm)	RW (g)	SW (g)	H/D	SW/RW	QI
H (cm)	1.00							
D (mm)	0.76**	1.00						
RL (cm)	0.35**	0.47**	1.00					
RW (g)	0.78**	0.67**	0.26**	1.00				
SW (g)	0.68**	0.67**	0.25**	0.81**	1.00			
H/D	0.53**	-0.15*	-0.08	0.31**	0.16*	1.00		
SW/RW	-0.11	0.04	-0.02	-0.24**	0.36**	-0.21**	1.00	
QI	0.54**	0.79**	0.31**	0.85**	0.85**	-0.20**	0.04	1.00

Correlations – Labels for t-test: * - correlation is significant for $p<0.05$; ** - correlation is significant for $p<0.01$ N=180
H – average height, D – diameter, RL – root length, RW – root weight, SW – shoot weight, H/D – height/diameter ratio, SW/RW – shoot weight/root weight ratio, QI – quality index

Between height and all other studied morphological characteristics, except the ratio of weight of aboveground and underground part of the plant in absolutely dry condition, there is a significant positive correlation. The strongest relation is with the weight of underground part in dry condition (0.78) and the weakest with the root length (0.35). A great relationship was recorded between the root collar diameter (0.76) and the weight of aboveground part in dry condition (0.68).

The root collar diameter of seedlings shows the strongest correlation with the quality index (0.79) and the lowest with the root length (0.35). Poor negative significant correlation exists between the root collar diameter and the ratio of height and root collar diameter. A great correlation was found with the weight of aboveground part (0.67) and weight of underground part in absolutely dry condition. Similar relations of morphometric characteristics in one-year-old seedlings of wild cherry determined by Stjepanović and Ivetić (2013) as well as by Binotto et al. (2010) found that the root collar diameter is the best single morphometric indicator of quality, showing a strong correlation with the quality index. The root collar diameter is significant in predicting future performances when transplanting seedlings into the field (Mattsson, 1996; Rawat and Singh, 2000; Davis and Jacobs, 2005) and a method for measuring this characteristic is simple in comparison to measurements of characteristics necessary for calculating the quality index.

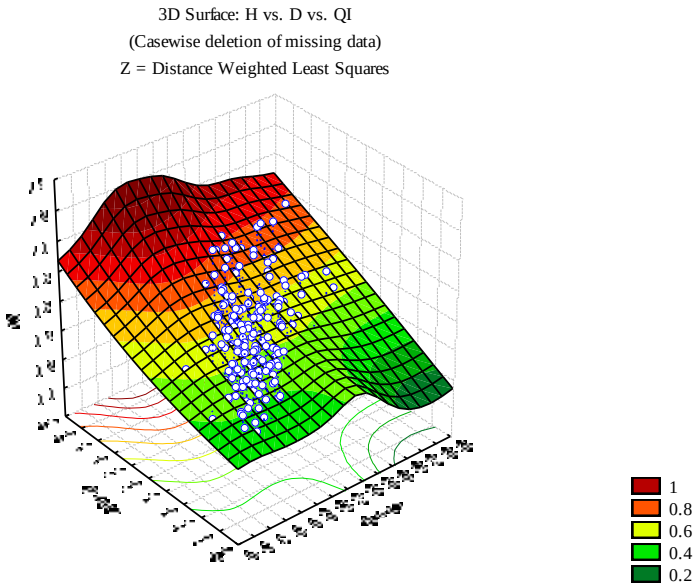
The graph 1 shows the dependence of QI and root collar diameter.



Graph 1. Regression analysis – linear dependence of quality index and root collar diameter

The strongest significant correlation was found between the quality index and the weight of aboveground part (0.85) and underground part of the seedlings (0.85) in dry condition. This was expected due to the method of calculating the quality index (Binotto et al., 2010; Stjepanović and Ivetić, 2013).

Graph 2 shows the dependence of quality index variable in relation to the height and the root collar diameter. With the increasing of the root collar diameter constantly is being increased the value of the quality index. When increasing the height of seedlings with the largest root collar diameter the quality index increases to average value of the height and then it starts to decrease. In seedlings with smaller root collar diameter the value of the quality index is equable. In seedlings whose height is around 20 cm to seedling with height of around 26 cm the quality index increases and afterwards its values decline.



Graph 2. *Area of a combination of height (H) and diameter (D) as a predictor as opposed to Quality Index (QI) as the dependent variable*

Conclusions

The analysis of morphological indicators of quality of Turkish hazel one-year-old seedlings led us to the conclusion that the height and the root collar diameter are good quality indicators, but the root collar diameter shows stronger correlation with the quality index than the height.

Both the weight of aboveground and the weight of underground part of the seedlings in absolutely dry condition have the strongest positive dependence with the quality index. The advantage of height and diameter for the assessment of quality is in the method of quantifying these characteristics, because the measurement of the weight is a “destructive” method.

The quality index which includes the height, the root collar diameter and their relationship, as well as the weight of aboveground and underground part of the plant in absolutely dry condition and their relationship can be considered the most comprehensive morphological indicator of quality.

APPLICATION OF GENETIC MARKERS IN DETERMINATION OF FOREST TREES SEED ZONES IN SERBIA

Vasilije ISAJEV[1,3]*, Saša ORLOVIC[2], Milena STANKOVIĆ[3], Stefan STJEPANOVIC[3]

[1]Faculty of Forestry, Belgrade, Serbia
[2]Institute of Lowland Forestry and Environment, Novi Sad, Serbia

Abstract

Studying genetic potential and characteristics of different habitats of seed stands of black pine (*Pinus nigra* Arnold), Norway spruce (*Picea abies* Karst), Scots pine (*Pinus sylvestris L.*), and beech (*Fagus moesiaca* Domin./Czezccott) was base for separation of forest trees seed zones of these species in Serbia. In conveyed studies the testing of structure of the genome of their population was done by protein markers application as the most often used polimorphic markers at the level of gene products and molecular DNA markers based on PCR phenomenon. Results of analyses revealed that interpopulation diversity within these species was greater than that registered among their seed stands. Genetic distances between analyzed seed stands were obvious, so the future seedlings production as well as domestic and international trade of seed material should be realized in accordance with these results. On the basis of obtained results the seeds zones were separated, and of Austrian pine, spruce, Scots pine and beech in Serbia were defined.

Key words*:* *Austrian pine, spruce, Scots pine, beech, seed zones, Serbia*

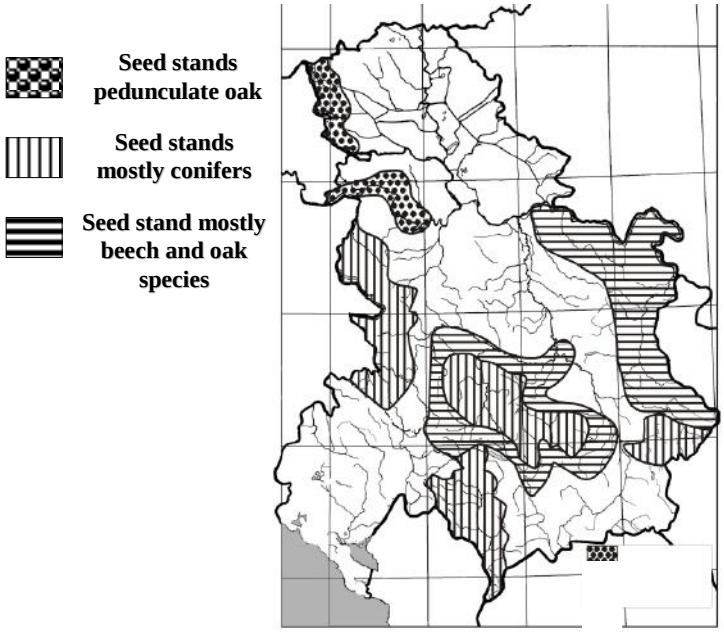
Introduction

Study of potential and spontaneous trait variability, which influences the generative multiplication and yield of tree species in a lesser or a greater extent, is necessary for organization of production and seed material trade control. Production, trade and usage of seed of tree species should exclusively be organized at the level of seed zones, seed stands, and seed trees, Isajev et al. 1999, 2002. Revision of existing, and nomination and separation of new seed stands of economically important species such as Austrian pine (*Pinus nigra* Arnold), Norway spruce (*Picea abies* Karst), Scots pine (*Pinus sylvestris L)* and beech (*Fagus moesiaca* /Domin./Czezccott) are permanent activities, and they are of a primary significance for forestry in Serbia. These activities should be synchronized with activities of lumber camps and scientific institutions because some stands are aged or destroyed by climatic factors or insects, diseases and anthropogenic factors, and they should be replaced with new and young stands satisfying prescribed criteria, which should be registered as seed objects, Djorović et al. 2003. Success of these activities is associated with separation and limitation of areas where appropriate new selections can be used. Aimed at running the above mentioned activities, the investigations encompassed the following:

- Determination of the precise area of these species in Serbia
- Geographic distribution, geographical latitude and longitude, scope of heights above sea level, area, location;
- Definition of ecological characteristics of their populations – climatic, pedological, phyto-cenological etc.
- Separation of seed zones, and
- Creation of maps of seed zones in GIS

Material and methods

To meet the need for the increasing quantity of diverse and selected forest seeds, numerous seed sources were designated in Serbia, to ensure the production of good quality nursery stock. According to the Register of Sees Sources of the Ministry of Agriculture and Forestry of the Republic of Serbia, the number of seed sources in Serbia is 310, on the area of 2,135.85 ha, which is 0.095% of the total area of the forest land in Serbia (2,360,400 ha)., map 1.



Map no 1. Distribution of natural seed sources in Serbia

Establishment of field experiments network enabled testing of seed stand of Norway spruce, Austria pine, Scots pine and beech, i.e. seed zones of these species in Serbia. Multi-annual studies in Serbia included ecological characteristics and stand condition of seed objects and productivity and yield quality of individual subpopulations, which is the basis for location of seed objects, i.e. separation of seed zones. Studies at population level – in seed stands and in laboratories (Faculty of forestry, Belgrade, Institute of forestry, Belgrade, and in the Laboratory of biotechnology, Institute of maize “Zemun Polje”, Zemun) have been carried out since 2003. Fieldwork was carried out in seed objects, table 1.

The following activities were completed in seed stands, table 1:

- Test trees were separated by applied method of individual selections (candidate, evaluation and marking). Ten test trees were selected as working sample in each seed stand - total of 460 mother trees were separated for analyses.
- Collecting plant material – cones and seeds for laboratory analyses was collected.
- Cones and beach nuts were selected and seeds were extracted for determination of genetic similarity i.e. genetic diversity of these species growing in different populations;
- For determination of genetic similarity i.e. genetic diversity of different populations of Norway spruce, Scots pine and beech under laboratory condition one year old assimilation organs were used;
- Collected plant material was properly packed and frozen until usage.

In the laboratories of Faculty of forestry and Institute of forestry in Belgrade samples were prepared for biochemical and genetic analyses using crypto technique and mechanical processing, aimed at determining the degree of similarity between seed zones within the same and different regions.

Table no 1. Seed objects where field works were carried out

SPECIES	FOREST ESTATES	TOTAL NUMBER OF SEED STAND
Austrian pine *Pinus nigra Arnold,*	„Forestry" Raška (2), L.C. "Prijepolje" Crijepolje, L.C. "Užice" Užice, L.C. "Stolovi" Kraljevo, TB „Goč“ Faculty of forestry, Beograd	**6**

Determination of genetic similarity i.e. diversity of different seed zones of the above mentioned species was done in the Laboratory of biotechnology of the Institute of maize “Zemun Polje” Zemun, using standard methods for protein isolation (according to Wang C.,et al.1994) from seeds and DNA marker technique based on PCR method (according to Jones C.J. et al.1998,

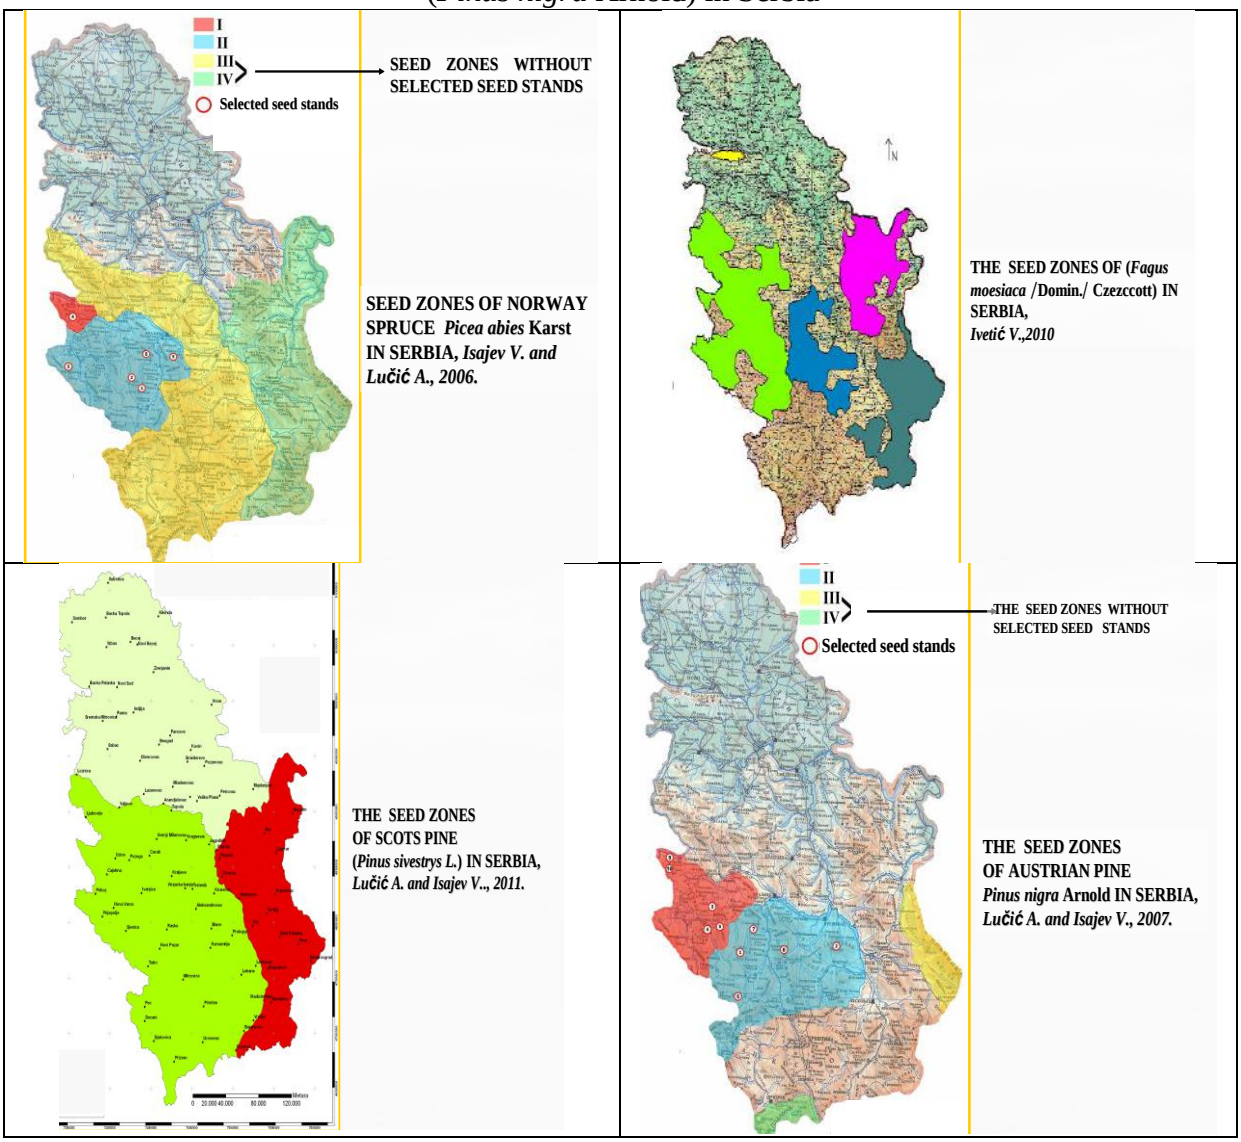
Results and discussion

Spatial distribution of seed zones, map 2. encompassed the greatest part of cenological, ecological and population diversity in Serbia. Improvement of forest seed science, application of contemporary methods of forest genetics and forest typology led to better understanding of the type of adaptability, productivity and quality of individual subpopulations, which provided production of quality seed of economically important tree species. Separation of seed zones was initiated by ecological-geographical studies, and analyses of genetic distance between seed stands run by application of genetic markers made it precise.

Investigation of genetic structure of the seed zones of these species acquiring information regarding group and individual variability. Applied genetic markers were the tools for better understanding the nature of; a) genetic similarity, i.e. diversity of populations studied by analysis of protein complexes from assimilation organs; b) interrelation of ecological traits characteristic for habitats from which samples originated. Results obtained by applied genetic markers revealed that inter-population diversity was higher than it was registered within studied Norway spruce, Austria pine, Scots pine and beech seed stands. On the basis of obtained results seed zones in Serbia were defined in accordance with the Law on reproductive material of forest trees (Articles 6 and 7), map 2.

Since genetic distance was determined between analyzed seed stands intended for nursery production, the trade of seed material should be realized in accordance with defined seed zones regions.

Map no 2. Spatial distribution of seed zones of, Norway spruce (*Picea abies* Karst), beech (*Fagus moesiaca* /Domin./Czezccott) Scots pine (*Pinus sylvestris L)* and Austrian pine (*Pinus nigra* Arnold) in Serbia



The aim of preserving genetic specificity of natural populations of these species has two aspects: genetic differentiation, and preservation of gene pool of these species (*in-situ* and *ex-situ*).

Areas and continuation of Norway spruce, Austria pine, Scots pine and beech forests are such that it is practically impossible to separate greater complexes of seed objects, so the selection must be directed toward separation of group of trees or individual trees, Mataruga et al. 1998, 2005. According to the **Spatial plan of the Republic of Serbia** and **National Strategy of forest development**, by which the huge work relating to aforestations was predicted, it is necessary to separate the seed zones and seed objects in these areas as the carriers of seed and seedlings production.

Analyses of protein content in assimilation organs of 400 test trees were used to test genetic structure of seed stands and some information on population and individual variability of

spruce, Austrian pine, Scots pines and beech was obtained. Interaction between ecology traits characteristic of habitat of population from which assimilation organs originated and the results obtained by analysis of protein complexes was determined.
Analyses results revealed that assimilation organs of different seed stands had different protein patterns. Differences in number, distribution and intensity of protein fractions were determined. Genetic similarity within each seed object was calculated on the basis of analysis of needle-associated protein complex taken from mother trees. Cluster analysis of tested populations revealed expressed genetic diversity of studied populations illustrated by a dendogram.
Obtained results are the basis for future work on development of model of crossing of test trees of different seed stands, and it is supposed that the obtained hybrid seed will show heterosis. On the basis of: ecological characteristics of seed objects, yield quality obtained by biochemical analyses, and determinations of genetics distances among Austrian pine, spruce, Scots pine, and beech seed stands, the maps of seed zones for these species in Serbia were created (Maps 2,). These maps make the basis for more reliable trade of seed material within Serbia, and they are also needed for issuing documentation for the purpose of exportation.

Conclusions

The orientation to desired properties of seeds and nursery stock for the afforestation programmes requires the abandoning of the technology of seed and nursery stock production at the species level, because their quality is difficult to guarantee. Seed production should be organised at the level of seed zones, i.e. seed stands. Studying genetic potential and characteristics of different habitats of seed stands of black pine (*Pinus nigra* Arnold), Norway spruce (*Picea abies* Karst), Scots pine (*Pinus sylvestris L*.), and beech (*Fagus moesiaca* Domin./Czezccott) was base for separation of forest trees seed zones of these species in Serbia, and their transfer into the seed traits.
By studying individual or group variability and the genome structure of these speciess using protein markers as the most often used polymorphic markers at the level of gene products, and molecular DNA markers based on PCR phenomenon we should get better acquainted with the nature:

1. Mutual relationships between ecological traits, which characterize habitats of Austrian pine, Norway spruce, Scots pine, and beech stands, from which analyzed seed and assimilation organs originate, and results obtained by laboratory analyses;
2. Degree of variability of certain morphmetric characteristics of seed, and assimilation organs, and existence of mutual dependence between studied characteristics;
3. Genetic similarity, i.e. diversity among studied populations;
4. Separation of Austrian pine (*Pinus nigra Arnold*), Norway spruce (*Picea abies Karst*), Scots pine (*Pinus sylvestris L*.), and beech (*Fagus moesiaca* /Domin./ Czezccott) seed zones regions in Serbia.
5. Separated seed zones are presented on maps: four for Austrian pine, Norway spruce and Scots pine, and five for beech.

Abstract

Douglas-fir is one of the most productive and economically most important conifer species in Canada and North America. The large natural range in horizontal (from British Columbia to New Mexico) and vertical (from sea level to 2800 meters above sea level) terms is the reason of existing the great ecological, population and genetic variability of the species. Introduction of the species with such a wide natural range inevitably requires testing by the provenance test method. The analysis of development, adaptation and progress of plants in new site conditions is an important prerequisite for the selection of promising provenances.

The provenance test of Douglas-fir with the original seed originated from North America was performed in the system of field trials (random block system) on the area of 2.5 ha on the mountain Juhor in the Central Serbia. In this paper are presented results of development of 20 Douglas-fir provenances and these results refer to 28-year period since the founding of the experiment (plants at age of 32 years). The best results in terms of survival, diameter, height and volume growth showed the provenances from lower elevations of the coastal part of federal state Washington.

Keywords: *Douglas-fir, provenances, diameter, height, volume.*

Introduction

Douglas-fir (*Pseudotsuga menziesii* (Mirb.) Franco) is one of the most productive and economically most significant conifer species in Canada and USA. The large natural range in horizontal (from British Columbia to New Mexico) and vertical (from sea level to 2800 meters above sea level) terms is the reason of existing the great ecological, population and genetic variability of the species and a consequence of that is a great number of provenances (Göhre, 1958.). Introduction of the species with such a wide natural range inevitably requires testing by the provenance test method because it is necessary to have a prior knowledge about thriving of individual provenances.

Institute of Forestry in Belgrade in 1977 got seed of 20 different provenances originating from North America. The aim of this study was to determine which provenances grow best in Serbia, and for that reason three field trials in different environmental conditions have been established. This paper presents the results of field trial in mountain Juhor in central Serbia.

Material and methods

Douglas-fir field trial is located in FMU “Juhor I” department 53d managed by Forest enterprise Juzni Kucaj Despotovac, Forestry administration Jagodina, on the site of mountain beech (*Fagetum moesiaca montanum* Jov. 1976) forests, on elevation of 660-700 m. Douglas-fir seedlings were produced in the nursery of the Institute of Forestry in Belgrade from seed imported from North America. The seed originated from 20 provenances that have a different latitude, longitude and elevation and they cover a part of the natural range of species (Table 1). Produced seedlings were transplanted into the field (in 1982) at the age of 2 + 2 and the field trials were established on the principle of randomized block design, so-called “random

block system”. In the field trials were regularly carried out measures of tending and protection of seedlings.

Table 1: Geographical characteristics of Douglas –fir provenances from North America

Code	Mark	Latitude (° N)	Longitude (°E)	Elevation (m)

Oregon 204–04	30	45.0	121.5	900
Washington 205–17	31	47.7	123.0	300

In spring 2010, at plants age of 32 years or 28 years since the founding of the experiment, the measurements of diameter at breast and height were carried out and the survival of seedlings was recorded. Diameter at breast height was measured with an accuracy of 1 mm and height of the seedlings with an accuracy of 1 cm. For studied characteristics were conducted descriptive statistics, analysis of variance and for all testing the error of 5% was considered as statistically significant. Statistical analyses were done using the statistical package Statgraph 5.01.

Results and discussion

The survival of the plants ranged from 25 to 91.7 %. The highest percentage of survival had the provenance Oregon 205-08 and the smallest percentage the provenances Washington 204–07, Oregon 205-18 and Oregon 202-31 (table 2). Better results in terms of survival showed the provenances from lower elevations of western part of the species range. Similar conclusions in their researches reached (Dittmar, Knapp, 1987; Orlić, Perić, 2005; Schultze, Raschka, 2002).

Table 2. Survival of the plants

Code	Mark	Survival %
Oregon 205–15	1	58.3
Oregon 205–14	2	83.3
Oregon 202–27	3	75
Oregon 205–38	4	41.7
Washington 204–07	9	25
Oregon 205–13	10	66.7

Code	Mark	Survival %
Oregon 205–18	11	25
Oregon 202–22	12	50
Washington 202–17	15	66.7
Oregon 201–10	16	41.7
Washington 201–06	17	66.7
Oregon 202–19	18	75
Oregon 205–11	20	66.7
New Mexico 202–04	22	33.3
New Mexico 202–10	23	58.3
Oregon 202–31	24	25
Oregon 205–29	26	50
Oregon 205–08	27	91.7
Oregon 204–04	30	58.3
Washington 205–17	31	66.7

The diameter at breast height of plants at age 32 ranged from 13.8 to 32.1 mm. The best result had the provenance Oregon 205–29 and the worst the provenance Washington 204–07. Maximum value of diameter at breast height of 43.3 cm was measured in provenance Oregon 205–14. Minimum value of diameter at breast height of 12 cm was measured in provenance Oregon 201–10. The greatest distribution of measured values of diameter at breast height around mean value was in provenances which had a more intensive growth (table 3). As with the plant survival, better results in terms of diameter at breast height showed the provenances from lower elevations of western part of the species range.

Table 3. Data on diameter at breast height of the plants

Code	Mark	Mean	Max	Min	SD
Oregon 205–15	1	25.6	33.6	14	9.02
Oregon 205–14	2	26.1	43.3	20.2	6.10

Oregon 202–31	24	14.6	14.6	13.2	0.99
Oregon 205–29	26	19.7	20.7	19	0.91
Oregon 205–08	27	18	20.6	16.6	2.25
Oregon 204–04	30	18.8	20.5	17.5	1.55
Washington 205–17	31	22	24	20.6	1.75

In provenance tests of Douglas-fir in Austria the best results have shown the provenances from lower elevations so their use is recommended in the future (Schultze, Raschka, 2002). The best provenances in Germany have been those from western part of the peninsula Olypic and western from Caseades Washington (Kleinschmit at all, 1991). The best results at plant age of 10 years in terms of quality and growth intensity in Bosnia has shown provenance Alberni from British Columbia from elevation of 150 m (Pintarić, 1989). In Douglas-fir trials in eastern Germany at plant age of 27 years the best results have shown provenances from lower elevations (Dittmar, Knapp, 1987). In Croatia the best results in terms of plant growth and survival have shown provenances from federal state Washington from lower elevations-to 300 m (Orlić, Perić, 2005). In Serbia at plant age of 20 years better results in terms of plant growth and survival have shown provenances from western part of the species range from lower elevations (Lavadinović et al. 2001).

Conclusion

The results on survival, diameter and height growth of Douglas-fir provenances presented in this paper make easier the operation of afforestation in conditions of Serbia and at the same time they show how significant is the seed origin for introduction in new stand conditions.

Results of growth and adaptability of Douglas-fir provenances at age of 32 show the potential of particular provenances. The best adaptive and development characteristics show provenances at lower elevations from western part of the species range.

Initiated researches have to be continued at later stages of development and it would certainly be very useful to conduct a research on the second generation. Only after these findings we could make more reliable conclusions and give recommendations for future afforestation.

EFFECT OF FOREST SITE TYPE ON THE GROWING STOCK OF FOREST-FORMING SPECIES UNDER CONDITIONS OF THE DNIEPER STEPPE, UKRAINE

Svitlana SYTNYK, Viktoriia LOVINSKA, Mykola KHARITONOV, Iryna LOZA

Dnepropetrovsk State Agrarian and Economical University, Voroshylova st., 25, 49060, Dnepropetrovsk, Ukraine

Abstract

In the article, it was carried out analyze of age structure and detection of regularities in average growing stock within stands from *Pinus sylvestris* L. and *Robinia pseudoacacia* L. under forest site conditions within the Dnepropetrovsk region. *Robinia pseudoacacia* stands reach the maximum growing stock (193.9 m^3/ha) in conditions of high moisture at the age of fifty years. Soil moisture influenced significantly on the timber volume per hectare in stands from *Robinia pseudoacacia*. *Pinus sylvestris* reached the highest values of average growing stock (323 m^3/ha) under mesic conditions in 7^{th} age class. Average growing stock in *Pinus sylvestris* under wet-mesic and wet habitat conditions was three times higher than the one under very dry conditions. Rising of soil fertility determined increasing of average growing stock in the *Pinus sylvestris* stands. The highest values of average growing stock were registered in 8^{th} age class within the bir and subir, and in 7^{th} class within the suhrud. When increasing the age, it is observed the maximum values of growing stock in the 8^{th} and 13^{th} age classes in the *Pinus sylvestris* and *Robinia pseudoacacia* stands, and decreasing of growing stock values at a later time. Under different moisture conditions, contrasting energy of growth of *Pinus sylvestris* and *Robinia pseudoacacia* caused significant differences in development and structure of their stands with age. Due to transition from optimum to the worst soil moisture conditions, it was observed decrease of shoot, fir needle and leaves formation, crown density, size of individual trees, and their resistance.

Key words: *Pinus sylvestris* L., *Robinia pseudoacacia* L., Dnieper Steppe, age structure, growing stock

Introduction

Poor forest cover in Steppe zone of Ukraine does not exceed 3–5 % of the total native area. It determines the spread of negative climate changes, especially desertification and deflation (Medvedev, 2001). In the Steppe zone, it is planned new forests stands with various functional purposes, where *Pinus sylvestris* (Scots pine) is actual species to create forests of recreational and functional categories. *Robinia pseudoacacia* (black locust) is used as species for protective afforestation (Koval et al., 2002).

Large variety of area and landscape within the Steppe zone provides a wide range of habitat conditions and their climatic characteristics. Therefore, to ensure reforestation and afforestation in the Steppe, it is need to consider in detail the types of habitat conditions (Geltman, 1983; Golubets, 2007; Koval et al., 2002; Turkevich et al. 1973; Vedmid′, 2010). Thus, it is important to use the combination of forest typology approach and forestry practice principles being an essential basis for successful functioning of forests in the Steppe. These issues were considered by the authors in scientific publications (Loza and Nazarenko, 2006; Bezrodnova et al., 2013; Lakyda and Lovinska, 2014; Lakyda and Sytnyk, 2014). An organism and environment unity allows considering the plant communities and their habitats as an integral consistent system. Rise of soil moisture and amount of organic matter within the sequence of trophogen gradation causes numerous qualitative transitions and leads to changes

in behavior of physiology-biochemical processes. It affects to productivity changes as an integral indicator of plant growth and development.

Current forest ecosystem survey is devoted to identification of mechanisms for formation of maximally efficient forest stands, and to determine effect of edatope abiotic factors on phytomass accumulation processes. Search of interdependence between abiotic habitat conditions, qualitative and quantitative productivity characteristics of the tree species is necessary for some applied purposes, formulation of forest management directions, and further development. According to E.S. Migunova, typological approach application improves significantly on quality of forest management. Issues of forest stands creation and cleaning cutting must be solved in accordance with the certain forest types (Migunova, 2014). Background of forest typology represents a reliable estimation of the forest site capacity in new forest planting and identification of definition of land typological. It allows to increase greatly the efficiency of forest melioration in natural areas, where lack of soil moisture is the main limiting environmental factor (Migunova, 2014).

To achieve maximal implementations of grow capacity and development of forest-forming species, it is necessary to establish influence pattern of the basic edatope characteristics: soil fertility (trophotope) and moisture (hygrotope) on the values of average timber resource in the main forest-forming species, as a quantitative forestry-biological index. The goal of this survey was to analyze of age structure and to detect of relationship in average timber resource formation for *Pinus sylvestris* and *Robinia pseudoacacia* under forest site conditions (nutrient status and soil moisture).

Materials and methods

The survey was conducted in the forest plantations with Scots pine and black locust subordinated to the Dnepropetrovsk Administration of Forest and Hunting Management during 2009–2014 years. Analysis of age structure and average growing stock in Scots pine and black locust was conducted on the basis of stratum database in forest inventory materials with mathematical statistics (Medvedev, 2001; Vedmid′, 2010). The indexes of actual area and growing stock have been used to calculate age classes that combine in age groups. The total sample size for Scots pine was 5158 stratums with the total area 21472.9 ha, and for black locust it was 4739 stratums with the total area 17683.7 ha.

The classification schemes of trophotops and hygrotops is based on the edaphic factors, such as soil fertility and humidity. Soil fertility is characterized by trophogenic sequence and denoted by the letters A, B, C, and D. Each individual unit of trophogenic sequence called trophotope. Each trophotope is represented by the forest site with equal soil fertility within its boundaries, distinguished from the next by one gradation (Pogrebnyak, 1955). Trophotope "A", "bir" or “pure pine forest”, indicate very poor soil conditions, predominantly with sandy soil, sometimes loamy sands with a short rhizosphere zone; gritty consistency stipulate their poorness. It includes peaty soils, which occurred as a result of swamping by the sphagnum (raised) type. Vegetation is exclusively oligotrophic.

Trophotope "B", "subir" or “pine mixed forest” is characterized by relatively poor soils. It is represented by loamy sand or sandy soil with thin sandy-loam or loamy layers, or with a heavy layers of that at a considerable depth. In the other cases, this trophotope is represented by sandy-loam and loamy soil with low thickness of soil layer, including skeletal soil on mountain slopes. It includes the peat soil with transitional swamping. The vegetation consists of pine-forest oligotrophes with admixed mesotrophes.

Trophotope "C", "suhrud" or “oak mixed forest” has a relatively rich habitat conditions. Soils are represented by sandy-loam, sometimes sand with layers of loam and sandy-loam, or denuded shallow grey forest soil, sometimes brown soil with the little humus horizon, skeletal, derived from volcanic rocks and sandstones. Vegetation is composed of

oligo-, meso- and megatrophes. Trophotope "D", "hrud" or “oak pure forest” has the most fertile habitat conditions. The soils are loam with the heavy (greater than 0.8 m) rhizosphere, more rarely sandy and sandy-loam soils with the layers of loam and clay, available to plant roots. Sometimes the sandy and sandy-loam soils occur with shallow horizon of flow “mineralized” groundwater. This includes also the richest soils of lowland swamps. Megatrophes dominated in composition of climax forest vegetation.

Whereas, the trophotopes are divided by six hygrogene ranges: *hygrotopes* with indicators of soil moisture 0 to 5 (Pogrebnyak, 1955; Sviridenko et al., 2004). Hygrotope of 0 range respond to very dry (xerophilic) conditions; 1 – dry-mesic (meso-xerophilic); 2 – mesic (mesophilic); 3 – wet-mesic (meso-hygrophilic); 4 – wet (hygrophilic); 5 – swamp (ultrahygrophilic).

Very dry types. The habitat conditions include the top of sand dune hills, denuded soil of the beam foreheads, and drained upland edaphotopes within the Chernozem Steppe. Groundwater under these conditions is very deep, and the only source of water is precipitation, which is able to moisten the top of soil, usually dry, only for a short period of time. ***Dry types.*** Conditions for sandy soils with low water storage capacity; dryness of them depends on the groundwater depth; on the clay soils it depends on dryness of climate, surface runoff (on the slopes), high evaporation (southern exposure), and low total water capacity (shallow and lithosolic clay soils of mountain slopes).

Dry-mesic types. Sandy soil in well-moistened habitat is provided by higher groundwater level (2–4 m); in the loamy lands the groundwater is deeper than 4 m, often outside the layer available for plant roots. In southern regions, the satisfactory moistening is carried out by surface runoff reducing, increasing total soil water capacity, and more complete saturation of the soil by winter precipitation (steady winters).

Mesic types. In southern regions, good moisture is provided by the same conditions as in the previous type, and in Northern regions due to the better drainage (tops of hills, slopes). The groundwater level in sandy soils is 1–2 m, and 2–4 m in loamy and clay soils. The subsoil is blowdown, the land form is undulating or gently rolling.

Wet-mesic types. The overwetting habitats. Increasing of soil moisture depends on the higher groundwater level (at a depth of about 1 m in the sands, and 1–3 m in the sandy-loam soil). ***Wet types (bog forest)***. The habitats have excessive moisture and peat soils. Much of vegetative period, the groundwater level is near of the soil surface (Sviridenko at al., 2004).

According to the classification scheme, each site of forest is characterized by two classification units: trophotope and hygrotope. In the surveyed forest stands we selected 20 sampling units for black locust and 16 sampling units for Scots pine in existing grades of trophotopes and hygrotopes within stands of different ages. The sampling units delimitation was carried out instrumentally with surface marking and binding to net of rides. The size of sampling units was ranged from 0.25 to 0.5 hectares. Within the sampling units it was determined the total growing stock with the model trees by way of step representation. Model trees were selected for each level of thickness. Work on the sampling units was performed in the following order:

1) complete tree enumeration;
2) determination of the mean diameter of the stands with usage of average cross-sectional area according to tally sheet, by dividing the sum of basal areas on the total number of trees within the forest stand;
3) selection of three medium-size and shape sample trees in the each level of thickness;
4) measurement of diameter of the sample tree accurate to 0.1 cm;
5) measurement of height of the sample tree accurate to 0.1 m;
6) cutting of the sample trees;
7) determination of volume of the sample tree by the formula:

$V_{aver} = g_{aver} \times h_{aver} \times f_{aver}$

where: g_{aver} – cross-sectional area of the average sample tree; h_{aver} – average height of the average sample tree, f_{aver} – form factor of the average sample tree;

8) determination of stock in the sampling unit according to the formula:

$M = V_{aver} \times N$

where: M – growing stock, V_{aver} – volume of the average sample tree, N – number of trees within the stand.

Values of the growing stock obtained on the sampling unit for investigated tree species was transferred on 1 ha according to the formula:

$M = M_{samp.un} \times F_{conv}$

by multiplying it on the conversion factor $F_{conv} = 1\ ha/S_{sampl.u}$.

According to the materials of forest management, there were found the area of black locust and Scots pine stands belonging to a particular age class, and the total growing stock of these species within these areas. The age class for black locust as a fast-growing species was 5 years, and 10 years for Scots pine. In the stands of the same age, determination of dependence of growing stock formation on the type of trophotope and hygrotope was determined by usage of the average growing stock by the formula:

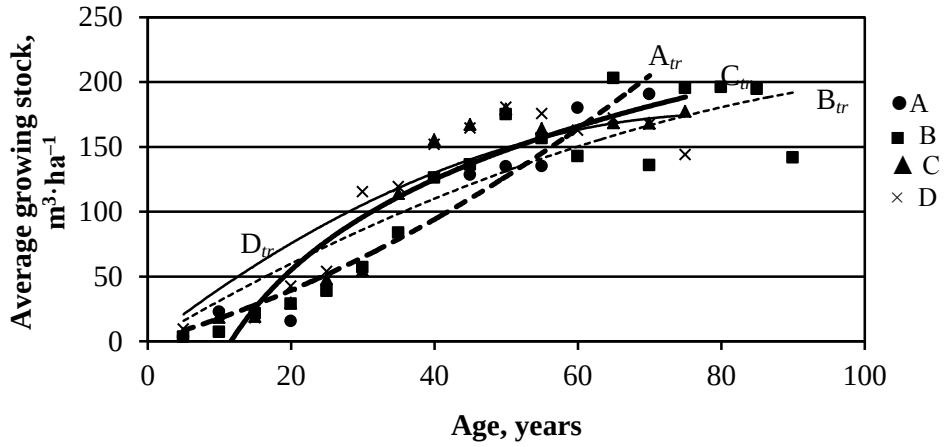
$M_{aver} = M_{total\ age\ cl}/S_{stand\ age\ cl}$

where $M_{total\ age\ cl}$ is the total growing stock in the same age class stands, $S_{stand\ age\ cl}$ is the area of the stand of given age class.

Results and discussion

Forest inventory data analysis allowed determining the current age structure of black locust stands; it was characterized by a significant predominance of overmature age group, which occupied 72.3 % (12786.0 ha) of the total black locust stands area, with a very small area of young stands (0.2 %, 375.2 ha). The age range was 5 to 95 years, average age was 43 years. According to variations of trophic graduation, the largest area of black locust stands (9596.5 ha, 54.3 %) was growing among suhrud, where it was located 53.1% of the total growing stock. The black locust stands occupied more than a third of total oak forest area (6732.2 ha, 38.1 %) with 40.8 % of total growing stock. The area of black locust stands is thinly represented under the poorest soil conditions within bir (139.8 ha, 0.8 %), where it is presented by the smallest part of growing stock (0.8 %).

The calculated values of black locust average growing stock demonstrated differences in age classes under different soil trophic conditions (Fig. 1).



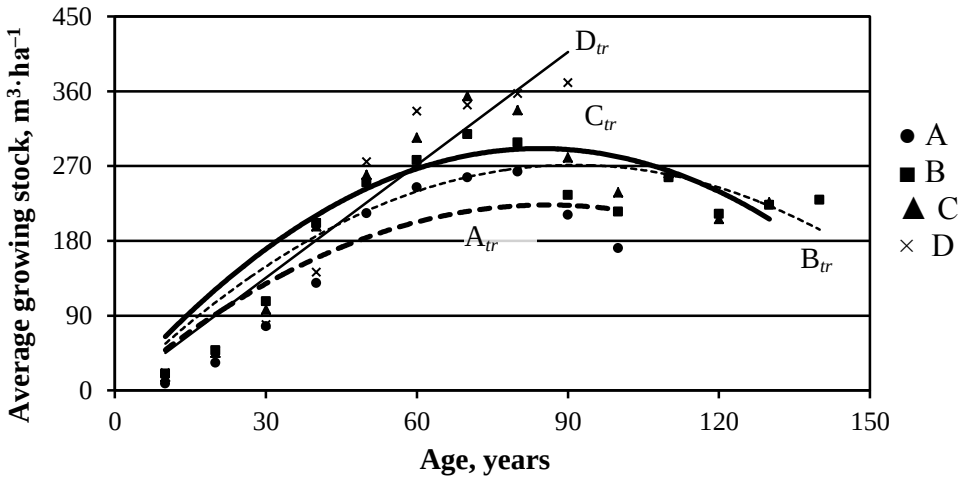
Note. Index *tr* – fitting trendline of growing stock in corresponding forest type.

Fig. 1 – Dependence of dynamics of the average growing stock on age of black locust stands in trophotopic sequence

Maximal values of average growing stock in trophotopes amounted: A – 180 m^3/ha^{-1} (12-th age class); B – 202 m^3/ha^{-1} (13-th age class); C – 178,9 m^3/ha^{-1} (10-th age class); D – 180 m^3/ha^{-1} (13-th age class). These data show the absence of significant differences in maximum average growing stock between the poorest soil conditions in the pure pine and oak forests, and the most fertile soils. It was noted decrease of the studied parameters, after attainment the age of 75 years for black locust (suhrud), 70 years (bir), and 65 years (subir and hrud).

Unlike black locust, ⅔ of the Scots pine stands area were concentrated in subir with the total growing stock 3017.66 $m^3 \cdot ha^{-1}$. Scots pine forms stands in hrud on the more small area (1.2 %). When soil fertility increases in pine stands from bir tosubir, respectively, it was experienced growth in the average growing stock value: it was 27.5 % more in trophotope D than A (Fig. 2).

In the pine stands, the highest values of average growing stock were registered in 8th age class within the bir andsubir, and in 7th class within the suhrud. Note that trend of gradual increase of stock amount in the hrud, before overmature 9th age class.



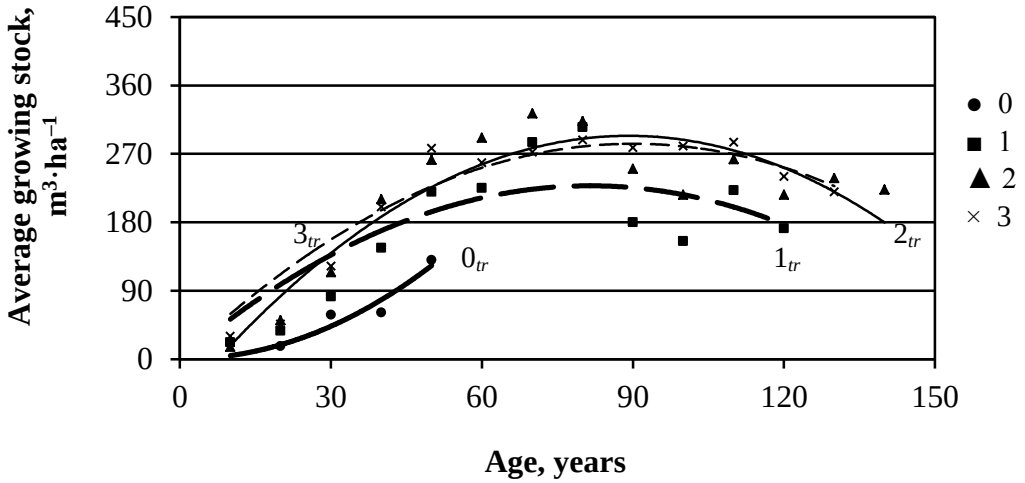
Note. Index *tr* – fitting trendline of growing stock in corresponding forest type.

Fig. 2 – Dependence of dynamics of the average growing stock on age of Scots pine in trophotopic sequence

With increasing the age, both for Scots pine and black locust, registered decrease of this index after attainment by pine the maximum growing stock in 8th and 13th age classes, respectively. It may be due to sanitary conditions deterioration within the stands, top-drying and twig blight.

Analyzing the area distribution of black locust stands depending on soil moisture conditions, it was found that the overwhelming majority was concentrated in the dry hygrotope conditions (13916.7 ha, 78.7 %). The area distribution in relation to moisture gradation was following: 1034.2 ha (5.8 %) of the stands area grows in the very dry hygrotope; 2594.1 ha grow in dry-mesic (14.7 %) and 95.5 ha (0.5 %) grow under wet condition. Compared to black locust, Scots pine forms the forest stands mainly in dry-mesic (12136.4 ha, 56.5 %) and dry (8817.1 ha, 41.1 %) hygrotopes, while the other moisture ranges had less than 3.0 % of the total pine forests area (Fig.3).

Determined average timber for different age of black locust stands in hygrotopes, it was found the studied index dependence on the moisture conditions: mean growing stock under wet conditions was 181.6 % compared to black locust stands occurred in the very dry hygrotope. Also, the similar trend is revealed for Scots pine, with a fixed predominance of average growing stock in mesic and wet habitat conditions in three times in comparison with the very dry conditions.

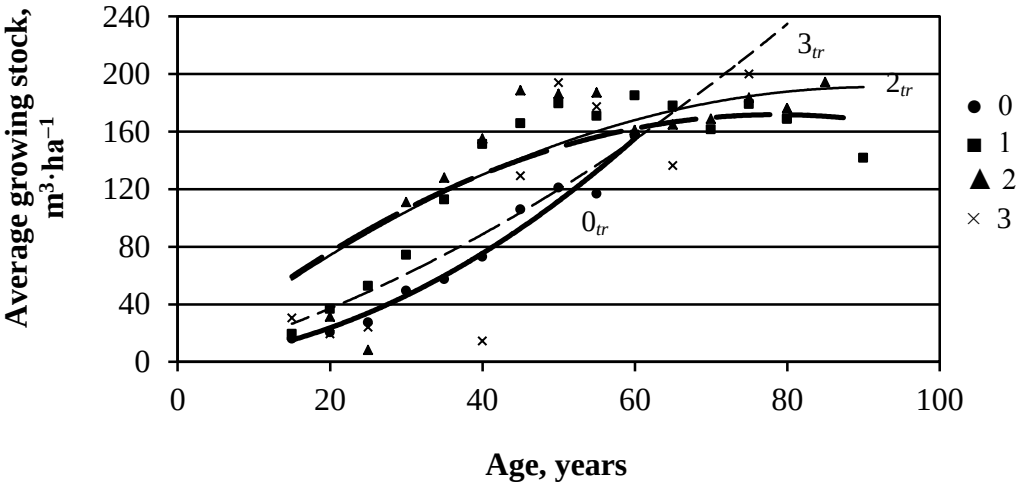


Note. Index *tr* – fitting trendline of growing stock in corresponding forest type.

Fig. 3 – Dependence of dynamics for the average growing stock on the age of Scots pine in hygrotopic sequence

It was observed increase the average value of growing stock in even-aged stands both Scots pine and black locust when changing of moisture conditions. However, it should be noted that this index decreased for pine in wet hygrotope, almost three-fold.

Black locust stands reach the maximum growing stock (193.9 m^3/ha^{-1}) in conditions of high moisture at the age of fifty years (10 age class). In different hygrogenic ranges, the following values of average growing stock were available for the same age: very dry – 121.0 m^3/ha^{-1}; dry – 179.4 m^3/ha^{-1}; mesic – 186.1 m^3/ha^{-1}, rather, it was observed the influence of moisture conditions on the studied indexes (Fig. 4).



Note. Index *tr* – fitting trendline of growing stock in corresponding forest type.

Fig. 4 – Dynamics of the mean growing stock from age of black locust in hygrotopic sequence

We determined that soil moisture conditions effect significantly on the yield of timber volume per hectare in Scots pine, as well as black locust. Scots pine reached maximum average growing stock (323 and 313 m^3/ha^{-1}) under mesic habitat conditions in the 7^{th} and 8^{th} age classes. The trend of this index increasing was not observed in different types of soil moisture, after 50 years in black locust stands, and 80 years in pine stands.

In Table 1 and 2, it was given the regression equations for average growing stock and its dependence on the age of stand in different gradations of tropho- and hygrotopes.

Table 1. Regression models of the average growing stock dependence on the age in different ranges of trophotopic sequence

Forest-forming species	Trophotope			
	A	B	C	D
Scots pine	$y = –0.0301x^2 + 5{,}19x$	$y = –0.0326x^2 + 5{,}95x$	$y = –0.0409x^2 + 6{,}90x$	$y = 4{,}526x$
	$R^2 = 0.79$	$R^2 = 0.81$	$R^2 = 0.80$	$R^2 = 0.91$
Black locust	$y = –0.0192x^2 + 1{,}58x$	$y = –0.0124x^2 + 3{,}24x$	$y = 100.9 \ln x – 247.3$	$y = –0.0264x^2 + 4{,}31x$
	$R^2 = 0.96$	$R^2 = 0.84$	$R^2 = 0.86$	$R^2 = 0.86$

Table 2. Regression models of the average growing stock dependence on the age in different ranges of hygrotopic sequence

Forest-forming species	Hygrotope			
	0	1	2	3
Scots pine	$y = 0.041x^{2.05}$	$y = –0.0343x^2 + 6{,}00x$	$y = –0.0351x^2 + 6{,}30x$	$y = –0.0349x^2 + 6{,}29x$
	$R^2 = 0.92$	$R^2 = 0.71$	$R^2 = 0.80$	$R^2 = 0.90$
Black locust	$y = –0.035x^2 + 0{,}485x$	$y = –0.0278x^2 + 4{,}37x$	$y = –0.0226x^2 + 4.16$	$y = 0.018x^2 + 1{,}50x$
	$R^2 = 0.97$	$R^2 = 0.80$	$R^2 = 0.74$	$R^2 = 0.71$

The values of determination coefficients explain 73-90 % of studied characteristics variability in Scots pine, and 91-94 % in black locust. Overall, the average growing stock in both studied species are characterized by significant variability due to influence of habitat factors, and it is necessary to continue surveys in this direction to such dependency study.

Conclusion

According to trophic graduation, the largest area of black locust stands was located within the suhrud, when half of the total growing stock is situated. Maximum value of the average growing stock of this species in trophotopes was 202 m^3/ha^{-1} (trophotope B, 13th age class). The differences of maximum values between average growing stock within bir and hrud were not registered.

The major part of the Scots pine stands area was located within the subir, when the total growing stock was 3017.66 m^3/ha^{-1}. When soil fertility increased, it was observed increase in the values of average growing stock in the Scots pine stands. In the pine stands, the highest values of average growing stock were registered in 8th age class within the bir and subir, and in 7th class within the suhrud. When age increasing in the Scots pine and black locust stands, it is observed maximum values of growing stock at the 8th and 13th age classes, and decrease of growing stock values at a later time.

Average growing stock of black locust under wet conditions was 181.6 % relative to growing stock produced under very dry conditions. A similar tendency was revealed in the Scots pine stands: average growing stock under wet-mesic and wet habitat conditions was three times higher than one under very dry conditions. As well as black locust, soil moisture conditions influenced significantly on volume of timber per hectare for Scots pine. This species reached the highest values of average growing stock (323 and 313 m^3/ha) under mesic conditions in 7th and 8th age ranges.

Under different moisture conditions, contrasting energy of growth of Scots pine and black locust caused significant differences in development and structure of their stands with age. Due to transition from optimum to the worst soil moisture conditions, it was observed decrease of shoot, fir needle and leaves formation, crown density, size of individual trees, and their resistance.
