HONORARY COMMITTEE

Mr. Savo Minic, Minister of Agriculture, Water Management and Forestry of Republic of Srpska, Bosnia and Herzegovina
Dr. Zeljko Budimir, Minister of Scientific-Technological Development, Higher Education and Information Society of Republic of Srpska, Bosnia and Herzegovina
Prof. dr Mario T. Tabucanon, President of the International Society of Environment and Rural Development, Japan
Prof. dr Milan Kulic, Rector of the University of East Sarajevo, Bosnia and Herzegovina
Prof. dr Dusan Zivkovic, Dean of the Faculty of Agriculture, University of Belgrade, Serbia
Dr. Maurizio Raeli, Director of the Mediterranean Agronomic Institute of Bari, Italy
Prof. Dr. Hüseyin YILMAZ, Rector of the Selcuk University, Turkey
Prof. dr Aleksey Andreev, Rector of the Perm State Agro-Technological University, Russia
Prof. dr Alexey Yu. Popov, Rector of the Voronezh State Agricultural University named after Peter The Great, Russia
Prof. dr Zhang Jijian, President of Jiangsu University, People’s Republic of China
Prof. dr Barbara Hinterstoisser, Vice-Rector of the University of Natural Resources and Life Sciences (BOKU), Austria
Prof. dr Sorin Mihai Cimpeanu, Rector of the University of Agronomic Sciences and Veterinary Medicine of Bucharest, Romania
Prof. Shinichi Yonekura, Vice-President of the Shinshu University, Japan
Doc. Ing. Klaudia Halászová, Rector of the Slovak University of Agriculture in Nitra, Slovakia
Prof. dr Calin D. Oros, Rector of the Valahia University of Targoviste, Romania
Prof. Dr Katerina Melfou, Dean of the Faculty of Agriculture, University of Western Macedonia, Greece
Prof. dr Amr Ahmed Mostafa, Dean of the Faculty of Agriculture, Cairo University, Egypt
Prof. dr José Sergio Barrales Domínguez, Rector of the Chapingo Autonomous University, Mexico
Prof. dr Davut Karayel, Dean of Faculty of Agriculture, University of Akdeniz - Antalya, Turkey
Prof. Dr Eguchi Fumio, Rector of the Tokyo University of Agriculture, Japan
Prof. dr Muhammad Naeem, Vice-Chancellor of Arid Agricultural University, Rawalpindi, Pakistan
Prof. dr Zhang Zhanping, President of Cangzhou Normal University, People's Republic of China
Prof. dr Wang Zhanren, President of Nortwest Normal University, People's Republic of China
Dr Chokri Thabet, the General Director of the High Agronomic Institute of Chott Mariem, Sousse, Tunisia
Prof. dr Maya Ignatova, Director of the Institute of Animal Science- Kostinbrod, Bulgaria
Prof. dr Seyed Hamidreza Sadeghi, Professor at Tarbiat Modares University and the President of the Watershed Management Society of Iran, Iran
Prof. dr Francesco Tei, Director of the Department of Agricultural, Food and Environmental Sciences, University of Perugia, Italy
Prof. dr Viktor Kaminskyi, Director of National Scientific Center „Institute of Agriculture of NAAS“, Kyiv, Ukraine
Dr. Igor Hrovatič, President of South Eastern Advisory Service Network, Croatia
Prof. dr Mirza Dautbasic, Dean of the Faculty of Forestry, University of Sarajevo, Bosnia and Herzegovina
Prof. dr Bozidarka Markovic, Dean of the Biotechnical Faculty, University of Podgorica, Montenegro
Prof. dr Rade Jovanovic, Director of the Institute for Science Application in Agriculture, Serbia
Prof. dr Lazar Radovanovic, Dean of the Faculty of Economics Brcko, University of East Sarajevo, Bosnia and Herzegovina
Prof. dr Vojislav Trkulja, Director of Agricultural Institute of Republic of Srpska - Banja Luka, Bosnia and Herzegovina
Dr. Miodrag Tolimir, Director of the Maize Research Institute “Zemun Polje”, Serbia
Prof. Dr. Jegor Miladinović, Director of the Institute of Field and Vegetable Crops, Serbia
Prof. dr Nedeljko Tica, Dean of the Faculty of Agriculture, University of Novi Sad, Serbia
Prof. dr Rodne Nastova, Director of the Institute for Animal Science, Skoplje, Macedonia
Prof. dr Sasa Orlovic, Director of the Institute of Lowland Forestry and Environment, Serbia
Prof. dr Jonel Subic, Director of the Institute of Agricultural Economics, Serbia
Prof. dr Branko Kovacevic, President of the Academy of Engineering Sciences of Serbia, Serbia
Prof. dr Radovan Pejanovic, President of Balkan Scientific Association of Agricultural Economics, Serbia

SCIENTIFIC COMMITTEE

Prof. Fatiha Addyoubah, Moulay Ismail University, Morocco
Prof. dr Muhammad Ovais Omer, Faculty of Bio-Sciences, University of Veterinary & Animal Sciences, Lahore, Pakistan

ORGANIZATIONAL COMMITTEE

Chairperson: Prof. dr Vesna Milic, Dean of the Faculty of Agriculture, University of East Sarajevo, Bosnia and Herzegovina
Dr Marko Gutalj, Vice rector of the University of East Sarajevo, Bosnia and Herzegovina
Dr Jelena Krunic, Vice rector of the University of East Sarajevo, Bosnia and Herzegovina
Dr. Maroun El Moujabber, Mediterranean Agronomic Institute of Bari, Italy
Mrs. Rosanna Quagliariello, Mediterranean Agronomic Institute of Bari, Italy
Dr. Noureddin Driouech, Coordinator of MAIB Alumni Network (FTN), Mediterranean Agronomic Institute of Bari, Italy
Dr Milic Curovic, The journal "Agriculture and Forestry", Biotechnical Faculty Podgorica, University of Montenegro, Montenegro
Dr. Tatiana Lysak, International Relations Office, Voronezh State Agricultural University named after Peter The Great, Russia
Dr. Oksana Fotina, International Relations Center, Perm State Agro-Technological University, Russia
Prof. dr Fokion Papathanasiou, School of Agricultural Sciences, University of Western Macedonia, Greece
Dr Ana Marjanović Jeromela, Institute of Field and Vegetable Crops, Serbia
Prof. dr Engr. Teodora Popova, Institute of Animal Science - Kostinbrod, Bulgaria
Prof. dr Mehmet Musa Ozcan, Faculty of Agriculture, Selçuk University, Turkey
Prof. dr Arfan Yousaf, Arid Agricultural University, Rawalpindi, Pakistan
Dr. Abdulvahed Khaledi Darvishan, Faculty of Natural Resources, Tarbiat Modares University, Iran
Prof. dr Nikola Pacinovski, Institute for Animal Science, Ss. Cyril and Methodius University in Skopje, N. Macedonia
MSc. Erasmo Velázquez Cigarroa, Department of Rural Sociology, Chapingo Autonomous University, Mexico
Dr. Ecaterina Stefan, University of Agronomic Sciences and Veterinary Medicine of Bucharest, Romania
Dr. Jeeranuch Sakkhamduang, The International Society of Environmental and Rural Development, Japan

PREFACE

Dear colleagues,

It is with great pleasure that I introduce the *Book of Proceedings* for the 15th International Scientific Agricultural Symposium "AGROSYM 2024." I trust that you will find it a valuable resource in your work. This year, around 800 contributions have been accepted for inclusion in the *Book of Abstracts*. The themes of AGROSYM 2024 span the full spectrum of agricultural sciences, divided into seven key sessions: 1) Plant Production, 2) Plant Protection and Food Safety, 3) Organic Agriculture, 4) Environmental Protection and Natural Resource Management, 5) Animal Husbandry, 6) Rural Development and Agro-Economy, and 7) Forestry and Agroforestry.

There is growing consensus among scholars and practitioners that technological innovations have the potential to boost agricultural production, enhance supply stability, and reduce the environmental impact of farming. Technology has been especially pivotal in increasing the productivity of annual crops such as maize, rice, soybeans, wheat, and cotton. However, with trees having longer growth cycles, breeding programs for these crops require more time. New plant breeding techniques promise improvements in productivity, but they have sparked an ongoing academic debate regarding their advantages and drawbacks.

While much of the focus in the past has been on the production side of agriculture (e.g., productivity and efficiency), there is an increasing emphasis today on the consumption side and the intermediate stages of the food chain, such as processing and distribution. This shift is driving the transition toward a "farm-to-fork" approach. Globally, consumers are sending clearer signals about their preferences for higher quality, healthier, safer, and more flavorful products. In response, many agri-food companies are exploring innovative ways to gain greater control over production processes and ensure the quality and safety of final products. Furthermore, changes in investment strategies hold the potential to reduce the environmental and social costs of agriculture. It has become increasingly clear to investors that companies that prioritize sustainability and social responsibility tend to yield better long-term returns.

Agri-food systems are at the heart of global discussions surrounding sustainable development and the achievement of the United Nations Sustainable Development Goals (SDGs) by 2030. These systems are deeply connected to numerous global challenges, including climate change, poverty, food insecurity, biodiversity loss, resource depletion, and ecosystem degradation. A key goal of the sustainable agriculture movement is to create farming systems that mitigate or eliminate the environmental harms associated with industrial agriculture. Additionally, it is critical to improve the resilience of food systems to crises, shocks, and pandemics.

I would like to extend my heartfelt thanks to all the authors, reviewers, and colleagues who contributed to the editing of the *Book of Abstracts*. Special thanks are due to our co-organizers and partners for their unwavering collaboration and comprehensive support throughout this endeavor.

Dušan Kovačević

East Sarajevo, 10 October 2024
Prof. Dušan Kovačević, PhD
Editor in Chief, President of the Scientific Committee of AGROSYM 2024

CONTENT

PLANT PRODUCTION 31

CROP PRODUCTION: CURRENT STATE AND CHALLENGES, ADVANCES AND PROSPECTS TO BALANCE ENVIRONMENTAL, SOCIAL AND ECONOMIC IMPERATIVES
Steve QUARRIE 32

GENETIC IMPROVEMENT OF DATE PALMS - PROTOPLASTS CULTURE OF TEGGAZA, DEGLET NOUR AND TAQUERBUCHT CULTIVARS
Djamila YATTA-EL DJOUZI, Said. BOUDEFFEUR, Rosa. SLAMANI, Radia. AYADI, Sana. EZZOUAOUI, Lydia BOUAMRA,Mohamed KHARSSI 43

AGRICULTURAL ADAPTATION TO CLIMATE CHANGE IN ALGERIA
Wassila HANAFI, Nouara BOULFOUL 50

FACILITATING HYSSOP INTRODUCTION TO ARMENIA: ASSESSING GLOBAL GENEBANK RESOURCES AND CULTIVATION POTENCIAL
Alvina AVAGYAN, Laura TADEVOSYAN , Raya BALAYAN, Vladimíra HORČINOVÁ SEDLÁČKOVÁ**,** Marina HOVHANNISYAN, Margarita HARUTYUNYAN 54

A STUDY OF THE EFFECT OF BIOSTIMULANT ON THE YIELD AND QUALITY OF CUCUMBER (CUCUMIS SATIVUS)
Aleksandra GOVEDARICA-LUČIĆ, Tanja PEROVIĆ, Alma MEMIĆ, Lutvija KARIĆ,Ćerima ZAHIROVIĆ SINANOVIĆ Milica STOJANOVIĆ 60

INTERDEPENDENCE OF PRODUCTIVE CHARACTERISTICS AND FORAGE QUALITY OF RED CLOVER
Borislav PETKOVIĆ, Ilija KOMLJENOVIĆ, Vojo RADIĆ, Mihajlo MARKOVIĆ, Zoran MALIČEVIĆ 65

ECOLOGICAL CHARACTERISTICS OF MACROPHYTES OF THE PROTECTED HABITAT "GROMIŽELJ" (BOSNIA AND HERZEGOVINA)
Milica LJUBOJEVIC, Natasa MARIC, Sladjana PETRONIC 71

ORGANIC PLANT BIOSTIMULANTS AND TOMATO FRUIT QUALITY
Mirjana JOVOVIĆ, Verica MILOVIĆ, Zoranka MALEŠEVIĆ, Marko PETKOVIĆ 77

FLOWERING AND FRUIT SET OF CULTIVARS OF SWEET CHERRY IN AGRO-ECOLOGICAL CONDITIONS OF SARAJEVO
Mirjana RADOVIC, Mihajlo LIZDEK, Mirko KULINA, Dejan ZEJAK, Dragan TOMOVIC, Slavisa MILOVANOVIC 84

PROSPECTS OF CORN CULTIVATION AND PRODUCTION IN THE SEMBERIJA REGION IN BOSNIA AND HERZEGOVINA
Igor ĐURĐIĆ, Nedeljka ELEZ, Angelina PETKOVIĆ, Slađana JANKOVIĆ 90

YIELD AND CHARACTERISTICS OF BUNCHES OF RED WINE VARIETIES GROWN IN THE AREA OF TREBINJE (BOSNIA AND HERZEGOVINA)
Tijana BANJANIN, Snežana BRKLJAČ, Zorica RANKOVIĆ VASIĆ 96

THE YIELD OF POTATOES TESTED IN MULTIPLE ENVIRONMENTS IN REPUBLIKA SRPSKA (BOSNIA AND HERZEGOVINA)
Branka GOVEDARICA, Tanja MIJATOVIĆ, Igor ĐURĐIĆ, Vesna MILIĆ, Tanja JAKIŠIĆ 103

APPLICATION OF DIFFERENT VARIANTS OF SUPERABSORBENTS AND THEIR IMPACT ON YIELD OF SELECTED POTATO VARIETIES
Saša LALIĆ, Branka GOVEDARICA, Tanja MIJATOVIĆ, Igor ĐURĐIĆ, Aleksej LUKIN, Tatiana KRIUKOVA, Vesna MILIĆ 109

ENDANGERED AND PROTECTED PLANT SPECIES OF THE RAMSAR SITES OF BOSNIA AND HERZEGOVINA

Theano B. LAZARIDOU, Ioannis N. XYNIAS, Demetrios G. ROUPAKIAS 208

INVESTIGATION OF THE EFFECTS OF DOMESTIC WATER BUFFALO, HUNGARIAN RACKA SHEEP AND HUNGARIAN GREY CATTLE GRAZING ON DIFFERENT WOOD-PASTURES IN HUNGARY
Attila FŰRÉSZ, Szilárd SZENTES, Dénes SALÁTA, Zsombor WAGENHOFFER, Gabriella FINTHA, László SIPOS, Ferenc PAJOR, Károly PENKSZA........ 213

BIOLOGICAL DIVERSITY OF *SPINACIA OLERACEA* L. ACCESSIONS COLLECTED IN IRAN USING SOME MORPHOLOGICAL TRAITS
Naser SABAGHNIA, Mohsen JANMOHAMMADI........ 219

BIOLOGICAL VARIATION OF SOME GARDEN CRESS (*LEPIDIUM SATIVUM* L.) ACCESSIONS
Naser SABAGHNIA, Mohsen JANMOHAMMADI........ 223

GRAPHIC ANALYSIS OF GENOTYPE BY TRAIT INTERACTION IN SAFFLOWER USING BIPLOT METHOD
Naser SABAGHNIA, Mohsen JANMOHAMMADI........ 227

MECHANICAL PEAR HARVESTING WITH THE "MULTIBASKET" SYSTEM
Roberto TOMASONE, Carla CEDROLA, Mauro PAGANO 233

DEVELOPING A DECISION TREE MOBILE APPLICATION TO CONTROL A SMART GREENHOUSE IN THE JORDAN VALLEY
Lubna NASIR EDDEEN, Ola SHALBAK, Ansar KHOURI 240

APPROACHES TO ASSESSING THE ENERGY POTENTIAL OF BIOMASS OBTAINED FROM CROP RESIDUE IN REPUBLIC OF NORTH MACEDONIA
Igor ILJOVSKI, Zoran DIMOV, Zlatko ARSOV, Ile CANEV 247

CORRELATION ANALYSIS OF CORN BIO-MORPHOLOGICAL TRAITS IN THE INITIAL GROWTH PHASE UNDER DIFFERENT TEMPERATURE CONDITIONS
Raisa IVANOVA, Elena LUTCAN, Alla BOROVSKAIA, Nicolai VANICOVICI........ 254

EVALUATING STRAWBERRY CULTIVAR PERFORMANCE AND RUNNER HEALTH ACROSS VARIED CLIMATIC ZONES IN POONCH DISTRICT, AZAD JAMMU AND KASHMIR IN PAKISTAN
Noosheen ZAHID, Mehdi MAQBOOL, Raheel ANWAR 260

ENHANCING APPLE QUALITY ASSESSMENT THROUGH ANOMALY DETECTION WITH AUTOENCODERS
Adrian IOSIF, Edmond MAICAN, Sorin-Stefan BIRIȘ, Nicolae-Valentin VLĂDUȚ 266

EXPLORING INSECTS DETECTION PERFORMANCE IN CORN PEST CONTROL WITH MOBILENET-SSD NEURAL NETWORK AND HIGHER-RESOLUTION INPUT
Edmond MAICAN, Sanda MAICAN, Sorin-Ştefan BIRIŞ, Adrian IOSIF 272

RESEARCH ON DETERMINING THE PERFORMANCE OF A VARIABLE WIDTH PLOUG DESIGNED FOR HIGH-POWER TRACTORS (180-240 HP)
Sorin-Ștefan BIRIȘ, Constantin LĂCĂTUȘU, Nicolae-Valentin VLĂDUȚ, Neluș-Evelin GHEORGHIȚĂ, Nicoleta UNGUREANU, Edmond MAICAN, Adrian IOSIF 279

DIGITAL TECHNOLOGIES IN AGRARIAN SCIENCE AND EDUCATION
Daniil IAKOVLEV, Alexandr PCHELNIKOV 286

INFLUENCE OF STEM CUTTING HEIGHT ON THE NUTRITIONAL VALUE OF CORN SILAGE
Aleksandar VUKOVIĆ, Dragana LALEVIĆ, Rade STANISAVLJEVIĆ, Saša BARAĆ, Milan BIBERDŽIĆ, Dragoslav ĐOKIĆ 292

APPLICATION OF THE SENSOR IN AGRICULTURE: A REVIEW OF RECENT DEVELOPMENTS
Biljana BOŠKOVIĆ, Irina MARINA, Miloš PAJIĆ, Jonel SUBIĆ 299

CONTENT OF MINERAL MATTER IN THE GRAIN OF POPCORN IN A SUSTAINABLE CULTIVATION SYSTEM WITH COVER CROPS
Biljana SEVIC, Zeljko DOLIJANOVIC, Milena SIMIC, Vesna DRAGICEVIC, Dejan CVIKIC, Jelena STOJILJKOVIC, Ivana ZIVKOVIC 304

VARIATION OF SEEDS NUMBER IN PRIMARY SPIKE OF BREAD WHEAT
Desimir KNEŽEVIĆ, Dragan GRČAK, Milosav GRČAK, Tatjana IVANOVIVIĆ, Mirela MATKOVIĆ STOJŠIN, Danijela KONDIĆ, Adriana RADOSAVAC, Aleksandar PAUNOVIĆ, Veselinka ZEČEVIĆ 313

FORECASTING THE IMPACT OF CLIMATE CHANGE ON WATER AVAILABILITY FOR WINTER WHEAT CROP IN THE TOPLICA DISTRICT OF SERBIA
Dženita KOCA, Gordana MATOVIĆ, Vesna POČUČA, Enika GREGORIĆ, Mirjam VUJADINOVIĆ MANDIĆ 321

INFLUENCE OF GENOTYPE AND IRRIGATION ON YIELD COMPONENTS OF SWEET CORN (ZEA MAYS L. VAR. SACCHARATA STURT.)
Ivan TUPAJIĆ, Marija ĆOSIĆ, Aleksa LIPOVAC, Biljana ŠEVIĆ, Jelena STOJILJKOVIĆ, Maja SUDIMAC, Đorđe MORAVČEVIĆ... 328

MARKER ASSISTED SELECTION FOR β-CAROTENE RICH MAIZE: VALIDATION OF MULTIPLEX-PCR ASSAY FOR *crtRB1* AND *lcyE* FAVOURABLE ALLELES
Marija KOSTADINOVIĆ, Danijela RISTIĆ, Milica LUČEV, Dragana IGNJATOVIĆ-MICIĆ, Jelena VANČETOVIĆ 334

INFLUENCE OF THE CULTIVAR, FERTILISER, AND IRRIGATION ON ICEBERG LETTUCE MORPHOLOGY - SINGLE FACTOR VS INTERACTION EFFECTS
Milica STOJANOVIĆ, Zoran DINIĆ, Dragica MILOSAVLJEVIĆ, Aleksandra GOVEDARICA-LUČIĆ, Đorđe MORAVČEVIĆ, Jelena DRAGIŠIĆ MAKSIMOVIĆ, Vuk MAKSIMOVIĆ 339

NOVEL BATAVIA LETTUCE CULTIVARS-CHOOSING THE OPTIMAL CULTIVAR FOR FRESH AND PROCESSED PRODUCTS USING WASPAS METHOD
Milica STOJANOVIĆ, Dragica MILOSAVLJEVIĆ, Jelena DRAGIŠIĆ MAKSIMOVIĆ, Vuk MAKSIMOVIĆ, Aleksandra GOVEDARICA-LUČIĆ, Radomir BODIROGA 346

YIELD RESPONSE OF MAIZE TO IRRIGATION AND PLANTING DENSITY IN THE VOJVODINA ENVIRONMENT IN SERBIA
Miodrag TOLIMIR, Branka KRESOVIĆ, Zorica SREDOJEVIĆ, Katarina GAJIĆ, Milan BRANKOV, Marijana DUGALIĆ, Boško GAJIĆ 353

STRESS RESISTANCE INDICATORS AS THE TOOL FOR SELECTING DROUGHT-TOLERANT WHEAT GENOTYPES
Mirela MATKOVIĆ STOJŠIN, Veselinka ZEČEVIĆ, Dušan UROŠEVIĆ, Dragan BOŽOVIĆ, Jasmina BAČIĆ, Kamenko BRATKOVIĆ, Desimir KNEŽEVIĆ 361

SOCIAL NETWORKING IN STRESS-EXPOSED PLANTS
Mirjana VUKOSAVLJEV, Brankica KARTALOVIĆ, Nevena STEVANOVIĆ, Maša BUĐEN, Nikola STANKOVIĆ, Boris BRKIĆ, Nataša LJUBIČIĆ 367

THE NORMALIZED DIFFERENCE RED EDGE INDEX (NDRE) IN GRAIN YIELD AND BIOMASS ESTIMATION IN MAIZE (Zea mays L.)
Nataša LJUBIČIĆ, Vera POPOVIĆ, Marko KOSTIĆ, Mirjana VUKOSAVLJEV, Maša BUĐEN, Nikola STANKOVIĆ, Nevena STEVANOVIĆ 373

MONITORING STRESS IN ARUGULA (*Eruca sativa*) USING A PORTABLE MULTISPECTRAL DEVICE
Nevena STEVANOVIĆ, Nataša LJUBIČIĆ, Nikola STANKOVIĆ, Maša BUĐEN, Brankica KARTALOVIĆ, Mirjana VUKOSAVLJEV 379

EFFECTS OF NITROGEN FERTILIZATION ON THE YIELD OF TRADITIONAL VARIETIES AND LANDRACES OF WINTER WHEAT
Sanja MIKIĆ, Milan MIROSAVLJEVIĆ, Ljiljana BRBAKLIĆ, Vladimir AĆIN, Jelena VISKOVIĆ, Goran JAĆIMOVIĆ 384

RESULTS OF TESTING THE WORKING QUALITY OF DIFFERENT TECHNOLOGICAL-TECHNICAL SYSTEMS FOR PRECISION SOWING OF MAIZE
Saša BARAĆ, Milan BIBERDŽIĆ, Aleksandar ĐIKIĆ, Aleksandar VUKOVIĆ, Dragana LALEVIĆ 392

PLANT PRODUCTION

CROP PRODUCTION: CURRENT STATE AND CHALLENGES, ADVANCES AND PROSPECTS TO BALANCE ENVIRONMENTAL, SOCIAL AND ECONOMIC IMPERATIVES

Steve QUARRIE*

European Training Academy, Belgrade, Serbia
*Corresponding author: steve.quarrie@gmail.com

Abstract

Although current crop production trends are keeping pace with population growth, climate change challenges agriculture to maintain that food production. This challenges agriculture to develop new varieties whilst balancing yield gains with environmental, social and economic imperatives. Some examples of progress in breeding and technologies are presented here. Last century, AE Watkins collected 827 wheat landraces and old varieties. These are finally all sequenced, revealing around 70% unique haplotypes, which will considerably improve our ability to feed the world as it gets hotter, and agriculture comes under increasing climate stress. The ability now to sequence crop genomes rapidly and generate 'infinite' numbers of DNA markers for genetic maps, makes precise location of genomic regions regulating key genes much easier. A wheat doubled haploid population from Chinese Spring x SQ1, with a dense genetic map has been used to study genetic control of yield and many other traits from multi-year x location trials. We now have a candidate gene (TraesCS2B03G1460600) for yield on chromosome 2B. Novel advances can now make agricultural land more productive by combining crop production with solar panels capturing sunlight, and soil and plant sensors, such as *in planta* nitrate probes, are playing major roles providing farmers with decision-support systems. However, policymakers now have conflicting priorities - what is best for society? Thus, do we need more food or more biogas? We have a new Horizon Europe project Hort2thefuture and to encourage growers to adopt our project innovations, we have a behavioural change Work Package, which targets policymakers.

Keywords: *Crop production, Climate challenges, New technologies, Conflicting priorities.*

Introduction

The world population is currently increasing at around 0.9% per year, equivalent to around 70 million people per year. Although the trend in annual population growth is slowly decreasing, and is predicted to be only 0.47% by 2050, that still represents a population increase from around 8.2 billion in 2024 to 9.7 billion in 2050 (https://www.worldometers.info/world-population). Is crop production currently sufficient to meet this predicted population growth? According to a detailed recent OECD-FAO report (OECD/FAO, 2024), the increase in global food production is predicted to continue exceeding the increase in population for the next 10 years, with overall crop production projected to grow at an annual rate of 1.0%. Examples of trends in crop yields per hectare over the last 60 years are shown in Figure 1 for cereals and for tomato. While increases in cereal yields for developed countries (Fig 1a), such as the United Kingdom, have largely levelled off in recent years, yields for lower- and middle-income countries are continuing to show substantial percentage increases, though starting from a low baseline of only around 1 t/ha. A similar picture is evident for horticultural crops such as tomato (Fig 1b), though the impact of high-intensity production technologies on increasing yields in developed countries, such as the Netherlands and United Kingdom, from the 1980s to the new millennium is strikingly evident.

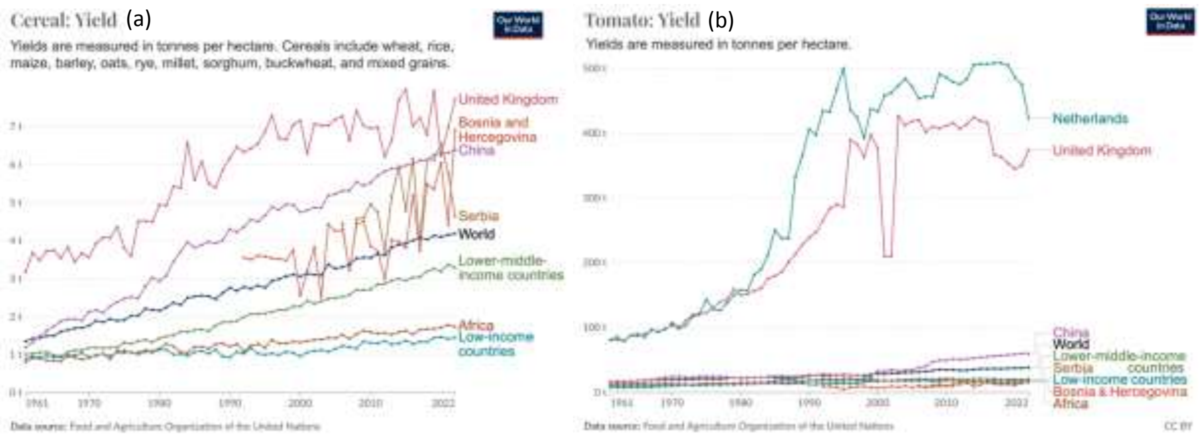

Figure 1. Changes between 1961 and 2022 in cereal yields (a) and tomato yields (b) in tonnes/hectare for selected countries and world production taken from https://ourworldindata.org/crop-yields.

According to the OECD-FAO report, future growth in production is expected to be driven mainly by yield gains in low- and middle-income countries, assuming the continued development of more intensive production systems. For example, while growth in food production in Europe and Central Asia is predicted to be only around 7% over the next 10 years, it is predicted to be over 25% in Sub-Saharan Africa and India. Projections suggest that 80% of global crop production growth will come from improvements in yields, as the long-term decline in agricultural land-use is expected to persist.
Crop yields in a given environment can be described in general terms by Figure 2. Here, traditional varieties give lower yields and respond little to increasing inputs, whereas modern varieties have inherently better yield potential and respond better to inputs.

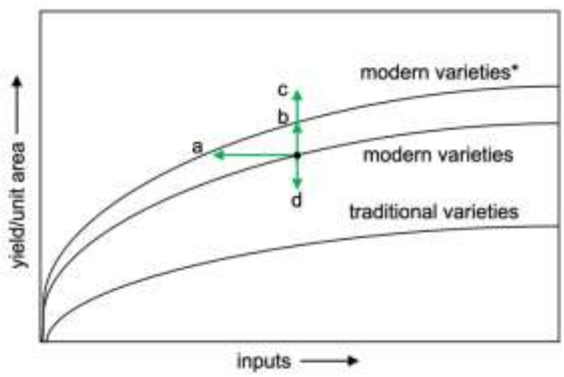

Figure 2. The relationship between crop inputs and yield per unit area for traditional and modern varieties.
* represents maximum yields attainable under current optimum technical and climatic conditions.

The original Green Revolution improved crop production by developing varieties more responsive to inputs, and the following years saw crop production increases mainly through increasing inputs, though with diminishing returns. Crop production now faces four scenarios in the coming years, represented in Figure 2 by the four arrows **a-d**. More recently, the emphasis, especially in the more developed world, has been on improving technical efficiency, replacing yet higher input use with improved information and managerial skills (drone technology to monitor fertiliser needs, for example), thereby moving towards line **b** (yield increases with existing crop varieties and inputs). Alternatively, with appropriate incentives or regulations (e.g. on input pollution) coupled with improved monitoring of input use, farmers may follow line **a**, reducing inputs, but using them more efficiently so that yields are not sacrificed. Thirdly, breeders are constantly striving to improve the yield potential of new varieties (line **c**), allowing farmers to benefit from genetic improvements.

However, aspects of climate change risk imposing serious obstacles on our ability to maintain the necessary increases in crop production, with the risk that farmers' yields in the future will follow line **d**. Climate change will increasingly impact crop yields through increased variability of both temperatures and rainfall. These are likely to lead to lowered efficiency in the uptake of inputs, resulting in lower yields. We are already witnessing an increasing frequency and severity of extreme weather events, such as droughts, floods, heat waves and storms, leading to localised soil erosion and, in some areas, increased soil salinity. While no amount of plant breeding or new technologies can insulate farmers from the devastations of severe flooding events, or soil erosion, predicted changes in crop water availability and temperature can be addressed by the scientific community, to reduce the impact of climate change on line **d**.

Some examples of recent progress with this, considering both genetic gains in future crop varieties and technologies to improve crop production, are described in the next two sections.

Advances in plant breeding

Increases in crop yield per hectare rely on a combination of improved agronomy and improved genetic potential. Traditionally plant breeding relied on 'crossing the best with the best and hoping for the best!'. Since those days, a revolution in molecular genetics has significantly affected the 'hoping for the best' aspect of plant breeding. Breeders are now able to identify relatively easily and quickly specific alleles of specific genes that will help to improve one or other aspect of crop performance, such as disease resistance, or quality.

Thus, the key to being able to exploit the huge wealth of genetic variation amongst agriculture's major crops and wild relatives is the rapid development of DNA sequencing technologies. While it took the International Wheat Genome Sequencing Consortium (IWGSC) 13 years to sequence the large hexaploid wheat genome with a consortium of around 200 scientists from 64 countries (IWGSC, 2018), sequencing wheat varieties has now become routine using long-read sequencing platforms such as the Illumina NovaSeq sequencer. Indeed, long read sequencing has been called the "Method of the year" by Marx (2023): "To large-scale projects and individual labs, long-read sequencing has delivered new vistas and long wish lists for this technology's future."

Long-read technologies are transforming genome studies, with reads considerably over 30 kb now being claimed by sequencing instrument manufacturers. Marx (2023) predicts that this recent revolution in generating long reads of either DNA or RNA could one day lead to routine sequencing of entire genomes, transcriptomes and epigenomes at high throughput rates and accuracy. Furthermore, costs of sequencing are expected to come down. Researchers are progressing towards a "one box" capability, replacing the plethora of bioinformatics tools currently needed to order the reads into the complete genome. Other "wish-list" items being achieved are higher accuracy and saving time. Early sequencers had error rates as high as 30%, but, for example, Oxford Nanopore Technologies (ONT) sequencing platform now regularly achieves 92% accuracy and claim it has achieved close to 99% at a base level. Although it took 13 years to complete the first full sequence of hexaploid wheat, it took the John Innes Centre, UK (Adamski, Simmonds and Uauy, 2023, unpublished information) a matter of weeks to sequence one of the wheat parents of a population my group has used for many years for Quantitative Trait Locus (QTL) analysis (see below).

Here are just a couple of examples of the opportunities this revolution in sequencing technologies offers to plant breeders in the coming years.

The Watkins wheats

During the 1920s and 1930s the British geneticist Arthur Watkins collected 827 old land races and varieties of wheat from around the world, especially Europe, the Middle East, the Indian subcontinent, China, USA and Australia. With the advent of rapid DNA sequencing technologies, these old wheats have now finally been sequenced (Cheng et al., 2024).
They mapped variants in the Watkins wheat collection that are absent from modern wheats, using linkage disequilibrium-based haplotype analysis to identify that of 71,282 haploblocks, almost 70% (49,626) are Watkins-unique haplotypes (Figure 3). From accompanying phenotyping studies, many of the haplotypes restricted to phylogenetically isolated Watkins ancestral groups were found to have beneficial effects on yield potential, adaptation, human nutrition and disease resistance.

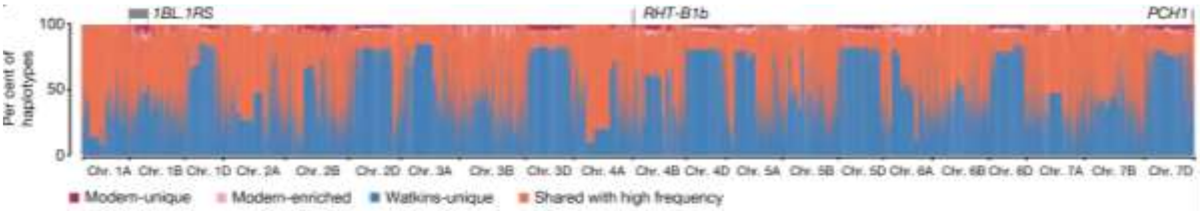

Figure 3. Genomic distribution and comparison of haplotypes between Watkins and modern wheats along the 21 chromosomes, including the proportion of haplotypes that are absent (Watkins-unique), shared with high frequency, modern-enriched or unique to modern wheat. Reproduced from Cheng et al. (2024) with permission.

Overall, their analyses of the genetic makeup of the Watkins collection revealed that modern wheat varieties make use of only 40% of the genetic diversity found in the collection. The Watkins wheats are full of useful variation which is simply absent in modern wheats. These lost traits are now being tested by plant breeders aiming to create new varieties that are made possible only because of the efforts of Arthur Watkins a century ago.
Thus, the results have provided a "gold mine" of opportunities for breeders to exploit the genetic variation revealed amongst these wheats. According to co-author Simon Griffiths "Essentially, we have uncovered a goldmine. This is going to make an enormous difference to our ability to feed the world as it gets hotter and agriculture comes under increasing climatic strain." These Watkins wheat collection resources, including germplasm, genomic and phenotypic data, are now publicly available through the Watkins Worldwide Wheat Genomics to Breeding portal (https://wwwg2b.com/).

Targeting a gene for yield

The ability now to sequence crop genomes rapidly, even the huge wheat genome (16 x rice), and generate an 'infinite' number of DNA markers for genetic maps makes precise location of genomic regions regulating genes of importance much easier. I have worked with a wheat mapping population of 95 doubled haploid lines from the cross Chinese Spring x SQ1 since 1991, and with support from many colleagues, we now have a dense genetic map to study the genetic control of yield and many other traits measured in multi-year and multi-location trials in the field and in pots (Quarrie et al., 2005, Czyczyło-Mysza et al., 2013, 2018, 2019). Nearly 6300 markers with known bp sequences have now been located on both the genetic and physical maps, allowing quantitative trait locus (QTL) analysis to locate genomic regions controlling yield with high resolution. Thus, many genomic regions influencing yield per plant have been identified to have around only 50 high-confidence genes. Furthermore, both parents of the mapping population have now been sequenced (Adamski, Simmonds and Uauy, 2023, unpublished information), and a gene database of SNP polymorphisms between

Chinese Spring and SQ1 has been created. This allows candidate genes for QTL effects to be readily identified.
An example of using the database of SNP polymorphisms to identify a candidate gene for yield per plant is shown in Figure 4. In collaboration with the team of Dragana Rančić at the Faculty of Agriculture, Belgrade University, who studied stem anatomy in the mapping population, a major QTL on chromosome 2B for number of stem vascular bundles was shown to be due to stem cell division traits, and was also coincident with QTLs from several other trials for the following traits: yield/plant, yield/ear, grains/spikelet, biomass/plant, biomass/stem and width of leaves 4, 5 and the flag leaf.

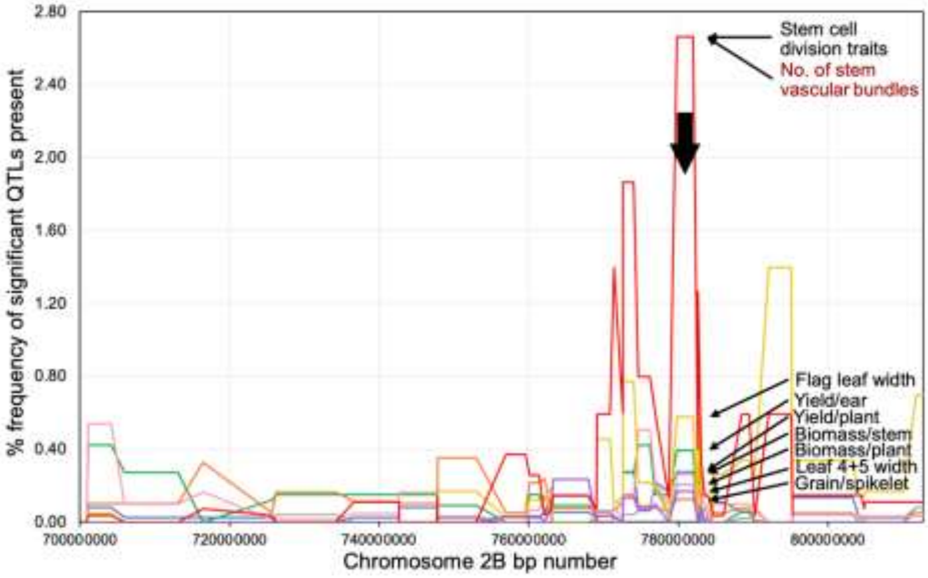

Figure 4. Percentage frequency (calculated as % of all QTLs identified for the trait on the genome) of significant QTLs present on a segment of chromosome 2B long arm (700,000,000 – 813,000,000 bp, Chinese Spring sequence v2.1), for several yield and related traits. Arrows point to the QTL region coincident across all traits.

Thus, the gene(s) responsible for modifying these traits likely affects meristematic cell division leading to differentiation of more leaf and stem vascular bundles, giving wider leaves, more vascular tissue in the stem, hence more biomass per stem and per plant, which would increase assimilate supply to developing ears, giving more grains per spikelet and hence, eventually, more yield per ear and per plant.
Marker polymorphisms on 2B showed this vascular bundle number QTL to be within a 4 MB region from 778594252 to 782573401, which encompasses 48 high confidence genes, of which 30 genes showed SNP polymorphisms between Chinese Spring and SQ1. One of those genes (TraesCS2B03G1460600, equivalent to TraesCS2B02G583800 of Chinese Spring RefSeq v1.1, with Gln→Arg at position 62/354) was identified to be a transcription factor with several gene ontologies consistent with effects on the traits coincident with the vascular bundle number QTL, including yield/plant, namely being located in the nucleus, DNA binding, transcription regulation, cell morphogenesis and differentiation.

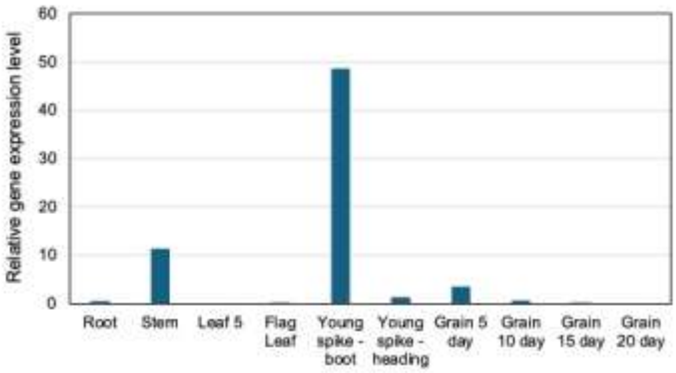

Figure 5. Relative gene expression level in several tissues of wheat at different stages of development.

Furthermore, expression of the gene (TraesCS2B02G583800), measured by Chi et al. (2019), was confined largely to the early stem and young spike at boot (Figure 5), which is consistent with QTL effects we found on the stem (vascular bundle differentiation) and the yield component grains per spikelet (Figure 4). The young spike at boot would be typically around 2 weeks before anthesis, at the time potential number of grains per spike would be determined (Kirby, 1988). Thus, these findings are consistent with TraesCS2B03G1460600 (TraesCS2B02G583800) being the functional gene for this effect on yield and other traits, though much more work would need to be done to confirm this.
The availability now of DNA technologies to sequence large genomes such as wheat relatively quickly, gives molecular biologists and breeders new tools and opportunities to identify genes and their favourable alleles to target yield improvements more effectively in the coming years. So, for wheat, the recent sequencing of the Watkins collection opens the way to more rapid progress in developing varieties which are better adapted to our climate change challenges.

Advances in technologies

Growing crops is becoming ever more sophisticated, with a host of new technologies providing decision support tools and all manner of air, plant, soil and water sensors to give farmers opportunities to increase productivity and reduce inputs. Here are a few recent examples.

Agrivoltaics
The railway from Cambridge to Ely in the UK (bottom right in Figure 6) passes alongside rows and rows of solar panels on what used to be prime agricultural land. These belong to AGR, a renewable energy company specialising in low carbon energy generation. Together with Clarke Energy (a company installing an innovative energy centre for supplying electricity and heat to the project), the glasshouse facility is being used to grow cucumbers. The Energy Centre for the glasshouse combines a heat pump system with a combined heat and power plant (CHP) comprising gas engines with CO_2 recovery. The heat pumps will provide renewable hot water heating to glasshouses and will recover renewable heat from local reservoirs (ponds) on site (Figure 6). The CHP is used to power the glasshouse, the LED grow-lights and various site auxiliaries. The waste heat generated from the engines is used as hot water to heat the glasshouses. The CO_2 recovered from exhaust gases is transferred to the glasshouse to help accelerate the growth of the crop. The glasshouse facility is expected to be able to grow 10% of the cucumbers consumed in Britain using 30% less CO_2 than conventionally heated glasshouses (https://www.clarke-energy.com/2021/agr-glasshouse-chp-heat-pump-project).

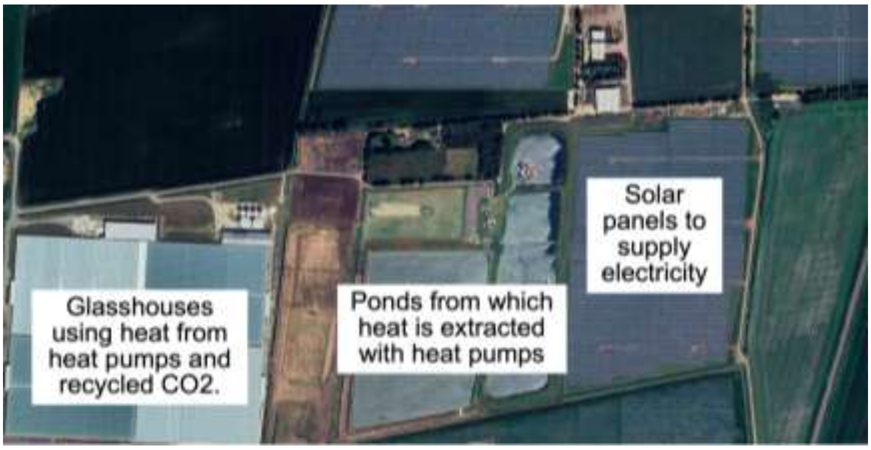

Figure 6. Google Earth image of the AGR facility using solar panels and heat pumps to grow cucumbers in glasshouses.

However, using agricultural land for solar panels does not inevitably mean that the land is lost from agriculture. A solar energy farm in Kosovo is using animals to keep the grass in check. A flock of sheep and goats is brought in twice a week to graze around and under the solar panels.

More sophisticated ways of using land for both solar energy and agriculture (agrivoltaics) are also available. Agrovoltaics is on the rise across France. Research is being carried in the north-east of the country by solar-energy company TSE. Here, solar collectors have been mounted high enough above the field to allow a crop to be grown and combined under the panels. The panels, which normally cover only about half the surface area of the crop, are able to rotate to follow the path of the sun and can also shift to a vertical position to let the rain pass. Horizontally, they can limit the damage of hail or make the ground temperature rise or cool a few degrees depending on the weather. The aim is to allow farmers to keep producing food while providing shade to protect crops from climate change, such as the very hot weather seen this summer across much of Europe, as well as providing renewable energy: (https://www.euronews.com/green/2022/10/19/french-farmers-are-covering-crops-with-solar-panels-to-produce-food-and-energy-at-the-same). A similar system of solar panels fixed at height above the crop is available from Fraunhofer ISE (https://www.ise.fraunhofer.de/en/key-topics/integrated-photovoltaics/agrivoltaics.html) in Germany. Another, less technically complex approach, particularly suited to temperate regions, is in trial by the company Next2Sun (https://next2sun.com/en/agripv) using vertical photo-voltaic panels. In this way, 90% of agricultural land is preserved, yielding more electricity than flat-inclined solar panels.

While agrivoltaics usually lead to slight reductions in crop yield, the economics can still be beneficial, and the topic of agrivoltaics has recently been reviewed extensively by Chopdar et al., 2024 and Garrod et al., 2024.

Sensors and tools

Sensing what is going on in the plant, soil and air and being able to apply that information through decision-support tools (DSTs) make it possible for farmers and growers to optimise input use by applying them where and when they are needed, thereby targeting lines **a** and **b** of Figure 2 (using inputs more efficiently to achieve the same yield and increasing yield towards the theoretical maximum for a crop variety).

More efficient use of fertilisers is a target for the current interest in developing sensors which monitor nitrate uptake and utilisation. Existing tools for probing nitrogen status *in planta* rely primarily on destructive and time-consuming methodologies, with low information content on the temporal characteristics of nitrogen uptake. Literature is accumulating on recent developments with nitrate-selective electrodes, and several sensing materials are summarised by Ibrahim et al., 2022. However, measuring nitrate concentrations continuously *in planta* has only just been demonstrated, using maize as the target crop plant (Ibrahim et al., 2022) and with a needle sensor giving a 200-2000 ppm nitrate concentration range. This allowed 10-h diurnal measurement of nitrate concentrations in a maize stem.

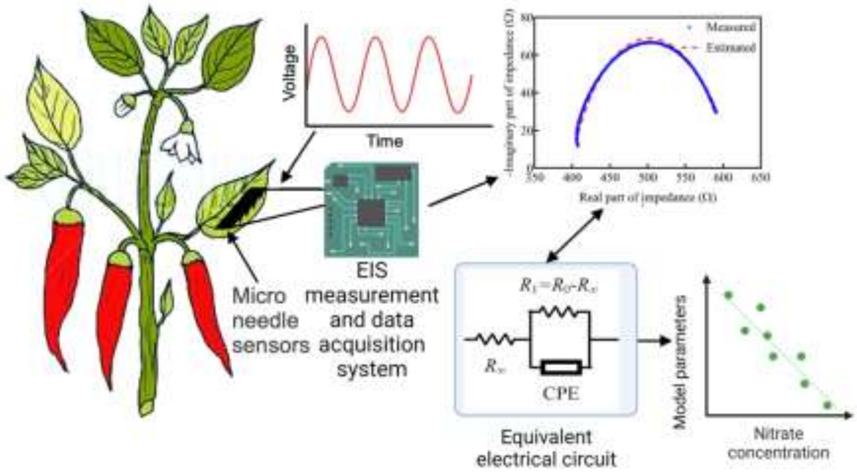

Figure 7. Design elements of an *in planta* probe to measure nitrate concentrations in pepper (*Capsicum annuum*) leaves with measurements based on electrochemical impedance spectroscopy.

Encouraging though this may be, *in planta* nitrate concentrations in horticultural crops, such as tomato and pepper, can exceed 4000 ppm (Magán Cañadas, personal communication), where the nitrate-selective electrode signal of Ibrahim et al. (2022) becomes asymptotic. To address this limitation, a Horizon Europe project (Hort2thefuture, https://hort2thefuture.eu/homepage-hort2thefuture/) plans to develop an *in planta* nitrate electrode allowing nitrate concentrations of pepper plants to be monitored. Design elements for this sensor are illustrated in Figure 7.

Effective use of such sensors requires the parallel development and application of DSTs, such as those recently reviewed by Zhai et al. (2020), Mabhaudhi et al. (2023) and Iakovidis et al. (2024). However, despite the plethora of such tools now available, their uptake by farmers and growers has been limited. Thus, even in the UK, Rose et al. (2016) estimated that of 359 DSTs available to farmers and advisers, only 49% of farmers used some form of DST, compared with 100% of advisers. Farmers found software (28%), paper-based (22%) and apps (10%) most useful, and 15 characteristics were found to influence effective uptake of DSTs (Figure 8).

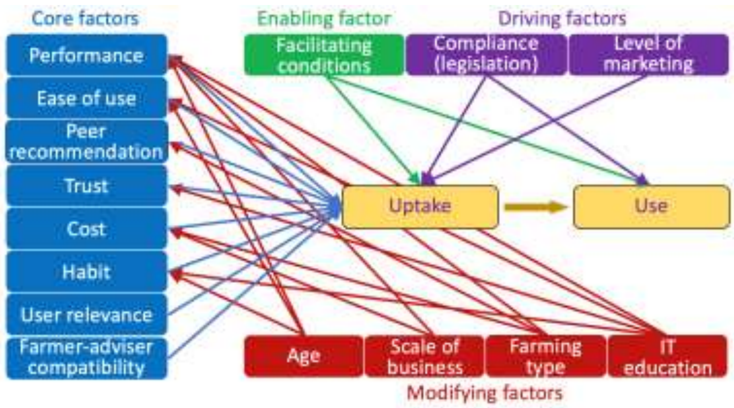

Figure 8. Theory of uptake and use of decision-support tools in agriculture. Redrawn from Rose et al., 2016.

Effective marketing of a new DST was, inevitably, a key determinant of tool uptake, and the authors proposed that instead of just focusing on designing DSTs that are easy to use, other important, but rarely highlighted, factors could be taken into account. Thus, the ability to help users satisfy legislative requirements via a DST was particularly helpful in encouraging uptake.

Balancing environmental, social and economic imperatives

The use of agricultural land by solar panels for the glasshouses growing cucumbers, shown in Figure 6, illustrates the conflict between using land directly to grow food and using that land for other purposes. Farmers will inevitably be tempted to use their land for the greatest economic benefit, so offering them state subsidies and lucrative contracts for anaerobic digestion of maize (https://www.soilassociation.org/media/4671/runaway-maize-june-2015.pdf) are encouraging farmers in the UK to cultivate energy crops, rather than food for either human or animal consumption. While the upward trend in meat eating is stagnating in high-income countries, expansion of maize production for animal feed to meet demand for animal feed is predicted to increase significantly in upper middle-income and lower middle-income countries over the next 10 years (OECD, 2024). Although the OECD report predicts that the intensity of agriculture’s global greenhouse gas emissions will decline overall by 2033, they will rise in lower and lower-middle income countries. This will be due largely to expansion of meat eating, where 1 kg of beef, for example, has a CO_2 footprint about 10 times that of soybean, and a soybean meat substitute (Herrmann et al., 2024). Policy makers need to decide where their country’s priorities lie. What is best for society as a whole? Do we need more food or more biogas, and should policies encourage a reduction in meat consumption? It is a very complex societal issue and every country will have difficult political choices to make in the years ahead, particularly in determining how agriculture could mitigate climate change.

Conclusions

The overall prognosis for crop production during the coming decade or so looks encouraging, with developments in DNA technologies facilitating breeding crop varieties with higher yields and better adapted to climate change, underpinned by an increasingly sophisticated supply of sensors and decision-making tools for farmers. However, the extent to which food production targets are met in the years to come will depend on farmers adopting these new varieties and practices (accepting behavioural change). Thus, projects such as Hort2thefuture (Figure 9) which targets reduced use of peat-based substrates and inputs as well as improved soil health in horticulture, supported by a new *in planta* nitrate probe and decision-support tools, includes activities to target behavioural change amongst its stakeholder groups – not only growers, but consumers and, most importantly, policy makers at the EU, national and local levels.

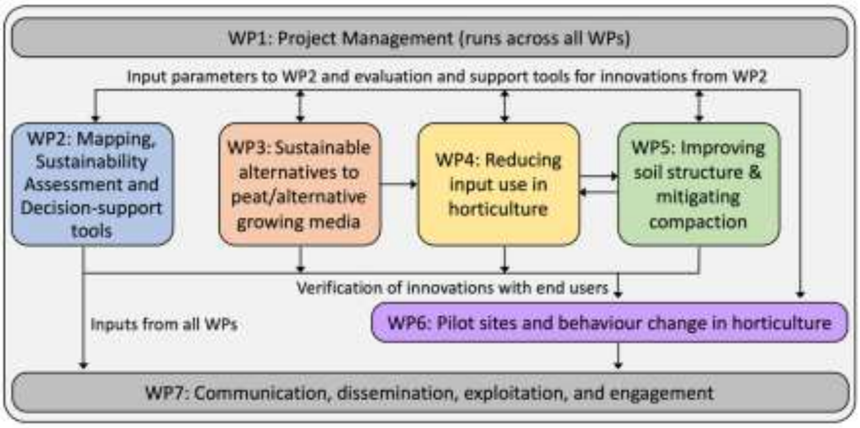

Figure 9. Relationships amongst Work Packages in the Horizon Europe Hort2thefuture project (2024-2028).

Abstract

Somatic embryogenesis is an efficient method for large-scale date palm propagation, offering high multiplication rates and rejuvenation of plant material, facilitating consistent multiplication or the creation of new varieties. Indirect somatic embryogenesis induces callus formation in Taquerbucht, Teggaza, and Deglet Nour cultivars. This study aims to establish cell suspensions from embryogenic calli in date palms for protoplast isolation, with the goal of obtaining somatic hybrids resistant to Bayoud disease through protoplast fusion.

Embryogenic calli initiated cell suspensions in liquid medium, achieving proliferation within 1.5 months. Calli (100 mg) were fragmented into small pieces, transferred to 25 mL of liquid medium, and stirred at 100 rpm. Subculturing resulted in dissociation of calli and release of variously shaped cells. For protoplast isolation, the highest yield (5.87x106 protoplasts/g) was achieved using a 2% cellulase RS and 6% hemicellulase solution after 24 hours of incubation without agitation. Protoplast yield improved with 45 minutes of stirring and 10 hours of incubation in the enzymatic solution.Protoplast fusion was achieved using 50% PEG (w/v) with a molecular weight of 8000 after 20-25 minutes of incubation. Fused protoplasts were transferred to a regeneration medium to produce callus, somatic embryos, and plantlets.

Key words: *Date palm, cultivars, somatic embryogenesis, cell suspensions, isolation and fusion of protoplasts.*

Introduction

The date palm (*Phoenix dactylifera* L.), named by Linnaeus in 1734, is an ancient fruit tree cultivated for millennia for its highly nutritious and succulent fruit, the date (Abul-Soad, 2012). It was first domesticated around 10,000 years ago in Mesopotamia and Egypt, later spreading to the Maghreb countries by the fourth century (Abul-Soad, 2012).For populations living in Saharan oases, the date palm is a fundamental resource. It not only provides vital products but also conditions the existence of other agricultural resources in the oasis. Date palm cultivation holds significant economic importance in Arab countries, particularly in the Maghreb, where globally renowned cultivars such as „Deglet Nour“and „Madjhool“ are extensively grown.

Algeria's palm-growing heritage spans 169,380 hectares, with over 18 million palm trees producing approximately 1247.403 tonnes annually (FAOSTAT, 2023). Ranking third globally, Algeria contributes 14% of total date production and exports valued at $37 million (FAOSTAT, 2023). These economic figures underscore the crop's significance in both financial terms and for sustaining oasis populations.

However, date palm cultivation faces significant challenges, notably Bayoud disease caused by the fungus *Fusarium oxysporum* f. sp. *albedinis* (Malençon, 1949). Various strategies, including enhanced farming practices and biological, chemical, and genetic controls, are employed to mitigate Bayoud's impact and ensure sustainable date palm cultivation.

Genetic enhancement through biotechnological methods is recognized as the primary approach for conserving and improving the date palm heritage. In vitro enhancement via protoplast fusion of of susceptible and resistant cultivars holds promise as a solution to this challenge. Early advancements in somatic hybridization of date palm were pioneered by Gabr and Tisserat (1984), who successfully isolated protoplasts that formed calli but did not survive. Subsequent efforts by Chabane et al. (2007) achieved viable protoplasts that developed into microcalli and calli, although with a low fusion rate. Yatta et al. (2013) isolated protoplasts from „Deglet Nour“and „Taquerbucht“ cultivars. Badr-Elden et al. (2017) established a protocol for isolating protoplasts from „Medjool“ and „Khalas“ cultivars, regenerating them through somatic embryogenesis. More recently, Yatta et al. (2020) successfully regenerated protoplasts from cell suspensions of 'Deglet Nour', 'Teggaza', and 'Taquerbucht' cultivars.This study aims to establish a preventive strategy against Bayoud disease using chemical fusion facilitated by PEG.

Materials and methods

Plant Material Collection and Dissection

Samples from three cultivars (Deglet Nour, Taquerbucht, and Teggaza) were collected on March 28, 2019, from palm groves in Adrar and Touggourt cities in Algeria, weighing between 2.67 to 4.45 kg. Dissection involved removing the roots and woody bases of the fronds to reveal the white, tender heart.

- Deglet Nour: good date quality, Bayoud susceptible.
- Taquerbucht: average date quality, Bayoud resistant.
- Teggaza: fairly good date quality, Bayoud susceptible.

Callus induction and Cell suspension establishment

Shoot tips were cultured on MS medium supplemented with 45 g l^{-1}sucrose, 1 mg l^{-1}thiamine HCl, 100 mg l^{-1}myo-inositol, 100 mg l^{-1} glutamine, 170 mg l^{-1}monosodium phosphate, 100 mg l^{-1}potassium phosphate monobasic, 200 g l^{-1}ammonium citrate, 7 g l^{-1}agar, 2,4-D, N6-(2-Isopentenyl) adenine, and activated charcoal. Cultures were incubated in darkness at 28 ± 2°C for 16 hours.

For cell suspension initiation, 100 mg of callus was chopped into 1 mm pieces and placed in 100 ml Erlenmeyer flasks with liquid medium containing MS elements, sucrose, thiamine HCl, myo-inositol, glutamine, monosodium phosphate, potassium phosphate monobasic, Picloram, N6-(2-Isopentenyl)adenine, and polyvinylpyrrolidone (PVP). Flasks were shaken at 100 rpm in darkness at 27 ± 1°C for 6 to 10 weeks. Filtration through sterile sieves (380 µm, 250 µm, and 60 µm) was used to establish an embryogenic cell suspension.

Obtaining and Somatic Hybridization by Chemical Fusion with PEG

We used an enzymatic solution (Cellulase Onozuka RS and Hemicellulase) to isolate protoplasts from cell suspensions. For fusion, we employed PEG 8000 at 30% and 50%. PEG solutions were prepared in 100 mL distilled water with 0.5 mM $CaCl_2$, then sterilized by autoclaving and filtration (Table 1).After enzymatic maceration and purification, protoplasts are suspended in 12 mL of fusion solution containing 91 $g.L^{-1}$ mannitol and 74 $mg.L^{-1}$ $CaCl_2 \cdot 2H_2O$. In a sterile 25 mL tube, 5 mL of protoplasts from a Bayoud-resistant cultivar are mixed with 5 mL from a Bayoud-susceptible cultivar. A 300 µL aliquot of this mixture is placed in a 9 cm Petri dish and settled for 10 minutes. In another sterile 25 mL tube, 10 mL of PEG is mixed with 10 mL of the fusion solution. A 300 µL of this PEG solution is applied around the protoplast mixture for 15 minutes at room temperature. Protoplast fusion progress is monitored using an optical microscope.

Table 1.Preparation of PEG Solutions for 100 mL of Water.

PEG (8000)	30%	30%	50%
$CaCl_2$	14.8 g	14.8 g	198 mg
Distilled water	Normal	Lukewarm	Lukewarm
pH	/	5.9	7
Sterilization	filtration	autoclave	autoclave

Culture of Fused Protoplasts

A 0.5 mL aliquot of the fused protoplast suspension is spread onto Petri dishes with a nurse layer and incubated at 28 ± 2°C in the dark. Development is monitored every 24 hours under an inverted microscope (Olympus DP 70) to check survival, cell wall formation, cell division, and microcalli formation.

Results and discussion

Callus induction andCell suspension establishment

The study aims to obtain cell suspensions from embryogenic calli for protoplast isolation to produce somatic hybrids via protoplast fusion. Using 8 offshoots with 8 to 12 explants per cultivar, the explants swell and grow on the culture medium within the first four months, with some developing faster than others.Some explants develop small white nodular calli which, after isolation, become embryogenic strains. The first signs of proliferation are visible after 5 to 7 months. Cultures generally respond within 5 months to a year, producing 164 strains for Deglet Nour, 134 for Taquerbucht, and 159 for Teggaza. Proliferating calli are subdivided during subcultures based on size (0.5 to 4 cm). After 2-3 subcultures, the number of embryogenic strains increases to 180 for Taquerbucht, 212 for Teggaza, and 251 for Deglet Nour. Friable calli grow rapidly, doubling in mass in a month, while compact calli grow more slowly. The initial phase of culturing Deglet Nour, Taquerbucht, and Teggaza cultivars showed callus initiation on medium with 2,4-D and IPA, influenced by growth regulator type and concentration. This supports findings by Abul-Soad (2012) and Yatta El Djouzi et al. (2023) that Murashige and Skoog medium enhances callus initiation and guides morphogenesis. Callogenesis is preceded by significant explant volume increase (Mirani et al., 2021).

For cell suspensions, calli are transferred to a fresh liquid medium with 5 mgL^{-1} picloram and 1 mgL^{-1} N6 -(2-Isopentenyl)adenine (2iP). After one week, embryogenic masses detach from the aggregates, with particles 2-3 mm in diameter. Date palm cells multiply easily in liquid medium, but resulting suspensions have variable regeneration potentials. Subcultures develop bright to pale yellow embryogenic cell aggregates. Viability, evaluated by Fluorescein diacetate (FDA) under an inverted microscope (Fig. 1D), shows isolated cells and variable-sized cell masses. Compact textured calli produce aggregates of dividing amyliferous cells mixed with elongated non-amyliferous cells. These findings align with Al-Khayri (2012) and Yatta et al. (2013), who state that these cells are the starting point of viable suspensions. Embryogenic suspensions typically contain free elongated, oval, or round cells, or cell aggregates (Al-Khayri, 2012). The increase in cell numbers and aggregates, with maintained viability (80-99%), indicates the favorable action of the culture medium.

Isolation and Somatic Hybridization Testing by Chemical Fusion with PEG

To isolate date palm protoplasts, we followed established methods (Assani et al., 2002 ; Chabane et al., 2007; Yatta et al., 2020).Protoplasts were isolated from cell suspensions using an ES enzymatic solution consisting of 2% Cellulase, 6% Hemicellulase, 0.5% CaCl2, 3% KCl, and 0.05% MES. This enzymatic combination effectively removed cell walls, yielding high-quality protoplasts.The combination of 2% cellulase RS and 6% hemicellulase was found to release the highest number of protoplasts, as observed in studies on date palm (Chabane et al., 2007). However, it's noted that concentrations of cellulase exceeding 2% can lead to the digestion of the starting plant material (Badr-Elden et al., 2017).Microscopic observation after purification revealed isolated, perfectly spherical protoplasts of various sizes. These protoplasts were colorless, lacked visible chloroplasts, and had large vacuoles (Fig. 2 A). The highest yields were obtained with the Taquerbucht and Teggaza cultivars, indicating that protoplast morphology depends on both the plant material origin and the cell suspension quality.Protoplast culture requires sufficient isolation, with yield and viability rates depending on the base material (Badr-Elden et al., 2017). High yield and viability rates from cell suspensions make them ideal for protoplast production, aligning with findings by Chabane et al. (2007). Similar results were reported for rice (Jain et al., 1995).For protoplast fusion, we used polyethylene glycol (PEG). We performed heterofusions of:

- Deglet Nour x Taquerbucht protoplasts from cell suspension
- Taquerbucht x Teggaza protoplasts from cell suspension

Under the inverted microscope, PEG caused protoplasts to attract, adhere, agglutinate, and fuse in pairs or groups (Fig.2A-B). The high density and disordered aggregation of fused protoplasts made it impossible to determine the fusion rate.We observed the entire fusion process, which took from a few minutes to half an hour (Tab. 2 and Fig. 3 A-F).

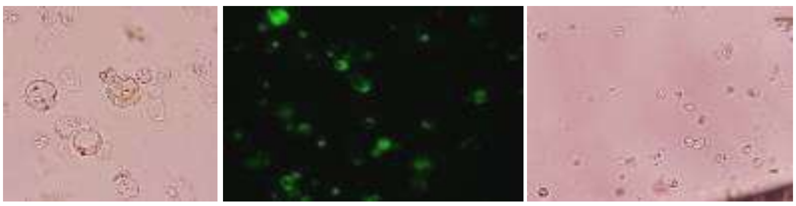

Fig.2:Protoplast suspension of cultivar Taquerbucht (A), Fusion of viable protoplasts stained with FDA using 50% PEG for 25 minutes of incubation (B), Protoplasts burst in 50% PEG after 30 minutes of incubation (C)

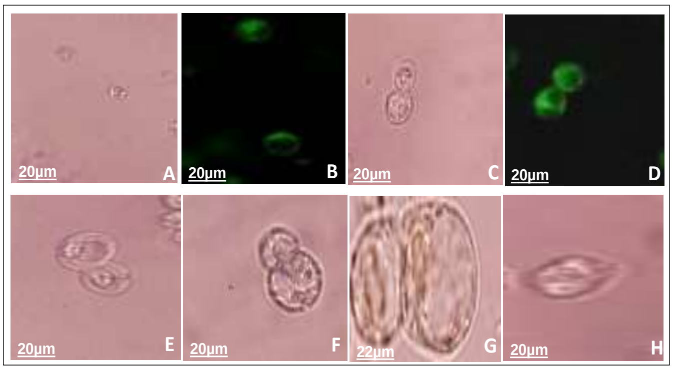

Fig.3. Fusion of TKB x DN cultivar protoplasts with polyethylene glycol: A, B, C, and D: alignment of two different protoplasts; E and F: beginning of one protoplast penetrating the other; G and H: two fused protoplasts.

The results are shown in Table 16. The application of 30% PEG solution did not initiate protoplast fusion. When this 30% PEG solution was adjusted with warm, sterile distilled water at pH 5.9, protoplasts began to align after 15 minutes of incubation. However, the protoplasts remained in this state without adhering or fusing.

Table 2. Effect of different PEG treatments on protoplast fusion (4 repetitions)

Incubation Time	PEG Concentration		
	30% SS pH	**30%, pH 5,9**	**50% pH 7**
15 min	No effect	Alignment	Alignment
20 min	No effect	No adhesion	Adhesion
25 min	No effect	No fusion	fusion
30 min and more	Protoplast death		

Observation of protoplasts treated with 50% PEG at pH 7 showed alignment. After 15 minutes, protoplasts adhered and fused after 25 minutes (Fig. 3 A, B, C). After 30 minutes of incubation, the protoplasts began to burst (Fig. 2C). Beyond this point, PEG becomes toxic, leading to protoplast death (Assani et al., 2002). High density and disordered aggregation made fusion rate evaluation difficult. Multi-fusion was also observed (Fig. 2B).

In Deglet Nour x Taquerbucht heterofusion, 86% of 15 Petri dishes showed no regeneration or embryogenic structures, likely due to aging cell suspensions and PEG treatment effects. Conversely, 33% of Teggaza x Taquerbucht heterofusion cultures developed. After five weeks, yellowish microcalli formed (Fig. 4A, B). The low division rate of protoplasts suggests PEG may disrupt mitotic activity (Assani et al., 2002). Electrofusion, using electric field pulses, yields more embryos and plantlets than PEG fusion (Guo and Deng, 1998).When transferred to germination medium, globular proembryos appeared after 6-8 months (Fig. 4C), developing into embryos. These embryos formed the first green leaf, crucial for developing into plantlets. Some calli necrotized or failed to develop into embryos (Fig. 4B).

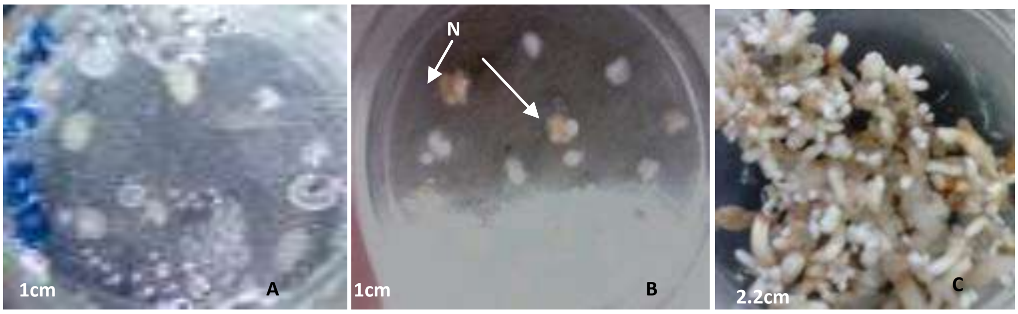

Fig 4. Evolution de la culture de protoplastes fusionnés et la cytologie des microcals issus de fusion. A: microcals issus de l’hétérofusion (Taquerbucht X Teggaza), B: multiplication des microcals issus de l’hétérofusion (Taquerbucht X Teggaza), C: obtention des proembryons.

Conclusion

Indirect somatic embryogenesis in date palm cultivars resistant and susceptible to Bayoud allows for the production of proliferating calli for protoplast isolation, although the PEG used for fusion results in a low rate of cell division. To improve culture and somatic hybridization, alternative methods such as cryopreservation, electric fusion, molecular characterization, and in vitro and greenhouse selection tests are recommended.

Abstract

Recent data indicates that global cereal production in July was around 7 million tonnes, bringing the total to 2792 million tonnes. This still marks a 0.6% decline from the 2021 figures. Agriculture's susceptibility to climate change is highlighted by the doubling of extreme weather events, such as heatwaves, droughts, floods, and storms, since the early 1990s, averaging 213 incidents annually from 1990 to 2016. These phenomena severely impact agricultural productivity, reducing food availability and income while increasing food prices. Climate change affects crops directly through heat and water stress and indirectly through changes in pest and weed dynamics. This research delves into the impacts of climate change on strategic crop production, with a focus on winter cereals and agricultural adaptation in Algeria. Various adaptation practices, such as new cropping systems, revised cropping calendars, and the introduction of resilient crop varieties, have been successfully implemented to mitigate climate change effects in Algerian drylands. This review synthesizes literature on climate change impacts and agricultural adaptations in Algeria, particularly concerning winter cereals. The insights aim to aid national policymakers in developing strategies for agricultural adaptation and ensuring food security.

Keywords: *climate change, winter cereals, adaptation, arid and semi-arid zones.*

Introduction

Climate change significantly impacts temperature and precipitation patterns, thereby alters the agro-climatic resources critical for crop growth and production (Fischer, 2015). In Algeria, the hot season, lasting about 2.8 months, features daily maximum temperatures exceeding 28°C, with peaks reaching 33°C and lows of 19°C. The cool season spans 4.1 months, with daily highs below 14°C and lows around 9°C (Weather Spark, 2021). Extreme temperatures, more than average temperatures, significantly affect vegetation growth, which only occurs within certain thermal limits—the minimum growth temperature and the maximum growth temperature (Bechikhi Kheira, 2010). Historical data from 1937 to 2009 show an increase in annual mean temperatures by more than 0.5°C, with the 1992-2002 decade being the hottest, witnessing a warming of about 0.7°C (Taibi and Souag, 2012). Additional studies by Nouaceur et al. (2013) identify four distinct periods of temperature trends from 1970 to 2012, characterized by varying incidences of cold and warm years. Regions such as the High Plateaus exhibit significant seasonal and regional temperature variations, with Mediterranean influences moderating temperatures in coastal provinces like Setif, Bordj Bou Arreridj, and Tissemsilt. Conversely, the steppe climate experiences extreme temperature fluctuations, exceeding 40°C in summer and dropping below 0°C in winter, leading to growth slowdowns and even vegetation destruction (Benchrif, 2011). Drought, defined as a significant water deficit compared to the norm for a specific period and region, presents a recurring challenge in Algeria (Benzerti and Habaieb, 2011). Climate constraints, such as water scarcity and uneven precipitation distribution, along with temperature extremes, adversely affect cereal crops. Historical analyses reveal periods of significant dryness in the early 20th century and a pronounced precipitation deficit from 1973 to 1992, intensifying from east to west (Aggoun Zoubida, 2022). Droughts impact crops differentially across developmental stages, delaying germination and potentially preventing crop emergence if water scarcity persists (Ghouer, 2006). During critical growth phases, such as late stem elongation and grain filling, drought severely affects yield components and overall productivity (Ghouer, 2006). Agricultural strategies must therefore address drought proactively, implementing measures to mitigate its impacts. Given these challenges, this paper aims to address the following research questions: What are the specific impacts of climate change on the production of strategic crops, particularly winter cereals, in Algeria? What agricultural adaptation practices can be implemented to mitigate these impacts? This study will explore new cropping systems, adjusted cropping calendars, and changes in crop varieties, assessing their effectiveness in enhancing the resilience of Algerian agriculture to climate change. By providing insights into these adaptation strategies, this review seeks to inform national policymakers and support efforts to ensure agricultural sustainability and food security in Algeria.

Impacts of Climate Change on Algerian Agriculture

Impacts Yield Potential

Climate change directly impacts agricultural yields, particularly for rainfed cereals, which are highly susceptible to drought. Insufficient moisture during germination delays crop emergence, while persistent drought can prevent it entirely. The most drought-sensitive period for Algerian cereals typically occurs between late stem elongation and the milk stage of grains, generally around April-May. During this phase, water deficits can significantly reduce yield components, such as tiller count, ear number, and grain size (Ghouer, 2006).

Simulations by Chourghal and Hartani (2020) on the phenology, water balance, and yields of durum wheat in Algeria reveal that climate warming shortens the vegetative phase by 31 days, negatively impacting dry matter accumulation and reducing yields by 36% under fixed sowing dates. Conversely, dynamic sowing dates, which allow for earlier planting, maintain yields by balancing the vegetative and reproductive phases more effectively.

Impacts of Agricultural Systems

Warming and reduced precipitation are shifting cultivated lands southward in Algeria. The southern limit for winter wheat cultivation has moved due to the presence of aquifers replenished by floodwaters from the Atlas Mountains, where annual precipitation can reach 350-450 mm. Studies indicate that despite limited recharge, these regions can achieve yields of 50 qx/ha compared to 18 qx/ha in the High Plateaus (MADR, 2023). Adopting multiple cropping systems, including no-tillage, direct seeding, and reduced tillage, can enhance total annual production in warmer climates. Transitioning from intensive tillage to simplified cultivation techniques improves soil porosity, structural stability, and water retention capacity (Moussadek et al., 2011). Studies indicate that direct seeding improves organic matter content and soil carbon levels, though the overall soil organic matter remains low, highlighting the need for increased organic input (Lahmar and Ruellan, 2007).

Climate change poses multifaceted challenges to Algerian agriculture, including reduced water availability, increased temperatures, and the frequency of extreme weather events. These factors collectively hinder crop productivity, particularly for water-sensitive crops like cereals. Analyzing historical climate data and crop yield trends reveals a clear correlation between rising temperatures, reduced precipitation, and declining agricultural outputs.

Adaptation Strategies

To counteract the harmful effects of climate change, Algerian agriculture must adopt robust adaptation strategies. These include changing sowing dates, using drought-resistant crop varieties and optimizing irrigation practices. Previously, early sowing could help crops avoid summer heat peaks (Fordyce, 2006), today, with climate change, late sowing of cereals can give satisfactory results. The period of its growth is limited by the water deficit at the beginning and end of the cycle combined most of the time with thermal stress (Chennafi et al., 2008a; Bouzerzour and Benmahammed, 2009). While advanced irrigation techniques can improve water use efficiency, ensuring that crops receive adequate moisture even during dry periods.

Crop Varieties

Developing and adopting new crop varieties that are more resilient to climate stressors is crucial. In northern Algeria, introducing stress-tolerant varieties has shown promise in mitigating yield losses. These varieties are better equipped to withstand high temperatures and water deficits, ensuring more stable production levels despite adverse climatic conditions. Varietal selection has taken on great importance in the cereal growing sector in Algeria, and there is numerous work in this area for the search for durum wheat varieties adapted to the semi-arid climate (Benlaribi et al. 1990). Other studies have focused on the modification of root growth dynamics in relation to the adaptation of varieties cultivated in semi-arid cereal zones (Benlaribi et al. 1990; Khaldoun et al. 1990).

Conclusion

The impacts of climate change on agriculture are essential to food security in Algeria. In this article, we examined the impacts on agricultural production associated with climate change and climatic hazards. We also mentioned recent research advances in Algeria, based on simulations of regional climate and crop models, as well as the exploration of adaptation measures. It is interesting to develop a more comprehensive assessment system for the agricultural impacts of climate change, which integrates cultural aspects, regional specifications and region-specific adaptation measures. Indeed, a system for evaluating the impacts of climate change on multiple aspects of agricultural production (potential productivity, adaptation measures specific to the region and comparative advantages and disadvantages according to crops) has been gradually established in Algeria. Climate change has radically modified the specific and temporal distribution of agro-climatic resources in Algeria. Environmental sustainability is becoming increasingly important, particularly in the arid and semi-arid growing areas of Algeria, due to an increase in potential evapotranspiration under a warmer climate. Weather and climate events have become more frequent and have caused serious damage to agricultural production, but a quantitative assessment is lacking. Most studies focus on a single aspect of an agroecosystem. A more systematic view of agroecosystems is needed to achieve multiple goals in food security and environmental sustainability. Adaptation plays an essential role in mitigating the impacts of climate change on production in the different growing areas of Algeria. Crop calendar, variety, cropping system, agronomic technique and field management must be adjusted to maintain production in the face of climate change. In regions where thermal conditions have improved thanks to warming, there is potential for agricultural intensification. Given the importance of local characteristics in agriculture, a more systematic simulation model of agricultural production and adaptation covering different growing areas across Algeria is crucial. Algeria, faced with the growing challenges of climate change, must implement agricultural adaptation strategies to maintain crop productivity and ensure food security. The combination of improved cropping systems, optimized sowing dates and adapted crop varieties can mitigate the impacts of climate change. The results of this study provide a basis for policy and practical interventions aimed at strengthening the resilience of Algerian agriculture, while providing guidelines for farmers and national policymakers.

Abstract

Climate change presents significant challenges to agricultural sustainability and biodiversity, particularly affecting spice plants valued for their aromatic and honey-producing qualities. Introducing new species and varieties of these plants holds promise for enhancing rural development through their aromatic properties and support for beekeeping. In Armenia, *Hyssopus officinalis* L., commonly known as hyssop, is recognized as a promising yet underutilized species. There is a current imperative to explore and evaluate the adaptive and productive potential of breeding varieties of Hyssopus for introduction in Armenia. To facilitate the adoption of modern varieties, comprehensive research was conducted on seed collections from various regions. This involved assessing available varieties and potential lines, evaluating accessibility to germplasm, and gathering characterization and evaluation data. To locate significant hyssop collections worldwide, and to determine the number of accessions held by various seed banks for facilitating the introduction of hyssop varieties to Armenia for study and cultivation, various online platforms were reviewed. These included international information systems and databases accessible through national gene banks. Additionally, field studies were conducted under valley conditions in the Republic aimed to assess the biological and agronomic characteristics of these plants. These efforts collectively aim to ensure the effective and well-founded introduction of modern breeding varieties.

Keywords: *inventories, origin, distribution, agronomic and biological parameters.*

Introduction

Climate change presents substantial challenges to the sustainability and productivity of agricultural systems and biodiversity, impacting diverse spice plants renowned for their aromatic and melliferous properties (Kumar et al., 2022). Introducing new species and varieties of spice plants can significantly boost rural development by tapping into their potential as aromatic additives and in beekeeping (Torre et al., 2023). One such promising yet underutilized plant in Armenia is *Hyssopus officinalis*, commonly known as hyssop. There remains a gap in understanding the productive and melliferous potential of breeding varieties of hyssop in Armenia, including the analysis of functionally important components under introduction conditions.

Hyssopus officinalis, commonly known as hyssop, is a perennial herbaceous plant belonging to the Lamiaceae family. It is native to the Mediterranean region and parts of Central Asia, but it has been naturalized in various regions worldwide due to its medicinal and culinary uses (Tobyn et al., 2011). Historically, hyssop has been revered for its therapeutic properties and has been mentioned in ancient texts for its medicinal virtues (Bespalyko et al., 2016).

Hyssopus officinalis holds significant importance both culturally and scientifically. It has been traditionally used in herbal medicine for its antiseptic, expectorant, and cough-relieving properties (Fathiazad and Hamedeyazdan, 2011). The herb is also valued in culinary practices, adding a distinctive flavor to soups, salads, and herbal teas. Moreover, *Hyssopus officinalis* is known for its ornamental value, with its attractive purple-blue flowers attracting pollinators, making it a valuable plant in ecological gardening (Maslova et al., 2021).
The chemical composition of *Hyssopus officinalis* highlights its medicinal efficacy, containing bioactive compounds like volatile oils (e.g., pinocamphone, isopinocamphone, β-pinene), flavonoids (e.g., hesperidin, diosmin), tannins, and phenolic acids such as rosmarinic acid (Baj et al., 2018). These compounds contribute to its antioxidant, antimicrobial, and anti-inflammatory properties crucial for therapeutic applications. In traditional medicine, Hyssopus officinalis treats respiratory ailments like bronchitis and asthma due to its expectorant and bronchodilator effects, and its antimicrobial activity supports its use in wound healing and as a natural antiseptic.
Hyssopus officinalis also serves as a nectar source for honeybees, producing abundant nectar for hyssop honey (Antonie, 2019). This honey is prized for its distinct flavor and potential health benefits derived from hyssop's medicinal properties. In Armenia, *Hyssopus officinalis* grows on dry stony slopes and rocks across various floristic zones, including Shirak, Lori, Ijevan, and Zangezur (Flora of Armenia, 1987). Despite its cultural, medicinal, and ecological importance globally, cultivation of Hyssopus officinalis is currently absent in Armenia. To facilitate the introduction of modern varieties of this plant the study of seed collections across various regions were studied in terms of available varieties and prospective lines, accessibility for getting germplasm and catheterization and evaluation data to make the introduction of modern breeding varieties effective and well-grounded.
The research aimed to gather detailed information on available varieties and prospective lines through identification of existing suitable germplasm as well as on accessibility of germplasm through assessing the ease of obtaining seeds or plant material from different sources to support introduction and cultivation efforts. Based on the gathered information, accessions of hyssop varieties were obtained, and a field study was conducted under valley conditions in the Republic to assess the biological and agronomical characteristics of these plants. By conducting this field study, the goal was to provide valuable insights into selecting hyssop varieties that can thrive and contribute effectively to agricultural practices in Armenia, aligning with local farming conditions and economic interests.
By addressing these aspects, the study aimed to establish a robust foundation for the introduction of modern breeding varieties of *Hyssopus officinalis*, ensuring that future cultivation efforts are both effective and scientifically grounded.

Material and Methods

To identify major hyssop collections globally, assess the number of accessions held by various seed gene banks to facilitate the introduction of hyssop varieties to Armenia for further study and cultivation, different web-based platforms, including international information systems and national gene bank's internet available databases were studied. These included:

- EURISCO (the European Search Catalogue for Plant Genetic Resources) being maintained at the Leibniz Institute of Plant Genetics and Crop Plant Research on behalf of the Secretariat of the European Cooperative Programme for Plant Genetic Resources (https://eurisco.ipk-gatersleben.de/apex/eurisco_ws/r/eurisco/home),
- GENESYS portal, a collaborative initiative involving Bioversity International on behalf of the CGIAR System-wide Genetic Resources Program, the Global Crop Diversity Trust,

and the Secretariat of the International Treaty on Plant Genetic Resources for Food and Agriculture (https://www.genesys-pgr.org/).
- Gene Bank of the Slovak Republic, Genetic Resources Information System of Slovakia, https://griss.vurv.sk/,
- Genebank Information System of the IPK Gatersleben, https://www.ipk-gatersleben.de/en/research/genebank,
- Institute of Biosciences and Bioresources, Italy, Mediterranean Germplasm Database, https://www.ibbr.cnr.it/mgd/
- MSBKew Millennium Seed Bank Kew- through Millennium Seed Bank Seed List, https://apps.kew.org/seedlist/SeedlistServlet
- The NARO Genebank, Research Center of Genetic Resources, Japan, https://www.naro.go.jp/english/laboratory/ngrc/database/index.html
- USDA ARS, U.S. National Plant Germplasm System, https://www.ars-grin.gov/Collections#plant-germplasm, and others.

Data from national databases were compared with information obtained from international databases like EURISCO and GENESYS to prevent the double-counting of accessions and to provide a clear understanding of the global distribution and availability of hyssop varieties for potential introduction and cultivation in Armenia.
During the field study, the biological characteristics that include studying the growth habits, flowering patterns, and overall adaptation to local climatic conditions were investigated. In addition, agronomical characteristics were studied through evaluating parameters such as yield potential, resistance to pests and diseases prevalent in the region.

Results and Discussion

The data were compiled from national inventories and genebank’s databases, detailing the availability of *Hyssopus officinalis* L. accessions as of 2024. The countries included in the Figure 1 are encompassing major regions where *Hyssopus officinalis* L. is conserved *ex situ* in seed collections.

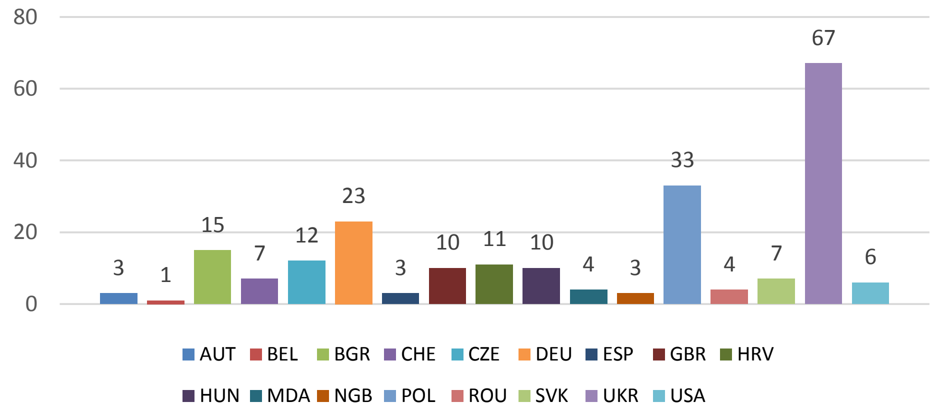

Figure 1. Distribution of *Hyssopus officinalis L.* accessions per national inventories
The Figure 1 illustrates the distribution of *Hyssopus officinalis* L. accessions across various countries' genebanks worldwide. Key findings from the figure include that the countries such as Ukraine, Polland, Germany have a substantial number of accessions, indicating a strong presence of genetic diversity for *Hyssopus officinalis* L. including varieties, prospective lines and wild forms. Conversely, some countries, such as Austria, Belgium, Czech Republic show lower numbers of accessions, suggesting potential gaps in conservation efforts or research focus.

Understanding the origin of *Hyssopus officinalis* L. accessions plays a crucial role in decision-making for selecting varieties to introduce in Armenia. Knowledge of their geographic and environmental adaptations helps assess potential for acclimatization and suitability to local growing conditions, ensuring successful cultivation and sustainable utilization in Armenian agriculture. The Figure 2 displays the distribution of *Hyssopus officinalis* L. accessions across various countries.

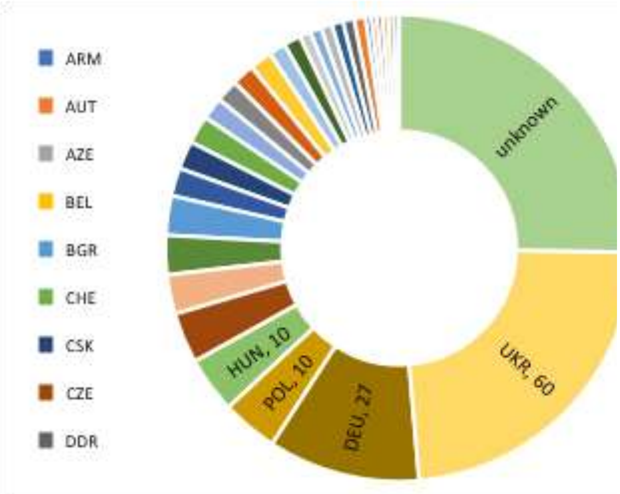

Figure 2. Distribution of Hyssopus officinalis L. accessions per origin

The distribution pattern underscores the Central European region as a primary focal point for research and conservation efforts in the global conservation of *Hyssopus officinalis* L. genetic resources.

Other criteria used to evaluate hyssop accessions availability in genebanks was accessions status. Accessions categorized as "Wild" refer to those collected from wild populations of *Hyssopus officinalis* L. make up 39 accessions. "Weedy" accessions, found in spontaneous or disturbed habitats, account for 1 accession. The category of "Traditional cultivars/landraces" comprises 63 accessions. The category of "Advanced or improved cultivar" includes 24 accessions crucial for our research, although absence on names of varieties for big number of accessions posed challenges during selection. A significant challenge in our research stems from the 84 accessions categorized as “Other” and "Unknown" lacking clear classification information. These figures underscore the difficulty in selecting appropriate varieties due to inadequate passport data on accessions stored in seed collections globally.

Table 1. Hyssopus officinalis accessions number per status

Hyssop accessions status	Number of accessions
Wild	39
Weedy	1
Traditional cultivar/landrace	63
Breeding/research material	8
Advanced or improved cultivar	24
Other	19
Unknown	84

Understanding the distribution of *Hyssopus officinalis* L. accessions per MLS (Multilateral System of the International Treaty of Plant Genetic Resources for Food and Agriculture) status is crucial because it ensures compliance with the international Treaty on plant genetic resources for food and agriculture. This knowledge helps in facilitating responsible sharing and promoting sustainable use of genetic resources under the Treaty's framework. The data presented in Figure 3 illustrates that while there are a sufficient number of accessions included in the MLS, a significant number of accessions have an unknown MLS status. This uncertainty hinders the exchange of data and germplasm, highlighting the importance of clarifying the MLS status for effective international cooperation and resource sharing.

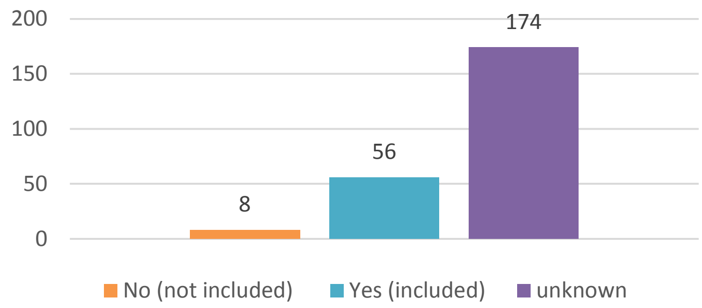

Fig. 3. Distribution of *Hyssopus officinalis* L. accessions per MLS status

The selection of varieties for introduction in Armenia was prevented by absence of characterization and evaluation data both in online available databases. Based on analysis of the data available the following varieties were preliminary selected for introduction: 'Lekar', Inej, 'Lazur', 'Accord', 'Belyj', 'Rozovyj', 'Otradnyj Semko'. To evaluate the adaptability of the selected hyssop varieties to local conditions the biological and agronomic indicators were used. Specifically, emphasis was placed on assessing green mass, measuring green mass yield and 1000-seed weight. Throughout the growing season, biometric measurements, morphological studies, and phenological observations will be conducted to monitor the progression and duration of the main developmental stages (Table 2).

Table 2. Agronomic and biological parameters of different hyssop varieties

Hyssop variety	Variables	DF	Agronomic indicators		Biological indicators	
			Green mass yield (kg/m^2)	1000 seeds weight (g)	flowering state duration (days)	ripening
'Lekar'	Samples	30	0.51*	1.19*	150*	mid-ripening
	Errors	105	0,89	0.04	0.96	
	CV%**	-	4.31	4.83	4.82	
'Inej'	Samples	30	0.58*	1.21*	160*	early-ripening
	Errors	104	0.41	0.06	0.89	
	CV%**	-	6.28	4.65	3.83	
'Lazur'	Samples	30	0.41*	1.24*	153*	mid-ripening
	Errors	104	0.92	0.04	0.87	
	CV%**	-	*5.64*	3.68	4.68	
'Accord'	Samples	30	0.48*	1.19*	155*	late-ripening
	Errors	106	0,79	0.03	0.91	
	CV%**	-	4.34	3.97	5.28	
'Belyj'	Samples	30	0.47*	1.14*	158*	early-ripening
	Errors	104	0.86	0.04	0.89	
	CV%**	-	5.47	4.58	4.88

	Errors	104	0.92	0.04	0.97	
	CV%**		5.03	4.29	4.96	
'Otradnyj Semko'	Samples	30	0.33*	0.99*	148*	mid-ripening
	Errors	105	0.88	0.18	0.87	

	CV%**	-	4.39	3.96	4.96	

*correlation is significant at the 0.01 level (2-tailed)
**ratio of the standard deviation to the mean

Conclusions

Based on the findings, the varieties ‘Inej’, ‘Lekar’, ‘Accord’, ‘Belyj’ that demonstrate optimal performance and potential for commercial cultivation in Armenia, considering both agricultural productivity and environmental sustainability.
The conducted gap analysis underscores the importance of international collaboration in the conservation and utilization of plant genetic resources, particularly for medicinal and aromatic plants like *Hyssopus officinalis* L.
The next step of the research will be quality assessment, in particular, the analyzing the chemical composition of essential oils and other bioactive compounds, which contribute to the plant's aromatic, medicinal and melliferous properties.

Acknowledgments

The studies were supported by the Committee for Science of the Ministry of Education, Science, Culture and Sports of the Republic of Armenia within the framework of scientific project no. 21T-4B081 and Visegrad Scholarship Program (ID #52410181).

Abstract

In today's time, with the aim of reducing chemization and increasing yield, the improvement of plant production is moving towards the introduction of biostimulants. Many biostimulants help the plant to withstand the effect of biotic and abiotic stresses, increasing quality and yield, and stimulating physiological processes in the plant. The purpose of this study, improvement nutritional conditions of cucumber and production with maximum yield by using biostimulants so if possible recommend this biostimulants asreplacement of current chemical fertilizers.The experiment was conducted in 2021.year in a greenhouse as a two-factorial experiment with a completely randomized block design in four replications on two cucumber varieties. Treatments included three concentrations of 0 (control), 0.5%, 1%, 1.5% by foliar application in three phases.The best treatment in this study was the biostimulant at a concentration of 1.5%, which led to a statistically significant increase in yield. The highest yield in all tested variants was recorded in the Besta variety (14.64 kg m^{-2}) with nutrition with a biostimulant at a concentration of 1.5%, which is statistically significantly higher compared to the same variety fed up with a biostimulant at a concentration of 1% (7.33 kg m^{-2}) and 0.5% (8.13 kg m^{-2}) .

Keywords: *cucumber, biostimulant, yield, quality.*

Introduction

Cucumbers are important for human nutrition are their consumption is a guarantee of health. Cucumbers have about 96-97 percent water content, are low in calories and are an essential part of a healthy diet. Many studies indicate that cucumbers contain a significant amount of vitamins and minerals necessary for human health (Daneshvar, 2004; Peyvast,2009). In nutrition of vegetable, organic and mineral fertilizers are used. Organic fertilizers play a major role in plant growth and developmentas a source of all necessary macro and microelements, where during mineralization they improve the physical and chemical properties of the soil. However, according to many studies (Ogbonna, 2008; Ndaeyo et al., 2005; Makinde et al., 2007) fertilizingthe soil with only organic fertilizers for needs of vegetable nutrition does not give good results in achieving high and stable yields. Therefore, these types of organic fertilizers should be used in combination with mineral fertilizers achieve the best yields (Rašević, 2017).Applying mineral fertilizers achieves high yields, but their application can have a harmful impact on plant quality, reduce dry matter content, increase erosion, and instability of soil aggregates (Adeoluwa and Adeogun, 2010). In order to reduce chemization, increase yield, and improve plant production, the introduction of biostimulants is necessary.

Biostimulants with compared to chemical fertilizers have enormous economic and environmental advantages. Now, biological fertilizers have special significance as a suitable replacement for chemical fertilizers, aiming to improve of soil fertility and ensure plant health (Shahdi Komalah, 2010), environmental safety, improved agricultural crop quality, economic benefits, soil resources stability , long-term production potential protection, and on the other hand, the production of food crops for raising consumer quality(evaluation of biological fertilizers) and consumer health protection(Wu et al.,2005). Adediran and Akande (2005) state that there is a significant difference in the yield growth and plant efficiency due to the use of biostimulants and mineral fertilizers.
The goal of this research was to improve cucumber nutrition and achieve the highest yield by applying biostimulants in order to recommend these fertilizers as a substitute for chemical fertilizers.

Materials and methods

The experiment was conducted in the experimental greenhouse of the Faculty of Agriculture, University of East Sarajevo (City of East Sarajevo, Entity of Republic of Srpska, Bosnia and Herzegovina) in 2022. The area where the greenhouse is located is at an average altitude of about 500m (18^{o}22'59.45" longitude and 43^{o}49'36.95" latitude).Cucumbers were planted et the beginning of April. The plant spacing was 50 cm, the row spacing was 60 cm. The total area of the experiment was 100 m^2. Cultivation and care were conducted according to standard method.The study was conducted with completely randomized block design at four replicates.
The biostimulant "Humistar" was used in concentrations: 0 (control),0.5%, 1%, 1.5%. When cucumber had 7 to 8 leaves conducted the First stage of spraying, and the second stage was after 15 days of first stage and the three stage of spraying conducted when cucumber in flowering stage.Two varieties of cucumber were analyzed: Monolit F_1 and Besta F_1. In during period of harvest were measured the characters like length of fruit, diameter of fruit, mean of weight single fruit, yield per m^2. Were measured the qualitative characters like of the content of: dry matter content, total sugars, vitamin C.
The data were processed by the method of analysis of variance of the two-factorial experiment (ANOVA) using SPSS 4.5 software.We tested the significance of differences between individual means using the LSD test for general means and interaction.

Results and discussion

The morphometric properties of the plant and variance analysis for the cucumber plants grown using different concentration biostimulant are given in the Table 1. The effect of biostimulants on the characteristics of fruit length, fruit diametar average individual fruit weight was not significant. The findings of the present study were in line with the results of the studies carried out by Raeisi et al., (2013) in which he was reported that the diferent doses of biostimulant had insignifikant effect on the number of fruit, diameter of fruit, weight of single fruit, length of internode and diameter of stem cucumber.
The highest yield was recorded in the Besta variety (14.64 kgm^{-2}) when plant nutrition with a biostimulant in a concentration of 1.5%, which is statistically significantly higher compared to the same variety nutrition with a biostimulant in a concentration of 1% (7.33 kgm^{-2}) and 0.5% (8.13 kgm^{-2}) (tab.2). The qualitative characters like of the content of: dry matter, total sugars, total acids, vitamin C are given in the Table 3 The average percentage of dry matter in cucumber was in the range of 3.41% to 4.19%. The highest percentage of dry matter was in the control variant at the variety Monolit (4.19%), which is statistically highly significant compared of the biostimulant at a concentration of 0.5% (3.69%),concentration of 1%

(3.75%) and concentration of 1.5% (3.76%).The percentage of dry matter in cucumber fruits was not directly dependent on the biostimulant. Besides,many researchers have reported that the use of biostimulants does not change the chemical characteristics of the fruit (Hassan et al., 2021; El-Ghadban et al.,2006).

Highest content of total sugar was when using the biostimulant at a concentration of 1.5% (4.09 g $100g^{-1}$), which is statistically significantly higher compared of the biostimulant at a concentration of 0.5% (3.56 g $100g^{-1}$) and concentration of 1% (3.24 g $100g^{-1}$).

The variety Besta variety had the highest total acids content in the control variant of 1.227 g $100g^{-1}$, which is statistically significantly higher compared to the same variety fed with a biostimulant at a concentration 1%(0.920 g $100g^{-1}$) and biostimulant at a concentration 0.5% (1.167 g $100g^{-1}$). However, the variety Monolit had the highest content of total acids when using the biostimulant at a concentration of 1.5% (1.277 g $100g^{-1}$), which is statistically significantly higher compared to the application of the biostimulant at a concentration of 0.5% (1.022 g $100g^{-1}$).

Cucumber provides a large amount of vitamin C (mg $100g^{-1}$ of fresh base), and in this experiment the treatments with the highest content were when using biostimulant concentration 0.5% (4.81 mg $100g^{-1}$) and concentration 1% (4.79 mg $100g^{-1}$).The lowest vitamin C content was in the control treatment (3.70 mg $100g^{-1}$). Similar results were reported by Radames et al.,(2018).

Table 1. Variance analysis of the morphometric properties

Different concentrations of biostimulants	variety Monolit			variety Besta		
	fruit length (cm)	fruit diametar (cm)	individual fruit weight (g)	fruit length (cm)	fruit diametar (cm)	individual fruit weight (g)
0 (control)	13.64	4.33	168.13	33.48	4.02	287.93
0.5%	12.36	4.48	177.61	18.24	4.30	237.22

Conclusion

According to the experimental data obtained, authorscan conclude that the use of biostimulants can reduce the irrational and ecologically harmful use of mineral fertilizers, and that quality of the fruits will not be reduced.The biostimulant applied in a concentration of 1.5%may be a viable alternative to the conventional fertilizer to increase cucumber productivity.

Abstract

Red clover is an important plant species due to the possibility of cultivation on poor quality soils, it gives high yields of bulky fodder that are characterized by good nutritional values. The goal of this research was to determine the correlation between yield, productive traits and yield quality of eight genotypes of red clover grown on acidic soil in the hilly area of the city of Banja Luka. Field trial were carried out in the first cutting of 2010 and the first cutting of 2011. In both season, 13 characteristics of yield and forage quality were analyzed. In the first cutting of the first year, the highest correlations was found between green mass yield and hay yield (0.95**) and between leaf width and leaf and flower content (0.87**). In the first cutting of the second year, statistically significant ($p<0.01$) positive correlations were found, which was the highest between tree thickness and NFE (0.94**), followed by high correlation values between green mass yield and hay yield (0.90**), fat content and protein content (0.88**), number of trees per plant and tree thickness (0.86**), leaf and flower content and protein content (0.85**). A high negative correlation was found for the number of stems per plant with leaf and with flower content (-0.90**), as well as between ash content and NFE (-0.89**). Knowledge of the positive correlative relationships of certain productive and nutritional traits is desirable for breeding programs and production practices in order to produce high-quality animal feed.

Key words: *Red clover, correlative relationships, yield, nutritional value*

Introduction

Red clover is a perennial leguminous plant important for fodder production. It can be successfully cultivated in hilly and mountainous areas, namely on: acidic, poor, shallow, soils above 250 m above sea level and on soils where alfalfa does not give satisfactory results (Osztoics et al., 2005). In the Republic of Serbia, the production of coarse fodder on soils with poor chemical composition and in hilly and mountainous areas is mainly realized by growing red and white clover, bird foot trefoil and sainfoin (Radović et al., 2010). The height of the red clover plant is mainly determined by the genetic characteristics of the variety and environmental factors (Leto et al., 1998). The width and length of coot red clover was investigated by Primorac et al. (2008), Gatarić et al. (2010), Popović et al. (2011), Radinović et al. (2022a). Red clover forage is of good quality with high nutritional value, which favors the diet of ruminants, especially cattle (Lee et al., 2009). By growing red clover, high yields of green mass and hay can be achieved, the most productive being the first cutting in the second year of life (Petković et al., 2021). Hay from the first swath is richer in proteins compared to the second swath from the same production year (Petković et al., 2020). In Europe, due to the high yield of digestible organic matter, protein content and metabolic energy, red clover is grown on large areas for the production of animal feed (Staniak, 2019). In the Republic of Serbia, in two-years studies of the correlation between morphological traits, yield and quality of red clover the highest correlation was found between the yield of

green mass and the yield of dry matter were were found in the second year of the study (Radinović et al., 2022b). Differences in morpho-agronomic traits and forage quality are conditioned by genetic variability, but are also influenced by production conditions, stage of maturity at the time of mowing, height and frequency of mowing (Swarup et al., 2021).
The aim of this study was to determine the correlation between yield, productive traits and yield quality of eight genotypes of red clover grown on acidic soil in the hilly area of the city of Banja Luka.

Material and methods

For the purpose of these research, the field experiment was carried out at an altitude of 527 m (44°39' N, 17°00' E). The research was carried out in the first swath of 2010 and the first swath of 2011. Four genotypes of domestically selected red clover from the breeding program of the Public Institution Agricultural Institute of the Republic of Srpska (G-1, G-2, G-3 and G-4) and four varieties of red clover (G-5 Nike, G-6 Viola, G-7 Kolubara and G-8 Start). All genotypes were sown in four repetitions. Sowing was done (manually) at a depth of 0.015-0.02 m. The sowing rate was 17 kg ha^{-1}, the distance between the rows was 0.2 m. The plot on which the field tests were carried out was well supplied with humus (5.2%), the phosphorus content was low (7.0 mg P_2O_5 in 100 g of soil) and well supplied with potassium (30.0 mg K_2O in 100 g of soil. The following parameters were analyzed: yield of green mass (t ha^{-1}), plant height (cm), number of trees per plant, tree thickness (mm), length and width of coot (mm), hay yield (t ha^{-1}), leaf and flower content (%). The yield of green mass was determined by measuring immediately after mowing on a field scale. Samples of 1 kg of green mass were taken from the mowed green mass, which were weighed on a Fisher scale to determine the yield of hay. The height of the plant (cm) was determined by measuring (five plants per repetition), the number of stems per plant (pieces) by counting on (five plants per repetition), the thickness of the tree (mm) was determined by a sliding scale (vernier), thickness measurement (five stems per repetition), the length and width of the trefoil (mm) was determined with a sliding scale, by measurement (five trefoils per repetition). Samples for testing morphological characteristics were taken from the middle rows of plots. Hay yield was determined from the ratio of the weight of 1 kg of fresh and dried sample. The leaf and flower content was determined by manually separating the leaf and flower from the stem by weighing the separated mass and the total mass - in the dry state.
The chemical analysis of hay was performed in the Animal feed quality control laboratory at the Faculty of Agriculture in Banja Luka, where the proportions of the following parameters were determined, expressed on the basis of absolute dry matter: dry mass (%), moisture (%), crude proteins (%), crude fats (%), crude cellulose (%), crude ash (%) and nitrogen-free extractives (%). After determining the percentage content of leaves and flowers, samples were prepared for chemical analysis of hay in such a way that the leaf and flower mass was mixed with the stems and ground on a mill. Chemical analyzes of hay were performed according to the methodology: crude proteins, using the micro-Kjeldahl method, modified according to Bermner (1960), i.e. crude proteins by multiplying by a factor of 6.25, crude fats in plant material, using the Soxhlet method, crude cellulose content in plant material, by the Henneberg-Stohman method, raw ash content in plant material, by annealing at 550^0C until constant mass. The measurement results were processed in the program version 22, Statistical Package for Social Sciences and Excel. The results of the investigated properties were processed by analysis of variance (ANOVA). The significance of the differences between the tested genotypes, and their ranking for the r=0.05 significance level, was determined by Duncan's multiple range test (Duncans Multiple Range Test-DMRT). Correlative relations between the analyzed traits were calculated as Pearson's correlation coefficients and significance was determined.

Weather condition

Meteorological data: mean monthly air temperatures and precipitation amounts were taken from the Hydrometeorological Institute of the Republic of Srpska, from the measuring station in Banja Luka - located in the Lazarevo settlement. Mean monthly temperatures in both years of the study were higher than the multi-year average. In relation to the multi-year average (1960-2010), in the first year, a higher amount of precipitation was found, and in the second, a lower amount. In the first year of research (2010) compared to the second (2011), a higher amount of precipitation was recorded (807.6 mm).

Results and Discussion

The obtained results showed differences in the mean values for most of the tested traits which are statistically significant. However the mean values of plant height in both year were not significant different. The lowest coefficient of variation in both years was found for NFE (Table 1).

* ($p<0.05$), ns- no significant,[a,b,c,d..] Values denoted by the same letter are not significantly different at the $p<0.05$ level of probability (*Duncan's Multiple Range Test*). *NFE* - nitrogen-free extract. Genotypes of domestically selected red clover (G-1, G-2, G-3 and G-4), varieties of red clover (G-5 Nike, G-6 Viola, G-7 Kolubara and G-8 Start).

Statistically significant differences in the yield of green mass of red clover were also obtained by Leto et al. (2004), Mihovsky et al. (2011), Tucak et al. (2013) and Radinović et al. (2022a). The presented data of these studies show that in the first cut in 2011, the length of the coot was in the range from 44.72 to 48.2 mm. Primorac et al. (2008) measured the middle coot of the second year of life in three mean values on 12 populations of red clover, and determined that its length was from 42.31 to 48.51 mm, in the same research the coot width was in the range from 21.62 to 27, 74 mm. In the first year (2010), the domestic genotype (G3) had the highest protein content of 19.3%, in the second (2011) 17.81% of the Viola variety (G6), in the research of Leto et al. (2004) cultivar Viola had a lower protein content.
Table 2 shows the correlation coefficients of the analyzed traits in the first cut of the first year. The highest positive correlation was between green mass yield and hay yield (0.95**) and between leaf width and leaf and flower content (0.87**). A high positive correlation (0.95**) in the first year of testing between green mass yield and red clover hay yield was obtained by Radinović et al. (2022b), Tucak (et al., 2013) (0.93**) and Radić et al. (2024) between green mass yield and fenugreek hay yield (0.81**).

$p<0.05$*; $p<0.01$**; N=8; Properties: 1-green mass, 2-dry mass, 3-plant hight, 4-number of plants, 5-steam of thickness, 6- leaflet length, 7-leaflet width, 8-leaf and flower, 9-proteins, 10-fats, 11-cellulose, 12-ash, 13-NFE.

The data obtained in the second year (table 3) show that the correlation coefficients between the 13 analyzed parameters were highly significant between stem thickness and NFE (0.94**), green mass yield and hay yield (0.90**), fat content and protein content (0.88**), number of stems per plant and stem thickness (0.86**), leaf and flower content and protein content (0.85**). A high negative correlation was found between the number of stems per plant and the content of leaves and flowers (-0.90**) and the content of ash and NFE (-0.89**).
On the base of the obtained results on the plots was established, a high positive correlation coefficient between the yield of green mass and the yield of hay (0.90**) (table 3) Similar values of correlation coefficient between the yield of green mass and the yield of red clover hay was found (0.86**) in second year of two year study by Radinović et al. (2022b) and as well as in study (0.93**) Tucak et al. (2013).

13	0.23	0.48	0.69	0.94**	0.81*	0.43	-0.41	-0.77*	-0.74*	-0.52	0.43	-0.89**	

p<0.05*; p<0.01**; N=8; Properties: 1-green mass, 2-dry mass, 3-plant height, 4-number of plants, 5-steam of thickness, 6- leaflet length, 7-leaflet width, 8-, leaf and flower, 9-proteins, 10-fats, 11-cellulose, 12-ash, 13-NFE.

In our research, protein content had high positive correlation with leaf and flower (0.85**), with ash (0.88**) and negative correlations of protein content with number og plants (-0.84**), with cellulose content (-0.89**) and with NFE (-0.74*) table3. However, the authors of Tucak et al. (2013) did not establish high correlative relationships of protein content with analyzed characteristics of red clover. Radić et al. (2024) determined positive correlations between yield and compost yield of green mass and fenugreek seeds.

Conclusion

Positive correlations were established between yield, productive traits and forage quality of red clover. Leaf width was positively correlated with leaf and flower content, and leaf and stem with protein content, which indicates that if we have plants with broad leaves and a higher leaf and flower content in hay, the hay is richer in proteins. A greater number of trees per plant is positively correlated with NFE and stem thickness, but also negatively correlated with leaf and flower, protein and fat content. Genotype 7 (Kolubara) had the highest yields of green mass and hay in both years, domestic genotypes have good forage production potential, and genotype 6 (Viola) high quality forage.

Abstract

The paper presents the ecological characteristics of the macrophyte flora of the protected habitat "Gromiželj". The protected habitat "Gromiželj" is located in the far northeast of Bosnia and Herzegovina in the Republic of Srpska, within the municipality of Bijeljina. The protected habitat covers an area of 8.31 km². In the studied area, the presence of 55 species of macrophyte flora was recorded. Ecological indices are provided according to Ellenberg, while data on life forms are taken from Oberdorfer. The analysis of ecological indices for temperature indicates that the macrophytes in the studied area are predominantly mesothermal species. In terms of the moisture index values, the most prevalent are species of wet habitats, while in terms of soil chemical reaction, there is a dominance of plants that mainly grow on alkaline soils. Regarding nutrient relationships, mesotrophic habitat species dominate, and in terms of the light regime, these are predominantly full daylight species that are tolerant to shade. The most present in the studied area are sub-oceanic and oceanic-sub-oceanic species. According to the ecological index for salinity, most macrophytes in the studied area are halophobic. The analysis of the biological spectrum of macrophytes determined the dominance of hydrophytes, followed by hemicryptophytes. Out of the total number of confirmed macrophyte species in the studied area, 6 species are listed on the Preliminary List of Species for the future Red Book of Bosnia and Herzegovina. According to the IUCN list, of the 55 identified macrophytes, 41 species are in the category of least concern (LC), while for *Urtica kioviensis*, there is insufficient data (DD).

Key words: *Macrophytes, Gromiželj, ecological indices, life forms.*

Introduction

The protected habitat "Gromiželj" is located in the far northeast of Bosnia and Herzegovina in the Republic of Srpska, within the municipality of Bijeljina (Map 1).

Map 1. Location of the Protected Habitat "Gromiželj" (1:200 000)

The protected habitat extends from the southwest to the northeast, spanning 5.5 kilometers and covering an area of 8.31 km². The Gromiželj wetland has an elliptical shape, 1600 meters in length (southwest-northeast direction) and 750 meters in width (northwest-southeast direction). The primary natural values of the "Gromiželj" protected area include the Gromiželj wetland, located in the central part of the reserve, and the partially channelized Prugnjača stream. The remaining areas are predominantly intensively cultivated, with occasional forest complexes: Mladenovača, Taborišta, Toplik, Pištalovac, Čitluk, and Tukar.
Until 2009, floristic research in this area was sparse. In the Flora of Bosnia and Herzegovina, Beck, Maly, and Bjelčić (1927, 1950, 1967) reported the presence of *Utricularia vulgaris* and *Hottonia palustris* in Bijeljina, and *Glycyrrhiza echinata* near Bijeljina and Rača. Šumatić (1997) conducted research on weed flora and vegetation in the Pannonian Basin of the Republic of Srpska, noting the presence of 85 species of weed plants in the Bijeljina area. Interest in the Gromiželj wetland was sparked by the discovery of the relict fish species *Umbra krameri*, prompting the Republic Institute for the Protection of Cultural, Historical, and Natural Heritage of the Republic of Srpska to initiate multidisciplinary research from 2009 to 2010. During this period, the vascular flora was extensively studied. Petronic et al. (2011) analyzed the weed flora of the protected habitat Gromiželj. Petronic et al. (2014) studied the floristic diversity and biodiversity conservation of Gromiželj. Habitat types of European significance in the Gromiželj area were documented by Petronic et al. (2017).
The protection of the area was carried out based on the Nature Protection Law and the Study for the Proclamation of the Protected Habitat "Gromiželj," with the declaration act issued by the Government of the Republic of Srpska ("Official Gazette of the Republic of Srpska" No. 19/18).

Materials and methods

The study utilized existing literature data from Petronić (2017), which presented the diversity of vascular flora. The conservation status and protection level were provided according to the Preliminary Red List of Endangered Plants of Bosnia and Herzegovina (Šilić, 1996) and the IUCN (2024). Ecological indices were given according to Ellenberg (Borhidi, 1993), while data on life forms were taken according to Oberdorfer (2001). Indicator values of plant species according to Ellenberg (Borhidi, 1995) were represented by indices for basic ecological parameters, such as temperature, moisture, soil reaction, nitrogen content in the soil, light intensity, continentality, and salinity. Ecological indices according to Ellenberg are given on scales of 1 to 9, or 1 to 12 (moisture index). Species names were adjusted according to the nomenclature from Euro+Med PlantBase (2006–2024).

Results and discussion

Previous research on the flora (Petronić, 2017) of the protected habitat "Gromiželj" recorded 55 macrophytes.

The ecological analysis of macrophytes in the studied area was conducted based on ecological indices for temperature, soil moisture, soil reaction, mineral nitrogen content in the soil, light regime, continentality and salinity (Table 2).

Table 2. Indicator values of ecological indices for the macrophyte flora of the studied area

The analysis of ecological indices for temperature indicates the dominance of species with an ecological index TB5 (52.8%). These are plants of the montane mesophilous broad-leaved forest belt. Species of the submontane broad leaved forest belt (TB6) also have significant representation (35.85%). Species of the montane needle-leaved forest or taiga belt (TB4) and species of the thermophilous forest or woodland belt (TB7) are not significantly represented (5.66%). The mean value of the ecological index for temperature is 5.42, indicating that the macrophytes in the studied area are predominantly mesothermal species.

Regarding the moisture index values, the most prevalent are plants of wet, not well aerated soils (WB9) (32.1%). The second most common are species with an index of WB10 (20.8%), which are plants of frequently flooded soils. The third place (15.1%) is occupied by plants of moist soils tolerating short floods (WB8). Plants of fresh soils with an index of WB6 and plants with floating or partly emergent leaves with an index of WB11 are represented by 11.3%. Plants most wholly submersed in water (WB12) are present with 9.43%. The mean value of the moisture index is 9.22. This value indicates that macrophytes in the studied area develop in wet habitats, which is expected given that they are species of aquatic habitats.

Regarding the soil's chemical reaction, there is a dominance of basifrequent plants, mostly on basic soils with an index RB7 (41.5%) and neutrophilic plants with an index RB6 (32.1%), which grow mostly on neutral soils but also in acid and basic ones, more or less indifferent plants. Plants of slightly acid soils with an index RB5 are represented by 11.3%, while plants of basiphilous sites with an index RB8 are present with 15.1%. The average value of the ecological factor for soil acidity is 6.6. Based on this, we can say that the macrophytes of the studied area predominantly inhabit basophilic habitats.

Regarding the nutrient content, the most represented are plants of mesotrophic habitats with an index NB5 (24.5%) and plants of submesotrophic habitats with an index NB4 (24.5%). Plants of moderately nutrient rich habitats (NB6) and plants of soils rich in mineral nitrogen (NB7) are present with 15.1%. N-indicator plants of fertilized soils (NB8) are present with 13.2%. Plants of habitats very poor in nitrogen with an index NB2 and plants of moderately oligotrophic habitats with an index NB3 are not significantly represented (1.89% and 5.66%). The average value of the ecological index regarding nutrient content is 5.43. This indicates that the macrophytes of the studied area are predominantly mesotrophic.

In terms of light as an ecological factor, halflight plants, mostly liying in full light but also shadow tolerants (LB7) have significant representation (54.7%). The second most common are light plants with photosynthetic minimum above 40% relative light intensity, less only in

exceptional cases (LB8) (15.1%). Shadow-halfshadow plants with photosynthetic minimum between 5 and 10% relative light intensity (LB4), are represented by 9.43%. Halfshadow-halflight plants with photosynthetic minimum between 10 and 40% relative light intensity (LB6), are present with 17%, while halfshadow plants receiving more than 10% but less than 100% relative light intensity (LB5), are represented by 3.77%. The average value of ecological indices for light intensity is 6.62, indicating that the macrophytes of this area are predominantly full daylight species that are tolerant to shade.
Regarding the continentality index, species with indices CB4 (32.1%) and CB3 (30.2%) dominate. These are suboceanic species that predominantly inhabit Central Europe but reaching to East and oceanic-suboceanic species these are in whole Central Europe. Species of the intermediate type with slight suboceanic-subcontinental character (CB5) are present with 22.6%. Oceanic species with an index CB2, mainly found in Western Europe and the western part of Central Europe, and continental-subcontinental species with an index CB7 are represented with 5.66%. Subcontinental species (CB6) are not significantly represented (3.77%). Regarding the ecological index for salinity, most macrophytes in the studied area are halophob species (SB0) (88.7%) not occurring in salty or alkalic soils.
The analysis of the biological spectrum of macrophytes established the dominance of hydrophytes (52.7%), which is expected since macrophytes are plant species of aquatic habitats. Hemicryptophytes (34.6%) are the second most common, their significant presence corresponding with the climatic conditions of the studied area, the biological spectrum of Bosnia and Herzegovina, and the Balkan Peninsula. Geophytes (5.5%), therophytes (5.5%), and chamaephytes (1.8%) are insignificantly represented.
Of the total number of macrophyte species recorded in the studied area, 6 species are listed on the Preliminary List of Species for the Future Red Book of Bosnia and Herzegovina (Šilić, 1996), categorized as vulnerable species (VU). These are: *Thelypteris palustris*, *Nuphar luteum*, *Hottonia palustris*, *Zanichellia palustris*, *Hydrocharis morsus-ranae* and *Utricularia vulgaris*. According to the IUCN list, of the 55 identified macrophyte species, 41 species are in the least concern category (LC), while for *Urtica kioviensis* there is insufficient data (DD). This research recorded the tertiary relict species *Urtica kioviensis* for the first time in the flora of Bosnia and Herzegovina.

Conclusion

The protected habitat "Gromiželj" is located in the far northeast of Bosnia and Herzegovina, in the Republic of Srpska, within the municipality of Bijeljina. The protected habitat covers an area of 8.31 km². Previous research on the flora of the protected habitat "Gromiželj" has recorded 55 macrophytes. In the macrophyte flora of the studied area, mesothermal, basic, mesotrophic, halophobic, suboceanic, and oceanic-suboceanic species dominate. Also, the most prevalent are species of wet habitats as well as species that thrive in full daylight but are tolerant of shade. The analysis of the biological spectrum of macrophytes established the dominance of hydrophytes, with hemicryptophytes being the second most common. Of the total number of macrophyte species recorded in the studied area, 6 species are listed on the Preliminary List of Species for the Future Red Book of Bosnia and Herzegovina. According to the IUCN list, 41 species are in the least concern category (LC), while for *Urtica kioviensis*, there is insufficient data (DD).

Abstract

The goal of the present experiment was to evaluate the effect of organic plant biostimulant application on the quality parameters of tomato grown under greenhouse conditions. This study was undertaken to determine the effects of humic acid on the ascorbic acid and total acids content of two tomato cultivars Rally F1 and Pink Rock F1. The experimental site was set up in the greenhouse of the Faculty of Agriculture in East Sarajevo, in 2022. Treatment with biostimulant "Humistar" was started with concentration 0, and 50, 100, 150ml L^{-1} were applied into soil every 15 days starting with transplanting in greenhouse and during of the growing seasons. In general,soil application of humic acid presented positive effects on physicochemical quality of tomato fruits irrespective of the dose of humic acid and the cultivar investigated. Soil application of humic acid treatment with 50mlL^{-1} al showed positive effects on the vitamin C of tomato fruits harvested from the cultivar Pink Rock F1. Higher dose of biostimulant of 100ml L^{-1} showed better results in increasing the content of total acids in cultivar Pink RockF1, and a lower dose of 50mL^{-1} in increasing the content of vitamin C in RallyF1 cultivar. Regarding the application of different concentrations of biostimulators, the highest content of vitamin C was recorded on the variant 50mlL^{-1},and total acids in variant with 100mlL^{-1} and that is statistically significant compared to the other investigated variants. A high level of negative correlation was determined between the parameters: Vitamin C - Total acids (- 0.8176).

Keywords: *tomato, cultivar, humic acid, fruits quality.*

Introduction

Plant biostimulants are natural products used to stimulate nutrient uptake and efficiency by crops, increase tolerance to abiotic/biotic stress and improve quality without negative impacts on the environment if obtained from renewed sources. Humic substances are some of the most used plant biostimulants in agriculture and play a central role in plant adaptation. The definition of plant biostimulants is strongly linked to changes in the physiological functions of plants (Ricci et al., 2019). The origin of plant biostimulants is diverse, being obtained from different organic sources, such as microbial fermentation of animal or vegetable raw materials, humic substances, algae extracts, protein hydrolysates, industrial residues, beneficial fungi and rhizobacteria that promote plant growth (Nardi et al., 2015; Rouphael et al., 2015). Humic acid is one of the types of plant organic fertilizer that has a great role in plant nutrition and soil fertility; in addition, produce higher yields, improved fruit quality and healthier plant (Pettit, 2004). Humic acid is particularly used to decrease the negative effects of chemical fertilizers and could have beneficial effects on the nutrition of the plant (Martinez et al., 1983). It is recognized as a major determinant of soil fertility, which covers physical-chemical and biological activities (Bronick, 2005). Also, Farahi et al. (2013) suggested that foliar application of humic acid led to improvement of quantitative and qualitative characteristics of strawberry (chlorophyll content, fruit number,total yield of plant, TSS,total acids, vitamin C, and fruit firmness).

Tomato (*Lycopersicon esculentum* L.), is one of the leading vegetable specie in protected areas and in the open field, belongs to the Solanaceae family. Tomato is an annual dicotyledonous plant in the continental climate. The fruit is used in botanical maturity. The fruit is rich in potassium, phosphorus, magnesium and iron. It also contains vitamins C, B1, B2, and vitamin PP. The color of tomatoes is given by lycopene, but it also contains other dyes, carotenoids (carotene and xanthophyll). It also contains glycoalkaloids which give it a characteristic smell and bitter taste. The taste of tomatoes is the first and most important step by which consumers decide for a given product. The leaf and stem contain tomatin, which has a fungicidal effect and is toxic to some insects. It has a high potential for yield, and the organization of seedling production is very important. The effects of humic acid on plant growth and quality of fruit are very complex and can be change depending on many factors. In this study two tomato varieties were evaluated on influence of humic acid to produce acids, special attention giving to ascorbic acid as one of the most abundant in tomatoes and very important for human health.

Material and methods

Plants of two tomato cultivars with indeterminate growth pattern, namely Rally F1and Pink Rock F1, were transplanted into prepared soil in greenhouse during the third decade of April in 2022. Rally F1 is an early hybrid, tall, characterized by a semi-open habitus with a very strong root, and is highly valued for its ease of cultivation. Pink Rock F1 is an indeterminate pink tomato with short internodes. An early hybrid, very productive, high resistance to diseases.The experimental site was set up in the greenhouse of the Faculty of Agriculture in East Sarajevo (Republic of Srpska, Bosnia and Herzegovina). The greenhouse was maintained at 23 ± 1 °C day temperatures with 59.05 ± 2% RH during the course of crop growth. Average and maximum daily temperatures, air humidity and soil moisture values in the greenhouse during the experimental period are given in Table 1. A recent analysis reveals that the soil (pH 7.38) contains <1% of $CaCO_3$, 6.00% of organic matter, 0.40 mg kg^{-1} of nitrogen, >40 mg kg^{-1} of phosphorus, and 19.60 mg kg^{-1} of potassium. Plants were grown upright and trained onto a single stem. They were supported by iron wires fixed to their main stems. The experiment was set-up as a Randomized Complete Block Design arranged in a split plot system replicated four times. There were 8 combinations with 12 plants per variant. The plants are planted at a distance of 0.6x0.5 m, which makes an assembly of 333 plants/100m^2.

Table 1. Average and maximum daily temperatures, air humidity and soil moisture values in the greenhouse during the experimental period

Month	Greenhouse daily temperature (°C)		Relative air humidity (%)		Soil daily moisture (%)	
	Average	max.	Average	max.	Average	max.
April	13,45	23,2	59,05	99,9	48,87	78,70
May	28,96	43,6	50,79	90,0	36,54	80,80
June	34,89	44,0	38,15	99,2	40,04	79,80
July	32,68	42,7	44,13	95,5	46,46	78,20

Humistar is a special liquid preparation, which contains a high amount of humic acids. The product was obtained by extraction from leonardite, without heavy metal content. Humistar promotes more intensive absorption of all forms of nutrients from the soil, affects the initial development of roots in plants (after transplanting), improves the structure and water - air properties of the soil, and promotes the development of beneficial microbiological fauna. In addition to humic acids, Humistar contains a high amount of other organic compounds (amino acids, peptides, peptones, proteins, biostimulators, etc.) that the plant can quickly and

efficiently absorb through the roots. Composition - Total humus supplement: 15% w/w Humic acid: 12% w/w, Fulvic acid: 3% w/ w.
The following variants are represented within the second tested factor (B) biostimulator:
B1-control, B2-50 ml L^{-1} (0.5%), B3-100 ml L^{-1} (1%), B4-150 ml L^{-1} (1.5%).
The first application of Humistar was well incorporated into the soil before planting. The second soil drench was applied under the growing plants, about 10 cm around their main stems (Salman et al., 2005) using a back-held spray pump and a spade. The thirdtreatment was in the phenophase of tomato flowering, then after 15 days in the phenophase of fruit formation, the fourth treatment in the phenophase of fruit ripening and the fifth application of Humistar in the phenophase of full fruit ripening. The control treatment consisted of soil applications of water only. Harvesting started in mid Julyand continued periodically, depending on fruits ripening. Each lot (5 fruits) assigned for analysis of fruits quality was homogenized in a kitchen blender. Vitamin C content were expressed as mg ascorbic acid 100 g^{-1} fresh weight (FW). The content of total L-ascorbic acid was determined by titration with the Tillman solution (Tillman's Method). Plant material (50 g) was mixed with 200 cm^3 citric acid, and after 30 min the extract was titrated with the Tillman's reagent (2,6-dichloro-indophenol). Content of total acids ($g100g^{-1}$) was determinated using metod (Turhan and Seniz, 2009), titration with sodium hydroxide solution in the presence of phenolphthalein as an indicator . A total of 10 ml of tomato juice is put in to a 100 ml measuring flask, diluted to a tera mark with aquades. Filtered sample, take 20 ml of obtained filtrate and inserted in to Erlenmeyer. The sample was added 2 drops of Phenolphtalein and titrated with 0.1 N NaOH until pink. Also, the microclimatic conditions in the greenhouse were monitored using a digitalization system. The following parameters were monitored: air and soil temperature, relative air and soil humidity. We monitored all of the above via an application on a mobile device (Virtuino 6). Through this application, the experimental greenhouse was regularly ventilated. Identification of significant differences between the studied varieties for the investigated quality parameters showing a normal distribution was evaluated using the one-way one-factor analysis of variation (ANOVA) followed by the least significant difference (LSD). The mean value within each group with different letters showed significant differences with $P < 0.05$.

Results and discussion

Application of humic acid has generally been suggested to improve the nutrient-uptake efficiency of tomato plants from the soil/environment. Atiyeh et al. (2002) reported that following incorporation of humic acid into the soil-less container medium, tomato seedlings showed better vegetative growth. They ascribed it to their improved nutrient uptake efficiency. Similarly, Yildirim (2007) and Ebrahim et al. (2012) found that foliar sprays of humic acid increased vegetative growth of tomato plants as a result of increased nutrient uptake. These nutrients are involved in plant bioactivities and plant growth induction (Abdel-Mawgoud et al., 2007). In addition, humic acid plays a vital role in the uptake and transport of nutrients as a result of increased cell permeability (Dursun et al., 2013). Since humic acid seems to have an ability to interact with various structures of phospholipid in cell membranes thereby serving as carriers of nutrients it might have a role in transport and availability of both micro- and macro-elements in plants (Asri and Demirtas, 2015). Fruits have the characteristics and levels of maturity vary so that the content of substances contained there in also varies. Types of acids are found in many types of plants, especially fruits. These acids are present in small amounts which are the intermediate results in metabolic processes in the Krebs cycle of the tri carboxylic acid, the glycoxylic acid, and the shikimic acid cycle. Citric acid is the most dominant organic acid in tomatoes. In addition to citric acid, malic acid is the most organic acid that contributes to the taste of tomatoes. Some authors suggest that biostimulants improve stress tolerance due to a greater production of anti -oxidants (Ertani et al., 2013). The present data showed that biostimulant application positively affected lycopene, but negatively affected b-carotene and vitamin C contents, thus the influence on total antioxidant activity was not significantly different among the experimental treatments. Ascorbic acid content also known as vitamin C, is a non-enzymatic antioxidant that possesses beneficial effects for the human body. According to Malacrida et al. (2006), a higher AA content in tomatoes improves the postharvest fruit quality. Alenazi et al.(2020) found that ascorbic acid is responsible for a better plant olerance of biotic and abiotic stress. Thus, varieties with a high ascorbic acid content are of particular importance for the breeding programmes and the fresh produce market.

Table 2. Effect of cultivars and humic acid application on vitamine C content mg $100g^{-1}$ FW

Treatments (ml L^{-1})	Cultivars		Average for biostimulant
	Rally F1	Pink Rock F1	
Control	9,32a	9,26b	9,29ab
50	9,09bc	9,57a	9,33a
100	8,89c	8,97c	8,93c
150	9,14b	9,29b	9,21b
Average for cultivars	9,11	9,27	9,19

Means followed by the same letter in each season are not significantly different at the 0.05 level

In the present study, the ascorbic acid content differs significantly among the studied varieties (Table 2.). Regarding the application of different concentrations of biostimulators, the highest content of vitamin C was recorded on the variant $50mlL^{-1}$ and was $9.33mg100g^{-1}$, which is statistically significant compared to the B3 (100 ml L^{-1}) and B4 ($150mlL^{-1}$) variants. The variety Pink RokF1 had a statistically higher content of vitamin C 9.27 $mg100g-^{1}$ compared to the other tested variety ($9.11mg100g^{-1}$). The highest vitamin C content were recorded for the fruits harvested from the plants of Pink Rock F1 cultivar, in treatment with 50ml L^{-1} compared to the other tested concentrations of humic acid and that was statistically significant. Radzevičius et al. (2013) suggested that environmental conditions and plant cultivar have major influences on vitamin C content in tomato fruits. Similar results to ours were obtained by (Zodape et al., 2011) with the foliar application of Kappaphycus alvarezii sap (seaweed) in tomatoes. There was an increase of more than 20% in the levels of ascorbic acid, acidity and total soluble solids, in addition to the levels of N, P, K, Mn and Zn compared with the treatment control. Padem and Ocal (1999) showed that just a single application of humic acid during the plant growth cycle was sufficient to increase vitamin C content in tomato fruits grown for processing industry.

Table 3. Effect of cultivar and humic acid application on total acids content $g100g^{-1}$FW

Treatments (ml L^{-1})	Cultivars		Average of biostimulant
	Rally F1	Pink Rock F1	
Control	5,96b	5,92b	5,94b
50	6,11a	5,53c	5,82c
100	6,09ab	6,20a	6,14a
150	5,74c	5,89bc	5,81c
Average for cultivars	5,97	5,88	5,92

Means followed by the same letter in each season are not significantly different at the 0.05 level

In the present study, the total acids content differs significantly among the studied varieties (Table 3.). Regarding the application of different concentrations of biostimulators, the highest content of total acids was recorded on the variant $100mlL^{-1}$and was $6,14g100g^{-1}$. The Rally F1 variety had a statistically significant higher average content of total acids ($5.97g100g^{-1}$) compared to the Pink Rock F1 variety ($5.88\ g100g^{-1}$). The highest content of total acids in the Rally F1 variety was recorded in the $50mlL^{-1}$($6,11g100g^{-1}$), which is statistically significant compared to the other varieties. The content of total acids in the variety Pink RockF1 was recorded at the variant $100mlL^{-1}$ ($6,20g100g^{-1}$) which is statistically significant compared to the control and the treatment B4 with $150mlL^{-1}$. A high level of negative correlation is determined between the parameters: Vitamin C – Total acids (- 0.8176). The correlation analysis showed that the vitamin C content was negatively correlated with the total acids content. One possible theoretical explanation of this result is that the vitamin C content in tomato fruit increases till beginning of ripening and then begins to decrease due to an increase in the ascorbate oxidase activity (Yahia et al.,2001). Asri and Demirtas (2015) recorded that total acids of tomato fruits has been increased with increasing doses of humic acid application, though remained in the range of 0.3-0.5% citric acid. It was found that water stress increased the sugar and acid contents (ascorbic, malic and citric acid) of the tomato fruits and thus improved the fruit quality. During the experimental period, there were not favorable conditions when it comes to soil moisture and air temperatures. The relative soil moisture ranged from 40,04 to 79,80% in June and 46,46 to 78,20% PVK in July, which is not suitable for successful greenhouse production. Unfavorable conditions were as far as the air temperature is concerned, they were over max. 44,0 ˚C in June and 42.7˚C in July, which is not favorable for growth and development of plants.

Conclusion

Tomato contains several health-beneficial compounds and has high commercial importance throughout the world. Nowadays, water shortage is a challenge for agricultural production, especially for vegetable crops, and long-term and sustainable strategies should be adopted to enhance productivity without compromising the quality of fruits and vegetables. Our results indicate that soil drenching with different concentrations of humic acid influenced to increases the efficiency of both cultivars to produce of quality fruits under protected environment.Soil drenching of humic acid 50 and 100mlL-1 increase the efficiency of both cultivar to produce higher quality fruits under protected environment. A high dose of biostimulator $150mlL^{-1}$ did not affect the improvement of the tested quality parameters of tomatoes in both tested varieties. The occurrence of a negative correlation between total acids and ascorbic acid in tomato fruit should be investigated in further studies. When analyzing the results, it is necessary to take into account the characteristics of the variety for the given tested parameters as well as its resistance to lack of water for a certain period and high temperatures in the greenhouse. Differences in temperature and soil water content between June and July can be one of the causes of the low content of vitamin C in the RallyF1 variety and total acids in the tomato fruit at single treatments in both cultivars.Therefore, further research is needed to fine-tune the application of those formulations of humic acid that had beneficial effects in order to suggest an application protocol that may improve processing tomato fruit quality under water limitation condition, high temperatures or choose a different cultivar. Biostimulants offered advantages for greenhouse tomato through protection of plants against abiotic stresses and have a potential to improve yield quality.

Abstract

Phenological traits and initial and final fruit set of five sweet cherry cultivars (Burlat, Schneider's Spate Knorpelkirsche, Kordia, Karina and Regina) were studied in the region of Sarajevo (Bosnia and Herzegovina) over one-year period (2024). The beginning of flowering of the tested cultivars was at the end of the third decade of March, respectively at the beginning of the first decade of April. The phenophase of full flowering was in the interval from April 1 to April 9. The end of flowering of all cultivars was in the second decade of April. The shortest duration of flowering was 8 days, and the maximum was 12 days, while the abundance of flowering was in the interval 2.8–4.5. The initial fruit set in open pollination was in the interval from 15.2% to 53.2%, while the final fruit set in open pollination was in interval from 0% to 2.6%. The cultivar Burlat was statistically significantly different from other cultivars according to the initial and final fruit set in open pollination.

Key words: *sweet cherry, phenological properties, initial fruit set, final fruit set.*

Introduction

Flowering represents one of the most important phenophases and simultaneously the most critical phase on which the yield largely depends. The time of flowering varies from year to year and is conditioned by agro-ecological conditions before and during the flowering. The start and duration of flowering, depends on the hereditary basis of the variety, but also on the temperature or the sum of the active temperatures after the end of the dormancy period. A significant problem in studying the phenology of sweet cherry flowering and its impact on the proper formation of cultivar composition is determining the temporal overlap of different cultivars in the full flowering phenophase, which is a prerequisite for potential pollination. The interval between the flowering of the earliest and the latest sweet cherry cultivar in our agro-ecological conditions ranges from 8 to 15 days, while in warmer areas, this range is greater, extending from 15 to 20 days. The flowering of one cultivar on average lasts 12 to 15 days. Cultivars with longer flowering periods have a greater chance for successful pollination and fertilization. They also have a lower chance of being damaged by late spring frosts. Observing the flowering time of sweet cherries over a longer period, a tendency for its advancement can be noticed, which is associated with the phenomenon of global warming. Fertilization is a process that occurs after pollination and is a necessary condition for the development of the sweet cherry fruit. This physiological phase is conditioned by biological factors and ecological conditions. The success of sweet cherry fertilization depends on three factors: stigma receptivity, the growth rate of pollen tubes, and the vitality of the embryo sac. The receptivity of the sweet cherry stigma lasts 1 to 7 days depending on weather conditions. It has been established that at a temperature of 10 ˚C, sweet cherry stigma receptivity lasts up to nine days, at 20 ˚C, five days, and at 30 ˚C, two to three days (*Milatović et al.,* 2011).

Pollen germination does not occur at temperatures lower than 5 ˚C. The optimal temperature is between 20–25 ˚C, and under these conditions, the period from pollination to fertilization is 2–4 days. In sweet cherry, pollen tubes reach the base of the style in 2–3 days, and it takes 6–8 days for most pollen tubes to reach the embryo sac. The vitality of the embryo sac primarily depends on temperature, as low temperatures prolong, while high temperatures shorten the period of functional ability.
Various biological and ecological factors affect the percentage of initial and final fruit set in open pollination in sweet cherry. The percentages of initial and final fruit set in open pollination can serve as indicators of yield, the degree of self-fertilization, the quality of fertilization, and the suitability of the cultivar as a pollinator. The cause of poor fruit set can be the absence of pollinators (insects) as well as poor weather conditions during the flowering phenophase. *Glišić et al.* (2012) state that the percentage of final set fruits indicates the suitability of pollinators, as the percentage of initial set fruits includes those that are degenerated and defective. Fruit set depends on the compatibility and vitality of the pollinator's pollen, temperature, and insect activity. Low temperatures during the winter period can result in damage to flower buds, indicating potentially lower yields. Environmental factors influence different fruit set rates between cultivars and within a cultivar over the years (*Nava et al.,* 2009). The same authors note that the genetic factor has the greatest impact on the sensitivity of fruit trees to higher temperatures during the flowering phenophase. In sweet cherry, higher temperatures during the flowering phenophase can significantly reduce fruit set (*Hedhly et al.,* 2007). The aim of the study was to examine the flowering phenophases, as well as the initial and final fruit set in open pollination of sweet cherry cultivars under the agro-ecological conditions of Sarajevo.

Materials and methods

The research was conducted in 2024, in the area of Sarajevo, within the experimental sweet cherry orchard of the Federal Institute of Agriculture of Bosnia and Herzegovina, which was established in the spring of 2007 at an altitude of 600 meters. The rootstock for all the studied cultivars (Burlat, Schneider's Späte Knorpelkirsche, Kordia, Karina and Regina) was the vegetative rootstock Gisela 5. The phenological characteristics of flowering and the percentage of initial and final fruit set were analyzed. Flowering was recorded by recommendations of the International Working Group on Pollination: start of flowering – 10% open flowers, full bloom – 80% open flowers, end of flowering – 90% of the petal fall (*Wertheim,* 1996). The duration of flowering was determined by the number of days from the beginning to the end of flowering, while abundance was assessed on a scale from 1 to 5 (1–trees without flowers, 5–abundant flowering). Fruit set was determined based on open pollination on six selected branches (two repetitions with three branches each) from each cultivar. The counting of initial fruit set was done three to four weeks after pollination, and final fruit set at the beginning of the fruit ripening phenophase. The fruit set expressed as a percentage was calculated by the ratio of the number of set fruits to the number of flowers. The obtained data for the percentage of initial and final fruit set were statistically processed using Fisher's model of analysis of variance (ANOVA) for a one-factor experiment, applying the F-test (*Fisher*, 1953) for $R \leq 0.05$ (using the statistical package IBM SPSS Statistics 20 (SPSS Inc, Chicago, IL, USA)). Differences in the means of the observed traits were determined using *Duncan's* multiple range test for a significance level of $P \leq 0.05$. Correlation analysis between individual phenological traits and fruit set was performed using IBM SPSS Statistics 20 (SPSS Inc, Chicago, IL, USA).

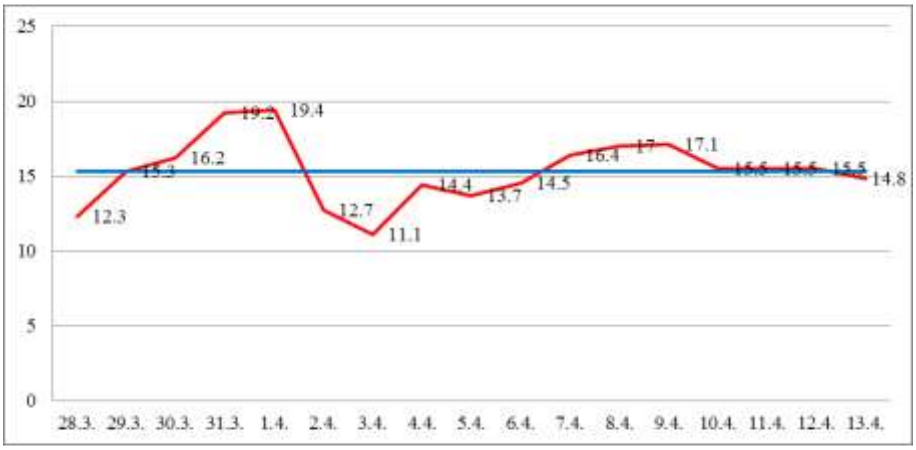

Chart 1. Dynamics (red line) of mean daily air temperatures during the flowering phenophases. The blue line inside the graph represents the average value of the average daily air temperature for the duration of flowering.

Air temperature–the area where the experimental sweet cherry orchard is located is characterized by a distinctly continental climate, with an average annual air temperature for the period 1961–1990 of 9.8 ˚C (http://www.fhmzbih.gov.ba/). According to the same data source, the average annual air temperature for the period 2000–2018 was 11.6 ˚C. For the first five months of 2024., when the research was conducted, the following air temperatures were recorded: January (0.7 ˚C), February (6.5 ˚C), March (9.5 ˚C), April (12.4 ˚C), and May (16.1 ˚C). Observing the flowering period, it is characteristic that the average daily air temperatures during the first five days were stable, showing a gradual increase, while from the sixth to the tenth day, slightly lower values than the established average for the flowering period this year were recorded (Chart 1). After the tenth day, an increase in daily air temperature was observed. The average value of the mean daily air temperature during the flowering period in 2024. was 15.3 ˚C.

Results and discussion

The results of the study of the start, full, end and duration of flowering are presented in table 1.

Table 1. The flowering phenophase of sweet cherry cultivars in 2024

Cultivar	Flowering dates			Duration of flowering (days)	Abundance of flowering
	Start	Full	End		
Burlat	28.3.	2.4.	9.4.	12	4.5
Schneider's Spate Knorpelkirsche	29.3.	1.4.	10.4.	12	4.3
Kordia	1.4.	6.4.	11.4.	10	2.8
Karina	2.4.	9.4.	13.4.	11	4.0
Regina	3.4.	7.4.	11.4.	8	4.1

The earliest flowering start date of the studied cultivars was for the Burlat cultivar (March 28), while the latest flowering start date was recorded for the Regina cultivar (April 3). The difference between the earliest and latest flowering start dates was small, amounting to six days. The other flowering phases were consistent with the flowering start dates. For the trees of the Schneider's Späte Knorpelkirsche cultivar, the smallest number of days (three days)

was needed for 80% of the flowers to open (April 1). A day later, on April 2, the full flowering occurred for the Burlat cultivar. For the other cultivars, the full flowering dates were April 6 (Kordia), April 7 (Regina), and April 9 (Karina). The end of flowering date was correlated with the flowering start date, with the earliest being for the Burlat cultivar (April 9), and the latest end of flowering was in the Karina cultivar (April 13). *Milatović et al.* (2020) consider that longer flowering duration is a desirable trait as it increases the possibility of successful pollination. The average duration of flowering was 10.6 days, with variations ranging from 8 to 12 days (Table 1). The average flowering abundance ranged from poor (2.8) to excellent (4.5) (Table 1). *Hodun* and *Hodun* (2002), examining the characteristics of 80 cultivar, state that the average duration of the sweet cherry flowering phenophase is 8–10 days. *Nyéki* and *Soltész* (1996), dealing with the characteristics of the sweet cherry flowering phenophase as a species, note that the sweet cherry is a species with a short full flowering period, lasting up to three days. The flowering dates recorded in our studies under the agro-ecological conditions of Sarajevo were consistent with the dates recorded for the conditions of the Belgrade (*Milatović et al.,* 2013), as well as for the agro-ecological conditions of the Sub-Mediterranean part of Herzegovina (*Badžak et al.,* 2021).
Analyzing the data on fruit set under open pollination presented in Chart 2, we can state that there are variations in initial and final fruit set among the studied sweet cherry cultivars.

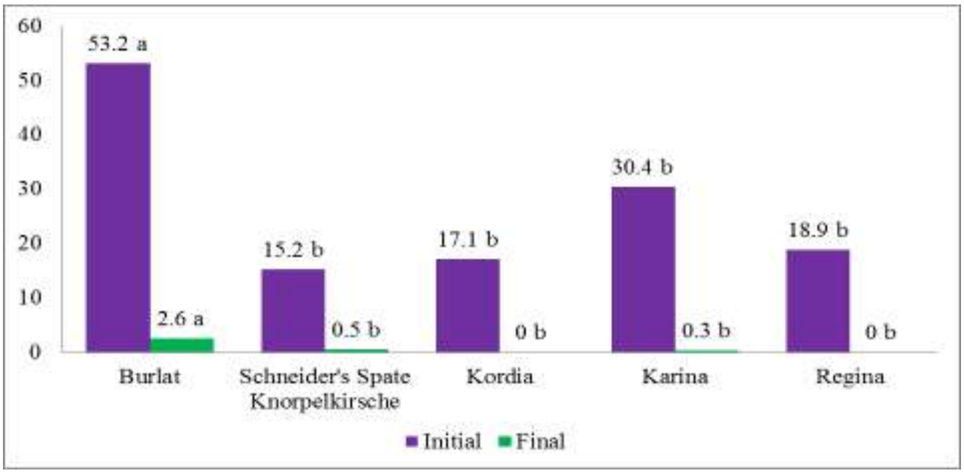

Chart 2. Fruit set of sweet cherry cultivars in 2024
Different letters for individual factors indicate significant differences for R≤0.05 using Duncan's test of multiple intervals

The highest initial and final fruit set in open pollination was in Burlat cultivar (53.2%), respectively 2.6% (Chart 2). On the other hand, there were no statistically significant differences in the percentage of initial and final fruit set between the Schneider's Späte Knorpelkirsche, Kordia, Karina, and Regina cultivars. The percentage of initial fruit set for the studied sweet cherry cultivars followed this trend: Karina (30.4%) > Regina (18.9%) > Kordia (17.1%) > Schneider's Späte Knorpelkirsche (15.2%). However, what can be concluded from the results of the final fruit set is that this percentage was significantly low, with the Kordia and Regina cultivars having a final fruit set of 0%. *Nyéki et al.* (2003) classified sweet cherry cultivar into three groups based on the degree of fruit set: low fruit set (below 20%), medium fruit set (20–30%), and high fruit set (above 30%). According to this classification, most of the studied cultivars in our research had low fruit set. For high sweet cherry yield, it is necessary to achieve a fruit set of 20–30% during abundant flowering (*Milatović et al.,* 2011). In our research, the abundance of flowering ranged from poor to excellent, but the percentage of fruit set was recorded as low. The reason for this can be found

in the air temperatures. During the period from the beginning to the end of flowering (a total of 17 days), the average air temperature was 15.3 °C (Chart 1), which is one of the potential reasons for poor fruit set of cultivars. *Postweiler et al.* (1985) note that higher flowering temperatures shorten the lifespan of the seed embryos of some sweet cherry cultivars, and at a constant temperature of 20 °C, their vitality is lost within one to two days. Additionally, during the second half of April, lower air temperatures were recorded, which could have led to the dropping or rejection of set fruits of sweet cherry cultivars since early degeneration of primary seed embryos is strongly influenced by environmental factors (*Lillecrapp et al.*, 1999).
The results shown in Table 2 indicate the correlation relationships between the number of days from January 1 to full bloom, the duration of flowering in days, the average daily temperature from January 1 to full bloom, the average daily temperature during the flowering phenophase, and the final fruit set.

Table 2. Correlation matrix among the examined indicators of flowering, fruit set and air temperature between sweet cherry cultivars (2024)

Traits	FD	TFB	TFP	FFS
NoD	-0.62	0.72	-0.11	-0.58
FD	1	-0.92**	-0.06	0.61
TFB		1	-0.10	-0.52
TFP			1	-0.72
FFS				1

NoD – number of days from January 1 to full bloom; FD – flowering duration in days; TFB – average daily temperature from January 1 until full bloom; TFP – mean daily temperature during the flowering phenophase; FFS – final fruit set.

**Correlation coefficients are statistically significant for R≤0.01 based on the t-test.

Analyzing the correlation between the number of days from January 1 to full bloom and the duration of flowering, a negative correlation (r=-0.62) was observed, without statistical significance. The studied cultivars with a greater number of days from January 1 to full bloom (i.e., later flowering time) had a shorter flowering duration. This phenomenon can be explained by the influence of air temperatures in the period from January 1 to full bloom. A positive, but not statistically significant, correlation was found between the number of days from January 1 to full bloom and the average daily temperature from January 1 to full bloom (r=0.72). Also, a negative correlation without statistical significance was found between the sum of days from January 1 to full bloom and the average daily temperature during the flowering phenophase (r=-0.11), as well as with the percentage of final fruit set (r=-0.58). The duration of flowering had a highly significant negative correlation with the average daily temperature from January 1 to full bloom (r=-0.92**), indicating that flowering duration was shorter at higher air temperatures.
Based on the presented results of the correlation analysis, a positive correlation coefficient is observed between the duration of flowering and the percentage of final fruit set, meaning that longer flowering resulted in a higher percentage of final fruit set (r=0.61). Negative correlation coefficients were found between the average daily air temperature from January 1 to full bloom and fruit set (r=-0.52), as well as between the average daily temperature during the flowering phenophase and fruit set (r=-0.72). Higher air temperatures resulted in a lower number of final fruit set, as they led to various disturbances in the pollination and fertilization process.

Conclusions

Based on the flowering time and the overlap of individual flowering phenophases, we can conclude that the sweet cherry cultivars are suitable as mutual pollinators and can be recommended for production orchards. However, meteorological conditions during the flowering period resulted in poor fruit set. The different behavior of cultivars in terms of final fruit set is a consequence of genotypic characteristics influenced by ecological factors, primarily air temperature. One of the possible reasons for the poor fruit set in the studied year is the air temperatures during the flowering phenophase. Specifically, the somewhat earlier occurrence of high temperatures in 2024, which led to flowering, created stressful conditions for the flowers, resulting in poor fruit set. Additionally, another reason that could have led to a significantly lower percentage of initial and final fruit set in the studied year is precisely the higher air temperatures during the period of flower bud differentiation.

Abstract

Corn is one of the most important agricultural crops, with a wide range of uses. In the Bosnia and Herzegovina, Semberija holds a significant position in the production and cultivation of corn, owing to its natural characteristics. Previous research has demonstrated that Semberija possesses all the necessary conditions for high levels of corn production. However, the question arises whether this undeniable potential of the area has been fully utilized. The goal of this paper is to address that question. For this research, 50 corn producers from the Semberija area were included. The study hypothesized and confirmed that corn cultivation in Semberija is predominantly geared towards meeting the personal needs of producers and the domestic market rather than the export market. The findings are crucial for assessing the current status and future prospects of corn cultivation in this region. Additionally, they provide recommendations for further developing corn production in this naturally fertile area.

Keywords: *corn, agriculture, production, export, market research.*

Introduction

Corn is utilized for human and animal nutrition, as well as in industrial applications across the food, pharmaceutical, textile, and chemical sectors. Globally, approximately 889 million tons of corn are produced annually, equating to 129 kilograms per person. The leading producer of corn worldwide is the United States of America, accounting for 36% of global production (an average of 1,020 kilograms per capita), followed by China (22%), Brazil (7%), Argentina (3%), and Mexico (2%). The United States is also the largest exporter of corn, responsible for 46% of global exports. Other major exporters include Argentina (13%), Brazil (9%), and France and Ukraine each with 6% (Zlatanović, 2017).

In the Bosnia and Herzegovina, Republic of Srpska, according to data from the Republic Institute of Statistics in 2022, corn production totaled 372,083 tons (Institute of Statistics RS, 2023). The territory of Republic of Srpska is divided into two main agricultural production regions based on relief and climatic conditions. The first region includes plains along rivers, undulating coastal areas, and lower to medium-high mountain areas (such as Banjalučka Krajina, Posavina, Semberija, and Birač). The second region comprises mountainous areas with karst fields (including the Sarajevo-Romanija region and Herzegovina). In the first region, the primary agricultural crops are corn and wheat (Milić et al., 2016). At the level of the Republic of Srpska, the Semberija area holds particular significance, rich in soil and climatic conditions conducive to the cultivation of corn.Corn is the predominant and most significant crop in agricultural production in the Semberija region. Other crops such as wheat, barley, oats, and rye are cultivated to a much lesser extent. The average annual corn production from 1997 to 2017 was 114,950.7 tons, while wheat averaged 47,187.4 tons and barley 6,721.1 tons annually. Corn achieves slightly higher yields per hectare (4.48 tons/ha) compared to wheat (3.81 tons/ha) and barley (4.03 tons/ha) (Popov and Delić, 2019). Despite being a staple food in many parts of the world, corn serves various purposes including animal feed, biofuel, and sweeteners (Chavas and Mitchell, 2018). Global forecasts indicate that by 2025, corn will surpass all other crops, with demand doubling in developing countries (Nedeljković, 2019). Globally, corn is grown on over 160 million hectares across 166 countries, under diverse soil, climate, biodiversity, and management conditions. Maize contributes 40% annually to global food grain production (Kumar et al., 2012). Maize thrives in varied climatic and ecological conditions, favoring warmer climates. The optimal planting time is mid to late April, as corn is resilient to colder temperatures (Kazerooni et al., 2019). In the period from 1997 to 2017, Semberija has experienced a downward trend in corn production (decreasing by 1,148.3 tons annually) and a minor, insignificant decline in corn yield by 17.2 kg/ha per year. When a small number of plants survive with poor health conditions, it becomes impractical to continue producing the same crop due to insufficient returns to cover costs. Reseeding, if feasible under agroecological and organizational conditions, is advisable (Simić and Prodanović, 2018). These trends in corn yield and production are heavily influenced by temperature and moisture availability during critical development stages. Corn yield is particularly sensitive to weather conditions between 90 to 110 days after planting, coinciding with tasseling and silking stages. High temperatures, low humidity, and inadequate rainfall during this period adversely affect corn growth. Precipitation, especially during summer months, significantly impacts annual yield variability. Unfavorable conditions for corn development include temperatures exceeding 30°C and relative humidity below 60% (Popov and Delić, 2019). The production of hybrid corn seeds is crucial, requiring substantial investments in labor and professional expertise (Lopandić et al., 2007). Given corn's importance to Semberija agriculture, this paper aims to explore its cultivation prospects, analyzing results obtained from surveys of local corn producers. These findings will assess the extent to which Semberija's natural potential for corn production is utilized for export markets. The hypothesis explored in this paper is that corn produced in Semberija is primarily intended for domestic consumption rather than export.

Material and Methods

The paper is based on the analysis of data collected through a survey questionnaire regarding corn cultivation practices, the purpose of production, and the market orientation of producers. The research was conducted among corn producers in the Semberija region, Bosnia and Herzegovina. The survey involved 50 corn producers. The survey questions covered, among other things, the amount of corn yield per hectare, the intended market orientation of the corn, and the producers' plans for the future. Data analysis was performed using descriptive statistics.

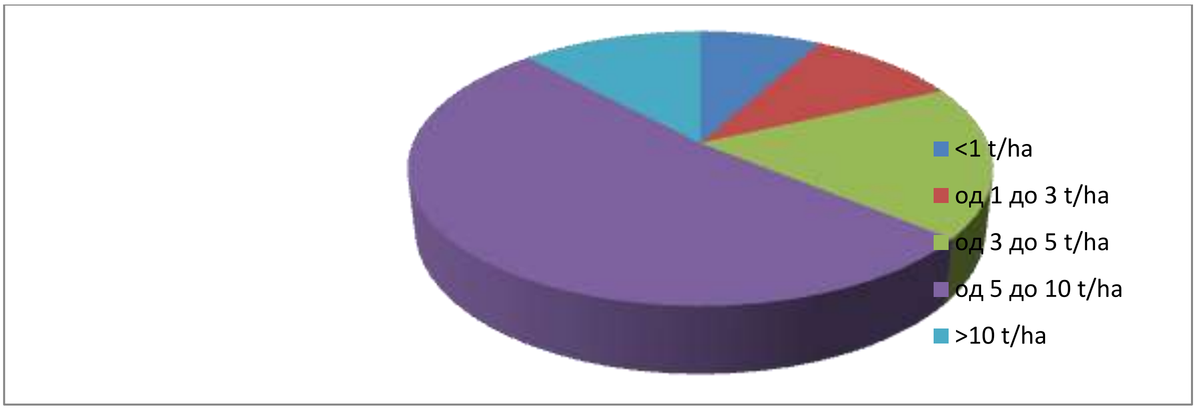
Results and Discussion

The results regarding the areas planted with corn by the companies that participated in this study are presented in the following table:

Table 1. Corn areas in surveyed companies

Companies that grow corn in the area of Semberija	
Number of companies surveyed	50
Areas of planted corn	Up to 27 hectares individually

*Source: Author’s elaboration based on the questionnaire survey results.



Graph 1. Achieved corn yield

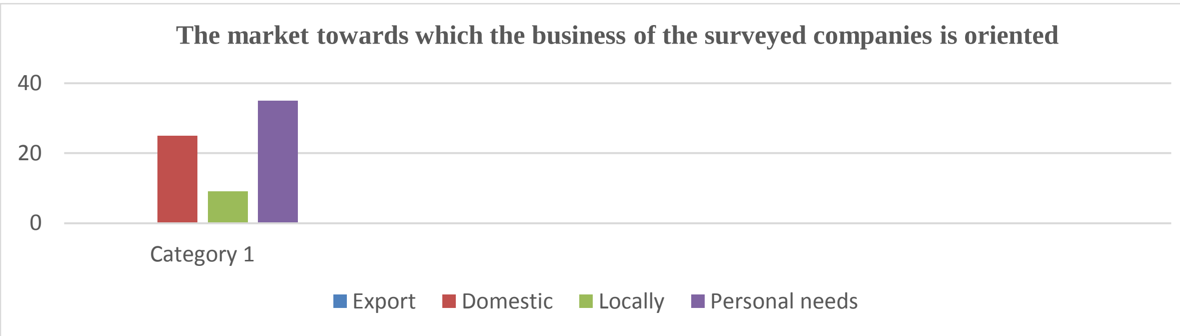
Based on the presented data, it is evident that the majority of surveyed corn producers in the Semberija area derive income from corn yields ranging between 5 and 10 tons per hectare, with 26 producers, representing over 50% of those surveyed. Following this, 9 producers achieve yields ranging from 3 to 5 tons per hectare. In third place, 6 producers achieve yields exceeding 10 tons per hectare. Additionally, 5 producers achieve yields between 1 and 3 tons per hectare, while 4 producers achieve less than 1 ton per hectare. Regarding the target markets of the surveyed companies, the research results indicate the following.

Table 2. Presentation of the market towards which the business of the surveyed manufacturers is oriented.

The market towards which the business of the surveyed companies is oriented			
Export	Domestic	Locally	Personal needs
0	25	9	35

Source: Author's elaboration based on the questionnaire survey results.

The obtained results will be graphically displayed in the following graph:



Graph 2. Presentation of the market towards which the business of the surveyed producers is oriented

Based on the results obtained, it is evident that none of the 50 surveyed producers export corn outside the territory of Bosnia and Herzegovina. Nine producers are oriented towards the local market, 25 towards the domestic market within Bosnia and Herzegovina, and a significant 35 producers cultivate corn primarily for personal consumption. Additionally, it is noteworthy that the surveyed producers expressed their intention to increase corn plantings in the following manner:

Table 3. Presentation of the planning of the increase in the area with corn in the following period by the surveyed producers

Producers who plan to increase corn production in the future period	36
Producers who do not plan to increase corn production in the future period	14

Source: Author’s elaboration based on the questionnaire survey results.

It is very important for the further development of this area and provides opportunities for expanding the placement of this culture.
The presented results confirm the hypothesis that corn cultivation in the Semberija area is predominantly oriented towards meeting the personal needs of producers and the domestic market rather than the export market. Despite historically being known as the breadbasket of Bosnia and Herzegovina, the current situation is concerning. Corn remains the most widely cultivated crop in this region, with production levels of other crops even lower.
While the natural characteristics of the area, particularly the soil and climate, provide ideal conditions for high production yields, this potential has not been fully realized in practice. Factors such as unfavorable weather conditions, drought, and current inflationary trends have hindered optimal production outcomes. Additionally, the cultivation of corn in Semberija faces challenges exacerbated by significant emigration, particularly among the younger population, leading to abandonment of arable lands.
Despite challenges in market orientation reported by surveyed producers, there is some optimism indicated by their plans to expand corn cultivation areas in the upcoming period. Specifically, 36 surveyed producers expressed intentions to increase their corn-growing areas.
To enhance corn cultivation results in the Semberija area, it is essential for state and local authorities to implement measures aimed at increasing subsidies for farmers. Additional funding would enable farmers to invest in improved agricultural machinery and irrigation systems, which can mitigate the adverse impacts of weather conditions on corn production. Previous research indicates that rainfed systems often outperform irrigated systems in terms of energy efficiency, productivity, profitability, and overall environmental impact, including water scarcity and carbon footprint (Mitrović et al., 2023). However, both systems heavily rely on non-renewable energy sources, with inputs like fertilization and mechanization contributing to negative environmental effects. Optimizing these inputs is crucial for reducing environmental impact and promoting sustainability in maize cultivation in Bosnia and Herzegovina. Many small-scale agricultural producers, including those surveyed, lack resources to implement adequate agrotechnical measures that could significantly boost production. Addressing issues such as mycotoxin occurrence through investment in protective treatments is crucial. Furthermore, proper fertilization systems are integral to increasing corn yields and are among the most important agrotechnical measures in agriculture. Rational and adequate use of both organic (e.g., manure) and mineral fertilizers is essential for effective implementation. All the aforementioned measures necessitate substantial financial investments, making the proactive involvement of the state crucial. This is particularly significant considering that such investments would yield returns and positively impact the national economy through increased exports to foreign markets.

Conclusion

The data presented and analyzed in this paper indicate an inadequate level of development in corn cultivation within the Semberija basin, suggesting that the region's soil and climatic potential are not fully utilized. The areas currently planted with corn are insufficient to achieve significant market results. Regarding market orientation, none of the surveyed producers export their corn beyond Bosnia and Herzegovina's borders, while 70% grow corn primarily for personal consumption. Only 50% of the producers operate within Bosnia and Herzegovina, with 18% focusing exclusively on the local market. These findings underscore the insufficient development of corn cultivation in this highly fertile area, historically known as the granary of Bosnia and Herzegovina. Factors contributing to reduced production include adverse weather conditions, frequent droughts, price increases due to current political situations and the multi-year COVID-19 pandemic, and high levels of population emigration.
Improving production levels requires significant financial investments in irrigation systems and higher quality fertilizers to mitigate weather-related impacts. Additionally, greater investments in protective treatments, quality fungicides, and insecticides are needed to minimize damage from pests and diseases affecting corn. Given that many farmers lack the financial means to undertake these measures due to reduced incomes from lower production levels, the role of state and local governments in allocating budget resources for agricultural subsidies is crucial. These subsidies aim to enhance national agriculture development and secure a market position that aligns with the area's natural characteristics.

Abstract

In this study, we present the three-year results of research on the yield and cluster characteristics of four red wine grape varieties (Blatina, Vranac, Merlot, and Cabernet Sauvignon) cultivated in the Trebinje region (Bosnia and Herzegovina). The highest yield per vine was recorded for the Blatina variety (4.70 kg), while the lowest yield was found in the Cabernet Sauvignon variety (2.99 kg). Cabernet Sauvignon stood out with the highest number of clusters per vine (23.5), while Vranac had the fewest (15.0). Vranac led in cluster mass and peduncle weight with the highest values (350.49 g and 12.37 g, respectively), whereas Cabernet Sauvignon showed the lowest values (149.17 g and 6.31 g, respectively). Merlot had the longest and widest clusters and the highest number of berries (19.47 cm, 12.05 cm, 186.9, respectively), while Cabernet Sauvignon had the shortest and narrowest clusters (15.88 cm, 8.23 cm, respectively), and Blatina had the fewest berries per cluster (107.7). There is a very significant difference between the observed varieties for all yield indicators and cluster characteristics. The effect of the year is very significant for yield per vine, cluster length, and cluster width, but not significant for all other indicators. The combined effect of variety and year is significant for cluster length and very significant for cluster width and peduncle weight. For other indicators, the combined effect of variety and year is not significant.

Keywords: *Vitis vinifera, varieties, yield, year.*

Introduction

Grape yield per unit area is a fundamental indicator of a variety's fertility and depends on a multitude of factors. Foremost among these is the variety itself, followed by the climatic and soil conditions of the cultivation area, and finally, the level of applied agronomic and ampelotechnical measures in the vineyard (Jovanović-Cvetković et al., 2008). The fertility of the buds is expressed through the average number of blooms or clusters per pruned bud. The significance of this indicator lies in the fact that, based on it and the average cluster mass, the number of buds that should be left per vine to achieve a specific, desired grape yield is determined. Kojić and Lasić (2002) state that cluster characteristics such as shape, size, and mass largely depend on the biological traits of the variety, and for this reason, these features are used for ampelographic identification of varieties. The mechanical composition of the cluster and berry involves the absolute and relative proportion of individual parts within the cluster and berry (Marković and Pržić, 2020). This composition is an important technological and ampelographic feature of each variety and is of great importance in assessing the quality of grapes as a raw material for processing. Parameters determined during the mechanical analysis of the cluster and berry include cluster length, width, and mass, number of berries in the cluster, peduncle mass, berry mass, skin, mesocarp, and seed mass, and the number of seeds in the berry. Researching parameters such as bud fertility, cluster characteristics, and the mechanical composition of the cluster and berry has multiple significances in optimizing yield, ampelographic identification of varieties, technological quality assessment, and improving agronomic practices. The aim of this study is to compare different grapevine varieties based on yield indicators and cluster characteristics (such as cluster mass, cluster length, number of berries per cluster, and peduncle mass) over various years. The results will help increase productivity and quality in viticulture, enabling producers to better understand which varieties are best suited to specific growing conditions.

Materials and methods

The field experiment was set up in the production vineyards of AD Popovo Polje-Dubljani and AD Agrofin Petrovo Polje, located in the Trebinje area (Bosnia and Herzegovina). The experimental plots belong to the Herzegovina region, specifically the sub-regions of the middle Neretva and Trebišnjica and the Mostar wine-growing region. The material used in these studies included the autochthonous grape variety Blatina and varieties for the production of high-quality red wines: Vranac, Merlot, and Cabernet Sauvignon. All tested varieties were grafted onto the *Vitis berlandieri x Vitis riparia* Kober 5BB rootstock. The study of the Blatina variety's characteristics was conducted in a vineyard established in 2013, while the study of the Vranac, Merlot, and Cabernet Sauvignon varieties was conducted in a vineyard established in 2004. The planting distance for all four varieties was 2.8×1 m. The Blatina vineyard covers an area of 3.16 ha and is the only large vineyard with this variety in the Trebinje area. The study of the characteristics of the examined grape varieties was carried out during the years 2016, 2017, and 2018. The altitude of the plot where the Vranac, Merlot, and Cabernet Sauvignon varieties were grown is 269 m, located at Petrovo Polje, while the altitude of the plot where Blatina was grown is 242 m, located at Popovo Polje. The row direction for all studied varieties is north-south. The number of buds per vine for all studied varieties is 14. During the grape harvest period, the yield (kg/vine) and the number of clusters per vine were determined by measuring the mass of all clusters from each vine, and then the yield per unit area was calculated. In laboratory conditions, the structural composition of the cluster was determined, including the length (cm), width (cm), and mass of the cluster (g), the number, mass (g), and percentage of berries (%), and the mass (g) and percentage of the rachis (%). The mass of the components of the cluster and berry was measured on an analytical scale, ADL 600, with an accuracy of 1/10 g. The length and width of the cluster were measured using a caliper, "Meba" brand.

Results and discussion

The average values of yield indicators and cluster characteristics are presented in Table 1. The highest yield per vine was recorded in the Blatina variety (4.70 kg), while the lowest was in Cabernet Sauvignon (2.99 kg). The Cabernet Sauvignon variety had the highest number of clusters per vine (23.57), while Vranac had the fewest (15.0). In terms of cluster mass and rachis weight, the Vranac variety had the highest values (350.49 g and 12.37 g), while Cabernet Sauvignon had the lowest (149.17 g and 6.31 g). The Merlot variety had the longest and widest clusters and the highest number of berries per cluster (19.47 cm, 12.05 cm, 186.9), while Cabernet Sauvignon had the shortest and narrowest clusters (15.88 cm and 8.23 cm), and Blatina had the fewest berries per cluster (107.7). The Blatina variety showed the greatest variation in yield per vine, cluster mass, and number of berries per cluster (Cv=38.76%, Cv=42.99%, Cv=43.77%), which is considered a consequence of its uneven pollination (due to its functionally female flower type). The greatest variation in cluster length and rachis weight was observed in the Merlot variety (Cv=19.12%, Cv=46.44%). Regarding cluster width, the highest coefficient of variation was found in the Cabernet Sauvignon variety (Cv=29.68%), while Vranac showed the greatest variation in the total number of clusters (Cv=31.56%). In his research, Rogić (2009) reports that the average yield per vine of the

Blatina variety was 1.16 - 2.07 kg, and the average number of clusters per vine was 9.3 - 10.4. Examining six varieties of Cabernet Sauvignon, Matthew et al. (2006) found that the yield per vine varied between 1.8 - 2.3 kg, and Garić and Vukosavljević (2016) report that the average yield per vine for the same variety ranged from 1.81 - 2.85 kg, and the average number of clusters per vine was 21 - 38. Kraljević (2013) in his work states that the average yield of the Vranac variety under different vine load conditions was from 4.63 - 7.03 kg, while Milanov et al. (2014) highlight that the average number of clusters per vine for the Vranac variety was from 10.4 - 20.8, and the average yield per vine was 2.61 - 5.21 kg. Garić et al. (2010) report that the average yield per vine for the Merlot variety was 1.92 kg. The results of our research are consistent with those of Kraljević (2013), Milanov et al. (2014), and Garić and Vukosavljević (2016), while they differ from the values reported by Rogić (2009), Matthew et al. (2006), and Garić et al. (2010).

Table 1. Descriptive statistics for yield and grape cluster characteristics of studied varieties (2016-2018)

Proprety/variety	**Blatina**		**Vranac**		**Merlot**		**Cabernet Sauvignon**	
	$\overline{X}$	Cv (%)	$\overline{X}$	Cv (%)	$\overline{X}$	Cv (%)	$\overline{X}$	Cv (%)
Yield per vine (kg)	4.70	38.76	4.58	31.50	3.91	34.35	2.99	26.79
Total number of clusters	17.33	28.48	15.00	31.56	18.27	29.98	23.57	23.63
Cluster mass (g)	302.52	42.99	350.49	28.35	255.22	40.11	149.17	40.64
Cluster length (cm)	16.43	18.80	18.03	17.19	19.47	19.12	15.88	12.95
Cluster width (cm)	11.44	15.25	10.53	18.95	12.05	24.51	8.23	29.68
Number of berries per cluster	107.70	43.77	147.57	33.81	186.90	42.03	120.47	28.64
Rachis mass (g)	9.43	44.16	12.37	37.28	7.35	46.44	6.31	37.00

Analysis of variance revealed that there is a very significant difference among the observed varieties for all yield indicators and cluster characteristics. The impact of the year is very significant for yield per vine, cluster length, and cluster width ($p<0.01$), but it is not significant for all other indicators ($p>0.05$). The combined effect of variety and year is significant for cluster length ($0.01<p<0.05$), and very significant for cluster width and rachis mass ($p<0.01$). The combined effect of variety and year is not significant for the other indicators (Table 2). The Dunnett test determined that the Blatina variety has significantly higher values for yield per vine, cluster mass, cluster width, and rachis mass compared to the Cabernet Sauvignon variety. The total number of clusters in Blatina is statistically significantly lower than in Cabernet Sauvignon. Comparing the Blatina variety with the Merlot variety, the differences are not significant except for cluster length and number of berries per cluster, where the Blatina variety has significantly lower values for these indicators. The Blatina and Vranac varieties differ significantly in the number of berries per cluster and very significantly in rachis mass. There are no significant differences for the other indicators (Table 2). Cluster mass depends on several factors, the most significant of which are cluster length and width, and the mass and number of berries per cluster. The results of our research for the Blatina variety partially differ from those of Blesić (2001), who reports an average cluster mass of 250.39 g, from Rogić (2009), who studied the impact of defoliation on the quality of Blatina grapes and found that the average cluster mass ranged from 125.00 to 189.88 g, and from Jovanović-Cvetković et al. (2015), who report an average mass range of 171.65 - 307.32 g. Kojić et al. (2010) observed a significant impact of location on the cluster weight of the Blatina variety, with average values ranging between 537.90 and 200.10 g, which is consistent with our results. The results regarding the average cluster mass of the Vranac, Merlot, and Cabernet Sauvignon varieties partially differ from the results of previous studies by Milosavljević (2012), who states that Merlot has an average cluster mass of 40 to 150 g, Vranac 150 to 300 g, and Cabernet Sauvignon 60 to 130 g. They also differ from the results of Avramov and Žunić (2001), who report that the Merlot variety had an average cluster mass of 105.10 – 150.4 g, and Cabernet Sauvignon 90.40 – 130.10 g, and from Matthew et al. (2006), who state that the cluster mass of Cabernet Sauvignon varies from 171.7 g to 295.1 g. The results of our research are consistent with Banjanin et al. (2018), who report that the average cluster mass of the Vranac variety is 351.6 - 359.3 g, and Cabernet Sauvignon 105.1 - 163.1 g. Analyzing the cluster masses of the Blatina, Vranac, Merlot, and Cabernet Sauvignon varieties over the years of study and comparing them with literature data, certain discrepancies can be observed. One reason is the influence of ecological factors of the cultivation site and the response of the varieties to the applied agronomic and ampelotechnical measures.

*Not significant for p> 0.05; *for p< 0.05; **for p< 0.01.*

The impact of the year on yield indicators and cluster characteristics was analyzed using Tukey's HSD test. The impact of the year is very significant for yield per vine, cluster length, and cluster width, but not significant for all other indicators (Table 3). The yield per vine was significantly lower in 2016 compared to 2017 and 2018, while the differences between 2017 and 2018 were not significant. The cluster length was significantly greater in 2017 than in 2016 and significantly greater than in 2018. There is no significant difference in cluster length between 2016 and 2018. The cluster width in 2017 was statistically significantly greater than in 2016 and very significantly greater than in 2018. There is no significant difference in cluster width between 2016 and 2018.
When observing the combined effect of variety and year on cluster characteristics, it is noted that the cluster length of the Blatina variety in 2018 is significantly shorter than that of the Vranac variety and very significantly shorter than that of the Merlot variety (Table 4). The cluster width of the Blatina variety in 2016 is significantly greater than that of the Vranac variety and very significantly greater than that of the Cabernet Sauvignon variety. In 2017, the cluster width of the Blatina variety is very significantly smaller than that of the Merlot variety, while in 2018, it is very significantly greater than that of the Cabernet Sauvignon variety. The rachis mass of the Blatina variety in 2016 is significantly greater than that of the Merlot variety and very significantly greater than that of the Cabernet Sauvignon variety. The differences in rachis mass in 2017 between the Blatina variety and the other varieties are not statistically significant, while in 2018, the Blatina variety has a very significantly lower rachis mass than the Vranac variety.

Table 4. Statistical significance of the combined impact of variety and year on grape cluster characteristics of the studied varieties

Conclusion

For yield indicators and cluster characteristics (yield per vine, cluster mass, cluster width, and rachis mass), the Blatina variety has significantly higher values than the Cabernet Sauvignon variety. The total number of clusters of the Blatina variety is statistically significantly lower than that of the Cabernet Sauvignon variety. Comparing the Blatina variety with the Merlot variety, the differences are not significant except for cluster length and the number of berries per cluster, where the Blatina variety has significantly lower values for these indicators. The Blatina and Vranac varieties differ significantly in the number of berries per cluster and very significantly in rachis mass. For other indicators, the differences are not statistically significant. There is a very significant difference between the observed varieties for all yield indicators and cluster characteristics. Yield per vine was significantly lower in 2016 than in

2017 and 2018, while the differences between 2017 and 2018 were not significant. The cluster length was significantly greater in 2017 than in 2016 and significantly greater than in 2018. There is no significant difference in cluster length between 2016 and 2018. The cluster width in 2017 was statistically significantly greater than in 2016 and very significantly greater than in 2018. There is no significant difference in cluster width between 2016 and 2018. The impact of the year is very significant for yield per vine, cluster length, and cluster width, but not significant for all other indicators. The combined effect of variety and year is significant for cluster length, and very significant for cluster width and rachis mass. The combined effect of variety and year is not significant for the other indicators. The presented results provide grape growers and winemakers with important information that can assist in making decisions regarding the cultivation of different grape varieties, optimizing yields, and improving grape quality, all of which directly impact wine production.

Abstract

Potato is one of the main cultivated crops and ranks fourth in terms of sown areas worldwide, after wheat, maize, and rice. By selecting suitable cultivars and applying modern farming techniques, it is possible to achieve high yields.Research on five commercial potato cultivars (Agria, Faluka, Kennebec, Kuroda, and Desiree) was conducted during 2016 and 2017 in the field conditions of three locations (East Sarajevo, Bijeljina, and Rogatica - Borike) in the territory of Republika Srpska. The selected areas are located at different altitudes (from 90 to 1100 meters above sea level). The obtained results were analyzed using Analysis of Variance in the two-factorial design in statistical packages GenStat 12th and Microsoft Excel 10, and significance of differences between the mean values were compared in LSD test. The genotype by environment interaction and the stability were determined using the AMMI model. The cultivars and environment significantly influenced potato yield. Cultivars Agria and Kurada had the highest yields in the Rogatica-Borike area, while cultivars Faluka, Kennebec, and Desiree performed best in the Bijeljina area. Conversely, East Sarajevo showed the lowest yields for all cultivars except cultivars Desiree. In these studies, yield variability was most influenced by the environment (42.67%), followed by cultivars (34.54%), and genotype by environment interactions (22.79%). The first principal component (PCA1) explained 71.75% and the second (PCA2) 27.99% of the interaction. This research provides insights into the stability and adaptability of the tested potato cultivars in our agroecological conditions, suitability of regions for potato cultivation, and potential benefits of exploiting G *x* E interactions to increase tuber yields.

Key words: *AMMI analysis, environment, genotip, interaction, potato, yield.*

Introduction

Thanks to the existence of numerous varieties adapted to different ecological conditions, the potato is a cosmopolitan plant species grown around the world, from 47°N to 65°S latitude, though the most favorable cultivation area is considered to be the temperate zone (40–60°N). In the Republic of Srpska, the average production of commercial potatoes takes place on an area of about 15,000 ha, with an average yield of 11.9 t ha-1 (http://www.rzs.rs.ba). In addition to tuber yield, assessing the stability of varieties is crucial for evaluating their true value, along with other agronomically important characteristics. If the productivity and quality parameters of a cultivars do not change or are approximately the same under different environmental conditions, it can be said that the cultivars is stable. The concept of biological or static stability implies that a stable cultivars has minimal variation across different growing regions (Becker and Leon, 1988). Depending on external environmental conditions, varieties exhibit different reactions, meaning that varieties interact with the environment in which they are grown, and the extent of this interaction is determined by genetic composition and the intensity of environmental factors. Due to the specific combination of predictable and unpredictable factors, it is important to understand the varieties' reactions to environmental conditions (Gehan and Hala, 2013), which is crucial for successful breeding. To assess varieties' adaptability to environmental conditions, many statistical models are applied to analyze genotype-environment interactions (Rodrigues et al., 2008). Multivariate biometric methods (AMMI method) are used for data processing. This method is considered the most suitable model for evaluating genotype-environment interactions because it has significant predictive value when selecting the most stable and adaptable varieties, as well as in identifying mega-environments. Unstable and non-adaptable varieties and environments are excluded from further production, while stable varieties and environments are recommended for continued production. The significance of the AMMI method lies in determining genotype stability across different agroecological regions, grouping genotypes based on adaptability, identifying locations with the most favorable conditions based on average yields, detecting positive and negative specific interactions between genotypes and locations, and facilitating the selection of locations (Perišić, 2016).

Materials and Methods

The research was conducted over two growing seasons (2016 and 2017) at three locations: in the territory of the City of East Sarajevo (experimental field of the Faculty of Agriculture); on a private property (Perković family) in Bijeljina (village of Kojičinovac); and on the property of Solanum Produkt in Rogatica (Borike). The selection of locations was influenced by abiotic factors characteristic of each site: meteorological conditions, significant differences in altitude, differences in soil type and fertility, which can significantly affect the yield components, yield, and tuber quality. The experiment used five commercial potato varieties that are significantly represented in production in Bosnia and Herzegovina: Agria, Faluka, Kennebec, Kuroda, and Désirée. The experiment was set up as a two-factorial design in a randomized block design with four replications, with a layout of 53,333 plants. The area of the basic plot was 15 m² (four rows 5 m long with 20 plants per row; row spacing 0.75 m and plant spacing within the row 0.25 m). For determining tuber yield, samples were taken at the technological maturity of the potatoes, with ten boxes from the middle rows of each replication, and yield was calculated per hectare (t ha^{-1}). Basic data about the studied locations. The experimental field of the Faculty of Agriculture East Sarajevo is located at 550 m a.s.l. (43°49′01″ N, 18°20′57″ E). The ecological conditions in East Sarajevo are characterized by strong continental climate influences. The average annual temperature is 10.2°C, and the average amount of precipitation is around 900 mm. The experiment was set up on alluvial soil (fluvisol). The second location, Kojičinovac, is situated at 44°46′02″ N; 19°14′01″ E at 90 m a.s.l. This location is characterized by a moderately continental climate. The average annual temperature is 11°C, and the average amount of precipitation is around 850 mm. The experiment was set up on semi-gley soil. The company Solanum Produkt grows potatoes at 1100 m a.s.l., 43°51′16″ N; 19°05′57″ E. It is characterized by a mountain climate with heavy snowfalls, which last until late spring. The average annual temperature is 7°C, and the average amount of precipitation is around 1500 mm. The experiment was set up on acidic brown soil (dystic cambisol).

Table 1. Chemical analysis of soil

Locality	Depth (cm)	pH/H_2O	pH/KCl	Humus %	N %	Soluble mg 100 g^{-1} P_2O_5	K_2O
East Sarajevo	0–30	7,16	6,39	4,12	0,27	41	36,41
Bijeljina	0–30	7,67	6,61	4,66	0,3	> 40	36,91
Rogatica - Borike	0–30	5,02	3,85	2,55	0,16	8,98	25,38

The optimal soil pH value for potatoes is slightly acidic, ranging from 5.6 to 6.5 (Morar, 2008). Potatoes require high soil permeability, as tubers become deformed in compacted soils. Potatoes need well-drained soil, as waterlogged soils lead to numerous physiological changes in the tubers, making them watery and difficult to store. For successful potato production, the content of organic matter is crucial, as it improves the quality, structure, and water-holding capacity of the soil (Baniuniene and Zekaite, 2008).
Meteorological Conditions. Based on the data analysis in Table 2, it can be seen that in terms of temperature and precipitation, the year 2016 was considerably more favorable for growing potatoes at all three locations compared to 2017 and the multi-year average.

Table 2. Average Monthly Air Temperatures (°C) and Precipitation Amounts (mm) During the Experiment and Multi-Year Average

	Months / Season		I	II	III	IV	V	VI	VII	VIII	IX	X	XI	XII	Average/ Sum

Statistical Analysis. The obtained data were processed statistically, using the method of analysis of variance (ANOVA), for individual comparisons the least significant difference test LSD test (significance level 0.01) was used. The additive main effect and multiplicative interaction (AMMI) method was used, where an integrated ANOVA and principal component analysis (PCA) were applied to analyse the MET (Zobel et al. 1988; Crossa et al. 1991). ANOVA was used to determine the main effects of genotypes and environments and the PCA for the residual multiplicative interaction amongst genotypes and environments. After detecting a significant G x E interaction, the data were graphically analysed by biplot technique to simultaneously classify genotypes and environments (Zobel et al. 1988). Through this method, cultivars with high productivity and wide adaptability, as well as cultivars with specific adaptability, were identified.

Results and Discussion

The tuber yield varied from 31.38 t ha^{-1} (Désirée) to 35.67 t ha^{-1} (Kennebec). The lowest yield was recorded for potatoes at the experimental field in East Sarajevo (31.87 t ha^{-1}), while the differences in yield between the experimental fields in Bijeljina (35.67 t ha^{-1}) and Rogatica – Borike (35 t ha^{-1}) were negligible (Tables 3 and 4).

Table 4. Variation of yield (t ha^{-1}) of potato varieties in different localities

Genotip	Environment			Average
	East Sarajevo	Bijeljina	Rogatica - Borike	
Agria	30.73^{e}	34.51^{bc}	37.84^{a}	34.36^{B}
Faluka	33.08^{cd}	36.60^{ab}	35.79^{b}	35.15^{AB}
Kennebec	33.87^{bc}	37.83^{a}	35.31^{bc}	35.67^{A}
Kuroda	31.34^{de}	35.57^{bc}	36.11^{ab}	34.34^{B}
Desiree	30.34^{e}	33.84^{c}	29.94^{e}	31.38^{C}
Average	31.87^{B}	35.67^{A}	35.00^{A}	34.18

The Désirée cultivars had the lowest yield at all locations, while the highest yield at the East Sarajevo and Bijeljina locations (33.87 t ha^{-1}; 37.83 t ha^{-1}) was achieved by the Kennebec cultivars, and at the Rogatica-Borike location (37.84 t ha^{-1}), the highest yield was achieved by the Agria cultivars. Tuber formation is influenced by temperature, with particularly unfavorable high night temperatures (optimal around 18°C, and unfavorable above 22°C). High temperatures lead to a higher percentage of smaller tubers, which affects potato yield (Kumar et al., 2003). Optimal daytime temperatures and lower nighttime temperatures favored tuber bulking in the Rogatica area, as did the more evenly distributed precipitation at this location during the growing season. Low precipitation amounts during the most critical stages of potato growth and development significantly reduce yield and worsen tuber quality. Considering the high air temperatures during July and August, it can be conclusively stated that, apart from higher air temperatures and soil temperatures, one of the limiting factors for plant growth and tuber bulking in potatoes is the insufficient amount and irregular distribution of precipitation during the growing period. The first growing season had more favorable temperature conditions as well as the quantity and distribution of precipitation during the growing season. In the second growing season, all three locations experienced reduced precipitation, which was unevenly distributed. At the East Sarajevo location, the lack of precipitation was from June to August; at Bijeljina from May to August; and at Rogatica part of July and August, which was reflected in the average potato yield, in agreement with results obtained by Hassanpanah (2011), Hassanpanah et al. (2011), and Siano et al. (2024). Environmental conditions for potato cultivation in certain areas are very diverse, and thus the responses of some varieties under these conditions vary. Breeding can overcome the adverse effects of environmental factors, especially soil quality, water and air regime of the soil, high temperatures, and short growing seasons in mountainous areas. Optimal temperatures for tuber formation and bulking are between 16 and 19°C (Barkley, 2005; Struik, 2007).

Interaction of Genotype x Environment. The environments in which the experiments were conducted were diverse, causing the majority of the variation in average potato yield (42.67% environment; 34.54% genotype; and 22.79% genotype *x* environment interaction).

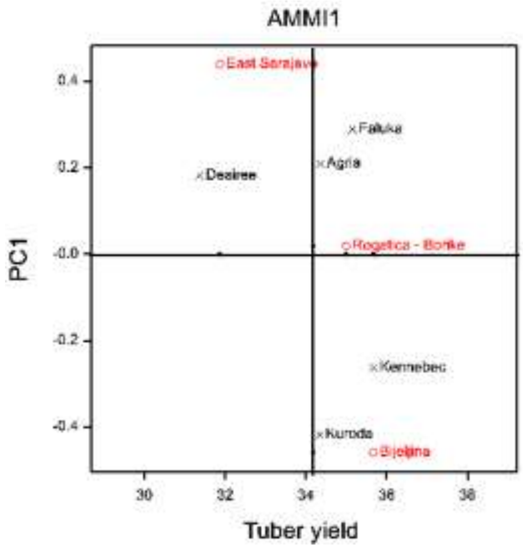

Fig. 1 Additive Main Efect and Multiplicative Interaction (AMMI1) biplot showing the Interaction Principal Component Analysis (PCA1) (Factor1) vs. estimated average tuber yield

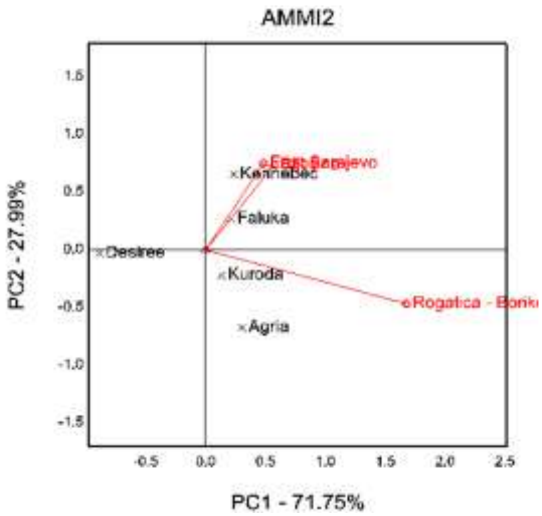

Fig. 2 AMMI2 biplot showing the frst two principal axes of interaction (PCA2 vs. PCA1) of five commercial potato cultivars evaluated in three environments in the Republic of Srpska during the 2016/17 growing season

The significant effect of the G x E interaction showed that genotypes performed differently in various environments. Stable genotypes have a lower impact on the G x E interaction and can be indicated by a lower IPCA1 value (Silveira et al. 2013). The Agria cultivars was ranked third based on average yield but exhibited the highest stability (broad adaptation) compared to other tested varieties. In contrast, Kuroda was identified as an undesirable genotype due to low productivity (ranked fourth) and low stability (IPCA1 values farthest from zero) (Gauch and Zobel 1988). The Désirée cultivars showed medium stability but had below-average yield, while the Faluka and Kennebec varieties had yields above average but displayed high instability. Genotypes and environments that are close to each other in the biplot have positive relationships, allowing for the formation of a group of genotypes within the agronomic zone. Thus, the Kennebec and Faluka genotypes performed better in the Bijeljina and East Sarajevo environments, while the Kuroda and Agria genotypes performed better in the Rogatica - Borike environment. The East Sarajevo environment is characterized by the fact that none of the tested varieties had a yield above the average tuber yield, indicating a stronger presence of abiotic stress. However, the Bijeljina and Rogatica – Borike environments only had below-average yield for the Désirée cultivars, indicating a weaker abiotic stress.

Conclusions

Multienvironmental research has shown that in the examined growing seasons, abiotic stresses associated with climate change, specifically heat and drought stress, have affected the yield of commercial potato varieties. The varieties displayed different sensitivities to abiotic stress. G x E analysis revealed location-specific adaptations among the tested commercial potato varieties. The Agria cultivar was the most stable and adaptable variety across different environments, while the Kuroda cultivar exhibited the lowest stability. The East Sarajevo environment is unsuitable for potato production, and this environment was not suitable for any of the tested cultivars. In the Republic of Srpska, such investigations have not been conducted so far, and there has been no effort to determine the most suitable areas for potato production. Additionally, no research has been done on selecting stable cultivars. Failures in the application of agrotechnical measures, poor choice of potato growing areas, and selection of unstable cultivars have contributed to the low average potato yields.

Abstract

The ability to retain water in soil is influenced by a series of agronomic measures: selection of suitable plant varieties of specific genotypes, sowing dates, planting density, fertilization, inter-row cultivation, irrigation, and application of water conservation products. The ultimate goal of such substances, which began to be used in the 1950s, is to improve the soil's water regime. These materials can enhance the physical and chemical properties of soil, affect the content and availability of nutrients in the soil, positively influence soil microorganisms, and soil fertility. Field trials with seven potato varieties (Agria, Faluka, Kennebek, Marabel, Laura, Rudolph, and Memphis) involved six variants based on a hydrophilic superabsorbent: control variant, superabsorbent alone, superabsorbent enriched with growth stimulators, superabsorbent enriched with microorganisms (*Bacillus subtilis*), superabsorbent enriched with micronutrients, and superabsorbent enriched with growth stimulators, microorganisms, and micronutrients at a rate of 20 kg ha^{-1}. The field trials were arranged in three replications with a planting density of 41666 plants per hectare. The main goal of these studies was to determine the impact of superabsorbents of different compositions on the yield of potatoes. Unfavorable climatic conditions, including high average air temperatures and precipitation deficits during critical periods (June – August), resulted in lower average potato yields in 2019 compared to 2018. The highest average yield was achieved by the Rudolph variety (34.35 t ha^{-1}), while the lowest average yields were observed for the Laura (24.72 t ha^{-1}) and Kennebek (24.28 t ha^{-1}) varieties. The lowest yield was recorded in the control variant (24.77 t ha^{-1}), and the highest yield (34.64 t ha-^{1}) was in the variant with superabsorbent enriched with growth stimulators, microorganisms, and micronutrients.

Key words: *potato, variety, superabsorbent, year, yield.*

Introduction

Increasing potato yields can be achieved through the full application of agronomic practices and adherence to optimal agronomic timings, as well as better adaptation of varieties to agronomic and agroecological production conditions (Broćić and Stefanović, 2012). To ensure sufficient food supply for the human population, it is necessary to double the average yields by 2050 (Ray et al., 2013). Climate change has led to increased water demands in agricultural production, influencing the development of various models aimed at preserving soil moisture and reducing water consumption in agriculture. The World Meteorological Organization (Alcamo et al., 2007) notes that climate change is particularly intense in Southern Europe, which includes our country. In addition to the continuous trend of rising air temperatures, further reductions in precipitation, accompanied by lower soil moisture and availability of water resources, significantly impact agricultural production uncertainty and cause substantial reductions in yields per unit area. The issue of rational water use is of great importance, as water increasingly becomes a source of strategic significance (Bates et al., 2008). Water conservation in agriculture can be achieved through the use of various substances (polymers) that alter the properties of water and air, as well as the physical composition of soil. Water-insoluble polymers (hydrogels) were introduced into agricultural production in the 1980s. Hydrogels also increase water use efficiency and reduce the frequency of irrigation (Sivapalan, 2006) and enhance fertilizer use efficiency (El-Hady and Wanas, 2006). Superabsorbents contain biodegradable fragments within a network structure obtained through radical polymerization in the presence of a redox system. Humic acids, microorganisms, and microelements have been incorporated into the superabsorbent matrix. Raw materials containing starch, pectin, chitosan, and other polymer materials that decompose into water, carbon dioxide, and nitrogen during degradation are used to produce superabsorbents. Superabsorbents have demonstrated positive effects on yield increase in many field and vegetable crops in multi-year experiments conducted in Russia (yield differences between the control variant and the superabsorbent variant of up to 2.5 times), and importantly, superabsorbents do not pollute the soil or crops (Lukin and Maraeva, 2018; Lukin et al., 2017a; Lukin et al., 2017b; Kuznetsov et al., 2017; Lalić et al., 2019).

Materials and methods

Over a two-year period, experiments were conducted in the territory of the city of East Sarajevo, at an altitude of 550 m (43°49'01" N and 18°20'57" E). The agroecological conditions in East Sarajevo are characterized by the strong influence of the continental climate. The average annual temperature is 10.2 °C, and the average amount of precipitation is about 900 mm. The experiment was set on alluvial soil (fluvisol). Soil samples were taken from experimental parcels and after laboratory analysis it was established that alluvial soil from East Sarajevo has pH H_2O 6.63, it contains 3.62% humus, 0.23% N, and in 100 g^{-1} soil, it has 14.75 mg of soluble P_2O_5 and 15.59 mg of soluble K_2O. The experiment included seven varieties and applied 6 variants of superabsorbent at a rate of 20 kg ha^{-1}. Field trials were set up using a randomized block design with three replications, with a density of 41,666 plants per ha. The plot size was 15 m^2 (four rows, each 10 m long, with 25 plants per row, a spacing of 0.6 m between rows, and 0.4 m between plants within the row). For the needs of the experiment, classic agronomic measures were carried out: primary tillage (plowing), secondary tillage (disking after plowing), pre-sowing preparation (rotovation), and no mineral fertilizers were used. Primary soil tillage to a depth of 30 cm and secondary tillage were performed during the fall. Protection was applied depending on the appearance of pests and disease pathogens. At technological maturity of the potatoes, samples were taken from each main plot, consisting of ten hills. The average number of tubers, average tuber mass, and average tuber yield were determined, and the yield was then converted to t ha^{-1}. The obtained data were processed statistically, using the method of analysis of variance (ANOVA), for individual comparisons the least significant difference test LSD test (significance level 0.05) was used.

Table 1. Factors covered by field research

Factor	Treatments
Varieties (A)	A_1 – Agria A_2 – Faluka A_3 – Kennebek A_4 – Marabel A_5 – Laura A_6 – Rudolph A_7 – Memphis
Adsorbent (B)	B_0 – control variant B_1 – superabsorbent "Tverdaya Voda" B_2 – superabsorbent "Tverdaya Voda" enriched with growth stimulants B_3 – superabsorbent "Tverdaya Voda" enriched with microorganisms B_4 – superabsorbent "Tverdaya Voda" enriched with microelements B_5 –superabsorbent "Tverdaya Voda" enriched with growth stimulants, microorganisms and microelements
Growing seasons (C)	C_1 – 2018. year C_2 – 2019. year

Table 2. Average air temperatures and precipitation sumsfrom April to September at East Sarajevo

Months	Temperature (°C)		Precipitation (mm)	
	2018.	2019.	2018.	2019.
April	14.8	11.4	61.4	98.2
May	16.6	12.3	178.1	102.3
June	17.9	21.1	131.5	97.1
July	19.7	21.0	119.6	67.8
August	20.7	21.9	87.5	69.7
September	16.2	16.5	25.9	44.1
Average/Sum	17.7	17.4	604	479.2

Meteorological conditions during the test period are shown in Table 2. During the potato growing season, the average monthly temperatures in 2018 (17.7 °C) and the amount of precipitation (604 mm) were higher compared to 2019 (17.4 °C and 479.2 mm). In 2019, there was 124.8 mm less precipitation compared to 2018. Although 2018 had a higher average temperature, 2019 was characterized by higher average temperatures in July and August, along with lower precipitation, which affected tuber bulking.

Results and discussion

Number of Tubers: The number of tubers per plant is a productive trait influenced by the choice of variety, agronomic practices applied in potato production, and agroecological conditions. The number of tubers per plant was significantly influenced by the factors examined, as well as by the interactions between variety and superabsorbent application (AB) and variety and growing season (AC). The effects of variety, production conditions, and growing season on potato productive traits have been studied by Razzaque and Ali (2009) and Zhao et al. (2012), who obtained similar results. Genetic factors determine the potential for stolon formation, the number of tubers, and their morphological characteristics (Barčić et al., 2003). Poštić et al. (2015) confirmed that the number of tubers per plant is a varietal characteristic.

Table 3. Influence of Superabsorbent and Growing Season on the Number of Tubers per Plant for the Tested Varieties

The variety Rudolph achieved the highest average number of tubers per plant (11.4), followed by Marabel (9.4), Memphis (8.9), Agria (8.3), and Laura (8.1). The lowest number of tubers per plant was found in the varieties Faluka (7.7) and Kennebek (7.1). The variety Kennebek had a significantly lower average number of tubers per plant compared to all other tested varieties. Reduced water use efficiency and the occurrence of water stress affect the reduction of yield components, including the number of tubers per plant, as confirmed by Alva et al. (2012). The use of the superabsorbent "Tverdaya Voda" enriched with growth stimulators, microorganisms, and microelements achieved the highest average number of tubers (9.8), whereas the control variant had the lowest (7.8). These differences were highly significant, as were the differences between the control variant and all other variants applied in the experiment. The superabsorbent "Tverdaya Voda" enriched with growth stimulators, microorganisms, and microelements had a significantly higher number of tubers per plant compared to the variants where superabsorbent "Tverdaya Voda" was used alone (8.3), with microorganisms (8.2), with microelements (8.6), and significantly more compared to the variant with superabsorbent "Tverdaya Voda" enriched with growth stimulators (9.5). The number of tubers per plant is also influenced by meteorological conditions, as confirmed by Van Dam et al. (1996). These authors found a higher number of tubers per plant at lower temperatures. Observing by years, the average number of tubers per plant was higher in 2018 (8.9) compared to 2019 (8.5). In 2018, the average monthly temperatures in June (17.9 °C) and July (19.7 °C) were lower than the temperatures in June (21.1 °C) and July (21 °C) of 2019. The varieties Agria, Faluka, Kennebek, and Marabel had the smallest number of tubers per plant in the control variant, while Laura and Rudolph had the smallest number in the variant with the superabsorbent "Tverdaya Voda" enriched with microorganisms. The variety Memphis had the smallest number of tubers per plant in the variant with superabsorbent "Tverdaya Voda." The highest number of tubers per plant in the variant with the superabsorbent "Tverdaya Voda" enriched with growth stimulators, microorganisms, and microelements was achieved by the varieties Agria, Faluka, Laura, and Rudolph, while Marabel achieved the best results for the number of tubers per plant with the variant using superabsorbent "Tverdaya Voda" enriched with growth stimulators. The variety Kennebek had the highest number of tubers per plant in the variants with superabsorbent "Tverdaya Voda" enriched with growth stimulators and superabsorbent "Tverdaya Voda" enriched with growth stimulators, microorganisms, and microelements, while the variety Memphis had the highest number of tubers per plant in the variants with superabsorbent "Tverdaya Voda" enriched with microelements and superabsorbent "Tverdaya Voda" enriched with growth stimulators, microorganisms, and microelements. The varieties Agria, Faluka, Laura, Rudolph, and Memphis had a higher number of tubers per plant in the first growing season, while Kennebek and Marabel had a higher number in the second growing season. For some varieties, higher temperatures can induce branching of primary stolons and create more sites for tuber formation, as confirmed by Struik et al. (1989).

Tuber Mass: Tuber size is a varietal characteristic but is also influenced by ecological factors, agronomic practices, the number of tubers per plant, the formation of hills, and stolon length (Singh and Ahmed, 2008). The average tuber mass was 81.70 g. The varieties Agria (92.71 g) and Faluka (92.97 g) had the highest average tuber masss, while Laura (72.74 g) and Rudolph (71.92 g) had the lowest. The highest tuber mass was observed in the variants with superabsorbent "Tverdaya Voda" enriched with growth stimulators (85.21 g) and superabsorbent "Tverdaya Voda" enriched with growth stimulators, microorganisms, and microelements (85.66 g). All variants with different combinations of superabsorbent "Tverdaya Voda" had significantly higher average tuber masss compared to the control variant. Significant differences were also found between the different combinations of superabsorbent "Tverdaya Voda" in terms of average tuber mass. Application of Superabsorbent Polymers affects the increase in water absorption and retention in the soil, the storage of essential nutrients for plant development, and the improvement of soil structure. This positively impacts plant growth and yield (Nazarli et al., 2010), whereas in the control variant (without the use of superabsorbent polymers), dry years may lead to a reduction in average tuber mass (Liu et al., 2006). In 2018, the average tuber mass was significantly higher compared to 2019. This was influenced by optimal daytime temperatures and lower nighttime temperatures that favored tuber bulking, as well as more evenly distributed rainfall during the 2018 growing season. The obtained results are consistent with findings by Poštić (2013), who established that high temperatures and a deficit of rainfall during critical periods for potato development significantly affect the average tuber mass. The smallest average tuber masss were observed in the control variants, except for the Marabel variety, which had the smallest tubers in the variant with superabsorbent "Tverdaya Voda".

The largest tubers were found in varieties Agria, Marabel, and Memphis in the variants with superabsorbent "Tverdaya Voda" enriched with growth stimulants and superabsorbent "Tverdaya Voda" enriched with growth stimulants, microorganisms, and microelements. The varieties Kennebek and Laura had the largest tubers in the variant with superabsorbent "Tverdaya Voda" enriched with growth stimulants, while the varieties Faluka and Rudolph had the largest tubers in the variant with superabsorbent "Tverdaya Voda" enriched with growth stimulants, microorganisms, and microelements. **Tuber Yield.** Yield is the most important quantitative characteristic and is subject to significant influences from agronomic and agroecological factors, making it variable. One of the primary goals of modern intensive agriculture is to increase yield. Special attention is given to varieties with high and consistent yield potential under different agroecological conditions. Previous research by Momirović et al. (2016) has highlighted the significant impact of variety and production conditions on tuber yield, while Esehaghbeygi (2010), Ayas (2013), Salavati et al. (2018), and Starovoitova et al. (2019) have demonstrated the significant effect of superabsorbent polymers (superabsorbents) on potato yield. Results presented in Table 5 show that the highest average tuber yield was achieved with the Rudolph variety (34.35 t ha^{-1}), followed by Agria (31.93 t ha^{-1}), Marabel (31.29 t ha^{-1}), Faluka (30.08 t ha^{-1}), and Memphis (29.62 t ha^{-1}).

Average			27,31	33,28	27,57	29,22	34,64	29,47
	A		B	C	AB	AC	BC	ABC
$LSD_{0,05}$	1,283		1,188	0,686	3,142	1,814	1,680	4,444

The lowest average yields were observed with the Laura (24.72 t ha^{-1}) and Kennebek (24.28 t ha^{-1}) varieties. The lowest yield was recorded in the control variant (24.77 t ha^{-1}), and the highest yield (34.64 t ha^{-1}) was achieved in the variant with superabsorbent "Tverdaya Voda" enriched with growth stimulants, microorganisms, and microelements. In 2018, the tuber yield (30.17 t ha^{-1}) was significantly higher compared to the yield in 2019 (28.76 t ha^{-1}). Adverse climatic conditions, characterized by high average temperatures and a deficit of rainfall during the critical period (June–August) for tuber formation and bulking, led to a lower average tuber yield in 2019, consistent with findings by Lahlou et al. (2003) and Tomasiewicz et al. (2003).

The lowest tuber yields for the Agria, Faluka, Kennebek, Marabel, and Laura varieties were observed in the control variant, while the Rudolph variety had the lowest yield in the variant with superabsorbent "Tverdaya Voda" enriched with microorganisms. The Memphis variety had the lowest yield in the variant with superabsorbent "Tverdaya Voda". All varieties had the highest yield in plots where superabsorbent "Tverdaya Voda" enriched with growth stimulants, microorganisms, and microelements was applied, except for Kennebek and Memphis varieties, which had the highest yield in plots with superabsorbent "Tverdaya Voda" enriched with growth stimulants. In the first growing season (2018), varieties generally had higher yields, except for the Marabel variety, which had a higher yield in the second season (2019).

Conclusions

Meteorological conditions during the trials (2018–2019) varied significantly, which affected the development of the productive traits of potatoes. The effects of variety, superabsorbent application, growing season, and their interactions were found for most of the examined traits. Superabsorbent polymers increase the percentage of water and nutrients in the soil for a longer period, allowing for more uniform and even water use by the crop, and promoting faster and healthier crop growth, especially in very hot and dry areas, as well as on light and sandy soils. Since their application has not been sufficiently studied in our regions, it is necessary to continue trials not only with potatoes but also with other crops, in order to address issues arising in plant production due to soil moisture deficits and irrigation problems.

Abstract

The Ramsar sites of Bosnia and Herzegovina, as part of internationally recognized wetland ecosystems, represent vital ecological resources with rich biodiversity. These areas face various threats that endanger their biodiversity. This paper presents the diversity of endangered and protected plant species of the Ramsar sites of Bosnia and Herzegovina. The aim of the Ramsar Convention is to stop the degradation and ensure the conservation and wise use of wetlands worldwide. Bosnia and Herzegovina adopted the convention through succession on March 1, 1993. To date, three sites in Bosnia and Herzegovina have been designated as Ramsar sites: Bardača in the Republic of Srpska, and Hutovo Blato and Livanjsko Polje in the Federation of Bosnia and Herzegovina. In the investigated areas, 161 endangered and protected plant species have been identified. The Livanjsko Polje area has 94 plant species, Bardača 69, and Hutovo Blato 59. The status of endangerment and the degree of protection are given according to the preliminary Red List of endangered plants of Bosnia and Herzegovina and the IUCN list. According to the IUCN list (globally, IUCN G), 112 species are in the category of least concern (LC), 4 species are data deficient (DD), 3 species are near threatened (NT), and 2 species are vulnerable (VU). In Europe (IUCN E), 82 plant species are least concern (LC), 4 are data deficient (DD), 4 are near threatened (NT), and 1 is vulnerable (VU).

Keywords: *Endangered species, protected species, Bardača, Hutovo Blato, Livanjsko Polje.*

Introduction

The aim of the Ramsar Convention (February 2, 1971) is to stop the degradation and ensure the conservation and wise use of wetlands worldwide, both for biodiversity conservation and for securing sufficient natural resources for people who depend on wetland systems (https://www.ramsar.org). Bosnia and Herzegovina adopted the convention through succession on March 1, 1993. In Bosnia and Herzegovina, Ramsar sites include: Bardača (April 12, 2007) in the Republic of Srpska, and Hutovo Blato (September 24, 2001) and Livanjsko Polje (April 11, 2008) in the Federation of Bosnia and Herzegovina. The Ramsar sites of Bosnia and Herzegovina are vital ecosystems that support a wealth of plant life, but they are also exposed to various threats (http://www.mvteo.gov.ba). Bardača (3,500 ha) is located in the northeastern part of Lijevče Polje, in the floodplain between the Sava River and the left bank of the Vrbas River, in the municipality of Srbac. The sub-Mediterranean wetland Hutovo Blato (7,411 ha) is located in the south of Herzegovina, in the karst landscape, in the Neretva River valley, in the municipalities of Čapljina and Stolac. Livanjsko Polje is located in the Cetina River basin and represents an extraordinary natural phenomenon in the karst on 46,000 hectares. Since half of this field is regularly under water, Livanjsko Polje is essentially a combination of wetlands of exceptional value, important bird habitats, and peatlands and meadows inhabited by endemic and rare species (Davidović, 2006).

Materials and Methods

This study used existing literature sources to present the diversity of endangered and protected species in the Ramsar sites of Bosnia and Herzegovina (Cvijić, 1900; Bjelčić, 1954; Riter-Studnička, 1954, 1955; 1972, 1973, 1974; Riter-Studnička and Grgić, 1971; Nedović and Mejakić, 1997; Šumatić et al. 2001; Nedović et al. 2004; Davidović, 2006; Redžić et al. 2008; Redžić, 2012; Milanović and Stupar 2017; Milanović, 2018). The status of endangerment and the degree of protection are given according to the preliminary Red List of endangered plants of Bosnia and Herzegovina (Šilić, 1996) and IUCN (2024). The species names are adjusted according to the Euro+Med PlantBase (2006–2024).

Results and Discussion

Based on the literature data, 161 endangered and protected plant species were identified in the investigated areas. An overview of the protected and endangered species of the Ramsar sites of Bosnia and Herzegovina, according to the preliminary list of endangered species of Bosnia and Herzegovina (PRLBiH) and the IUCN categorization, globally (IUCN G) and for Europe (IUCN E), is shown in Table 1.

From the total number across all three areas, there are 13 plant species represented. Bardača and Livanjsko Polje share 18 common plant species, while Livanjsko Polje and Hutovo Blato share 8, as well as Hutovo Blato and Bardača. According to the preliminary list of endangered species of Bosnia and Herzegovina (PCLBiH), 32 species are vulnerable (V), with the highest number found in Hutovo Blato (20), followed by Bardača (13) and Livanjsko Polje (10). The percentage representation of vulnerable species is 19.88%. These species include *Acanthus spinosus, Acorus calamus, Butomus umbellatus, Caltha palustris, Celtis tournefortii, Convallaria majalis, Cyclamen hederifolium, Cyclamen repandrum, Galanthus nivalis, Gratiola officinalis, Iris sibirica, Marsilea quadrifolia*, and others. According to the IUCN categorization (global IUCN G), 112 species are classified as least concern (LC), 4 species lack sufficient data (DD), 3 species are near threatened (NT), and 2 species are vulnerable (VU). Some of the species listed on the IUCN global list include: *Alisma plantago aquatica, Angelica sylvestris, Baldellia ranunculoides, Cardamine pratensis, Carex nigra, Pinguicula* *vulgaris, Populus nigra, Corrigiola litoralis, Glechoma hederacea, Hordeum murinum, Iris pseudacorus.* The percentage representation of species by categories is: 69.57% LC; 1.86% NT; 1.24% VU; 2.48% DD. According to the IUCN categorization (Europe IUCN E), 82 plant species are least concern (LC), 4 are data deficient (DD), 4 are near threatened (NT), and 1 is vulnerable (VU). These species are: *Anacamptis morio, Anacamptis palustris, Molinia caerulea, Najas minor, Rosa gallica, Salvinia natans, Scripus sylvaticus, Colchicun autumnale, Juncus articulatus, Meliolotus officinalis, Persicaria amphibia,* etc. The percentage representation of species by categories is: 50.93% LC; 2.48% NT; 0.62% VU; 2.48% DD.

Conclusion

The Ramsar sites provide habitat for many endangered plant species, thus offering vital support for biodiversity. Through effective protection measures, such as regulation of human activities, control of invasive species, and promotion of education, we can ensure the long-term sustainability of these ecosystems. Further research and monitoring of plant species populations will be essential for the successful conservation of the Ramsar sites of Bosnia and Herzegovina. To date, three sites in Bosnia and Herzegovina have been designated as Ramsar sites: Bardača in the Republic of Srpska, and Hutovo Blato and Livanjsko Polje in the Federation of Bosnia and Herzegovina. Based on literature data, 161 endangered and protected plant species have been identified in the investigated areas. The analysis determined that the Livanjsko Polje area contains 94 plant species, the Bardača area 69, and Hutovo Blato 59. Of the total number of plant species in the investigated area, 32 species are vulnerable (V) according to the preliminary Red List of endangered plants of Bosnia and Herzegovina. According to the IUCN list (globally IUCN G), 112 species are in the category of least concern (LC), 4 species are data deficient (DD), 3 species are near threatened (NT), and 2 species are vulnerable (VU). In Europe (IUCN E), 82 plant species are least concern (LC), 4 are data deficient (DD), 4 are near threatened (NT), and 1 is vulnerable (VU).

Abstract

This study was conducted to determine the effect of two chloride salts (NaCl and KCl) and their concentrations (0, 50, 100, 150, 200, 250, 300 mM) on the germination and early seedling growth of *Aegilops cylindryca* seeds. The trials were performed in two replicates of 25 seeds for each variant. Germination was carried out between rolls of filter paper with 20 ml of the respective test solutions at a temperature of 20 ± 1°C, for 10 days. Seeds were counted as germinated when the germ has reached at least 2 mm. The following characteristics were calculated: germination percentage (G, %), coefficient of velocity of germination (CVG), germination rate index (GRI, % day^{-1}), mean germination time (MGT, day) and relative injury rate (RIR). The data for the shoot and root length (cm) (LSh and LR), length of seedling (LS, cm), fresh weigh (mg plant^{-1}) of shoot and root (FWSh and FWR) and dry weight (mg plant^{-1}) of shoot and root (DWSh and DWR) were measured 10 days after germination. The three-way ANOVA analysis showed that the dose was proven to have the greatest effect on the studied parameters. The highest value of the relative injury coefficient above 0.80 was recorded when seeds were treated with NaCl at concentrations of 250-300 mM salt, as well as when they were treated with KCl at concentrations of 200-300 mM. Application of high salinity concentrations of both chloride salts had a greater inhibitory effect on shoot growth compared with root growth.

Keywords: *Aegilops cylindrica* Host, *NaCl, KCl, germination, seedling growth.*

Introduction

Salinity represents one of the most significant abiotic constraints on plant growth and productivity globally. The impact of salinity on plant growth is mediated by its influence on metabolic rates and pathways within the plant. Salinity affects plant growth at all stages of development, and the sensitivity to salinity varies between different growth stages (Yohannes et al., 2020). The presence of excess salts in soils and water can have a detrimental impact on seed germination and plant growth. This can occur either through osmotic effects, whereby the absorption of water is limited due to a low water potential, or ionic toxicity, which can result in cellular injuries and a reduction in metabolic activity due to the presence of excess ions (Dadach et al., 2023; Hadjadj et al., 2023**)**. The presence of soluble salts, such as calcium chloride ($CaCl_2$), potassium chloride (KCl) and sodium chloride (NaCl), has been demonstrated to have a detrimental impact on plant growth. The influx of these ions into the cells can result in the onset of significant physiological disorders. The accumulation of sodium ions (Na^+) has been shown to inhibit the absorption of potassium, an essential element for growth and development. This can lead to a reduction in productivity and, in severe cases, may even result in death (Kanjevac et al., 2021).

Seedlings and young plants are much more sensitive to salt stress than mature plants (Kanjevac et al., 2021). Jasim and Nulit (2019) noted that it is of paramount importance for plants to adapt to salinity during the germination and early seedling stages, as this is a crucial factor in the establishment of the plant stand. The adverse effects of salt stress on germination, seedling growth, and some physiological activities of a number of cultivated plant species have been extensively investigated (Kiran et al., 2021). A number of studies have indicated that salt stress tolerance varies among species and also depends on the stage of plant development, salt type and concentrations (Panuccio et al., 2014; Vishnu Priya et al., 2020). Consequently, the selection of salt-tolerant plant genotypes at both the germination and seedling stages represents an effective approach to addressing the issue of soil salinity (Hadjadj et al., 2023).
The aim of this study was to analyze the effects of NaCl and KCl on germination and seedling growth of *Aegilops cylindrica* Host seeds.

Material and Methods

The study examined the effect of six salinization levels (50, 100, 150, 200, 250, and 300 mM) using two chloride salts (NaCl and KCl) on seed germination and early seedling growth parameters. Deionized water was used as control variant. An experiment was conducted with seeds from five Bulgarian populations of *Aegilops cylindrica* Host, taken from an experiment established at IPGR-Sadovo in 2023, Bulgaria. For each variant of experiment, two replicates of 25 seeds were germinated on rolled filter paper (Grade FT 55) with 20 ml of the respective test solutions. The papers were replaced every 2 days to prevent salt accumulation. The seeds were allowed to germinate in the dark at $20\pm1^{o}C$ for 10 days. Seeds were considered germinated when the radicle had extended at least 2 mm. The number of germinated seeds was recorded daily until a constant count was achieved. From the germination counts several germination characteristics were studied including germination percentage (G, %), coefficient of velocity of germination (CVG), germination rate index (GRI, % day^{-1}), mean germination time (MGT, day) and relative injury rate (RIR). CVG was calculated according to Kader and Jutzi (2004), GRI and MGT according to the formula of Kader (2005), while RIR according to Li (2008).
On the eighth day of the experiment, ten seedlings were randomly selected from each treatment for the measurement of shoot and root length (LSh and LR in cm) and fresh weight of shoot and root (FWSh and FWR in mg/plant). Additionally, data for dry weight of shoot and root (DShW and DRW in mg/plant) were recorded after drying in an oven at 80°C for 24 hours. Seedling height reduction was determined using the method described by Islam and Karim (2010), and salt tolerance index (STI) was estimated according to Mujeeb-ur-Rahman et al. (2008).
A three-way analysis of variance (ANOVA) was employed to assess the influence of genotype, salt type, concentration, and their interaction on germination and seedling characteristics. The Duncan’s Multiple Range Test was conducted at a 0.05 probability to determine the significance of differences between the means of all germination and seedling parameters for each treatment. A simple correlation with the index (Pearson correlation) was employed to ascertain the interrelationships between the values of salt concentrations and germination parameters and seedling metrics. All statistical methods were conducted using JMP 17 statistical software.

Results and Discussion

A three-factor ANOVA analysis (Table 1 and Table2) showed a significant individual effect of genotype, salt type, concentration (dose) and their interaction on the most of studied parameter, except salt type for MGT, ShL and DRW, genotype for DRW, genotype*salt for RL and ShL, genotype*salt*dose for FRW. Dose was shown to have the greatest effect on the all parameters studied.

The *Aegilops cylindrica* seeds exhibited differential responses at the studied chloride salt concentrations, as illustrated in Fig. 1. The non-saline-treated seeds (control) exhibited the highest germination rate. The seeds demonstrated a higher germination rate under salinity stress caused by KCl than under stress caused by NaCl. The lowest germination rate was observed in seeds treated with 250 mM NaCl, while at the highest salinity levels of 300 mM NaCl, no seeds germinated in all samples included in the study. Only weak root system development was observed.

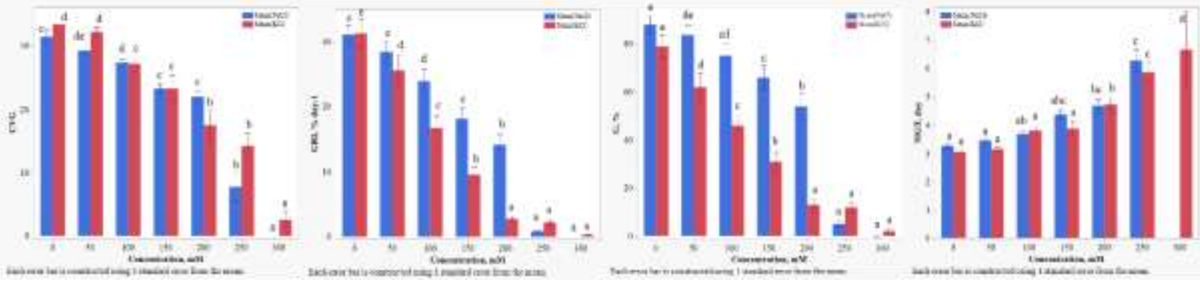

Fig.1 Variation of the germination characteristics of *Aegilops cylindrica* seeds treated with NaCl and KCl. Bars are mean values± standard error. Similar bars with different letters are significantly different from each other (Duncan’s Multiple Range Test, P < 0.05).

The linear regression analysis data presented in Fig. 2 showed a strong negative statistical correlation ($p<0.001$) between G, CVG, GRI values and salt doses with coefficients of determination (R^2) ranging from 0.684 to 0.790 and a strong positive statistical correlation between MGT and salt concentrations with R^2 ranging from 0.552 to 0.571. These results also provide clear indication of the inhibitory effect of NaCl and KCl salts on seed germination of *Aegilops cylindrica* Host.

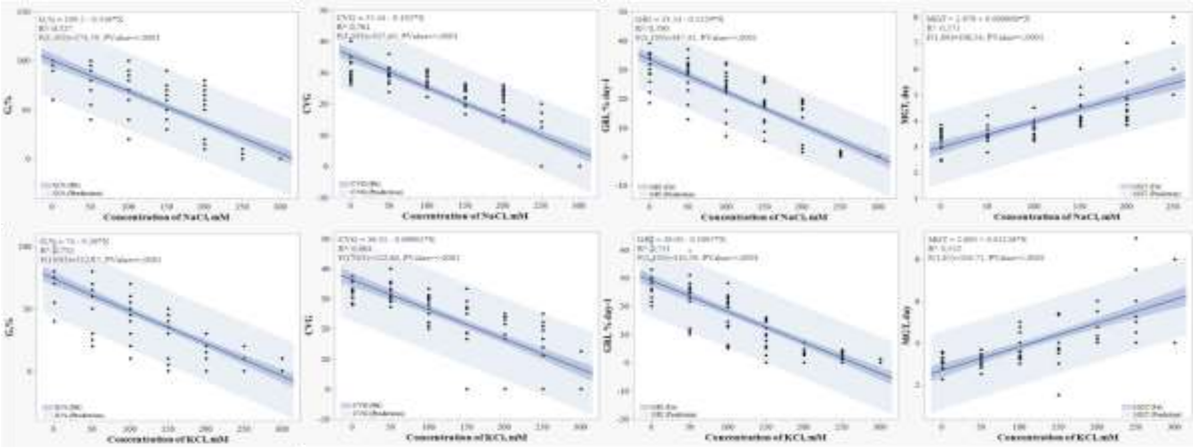

Fig.2 Regression plots for germination parameters (G-germination percentage, CVG-coefficient of velocity of germination, GRI-germination rate index, MGT-mean germination time) of *Aegilops cylindrica* seeds treated with NaCl and KCl

The highest value of the relative injury coefficient above 0.80 was recorded when seeds treated with NaCl at concentrations of 250-300 mM salt, as well as when treated with KCl at concentrations of 200-300 mM. The results also indicated that seeds treated with NaCl exhibited a lower relative injury rate at concentrations of 50-200 mM in comparison to those treated with KCl. However, at the highest salinity concentrations (250-300 mM), NaCl-treated seeds demonstrated the highest value of the relative injury rate (Fig.3).

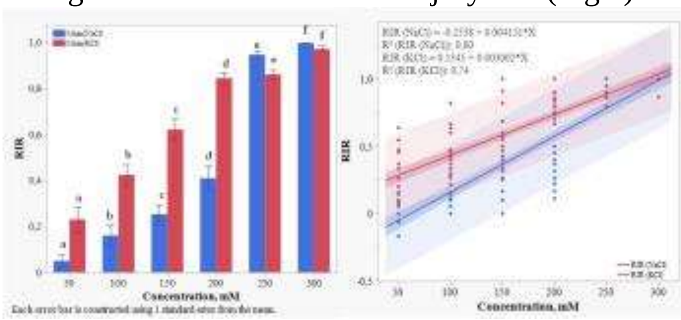

Fig.3. Variation of the relative injury rate (RIR) of *Aegilops cylindrica* seeds treated with NaCl and KCl and regression plot for RIR. Similar bars with different letters are significantly different from each other (Duncan’s Multiple Range Test, $P < 0.05$)

The results of our study showed that both of mean root and shoot lengths were significantly declined with the increase in salt levels. The reduction in root growth ranged between (0.11–0.88) and (0.07-0.91) as compared to those of controls, respectively for NaCl and KCl. For shoot elongation, the reduction rates ranged between (0.16-1) and (0.11–0.98), in this order for NaCl and KCl. Hence the growth of shoot was more sensitive to salt stress than root, particularly at higher salt concentrations (Fig. 4). The significant variations in salt tolerance indices with increasing salinity concentration for both salt types were found. The highest values of the indices were recorded at the lowest concentration, respectively the lowest at the highest concentration (Table 3).

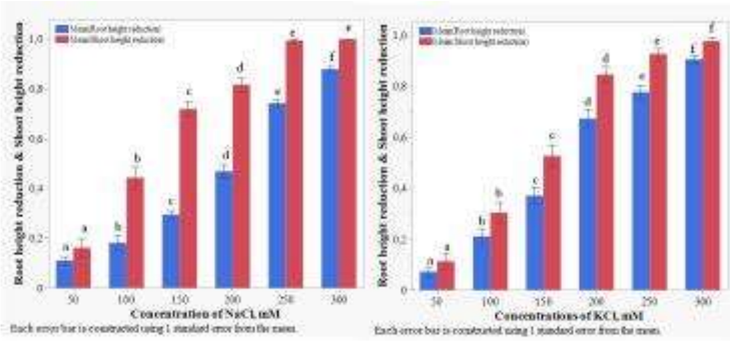

Fig.4. Variation of the root/shoot height reductions of *Aegilops cylindrica* seeds treated with NaCl and KCl. Similar bars with different letters are significantly different from each other (Duncan's Multiple Range Test, $P < 0.05$)

Germination Salt Tolerance Index (GSTI), Root Salt Tolerance Index (RSTI), Shoot Salt Tolerance Index (ShSTI),
Means within a column that have different superscript letters (a-g) are significant different from each other (Duncan's multiple range test, $p \leq 0.05$)

Aegilops cylindrica seeds showed high to very high tolerance to germination at 50-150 mM NaCl and 50 mM KCl, moderate tolerance at 100 mM KCl and at 200 mM NaCl, low to very low tolerance at 250 mM NaCl and 250-300 mM KCl. At the highest concentration of NaCl, seeds were sensitive to germination. RSTI varied from 9.38% to 92.24%, while ShSTI varied from 0% to 88.71%. At 50-150 mM doses of both salts, Aegilops cylindrica showed very high to high tolerance to root growth, while at the highest concentrations of 250-300, root tolerance varied from low to very low tolerance. In terms of shoot growth, at the highest concentration Aegilops cylindrica was sensitive to salinization with NaCl and very low resistant to salinization with KCl. The calculated average salt tolerance indices indicated that Aegilops cylindrica was more tolerant to NaCl salt in compere to KCl salt.

Conclusion

Genotype, salt type, concentration (dose) and their interactions had significant individual effect on the most of studied germination and seedling characteristics of *Aegilops cylindrica*. Application of increasing concentrations of both type of salts (NaCl and KCl) prolonged mean germination time and suppressed the studied germination and seedling characteristics and had a greater inhibitory effect on shoot growth compared with root growth. The relative injure rate above 0.80 was recorded at 250-300 mM NaCl and 200-300 mM KCl The significant variations in salt tolerance indices with increasing salinity concentration for both salt types were found. The effect of salinity on physiology, molecular and biochemical of properties of *Aegilops cylindrica* should be studied.

Abstract

In resent yeas there is a very special attention of the scientific community towards the investigations connected with the seed quality of the medicinal plants. That is due to the increased demand for these plants for the pharmaceutical industry together with the necessity of creation of rational mechanisms for their cultivation. The aim of the study was to determine the quality of seeds from members of the families. *Lamiaceae* produced in different years and to validate fluorescence spectroscopy in the proposed configuration as a non-invasive method to assess seed moisture, viability and purity. Seeds from 12 accessions from 4 species, belonging to *Lamiaceae* botanical family are included in the study and tested using mobile experimental installation for fluorescence spectroscopy. The water absorption of the seeds shows differences and similarities between species, between accessions as well as between variants. The main similarity is the rapid absorption of water of the seeds in all 12 variants during the first 8 hours, nevertheless that in *Ocimum basilicum* – lemon the process lasts 4 hours. The seeds of all other variants imbibed rapidly, no matter the year of harvest and obtain their maximum weight during the first hours. The average water absorption is similar in all variants (35%). There were no significant differences in % germinated seeds and germination time between Ocimum basilicum-limon and *Ocimum basilicum*. Seed germination was high at 96-100% and completed in 7-9 days except for *Ocimum basilicum*-2012 at 9%. Germination of salvia samples was longer about 20 days and germination percentage were in the range of 63-93% depending on the year of harvest. A mobile fibre-optic installation using fluorescence spectroscopy was successfully set up and tested. In the proposed setup, fluorescence spectroscopy was validated as a non-invasive method to assess seed moisture, viability and purity.,

Key words: *medicinal plants, seeds quality, fluorescence spectroscopy, Lamiaceae family.*

Introduction

Plants are an important source of medicinal substances and play key role for the human health. The increasing population, the insufficient supply with medicinal substances, the extremely high cost of medical treatments, the negative side effects caused by the synthetic drugs and development of resistance to many infection diseases has led to increasing demand of plant materials as a source for medicinal remedies.

Nowadays many medicinal plant species are threatened or nearly extinct. Unfortunately, they are not actively conserved. For example, there is very little material from them in gene banks.

The quality of the seeds is a very important factor for the successful growing of medicinal plants. Nowadays, there is a worldwide recognition of the importance of aromatic and medicinal plants not only on the basis of their medicinal and preventive properties, but also for their use in food, feed, cosmetic and pesticide industries, which is reflected in the growing demand for aromatic and medicinal products in the markets.

Seed germination is a very important stage from the live cycle of the plants ant there is a tendency to be strongly unpredictive in time.

A number of factors as temperature, salinity, light, water supply, nutrient substances and moisture content of the soil strongly influence the seed germination. The moisture content of the seeds as another very important factor for the viability of seeds.

In a well-organized program for production of seeds with high quality, the measurement of seed moisture content also determines the decision-making policies concerning seed harvesting, processing and marketing.

It is therefore important that the moisture content is consistent with the seed storage behavior and desiccation and chilling sensitivity/tolerance of a species,

Water absorption is the first step of seed germination. It starts with the uptake of water by absorption of the dry seeds, followed by expansion of the embryo.

To produce quality seedlings, good germination is necessary, which includes metabolic and morphogenetic mechanisms, summarized as follows: 1) absorption of water by the seeds, 2) activation of metabolism and the process of respiration, protein synthesis and mobilization of embryonic reserve substances, and 3) elongation of the embryo with rupture of the seed coat, through which the exit of the root is observed (Suárez and Melgarejo, 2010, Monroy-Vazquez et al., 2017). Water absorption is the first step of seed germination. It begins with the uptake of water by imbibition of the dry seeds, followed by expansion of the embryo (Suárez and Melgarejo, 2010)

Seed dormancy is one of the important limiting factors for exploitation of economically valuable species.

The chemical composition of seeds that contain essential oils are rich in lipids, in which specific oxidation processes occur during storage. They are believed to be a limiting factor for long-term storage depending on their specific chemical composition (Balešević et al., 2007). Loss of seed viability is associated with an increase in reactive oxygen species (i.e., singlet oxygen, hydrogen peroxide, and hydroxyl radical) causing DNA damage, protein adducts, and lipid peroxidation (Sano et al., 2016, Kurek et al., 2019).Therefore, the storage of such seeds requires special attention, otherwise the oxidation processes can occur too early, which can lead to the loss of seed germination and viability (Genes and Nyomora Agnes, 2018). Dormancy is an important component of seed physiological quality, and plants with a long history of domestication and reproduction generally have lower seed dormancy than wild or recently domesticated species. (Copeland and McDonald, 2001; Khalid et al., 2016).

Over the past decades, imaging and spectroscopy techniques have been developed rapidly with widespread applications in non-destructive agro-food quality determination. Seeds are one of the most fundamental elements of agriculture and forestry. Seed viability is of great significance in seed quality characteristics reflecting potential seed germination, and there is a great need for a quick and effective method to determine the germination condition and viability of seeds prior to cultivate, sale and plant (Xia et al., 2019)

The potential or practical applications in seed industry include the detection of viability, vigour, defect, disease, cleanness and the seed composition determination (Feng et al 2019). Fluorescence analysis of plant powders from medicinal plants is also used as a fingerprint for correct identification of crude drugs when other physical and chemical parameters of crude drugs are not sensitive enough (Beressa et al., 2021). Fluorescence spectroscopy is a high-precision method commonly used in the quantitative analysis of heavy metal elements and is also used to determine nanoscale metal concentrations (Nguyen et al., 2022).

Fluorescence spectroscopy in the analysis of powders can be used to solve the problem of quality control of herbal medicines, as well as in the initial stages when trying to determine their molecular properties and quantify photo components of the herbal products from which they are derived. (Chinese et al., 2020).

The aim of the study was to determine the quality of seeds from members of the families. Lamiaceae produced in different years and to validate fluorescence spectroscopy in the proposed configuration as a non-invasive method to assess seed moisture, viability and purity.

Material and methods

Seeds from 12 accessions from 4 species (table 1), belonging to *Lamiaceae* botanical family are included in the study using mobile experimental installation for fluorescence spectroscopy (Table.1.). They are from the collection of Institute of Plant Genetics Resources (IPGR) - Sadovo.

Table1. Seeds from *Lamiaceae* botanical family are included in the study.

Species	**year**	**Seeds**

Salvia officinalis	2022	
Salvia officinalis	2019	
Salvia officinalis	2016	

Seed moisture %;
Determined individually on 50 seeds of each variant. The seeds were dried for 4 days at a constant temperature (70±1 °C) in the dark. Initial and final weights were measured on an analytical balance (Scientech SA120, USA, with an accuracy of ±0.0001 g) and seed moisture was expressed as a percentage of weight loss relative to initial weight (International Seed Testing Association, 2010)
$\% \ Mc = \times 100$

Seed imbibition %
The seeds of the twelve variants were placed in petri dishes on filter papers moistened with distilled water. They are then stored in a controlled environment at a constant temperature (30±1 °C) and in the dark. Three replicates of each variant were evaluated, with 10 seeds each (n=30). Initial weight was recorded every 8 hours for 48 hours, a final recording was made after 72 hours from baseline. Absorption is expressed as the percentage increase in seed weight, by water absorption, relative to the initial weight,

Germination %
Seeds of the twelve variant variants were placed in petri dishes on filter papers moistened with distilled water with a cotton swab. They are stored at a constant temperature (30±1 °C) and in the dark. Four replicates of each variant were evaluated, with 25 seeds each (n=100). Seed germination (%) - ratio of the total number of normally germinated seeds to the total number of seeds at the end of the period. Germination was recorded daily for 20 days or until no germinating seeds were observed for more than five days.

Fluorescence spectroscopy

The mobile fiber-optical spectral installation for the study of fluorescence signals is designed specifically, for the rapid analysis of plant biological samples. The mobile experimental setup used by fluorescence spectroscopy includes the following components:

- Laser diode (LED) with an emission radiation of 245 nm with a supply volt-age in the range of 3V. It is housed in a hermetically sealed TO39 metal housing.
- Rod lens of the achromatic doublet type. It is composed of two bonded lenses with different Schott and Corning dispersion coefficients with an anti-reflective coating. The multimode optical fiber is FG200LEA. It has a core diameter of 200 µm and a step index of refraction.
- Quartz glass area 4 cm2.
- CMOS detector with photosensitive area 1.9968×1.9968 mm.
- Reception of the emission signal at 45°

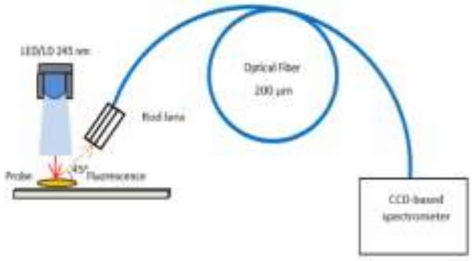

Fig. 1. Mobile experimental installation used by fluorescence spectroscopy

Results and discussion

Seed moisture content showed differences between *Ocimum basillicum*-lemon and *Ocimum basillicum* as well as between *Salvia sclarea* and *Salvia officinalis* samples (Fig.2).

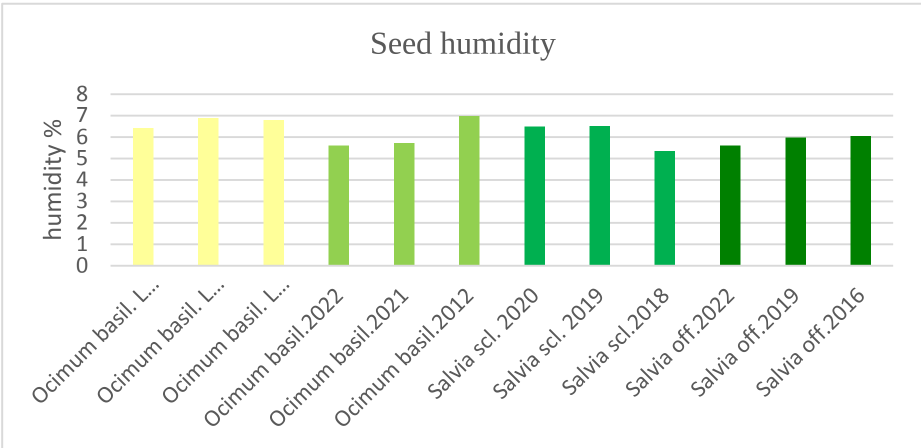

Fig.2. Seed humidity

The process of water absorption of the seeds is very rapid and easy way to be determined whether the seed coat is water transparent or not. The hard seed coat could cause physical latent of seeds (Ranber Chauhan, Sobha and JS Chauhan, 2020).

The water absorption of the seeds shows differences and similarities between species, between accessions as well as between variants (Fig.3). The main similarity is the rapid absorption of water of the seeds in all 12 variants during the first 8 hours, nevertheless that in *Ocimum basilicum* – lemon the process lasts 4 hours. After that rapid phase the average absorption remains constant during the next 24-32 hours. An exception is *Ocimum basilicum* -

2012, whose seeds continue to absorb water rapidly after 32 hours. Similar results are reported for *Opuntia* sp. where water absorption in most intensive during the first 8 hours. In O. megacantha and O. ficus-indica that time is with 4 or 8 h longer. (**Monroy-Vázquez** M.E et al.,2017)

The seeds of all other variants imbibed rapidly, no matter the year of harvest and obtain their maximum weight during the first hours. The average water absorption is similar in all variants (35%), and that coincides with the results, received by Foschi, M.L. et al.,(2022) in Capparis seeds (Capparis spinosa L.).

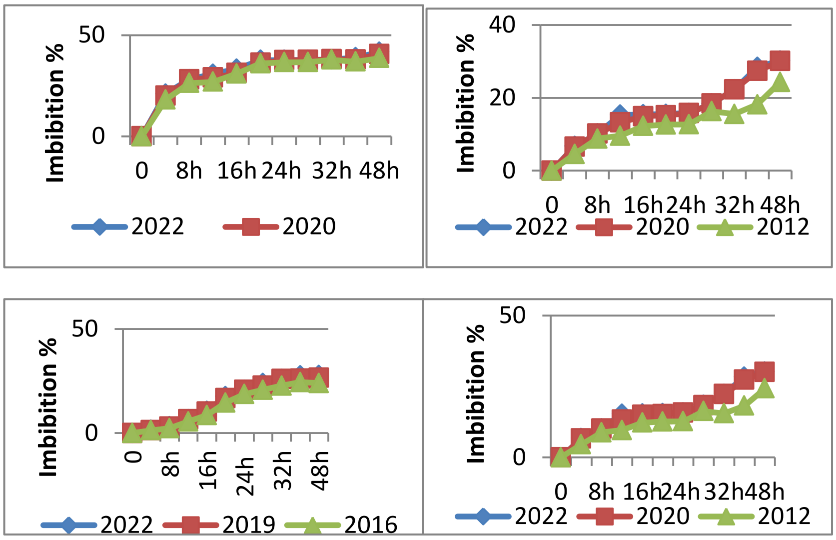

Fig.3. Cumulative water imbibition by seeds of twelve variants of (a) *Ocimum basilicum*-lemon; (b) *Ocimum basilicum*; (c) *Salvia sclarea*; (d) *Salvia officinalis*

The results of the seed germination test are shown in Fig.4. There were no significant differences in % germinated seeds and germination time between *Ocimum basilicum*-limon and *Ocimum basilicum*. Seed germination was high at 96-100% and completed in 7-9 days except for *Ocimum basilicum*-2012 at 9%. Germination of salvia samples was longer about 20 days and germination percentage were in the range of 63-93% depending on the year of harvest.

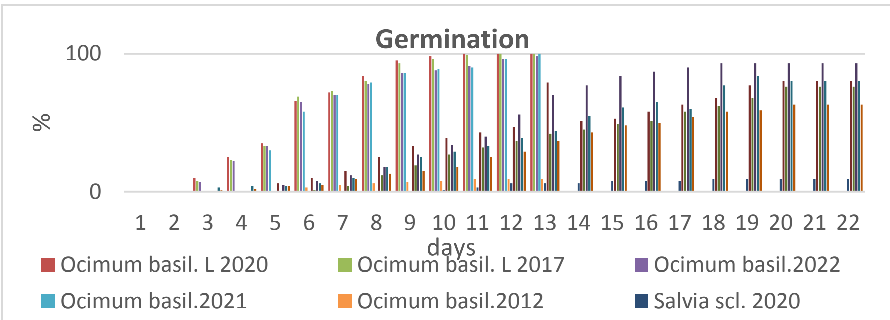

Fig.4. Results of the seed germination test.

The 7 species of medicinal plants, subject to that study (Tiwari and Kuntal, 2014) germinate with different frequency influenced by different storage components - storage materials, effect of storage temperature, Effect of storage duration, different plant species (R. Tiwari and Kuntal Das, 2014).

Results and discussion

Seed purity is directly proportional to the type of spectral distribution of the emission signal. Seed wetness is directly proportional to signal intensity. The viability is directly proportional to the intensity level and the spectral distribution along the ordinate of the signal.
Figure 5 presents the spectral distribution with wavelengths of the reflected emission of *Salvia sclarea* seeds collected in three different periods. Seeds from 2022 have the highest viability, the lowest moisture content and the highest purity, and their emission distribution is close to seeds collected in 2019. Seeds from 2018 have much lower values of these parameters. The close distributions in 2022 and 2019 of *Salvia sclarea* seeds show stability on these parameters for this variety.
Figure 5 presents the spectral distribution with wavelengths of the reflected emission of *Salvia officinalis*. Seeds collected from 2022 have the highest viability, lowest moisture content and highest purity. The close distributions in 2016 and 2019 of *Salvia officinalis* seeds indicate that to have stability in these metrics, seeds should not be stored for a longer period.

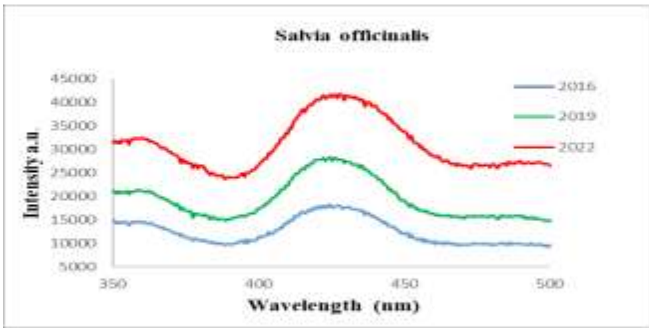

Figure 5. Emission wavelengths of *Salvia Sclarea* seeds harvested in three different periods

Figure 6 shows the spectral distribution with wavelengths of the reflected emission of *Ocimum bacilicum*- lemon. Seeds collected in 2022 had the highest viability, lowest moisture content and highest purity. The emission distributions of seeds collected in 2017 and 2020 were similar. The close distributions in 2017 and 2020 indicate that *Ocimum bacilicum* - lemon seeds are stable over a long period of time.

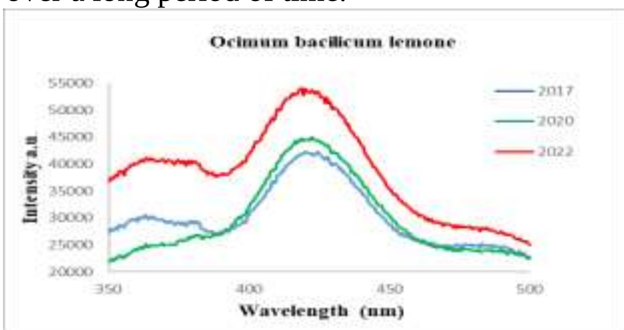

Figure 6. Emission wavelengths of *Ocimum bacilicum* lemone harvested in three different period

Figure 7 shows the spectral distribution with wavelengths of the reflected emission of *Ocimum bacilicum*. Seeds collected in 2012 had the lowest viability, highest moisture content and lowest purity. The emission distributions of seeds collected in 2022 and 2021 are extremely close. The close distributions in 2022 and 2021 of *Ocimum bacilicum* seeds indicate that the seeds are stable in these parameters immediately after harvest or for a short period afterwards.

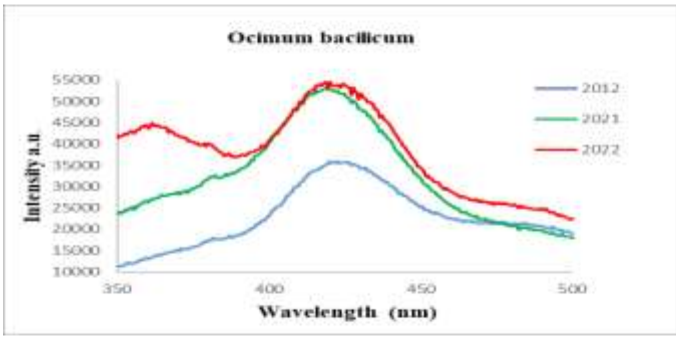

Figure 7. Emission wavelengths of *Ocimum bacilicum* harvested in three different periods

The spectral distributions are unique to the seeds of a particular species, cultivar or breeding line, warranting the use of the plant to identify available seeds of selected members of the *Lamiaceae* family harvested in different years and stored for different periods of time in a non-invasive manner with high accuracy.

Conclusions

The quality of seeds from representatives of the sem. Lamiaceae harvested in different years by standard and non-invasive methods. A mobile fibre-optic installation using fluorescence spectroscopy was successfully set up and tested. In the proposed setup, fluorescence spectroscopy was validated as a non-invasive method to assess seed moisture, viability and purity. Since the proposed method is quick, cheap and non-invasive, and could be easily engineered in order, it is our opinion that it could became an asset in the agro industrial sector helping to determine the quality of seeds in different plants.

COMBINING ABILITY OF MID-EARLY MUTANT MAIZE LINES FOR THE GRAIN YIELD AND LENGTH OF THE EAR

Mima ILCHOVSKA*, Valya BACHIYSKA, Nataliya PETROVSKA, Valentina VALKOVA

Maize Research Institute, 5835 Knezha, Agricultural Academy, 1373 Sofia, Bulgaria
*Corresponding author: ilchovska_mima@abv.bg

Abstract

The general combining ability (GCA) and specific combining ability (SCA) of seven mid-early mutant maize lines for the grain yield and length of the ear were assessed using Savchenko’s mathematical model (1978). The lines were tested in a top-cross scheme with three testers. In 2021 and 2022, their hybrid combinations were tested in field experiments at the Maize Institute – Knezha. High GCA for grain yield was demonstrated by lines XM 2014285, XM 2014298, and XM 2014325, and for length of the ear – by XM 2014285, XM 2014298, and XM 2014284. These lines can be utilized as components in the development of mid-early synthetic populations or as testers when determining GCA in the early stage of the selection. The mutant lines with high SCA for grain yield – XM 2014325, XM 2014298, XM 2014 301, and XM 2014285, and for length of the ear – XM 2014301, XM 2014284, and XM 2014 298, can be incorporated into heterosis selection programs for the purposes of a direct production of high-yielding hybrids with long ears. Lines with high GCA and SCA for both traits can be successfully utilized in both directions of the selection process.

Key words: *General and specific combining ability, Maize inbred lines, Grain yield.*

Introduction

The question of selecting and improving the genetic basis for maize selection is a fundamental aspect in the studies of all selection practitioners. In recent years, the introduction and use of output forms and closely related hybrids in terms of their origin have significantly narrowed the genetic base and created preconditions for vulnerability under stressful conditions. Experimental mutagenesis in maize is one of the possibilities for enriching and expanding its genetic diversity. Its application induces mutations in individual genes or groups of genes, making it possible to obtain a variety of sorts and lines with new traits, without affecting the basic genotype.

Chemical mutagenesis-induced phenotypic changes include important quantitative traits, such as higher grain yield, high protein content, changes in grain type, improved general and specific combining ability and other important traits of agronomic importance (Christov, N., 2004; Kostova, A. et al., 2006; Tomlekova, N., 2010; Gnanamurthy, S. et al. 2011; Eze J. and Dambo A., 2015; Muhammad A., et al., 2018, etc.).

Since 1973, the Maize Institute - Knezha in Bulgaria, has launched a selection program aimed at using experimental mutagenesis and mutational selection to accelerate the selection process by inducing additional genetic variability in elite lines and hybrids (Hristov K. and Hristova P., 1995). As a result, a large number of mutant lines with valuable biological and economic traits have been established at the Institute, and in 1980, for the first time in the world, the first mutant maize hybrids were simultaneously registered in Bulgaria and Ukraine. The combination of hybridization with the methods of experimental mutagenesis is undoubtedly the most effective in enriching the genetic potential of maize. Therefore, an important indicator of the use of a certain selection material in heterosis selection is its combining ability.

The assessment of combining ability allows for its more effective inclusion in well-established selection programs (Petrovska, Genova, 2009; Ilchovska, 2011; Ilchovska, 2013; Valkova, Petrovska, 2015; Valkova, Petrovska, 2016; Petrovska et al., 2019; Valkova et al., 2019, etc.). One of the methods for determining the combining ability of newly stabilized maize lines is the top-cross. In the initial stages of testing, this method allows for a quick and satisfactory assessment of the selection value of these lines (Savchenko, 1978).
The aim of the present study is to analyse the combining ability for the traits grain yield and length of the ear of seven newly developed mid-early mutant maize lines with good productive potential, with a view to their more rational inclusion in appropriate selection programs.

Materials and methods

Studies for the selection and improvement of output material for maize selection through experimental mutagenesis were conducted in the period 2015-2022 at the Maize Institute – Knezha. Heterozygous material treated with a solution of NMU (n-nitroso, n-methyl urea) solution at concentration of 10^{-4}% with an exposure of time of 24 hours was used as the object of mutagenic treatment. The selection of mutagens, exposures, and solution concentrations was applied according to the methodology of Morgun (1983).
After self-pollination and selection for economically valuable traits, the newly-developed mutant lines in the M_5 generation were tested in isolations with three testers: XM 92471, K 4652, and PAU 1617. Their hybrid combinations were tested in field trials using the Latin rectangle method, in three repetitions with a harvest plot size of 10m2, without irrigation, using an agronomic technique adopted for the region of the Institute.
The statistical analysis of the raw data was performed using the method of analysis of variance according to Shanin (1977). To evaluate the general and specific combing ability, the mathematical model of Savchenko (1978) was applied.

Results and Discussion

In the present study, the combining ability of a set of mutant lines was evaluated for the traits grain yield and length of the ear, tested with three testers K 4652, PAU 1617 and XM 92471, belonging to two different heterosis groups – Lancaster and Reid. The testers have a high combining ability and are effective in analysing new source material in the earlier stages of the selection process.
For maize growing, air temperature during the critical for it phenophases, as well as rainfall and its equal distribution during period of vegetation, are agro climatic factors of significant importance. Figure 1 presents data for these factors for the period of the study 2021-2022 compared to a 50-year period (1920-1969). The temperatures for the two years are similar in value and relatively higher than the average for the 50-year period. In 2021, the average daily temperature for the period June - August (flowering, pollination, and fertilization of the maize plant) was 23°C, and the total rainfall amounted to 62.5 l/m². For 2022, the values for the respective indicators were 23.6°C and 54.2 l/m². The data for temperatures and the distribution of rainfall amounts in 2022, especially in July (12.6 l/m²), characterize it as less favourable for maize cultivation, which explains the lower yields and shorter ears of the tested variants (Table 1, Table 2). The tables present averaged data for grain yield and length of the ear of the crosses of the mutant maize lines. The analysis of variance of the field trial data shows significant differences between them (F>Fcrit) for both traits.

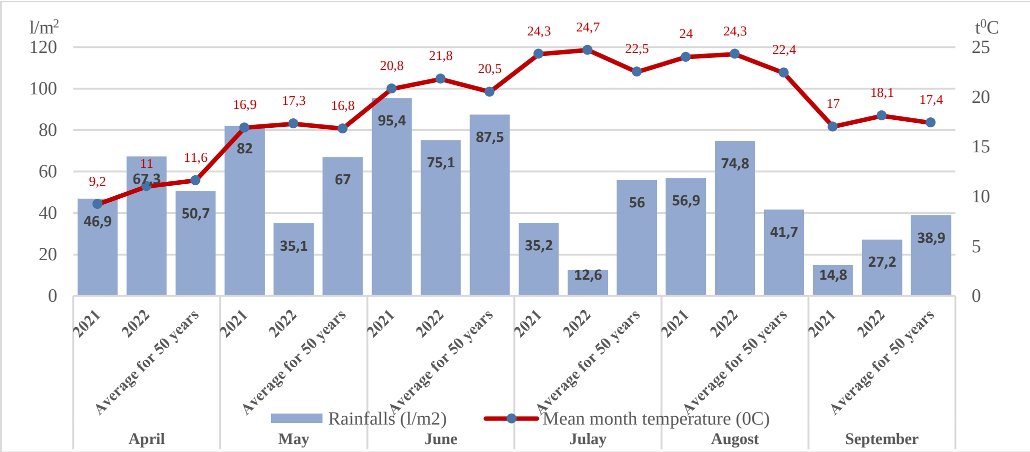

Figure 1. Average month temperature sum of the rainfall through the hybrids vegetation period

The average yield of the studied top-crosses in the first year was 85.460 kg/ha, and in the second year, it was 76.618 kg/ha. The best results for the “grain yield” trait, both by year and on average with the three testers, were shown by the crosses of lines XM 2014285 and XM 2014298 for 2021, and XM 2014325, XM 2014285, and XM 2014344 for 2022. As seen in Table 1 and Table 2, the hybrid combinations involving line K 4652 had higher yields compared to those with the other two testers. Two of them, XM 2014285 x K 4652 and XM 2014344 x K 4652 for 2021, distinguishes themselves with yields over 100.0 kg/ha.

Table 1. Grain yield (kg/ha) of the hybrids with medium-early lines mutant maize. 2021-2022

Tester lines Mutant lines	XM 92471	K 4652	PAU1617	Average for the lines

$LSD_{5\%}$-61.43				

Regarding the trait "length of the ear", the average length of the ear for 2021 was 25.3 cm, and for 2022 it was 19.3 cm. The crosses of lines XM 2014285, XM 2014298, and XM 2014325 for 2021, and XM 2014284 and XM 2014285 for 2022 had long ears both in those years and on average with the three testers. The trend of longer ears in hybrid combinations involving the tester K 4652 persists here as well. Two of the crosses, XM 2014298 x K 4652 (28.6 cm) and XM 2014325 x K 4652 (28.1 cm) for 2022, distinguished themselves with length of the ear over 28 cm. All hybrid combinations with high yields and long ears are of interest for selection, and their testing continues with their inclusion in competitive and ecological varietal trials.

Through analysis of variance of the general combining ability (GCA) and the specific combining ability (SCA) for grain yield and length of the ear, significant differences between the lines participating in the crosses were established (F>Fcrit). This allows for the continuation of the analysis for evaluation of their combining ability. The analysis of variances of the GCA and SCA provides the opportunity to assess the genetic characteristics of these lines, their selection value, and variability in these traits. The results enable their effective use and inclusion in appropriate selection programs, as well as the selection of a suitable selection method (Turbin et al., 1974).

As criteria for this evaluation, the parameters gi, gj for GCA and $\sigma^2 si$, $\sigma^2 sj$ for SCA were used (Table 3, Table 4). The comparison of the effects of GCA with the variances of the effects of SCA for a given line allows for assessing the relative importance of gene action. Lines XM 2014285 and XM 2014298 showed high and positive GCA values for grain yield for 2021, and XM 2014325, XM 2014285 for 2022. These lines are suitable for inclusion in selection programs aimed at obtaining mid-early high-yielding synthetic populations, as they possess more additive genes determining the trait. They can also be used as testers in analysed crosses to determine GCA at an earlier stage of the selection process. The high variances of the SCA effects of line XM 2014325, followed by XM 2014298 for 2021, and lines XM 2014301 and XM 2014284 for 2022, suggest their successful inclusion in combinations to produce hybrids with higher yields. They mainly exhibit dominant and epistatic gene effects.

Regarding the trait length of the ear, lines XM 2014285, XM 2014298 for 2021, and XM 2014284 for 2022 show high and positive GCA values. These lines can be included in selection programs to develop synthetics with long ears. The high variances of the effects of the SCA of lines XM 2014301 and XM 2014284 for 2021, and XM 2014298 and XM 2014284 for 2022, allow for their use in selection programs to create hybrids with long ears.
Based on the assessment of the mutant lines, the following most important conclusions are made:

Conclusions

The mutant lines XM 2014285, XM 2014298, and XM 2014325 are suitable for creating synthetics with high yield, and for synthetics with long ears, the suitable lines are XM 2014285, XM 2014298, and XM 2014284. These lines can also be used as testers in the analysis of general combining ability at earlier stages of the selection process.
For obtaining mid-early hybrids with high yields, the mutant lines XM 2014325, XM 2014298, XM 2014301, and XM 2014284, are suitable as parental components, and for those with long ears are suitable hybrids XM 2014301, XM 2014284, and XM 2014298.
The mutant lines XM 2014325 and XM 2014298 for the trait “grain yield” possess relatively high GCA and SCA and can be used in both selection directions.
The mutant lines XM 2014284 and XM 2014298 for the trait “length of the ear” can also be used in both selection directions due to their higher values for both GCA and SCA.

Abstract

Two hundred and twenty-two landrace and foreign maize populations were included in a research carried out during the period of 2022 – 2023: 105 of them belonging to the working assortment of Maize Research Institute – Knezha, 15 – to the genebank of IPGR – Sadovo and 102 were foreign, introduced synthetics. The trials were conducted in MRI – Knezha according to block method under non-irrigation conditions and with approval for the regional agricultural technology. Phenological observations (UPOV) were also performed during vegetation. Consequently, the vegetation period and FAO maturity group of the populations were established. Biometric screening of plants and ears (30 of each population) was made. The elements of yield – ear length, number of rows, number of seeds per row, weight of 1000 seeds – were analysed. The laboratory test included the grain chemical content and content of protein, oil and starch. The analysis was conducted with Infraliser (SupNIR – 2700). Forty maize populations, in which the content of protein varied from 10.0 to 14.7 %, that of oil – from 3.5 to 5.3 % and of starch – up to 69 %, were determined as reliable. The aim of the current research is to evaluate the assortment of landrace and foreign synthetic populations, as well as nominate lines for the purposes of hybridisation and creation of new adaptive maize hybrids for various applications (high-oil, high-protein, high-starch).

Keywords: *maize populations, biological and economic properties, chemical content.*

Introduction

The field of agriculture is among the most vulnerable ones to the effects of climate change in any economy. The developing countries that are highly dependent on agriculture and have fewer resources and options to prevent climate change damages are particularly exposed to risk. (Abumhadi et al., 2012). The climate change has been pointed out as one of the main factors leading to a decline in cereal yields in some parts of Europe, despite the continuous development of cultivation technologies. (Brisson et al., 2010). According to Gracen (2008), Hammer and Teklu (2008), Rao and Hodgkin (2002), Brown (2010) the most serious threats to the cultivation of agricultural crops will not be occasional severe droughts or heat waves, but high temperatures during key periods in the life cycle of any crop. Variability and decline in crop yields are expected to increase due to increased frequency of extreme climatic events and the spread of diseases and pests (Martinez, 2016) and the effects of these changes may be diverse in different parts of Europe (Smith, 2005). The preservation of old varieties and populations, landraces and wild relatives of cultivated plants is a priority task worldwide. Many of them have evolved in order to survive in harsh conditions, such as drought, moisture, high temperatures and poor soils. This means they can be a source of new genetic diversity that breeders can use to develop more sustainable food systems, as well as increase food security and ecosystem stability. The knowledge of genetic diversity and its distribution is essential for its conservation and use in specific breeding programs (Valchinkov and Valchinkova, 1993; Bespalova et al., 2017; Esquinas-Alcázar, 1993).

The objective of the current paper is an analysis of the biological and economic qualities of landraces and foreign maize populations in terms of the following indexes: vegetation period, grain moisture at harvesting, mass of 1000 grains, ear length, number of rows in the ear, grain length, protein, oil and starch content. The most valuable ones will be used as source material for hybridisation and creation of a new generation of stress-tolerant, high-yielding maize hybrids in various directions, with an enhanced grain quality.

Materials and Methods

The study was conducted during the period of 2022 – 2023 in the experimental field of Maize Research Institute – Knezha, Bulgaria. Two hundred and twenty-two landraces and foreign maize populations were analysed: 105 of them belonging to the working assortment of Maize Research Institute – Knezha, 15 – to the genebank of IPGR – Sadovo and 102 were foreign, introduced synthetics. The trials were carried out according to block method, in 3 repetitions, sowing density of 5000 plants per ha, harvest plot of 10 m^2, under conditions without irrigation and with approval for the regional agricultural technology. During the vegetation, phenological observations according to UPOV were carried out. As a result, the vegetation period of the populations was reported and their FAO maturity groups were determined. Biometric screening of plants and ears (30 of each population) was made. The structural elements of yield – ear length, number of rows, number of grains in a row, mass of 1000 grains – were also analysed. The laboratory analysis included chemical composition of grain (protein, oil and starch content) and was performed on an average plot sample with an Infraliser (SupNIR – 2700 SERIES). The grain moisture was recorded with an electronic moisture meter.

Results and Discussion

The auspicious crosses from the landraces and the foreign populations, which were pointed out as a consequence of phenotyping a total of 222 samples in relation to some yield elements, are displayed in Table 1. In the observations made during the vegetation period all populations (landraces and foreign ones) were found to be resistant to lodging. No damage from economically important diseases and enemies in the conditions of a natural infectious background was noted. The length of the period from emergence to flowering of the ear varies from 51 to 62 days in different landraces and foreign populations. The flowering periods of ears within each population itself ranged widely and high variability in terms of this parameter was observed among individual plants. The populations Svilengrad and Mestna 1 from the first group and Litkaya – Koreyskaya – visokaya and Synth min spons from the second one silked the earliest.

A slight divergence in the flowering of the ear and the panicle was reported in all populations (from 1 to 3 days), except for the landraces Glogovo and Pishurka, as well as Bst3 Epom 831575 pollan-3-3-1 from the foreign ones, where the desynchronisation in the flowering of the reproductive organs exceeds 5 days. This feature must be taken into account in breeding programs in which the indicated populations are used as parental components for hybridisation. In these cases, it is advisable to apply date sowing.

The selected populations belong to different maturity groups, from 300 to 600 according to FAO. The majority of them are members of the mid-late group and have a period of 55-58 days from germination to flowering of the ear and a standard moisture in the grain (up to 14%). After analysing the obtained results, landrace populations with the longest ear length were selected - Bdintsi, Karamantsi, Bozhentsi, Pishurka, Svilengrad, Spasova mogila, Gnoinitsa, Florosh and Zemen (18-19 cm). Some of them have 14 rows and a longer grain length (9-10 mm.)

The populations Gloginka, Pishurka, Zemen and Bdintsi have the highest mass per 1000 grains. In the landraces listed, the combination of these elements of productivity is favourable and seeds from them have been set aside for testing and determining their combining value.
Synthetic 16 (C_1), Synthetic L2 (C_o), Synthetic 2/96 "L" (C_o) and Synthetic L2 (C_2) belonging to the assortment of foreign populations and in which improvement selection was carried out using the method of recurrent selection posed an interest. The introduced populations have longer ears than the landraces. Two of them are also multi-row ones and can be used as components for synthetics with a long ear or a large number of rows.
The lower absolute weight reported in the populations SS, Litkaya - Koreyskaya - visokaya, Synthetic 1-4/86 Romania can be explained by the participation of teosinte in the genetic foundations of these populations or by a targeted selection of certain quality indicators carried out in them before including them in our breeding programs.
After a chemical analysis of grain quality indicators (Table 1) in the studied populations was done, those with the highest percentage of protein - Mestna 1 (12.9 %), Mestna 3 (12.4 %) and Vinishte (12.6 %) were pointed out. Glogovo (5.2%), Mestna 1 (4.7%) and Svilengrad (4, 9%) have the highest oil content. The landrace populations Markovo (68.1 %), Svilengrad (67.7 %) and Glogovo (67.0 %) have the highest levels of starch content. The populations Mestna 1 and Vinishte have both a high protein content and a relatively high oil content, which makes them a suitable starting material for maize breeding, in the direction of improving the hybrids’ nutritional qualities. The landrace populations Markovo and Svilengrad are most suitable for the food industry and the creation of hybrids with a high starch content. The most balanced in terms of quality indicators is the population Mestna 1, which displays high protein content (12.9 %), oil content (4.7 %), starch content (65.1 %) and low grain moisture at harvest (11.9 %). Then, we placed the landrace Vinishte, for which a high content of protein (12.6 %), oil (3.9 %), starch (64.7 %) and standard moisture of the grain at harvest (14.1 %) were reported. Worthy of interest is the population Mestna 3, which has a balanced profile of quality indicators - protein (12.4%), oil (3.8%), starch (65, 5%) and grain moisture – 12.6%. The landrace Hlevene, which is characterized by high content of protein (12.3%), oil (4.1%), starch (66.3%) and grain moisture – 12.8%, will be included in the breeding programs of Maize Research Institute – Knezha for improving the grain quality indicators. These four populations stand out as the best sources for maize breeding in a direction for enhanced grain quality due to their high protein content, balanced moisture levels and favourable starch and oil content.
The remaining local samples have good indicators too, but due to the higher grain humidity at harvest, they may prove problematic under certain agro-climatic conditions or when stored for a longer period. After analysing the chemical composition of the grain in the foreign synthetics as well, No. 13 (Argentina) proved to be the population with the highest protein (13.3 %), oil (4.0 %) and high starch content (65.8 %). This makes it a suitable source of geneplasm in the selection of high-protein maize hybrids. Population 16 (Yugoslavia) with a protein content of 12.6 % is also suitable in this direction.
In the direction of high-oil hybrids selection, the population Amerikanska can be successfully used as starting material due to its highest percentage of oil – 5.3%, as well as a high content of protein (11.3 %) and starch (65.5 %). The High-protein synthetic 9hp CEP – 4 can also be used successfully for the listed purposes, with oil content of 4.9 %, protein – 10.7 % and highest starch content – 69. 0 %. Synthetic - H 99-6-4-1 can effectively be used in the selection of high-starch corn, since the starch content is 68.1 %.
The listed four synthetic populations of foreign origin can be included in programs to improve the quality of the grain and as donors of geneplasm to increase the content of protein, oil and starch. We evaluated them as having a high potential for creating hybrids or improving selection with a view to creating maize hybrids with a balanced nutritional content.

Conclusions

The study of genetic diversity in landraces and foreign populations of maize is a huge resource for breeding under conditions of stress and unpredictable climatic changes. Phenotyping and evaluation of these starting materials are a reserve for creating adaptively valuable maize hybrids that respond adequately to environmental changes. After a study of 222 samples of local and foreign origin was done, 40 valuable maize populations suitable for different directions of use were selected.

For high-protein and high-oil hybrids, the most suitable landrace material is Mestna 1, which has high protein content (12.9 %), high oil content (4.7 %) and low grain moisture at harvest (11.9 %). The synthetic Argentina from the introduced populations is suitable for high protein hybrids.

For high-starch hybrids, it is recommended to use lines originating from the synthetics Markovo (68.1 %), Svilengrad (67.7 %), Florosh (67.3 %) and Glogovo (67.0 %), and from the foreign ones the High-protein synthetic 9hp CEP – 4 (69.0 %), Synthetic - H 99-6-4-1 (68.1 %) and Bst3 Epom 831575 pollan-3-3-1 (68.0 %) are suitable for this direction.

As a result of the conducted research, the working collection of Maize Research Institute - Knezha was enriched with 222 new samples, which were studied for biological and economic qualities.

Abstract

The grain yield of maize, wheat and barley depending on the nitrogen rate and fertilization system was studied in a long-term field fertilizer experiment for the period 1959-2015. Nitrogen fertilization was N_{80}, N_{160} and N_{240} (for maize); N_{60}, N_{120} and N_{180} (for wheat), and N_{40}, N_{80}, N_{120} (for barley). The fertilization systems were: Control, $N_{300}P_{400}K_{600}$+18 t vetch-oat mixture/ha, $N_{600}P_{400}K_{600}$ (stock fertilization), $N_{900}P_{400}K_{600}$, $N_{600}P_{400}K_{600}$+30 t manure/ha, $N_{600}P_{400}K_{600}$+4 t straw/ha, $N_{600}P_{400}K_{600}$ (annual fertilization) (I-IV crop rotations); Control, $N_{300}P_{300}K_{400}$, $N_{600}P_{300}K_{400}$, $N_{900}P_{300}K_{400}$, $N_{600}P_{300}K_{400}$+40 t manure/ha, $N_{600}P_{0}K_{400}$, $N_{600}P_{300}K_{0}$ (V-VII rotations); Control, $N_{250}P_{300}K_{200}$, $N_{500}P_{300}K_{200}$, $N_{750}P_{300}K_{200}$, $N_{250}P_{150}K_{0}$+60 t manure/ha, $N_{500}P_{0}K_{200}$, $N_{500}P_{300}K_{0}$ (VIII rotation). The obtained grain yields without fertilization were 6127 $kg.ha^{-1}$ for maize, 1453 $kg.ha^{-1}$ for wheat and 1617 $kg.ha^{-1}$ for barley, on average over a period of eight crop rotations. The rates N_{80}, N_{160}, and N_{240} in maize increased grain yield by 38.4%, 57.3%, and 68.8%, respectively, compared to the control. The grain yield of wheat and barley increased by 1.9-3 times an average in the nitrogen-fertilized variants, compared to the yields without fertilization. The regression analysis indicated that without fertilization in the crop rotation, average grain yields of 6164 $kg.ha^{-1}$ was possible to expect from maize; 1547 kg. ha^{-1} from wheat, and 1672 kg. ha^{-1} from barley. The possible additional grain yield for each kilogram of nitrogen input per hectare was 32.7 kg for maize, 43.2 kg for wheat and 40.4 kg for barley.

Introduction

The essence of modern concepts for the development of sustainable agriculture consists in finding the optimal productive level corresponding to each crop, by applying such systems that guarantee obtaining stable or increasing yields for a long period of time and preserving natural resources, including the main means of production – the soil (Alexander et al., 2015; Beckman et al., 2020). The emergence of these concepts is based on the results of long-term stationary experiments carried out in different regions of the world (Merbach and Deubel, 2008). The oldest permanent fertilizer experiment in the world is in in Rothamsted, England (Edmeades, 2003). Cereal crops were studied in it and it continues to this day (Edmeades, 2003). Fertilization is one of the most effective the means to increase productivity of the main cereal crops that require mineral nutrients in large amounts (Traikov et al., 2017). The different rates of fertilization in the agroecosystems and long-term cultivation of crops without fertilization allow establish the regulatory functions of fertilization and its absence on the state of soil fertility and productivity of the studied crops (Kunzova and Hejcman, 2010; Foulkes, 2009). According of Babulicova (2008) the long-term field fertilizer experiments are the main factor for managing the productivity and quality of crops according to the requirements for balanced nutrition and fertilization, for rational use of the land and preservation of soil qualities, and protection of agro-ecosystems as a whole from pollution. The fertilization system affects the physical, agrochemical and biological parameters of the

soil and largely determines the magnitude and stability of yields (Valcheva et al., 2015). Nitrogen fertilization is one of the most effective means of increasing the productivity of the main cereal crops that require mineral nutrients in large quantities (Kismányoky and Tóth, 2010; Lopez-Bellido et al., 2005; Traikov et al., 2017). At the same time this nutrient is easily mobile and its improper use can cause environmental pollution (Fixen et al., 2015). Agroecosystems in which good agricultural practices are followed demonstrate the increased yields, economically optimal nutrition and fertilization, minimal losses of soil nutrients and sustainable soil fertility (Mikkelsen et al., 2012).
The present research aims to study the effect of nitrogen rates and fertilization systems on the grain yields of the main cereal crops in Bulgaria maize, wheat and barley under conditions of long-term fertilizer experiment.

Material and Methods

A long-term fertilizer experiment conducted at the educational and experimental base of the Department of Agrochemistry and Soil Science at the Agricultural University of Plovdiv, Bulgaria, examined the grain productivity of maize, winter wheat, and winter barley over the period from 1959 to 2017. The cereal crops were grown under the conditions of field crop rotation (maize - winter wheat – sunflower - winter barley) with the application of different fertilization systems (Table 1). Maize was irrigated cultivation. Average data of the grain yields of the rotations with different fertilization systems were analyzed. The experimental design included seven variants of system fertilization, which were applied in four replications. The size of the experimental plots was 150 m^2.

Table 1. Fertilization systems by crop rotations

I-IV crop rotations	V-VII crop rotations	VIII-IX crop rotations
1. Control	1. Control	1. Control
2. $N_{300}P_{400}K_{600}$+18 t vetch-oat mixture.ha^{-1}	2. $N_{300}P_{300}K_{400}$	2. $N_{250}P_{300}K_{200}$
3. $N_{600}P_{400}K_{600}$ (stock fertilization)	3. $N_{600}P_{300}K_{400}$	3. $N_{500}P_{300}K_{200}$
4. $N_{900}P_{400}K_{600}$	4. $N_{900}P_{300}K_{400}$	4. $N_{750}P_{300}K_{200}$
5. $N_{600}P_{400}K_{600}$+30 t manure.ha^{-1}	5. $N_{600}P_{300}K_{400}$+40 t manure.ha^{-1}	5. $N_{250}P_{150}K_0$ + 60 t manure.ha^{-1}
6.$N_{600}P_{400}K_{600}$+4 t straw.ha^{-1}	6. $N_{600}P_0K_{400}$	6. $N_{500}P_0K_{200}$
7. $N_{600}P_{400}K_{600}$ (annual fertilization)	7. $N_{600}P_{300}K_0$	7. $N_{500}P_{300}K_0$

Applied nitrogen fertilization during the studied period was in rates N_{80}, N_{160} and N_{240} in the maize; N_{60}, N_{120} and N_{180} in the wheat, and N_{40}, N_{80}, N_{120} in barley. Phosphorus fertilization was done in the form of triple superphosphate and potassium fertilization as potassium chloride, which together with manure were plowed with deep autumn plowing (25-30 cm). The maize was fertilized twice with 1/2 of the nitrogen for pre-sowing fertilization, and the rest of the nitrogen rate for dressing in the 5-6 leaf phase. Nitrogen in wheat and barley was applied in parts: the half of the ammonium nitrate as pre-sowing fertilization, and the rest of nitrogen rate as winter-spring top dressing. The experiment was carried out on alluvial-meadow soil (Mollic Fluvisols) (FAO, 2006), a slightly solontic, a sandy-clay with the depth of groundwater 100 - 200 cm. The content of physical clay in the upper horizons reached 50% (in horizon A was 33%). The soil contained 1.63 – 3.00% calcium carbonate, which determined it favorable physico-chemical and water properties. Horizon A1 was up to 28 cm deep, brown-black, loose, with a rather well-defined powder-granular structure. The average content of humus was 3.72 %. The soil reaction, the content of mineral nitrogen (NH_4+NO_3) and available phosphorus and potassium after VIII crop rotation was presented in Table 2.

Table 2. Soil reaction and content of available forms of nitrogen, phosphorus and potassium in the soil (mg.kg^{-1}) after VIII crop rotation

The climate of Plovdiv region is transitional-continental, with frequent invasions of moist air masses from the warm sector of Mediterranean cyclones during the cold half-year. It is influenced by the Mediterranean and is called "Western Thracian", with a relatively low amount of precipitation. The average annual air temperature was 12°C. The area was characterized by high temperatures in the summer months of July and August, a mild winter with not very low average daily temperatures (the lowest average monthly temperature was in January - 0°C) and frequent warming. Spring comes relatively early and has an average monthly temperature of 6.5°C. Summer is hot with the highest temperature in July (23°C). Autumn is usually warmer than spring. The average amount of annual precipitation in the Plovdiv region was less than the average for the country (512 mm) and was unevenly distributed by month. Droughts are very common, starting from the beginning of summer and continuing until the end of October.

The data was analyzed with the ANOVA procedure and Duncan's multiple range test to find significant differences among the average values of grain yields of the crops. A regression analysis was applied to model the dependencies between the result parameter grain yield and the factor characteristic nitrogen fertilization. We used regression models of the type: $y = a + bx + cx^2$, where: y - theoretical levels of the result attribute and x - actual levels of the factor attribute.

Results and Discussion

Low productivity of studied cereals was obtained when the crops grown without fertilization (Table 3). Based on natural soil fertility the average grain yields were 6127 kg.ha^{-1} in maize, 1453 kg.ha^{-1} in wheat, and 1617 kg.ha^{-1} in barley. The lowest yields of corn and barley in the control variant without fertilization were established within I-IV crop rotations, and for wheat in the period of V-VII crop rotations. The lowest yields of maize and barley in the control variant were established within I-IV crop rotations, and for wheat in the period of V-VII crop rotations. The highest maize yield without fertilization was 6670 kg.ha^{-1} (V-VII crop rotations). Within the study the highest grain yield of wheat in control variant was 1610 kg.ha^{-1} (I-IV crop rotations) and the highest barley yield without fertilization was 1920 kg.ha^{-1} (V-VII crop rotations). As a result of nitrogen fertilization, the productivity of maize grain was changed from 7670 kg.ha^{-1} (N_{80} in I-IV crop rotations) to 10550 kg.ha^{-1} (N_{240} in V-VII crop rotations). Low productivity of wheat grain was found at N_{60} rate in VIII crop rotation (3520 kg.ha^{-1}). The application of 180 kg N.ha^{-1} in I-IV crop rotations resulted in a high wheat grain yield of 4880 within the study. Nitrogen fertilization changed barley grain yield from 3000 kg.ha^{-1} (N_{40} applied in V-VII crop rotations) to 4210 kg.ha^{-1} (N_{120} applied in VIII crop rotations). A positive effect of the applied nitrogen on the grain yield of three crops was established over the period of the eight crop rotations. Input of N_{80}, N_{160}, and N_{240} rates to maize increased average grain yield by 38.4%, 57.3%, and 68.8%, respectively, over the control.

*Values for each crop followed by the same letters are not significantly different at $p<0.05$ according to Duncan’s multiple range test

The average grain yield of wheat and barley raised by 1.9-3 times in nitrogen-fertilized variants, compared to the yields of the control. Higher nitrogen rates (N_{240} in maize, N_{180} in wheat, and N_{120} in barley) increased grain yields, but the difference with the moderate nitrogen fertilization (N_{160} in maize, N_{120} in wheat, and N_{80} in barley) was not significant.

Table 4. Correlations of nitrogen rates with grain yield of maize, wheat and barley

Crop rotation	Maize	Wheat	Barley
I-IV	0.985*	0.827*	0.834*
V-VII	0.984*	0.830*	0.903*
VIII	0.895*	0.926*	0.953*
Average I-VIII	0.965*	0.867*	0.906*

*Correlation is significant at the 0.05 level.

A strong positive correlation ($r > 0.830$) was found between the applied nitrogen rates and grain yields of the cereal crops maize, wheat and barley grown in crop rotations with different fertilization systems. The correlation coefficient of nitrogen fertilization with maize grain yields demonstrated the highest average value ($r = 0.965$*) in the period of I-VIII crop rotations. The obtained correlation coefficient of fertilized nitrogen input with the wheat grain yield was 0.867*. High average value of the correlation coefficient (r = 0.906*) was established and in regard to barley also.

Table 5. Regression dependences of grain yield (y) of maize, wheat and barley on nitrogen fertilization (x) under different fertilization systems

Crop rotation	Regression model	R^2
	Maize	
I-IV	$y = 5640 + 29.7x - 0.045x^2$	0.999
V-VII	$y = 6666 + 25.9x - 0.040x^2$	0.998
VIII	$y = 6185 + 42.4x - 0.045x^2$	0.967
Average I-VIII	$y = 6164 + 32.7x - 0.07x^2$	0.997
	Wheat	
I-IV	$y = 1755 + 50.6x - 0.19x^2$	0.941
V-VII	$y = 1302 + 40.7x - 0.15x^2$	0.947
VIII	$y = 1586 + 38.2x - 0.12x^2$	0.997
Average I-VIII	$y = 1547 + 43.2x - 0.15x^2$	0.968
	Barley	
I-IV	$y = 1374 + 49.8x - 0.28x^2$	0.933
V-VII	$y = 1964 + 28.1x - 0.14x^2$	0.969
VIII	$y = 1675 + 43.2x - 0.19x^2$	0.998
Average I-VIII	$y = 1672 + 40.4x - 0.20x^2$	0.977

The applied regression analysis of the dependences between the result parameter (grain yield) and the factor sign (nitrogen fertilization) in cereal crops indicated that the dependences were not linear (Table 5). The modeled dependencies were represented by quadratic equations. High values of the coefficients of determination ($R^2 > 0.933$) were found for all studied fertilization systems in the crop rotations. The regression model showed that the increase of grain yields was performed with a delay depending on the nitrogen fertilization up to a rate of 30 kg $N.ha^{-1}$ (in maize), up to a rate of 18 kg $N.ha^{-1}$ (in wheat), and up to a norm of 12 kg $N.ha^{-1}$ (in barley). Without fertilization, the expected average grain yields from the crops were as follows: maize 6164 $kg.ha^{-1}$; wheat 1547 $kg.ha^{-1}$, and barley 1672 $kg.ha^{-1}$. According to the standard interpretation of the regression coefficients in a quadratic polynomial, each increase in the amount of nitrogen fertilizer input by one kilogram per hectare will lead to an increase of the additional grain yield by 32.7 kg of maize, 43.2 kg of wheat and 40.4 kg of barley in the period I -VIII rotations.

Conclusions

The analysis of the data from the long term fertilizer trail of Department of Agrochemistry and Soil science of Agricultural University of Plovdiv, Bulgaria demonstrated that obtained grain yields of cereal crops grown without fertilization were 6127 $kg.ha^{-1}$ (maize), 1453 $kg.ha^{-1}$ (wheat) and 1617 $kg.ha^{-1}$ (barley), on average over a period of eight crop rotations. The N_{80}, N_{160}, and N_{240} rates in maize increased grain yield by 38.4%, 57.3%, and 68.8%, respectively, compared to the control. The grain yield of wheat and barley increased by 1.9-3 times an average in the nitrogen-fertilized variants, compared to the yields without fertilization. The regression analysis indicated that without fertilization in the crop rotation, average grain yields of 6164 $kg.ha^{-1}$ was possible to expect from maize; 1547 kg. ha^{-1} from wheat, and 1672 kg. ha^{-1} from barley. The possible additional grain yield for each kilogram of nitrogen input per hectare was 32.7 kg for maize, 43.2 kg for wheat and 40.4 kg for barley.

Abstract

The effect of nitrogen N_0, N_{200} and N_{400} on the uptake of nitrogen, phosphorus, potassium, calcium and magnesium of barley in maturity was studied. A pot experiment was carried out with five Bulgarian varieties of malting barley grown under greenhouse conditions. Nitrogen levels were created by adding NH_4NO_3 dissolved in water. A proven positive effect of the applied nitrogen on the formed dry biomass and the accumulated macronutrients by the plants was found. Fertilization N_{400} increased the average productivity of the varieties by 23.8% for grain, 36.1% for straw and 31.1% for grain+straw, compared to plants grown at N_0. Accumulated nutrients of grain+straw at N_{400} level were higher by 84.9% for nitrogen, 51.8% for phosphorus, 54.4% for potassium, 41.3% for calcium, and 47.3% for magnesium, on average. Grain harvest index decreased from 41.5% at N_0 to 39.3% at N_{400}. The nitrogen level had a slight effect on the percentage distribution of accumulated nutrients to the grain, although a tendency for a lower percentage was observed in regard to nitrogen, phosphorus and magnesium. A strong positive correlation of nitrogen level with grain and straw yield and amount of accumulated nitrogen was established. A negative correlation was observed between applied nitrogen and grain harvest index (r=-0.641*) and nitrogen harvest index (r=-0.479).

Keywords: *Phosphorus, Potassium, Calcium, Magnesium, Malting barley.*

Introduction

The specificity of mineral nutrition is rarely taken into account in the selection process of cereals (Emebiri et al., 2004). Research specifics of mineral nutrition are in two directions: characterizing the response of varieties and hybrids to mineral nutrition and creation of new varieties and hybrids that use nutrients efficiently and economically (Górny, 2009). Efficiency of nutrient uptake is defined as the ability of plants to absorb a particular nutrient at a low level of soil availability or nutrient medium (Gastal and Lemaire, 2002). Usually, however, crop selection is carried out under agrochemical conditions that do not limit their growth and productivity (Abeledo et al., 2008). It is known that barley productivity is mainly related to the assimilation of nitrogen and phosphorus, which are the main cause of donor limitation at grain filling (Popovic er al., 2011; Przulij and Momcilovic, 2001; Rogers et al., 2019). Nitrogen influences the development and maintenance of leaf area and photosynthetic efficiency (Abeledo et al., 2001) and the allocation of dry mass to reproductive organs (Prystupa et al., 2004). Plants take up potassium exclusively from the soil solution, which is in dynamic equilibrium with the exchangeable and, to a lesser extent, the non-exchangeable potassium stock in the soil (Marschner, 1997). The effectiveness of mineral nutrition depends on two integrated groups of plant factors, namely absorption efficiency and utilization efficiency (Barr et al., 2011). Absorption efficiency is the relative uptake of a given nutrient a given provision or supply. Utilization efficiency represents the total or primary production relative to the nutrient uptake. The genotypic specificity of mineral nutrition in agricultural

crops, including barley, has been proven and in a number of countries work is being done to adapt plant diagnostics according to the genotype (Collen, 2006).
The aim of the present research was to determine the effect of the soil nitrogen level on the accumulation and distribution of nitrogen, phosphorus, potassium, calcium and magnesium of barley in maturity.

Material and Methods

A pot experiment was conducted to study the effect of nitrogen levels N_0, N_{200}, and N_{400} on the uptake and distribution of macronutrients in five Bulgarian winter two-row barley varieties. The study was conducted in a cultivation facility in 2022. The nitrogen levels were created by adding NH_4NO_3 dissolved in water. Ten plants of each variety Emon, Obzor, Krami, Kristi and Kaskadior were grown in plastic pots filled with 5 kg Molic fluvy soil under greenhouse conditions. The main soil characteristics were as follows: $pH_{(H2O)}$ 7.3; humus content 3.2%; mineral nitrogen 43.8 mg $N.kg^{-1}$; available phosphorus 209 mg $P_2O_5.kg^{-1}$; and available potassium 450 mg $K_2O.kg^{-1}$. Each experimental treatment was studied in four replicates. The yield of grain, straw and the amount of nitrogen, phosphorus, potassium, calcium and magnesium in them were determined in a physiological maturity. Barley grain and straw were dried at 60°C to a constant weight. The concentration of macronutrients was analyzed using the common methods (Tomov et al., 2009). The content of macronutrients was calculated by multiplying the concentration of each of studied nutrient by the dry weight of plant parts. Grain harvest index was calculated according to the following formula: GHI (%) = Grain yield / (Grain+Straw) yield × 100. Nitrogen harvest index (NHI) was defined as the amount of accumulated nitrogen of grain divided by the amount of accumulated nitrogen of grain plus straw, and multiplied by 100. The harvest indices of the other macronutrients were calculated in the same way. An overall analysis of variance (ANOVA) was performed to evaluate the effect of the experimental treatments on the referred variables, and Duncan's multiple range test ($\alpha = 0.95$) was used in order to establish the difference among the means.

Results and Discussion

The yields of grain, straw and grain+straw proven increased with the higher amount of applied nitrogen (Table 1). The average grain yield of barley varieties without fertilization was 13.8 $g.pot^{-1}$. It rose by 14.5% and by 23.8% at N_{200} and at N_{400} levels, respectively. Grain productivity differences between the unfertilized plants and the plants grown at N_{200} level were not established. No mathematically proven difference was found between the two levels of nitrogen input N_{200} and N_{400} either. The obtained straw yield increased by 20.7% an average at N_{200}, and by 36.1% an average at N_{400}, relative to N_0 level. The grain harvest index changed from 37.2% (Emon variety at N_{400}) to 43.1% (Krami variety at N_0). Higher nitrogen fertilization of 400 mg $N.kg^{-1}$ soil lowered the average GHI of barley varieties from 41.5% in unfertilized plants up to 39.3%.
The accumulated nitrogen, phosphorus and potassium of barley significantly increased in parallel with the applied nitrogen (Table 2). The highest uptake of nitrogen, phosphorus, and potassium was found at N_{400} level. Their average values of grain+straw were 558.4 mg $N.pot^{-1}$, 276.8 mg $P_2O_5.pot^{-1}$, and 551.2 mg $K_2O.pot^{-1}$, respectively. This indicated that the plants accumulated very similar amounts of nitrogen and potassium in maturity. The absorbed phosphorus was almost twice less compared to them. The total nitrogen uptake widely varied from 265.4 mg $N.pot^{-1}$ (Obzor at N_0) to 651.5 mg $N.pot^{-1}$ (Kaskadior at N_{400}). The total phosphorus in maturity changed from 156.3 mg $P_2O_5.pot^{-1}$ (Emon at N_0) to 313.1 mg $P_2O_5.pot^{-1}$ (Krami at N_{400}).

Table 1. Barley productivity (g.pot^{-1}) in dependence of the nitrogen level

The content of potassium of grain+straw ranged from 289.6 mg K_2O.pot^{-1} (Obzor at N_0) to 616.0 mg K_2O.pot^{-1} (Kaskadior at N_{400}). Higher N_{400} fertilization increased absorbed nitrogen by 79.2% an average in terms of grain, by 96.5% of straw, and by 84.9% of grain+straw, compared to N_0 plants. The studied varieties demonstrated a high export of phosphorus and potassium of the aboveground dry mass when grown at N_{400} level. The average content of grain phosphorus and potassium of the fertilized plants exceeded by 24.8% - 44.8%, and 32.2% - 57.0% that of the N_0 plants, respectively.

Table 3. Uptake of calcium (CaO) and magnesium (MgO) of barley in dependence of the nitrogen level, $mg.pot^{-1}$

Parameter	N level	Min	Max	Average	% to N_0
Ca grain	N_0	25.2	38.3	34.4 b ± 5.4	100

	N_{400}	41.1	56.3	44.9 a ± 6.4	147.3

*Values for each parameter followed by the same letters are not significantly different at $p<0.05$ according to Duncan’s multiple range test

The amount of calcium and magnesium proven increased in the fertilized variants compared to N_0 (Table 3). The average uptake of grain+straw calcium was higher by 21.9 – 41.3%, and that of magnesium by 31.3 – 47.3%. However, no proven difference was found in regard to the calcium and magnesium content of the barley varieties grown at N_{200} and N_{400}. Total calcium uptake varied from 160.7 mg $CaO.pot^{-1}$ (Obzor at N_0) to 364.3 mg $CaO.pot^{-1}$ (Kaskadior at N_{400}), and that of magnesium from 28.0 mg $MgO.pot^{-1}$ (Kristi at N_0) to 56.3 mg $MgO.pot^{-1}$ (Kaskadior at N_{400}). Within the study, variety Kristi accumulated the most grain calcium 54.9 mg $CaO.pot^{-1}$ and variety Kaskadior accumulated the most grain magnesium 25.9 mg $MgO.pot^{-1}$.

Nutrient harvest indices indicate what percentage of the absorbed nutrient in the grain+straw at maturity is allocated to the grain, similar to the grain harvest index. The results of Table 4 showed that the barley plants alocated into the grain the most of accumulated nitrogen in maturity (64.6–66.7%), followed by the share of phosphorus (51.2–53.6%) and that of the magnesium (47.0–52.7%). The studied varieties distributed to the grain the least amount of calcium from its content of grain+staw in maturity, which averaged 15%. Low values of 23.5%-24.1% were also found regarding to the potassium harvest index. The nitrogen studied levels no significantly affect the percentage of nitrogen, phosphorus, potassium, calcium and magnesium distributed into the grain at maturity. There was a tendency to decrease the mean values of NHI, PHI and MgHI in the nitrogen-fertilized variants.

Our results indicated no proven varietal differences in the average yields of grain and straw (Table 5). The assimilated nitrogen, phosphorus and potassium in these parts had similar values. Significant difference was observed only in the uptake of grain phosphorus between Krami variety (average 148.3 mg $P_2O_5.pot^{-1}$) and Emon variety (average 103.4 mg $P_2O_5.pot^{-1}$). The Kristi variety accumulated more grain calcium and the Kaskadior variety more grain magnesium. The Emon variety was distinguished by a lower Grain harvest index of 38.3%, compared to the rest of varieties, where GHI was 40.3-41.3%, on average. The Kaskadior variety allocated less of the absorbed phosphorus (PHI=48.7%) and calcium (CaHI=13.1%) to the grain. Emon variety had a low KHI=21.9%, and the Obzor variety had a low MgHI=43.4.

*Values for each nutrient in the plant parts followed by the same letters are not significantly different at $p<0.05$ according to Duncan’s multiple range test
ns** Not significantly different at $p<0.05$

Correlation analysis indicated that the nitrogen level in the range of N_0 to N_{400} was strongly positively related to straw, grain+straw yields, as well as to the absorbed grain nitrogen (r=0.906**) and straw nitrogen (r =0.894**). Nitrogen fertilization was negatively related to GHI (-0.641*).

Conclusions

Fertilization N_{400} increased the average productivity of the varieties by 23.8% for grain and 31.1% for grain+straw, compared to plants grown at N_0. Nutrients accumulated of grain+straw at N_{400} level were higher by 84.9% for nitrogen, 51.8% for phosphorus, 54.4% for potassium, 41.3% for calcium, and 47.3% for magnesium, on average. Grain harvest index decreased from 41.5% at N_0 to 39.3% at N_{400}. The nitrogen level had a slight effect on the percentage distribution of accumulated nutrients to the grain, although a tendency for a lower percentage was observed in regard to the nitrogen, phosphorus and magnesium. A strong positive correlation of nitrogen level with grain and straw yield and amount of accumulated nitrogen was established. A negative correlation was observed between applied nitrogen and grain harvest index (r=-0.641*) and nitrogen harvest index (r=-0.479).

KNEJA 652 - A LATE HYBRID FROM PORTFOLIO OF THE MAIZE RESEARCH INSTITUTE - KNEZHA FOR 2024

Valentina VALKOVA*

Maize Research Institute , 5835 Knezha , Agricultural Academy - Sofia, Bulgaria
*Corresponding author: valkova_valentina@abv.bg

Abstract

Kneja 652 is a new high-yielding, stress-tolerant maize hybrid from the FAO Group 600+, selected for grain, silage and biogas production. Suitable for extensive and intensive cultivation. The hybrid is a single cross created by interline hybridisation of inbred lines XM 1617 and XM 9923. The hybrid is for early sowing with a fast initial rate of development. It has a tall, well formed stem, resistant to lodging and has good synchrony in the flowering period of the reproductive organs (ASI = 0-2). The cob is characterised by compact, large cobs 24-25 cm long; 16 rows; 50-52 grains per row, 230 g grain weight per cob; 273.5 g. MNV; hectolitre weight - 75 kg/hl. Kneja 652 has high quality indicators for grain and silage use, as follows: 10.38-10.43 % protein content in grain; 68,01 % starch; 2,07 % fibre. The hybrid is resistant to the economically important maize diseases Helminthosporium turcicum, Ustilago zea and Fusarium ssp. Kneja 652 is recognized by the Expert Commission, after two years of testing, by the Executive Agency for Variety Testing, Approbation and Seed Control and by order RD12-2/15.03.2023 is included in the Official Variety List of the Republic of Bulgaria. Hybrid Kneja 652 has certificate No 11294/25.01.2024 of the Patent Office of the Republic of Bulgaria. The hybrid was developed at the Scientific Research Institute of Maize - Kneja by Assoc. Prof. Valentina Vulkova. The Minister of Agriculture and Food presented an award for Kneja 652 hybrid for scientific activity and development in the innovation competition.

Keywords: *New maize hybrid, Kneja 652, Maize research Institute – Knezha.*

Introduction

As a consequence of the increasing human population worldwide; unfavourable agro-meteorological environmental conditions for plant development caused by the onset of climate change; reduced availability of arable land and soil erosion; and water scarcity, the need for increased agricultural production is growing.

Maize is the most produced crop in the world (FAO Statistical Yearbook, 2023). It is a major forage crop, with the highest feed and energy value of the cereal forage crops. According to Kostova A. (2012), it is a raw material for over 2000 industrial and technical products. Maize breeding in recent years has been very successful both at home and abroad. After the joining of Bulgaria to the European Union, a prerequisite was created for opening the seed market to foreign companies, expanding the varietal list and unhindered dissemination of foreign breeding achievements. The new conditions require radically different approaches to research and higher criteria for our hybrids to survive in the highly competitive environment of the European market.

Along with the requirement for new hybrids to be high yielding, there is an increasing demand for other qualities: resistance to diseases and pests; tolerance to abiotic stress factors; efficient water and nutrient use; grain quality; increased harvest index; rapid initial rate of development; rapid moisture release from the grain and stable yield. At the same time, the production life of maize hybrids is declining at a rapid rate. According to Duvick et al. (1999), hybrids persist in production for an average of seven years. For this reason, maize selection has a permanent character. Each newly recognized hybrid must be tested under different ecological-geographical regions and compared with the best standards of its maturity group to really evaluate its qualities.

In its 100-year history, more than 117 maize hybrids of different maturity groups and uses have been developed at the Maize Research Institute - Knezha, Bulgaria (Genov et al., 2005; Genova et al, 2009; Gacovski et al, 2011; Ilchovska et al, 2014, Petrovska et al, 2018; Valkova et al, 2018; Yordanov, 2019, 2021). Each newly recognized hybrid is better than the previous ones and builds on their qualities. According to a number of scientists (Yugenheimer, 1979; Russel, 1986; Hallauer, 1988; Reid et al, 2014), even the most thorough research and technological developments in breeding would be meaningless if they did not lead to the creation of new higher yielding, quality, sustainable and adapted hybrids and the achievement of real breeding progress.

The objective of this publication is to show the main characteristics, morphological and economic qualities of the new hybrid of the Maize Research Institute, Knezha, Bulgaria - Kneja 652.

Material and methods

Hybrid Kneja 652 is a late maize hybrid intended for grain, silage and biogas production. It was developed in 2017 as a topcross cross to evaluate the combinability of newly stabilized lines with testers that have proven over the years their high general and specific combinability for grain yield. The cross XM 1617 x XM 9923 (Kneja 652) was voted as high yielding in 2018 after testing in a preliminary variety trial. The results were confirmed in competitive and environmental variety trials over the next two years, and in 2021 the hybrid was submitted for evaluation for Distinctness, Homogeneity and Stability (DHS) and Biological and Economic Qualities (BEC) in the official country trial (Executive Agency for Variety Testing, Field Inspection and Seed Control). The trials were conducted under non-irrigated conditions in 2021 and 2022 at 3 sites - Selanovci, Brashlen and Radnevo. High temperatures and minimal rainfall at the latter site led to the scrapping of the trials there. Due to the convincing superiority of the yield of hybrid Kneja 652 over the Executive Agency for Variety Testing, Field Inspection and Seed Control standards, the hybrid was recognised after two years of testing. With Order No 12-2/15.03.2023 The Minister of Agriculture approved the recognition and entry in the Official Variety List of the Republic of Bulgaria of hybrid Kneja 652. The hybrid has certificate No 11294/25.01.2024 of the Patent Office of the Republic of Bulgaria

In 2021 and 2023, the Kneja 652 hybrid was tested under non-irrigated conditions, in randomized block trials in the Republic of Serbia and Romania, where it was compared to their own and foreign standards. The following parameters were studied: grain yield at standard moisture of 14% and moisture at harvest

The parental components of the hybrid are the product of mutational selection. Descriptions of the paternal form - XM 99 23 are available in two previous publications (Valkova V., 2006; Valkova et al, 2018). The maternal line of the hybrid XM 1617 was produced by treatment with chemical mutagens DES (diethyl sulfate) - 0.1% and NMU (nitroso methyl urea) on a heterozygous genotype. It was stabilized in M4 inbred generation in 2016.

Results and discussion

The maize hybrid Kneja 652 is a straightline cross between the inbred lines XM 1617 x XM 9923. According to the FAO classification, the hybrid belongs to the late genotypes - group over 600 with a growing period of 117-124 days. This period is extended by 3-5 days when grown under irrigated conditions. The hybrid is suitable for early sowing (10°C soil) with a rapid initial rate of development. Suitable for extensive and intensive cultivation. Kneja 652 is characterised by a tall stem (260-280 cm), well frondose (13-15 pcs.), resistant to lodging. It has good synchrony in the flowering period of the reproductive organs (ASI = 0-2). The hybrid is monocot. The cob is cylindrical, 24-25 cm long (Fig. 1). There are 16 rows and 50-52 grains per row in the cob. The kernel is orange horse tooth type, 10-12 mm long, and the weight of the kernel per cob is 220 -240 g. The weight of 1000 seeds is 273.5 g and the hectolitre weight is 75 kg/hl. The percentage of grain in the cob measured during the seed cast showed that the Kneja 652 hybrid also has a high percentage of 85-86%. The chemical analysis of the grain showed that the hybrid has an increased protein content in the grain - 10.38-10.43%, and on this indicator it significantly exceeds the standard P9903 with a protein content of 8.5% and the standard Kneja 435 - 9.5%. In the grain of the hybrid the percentage of starch is 68,01 and of fibre – 2.07%. These results give grounds to recommend hybrid Kneja 652 for production of quality forage.

Figure 1. Kneja 652

The results of the first two stages of the hybrid field trial at the Maize Research Institute are shown in Table 1.

Table 1. Results from the testing of Kneja 652 hybrid in condition without irrigation (2018-2019)

Year	Grain yield, kg/ha			% the yields to the standart		Grain moisture at harvest, %		
	Kneja 683A	Kneja M625	Kneja 652	Kneja 683A	Kneja M625	Kneja 683A	Kneja M625	Kneja 652
PVT -2018	1203.1	1116.3	**1289.7**	107.2	115.5	16.5	16.2	15.7
CVT-2019	1083.6	1178.6	**1183.9**	109.3	100.4	15.8	15.0	15.3
CVT-2020	713.3	699.2	**767.2**	107.6	109.7	14.2	15.8	14.0

*PVT - preliminary varietal trails, CVT - competititve varietal trails

The trials were carried out under non-irrigated conditions and following the agronomic technique adopted for the region. The highest yield of the hybrid was obtained in 2018 and its variation from year to year was due to different agro-climatic conditions. The excess of the yield of hybrid Kneja 652 over that of the standards ranged from 0.4% over hybrid Kneja M625 in 2019 to 15.5% for the same hybrid in 2018. The excess of the hybrid's productivity over that of the standards allowed the testing of the hybrid to continue in the ecological network of the country. The trial was conducted again under non-irrigated conditions at three sites - Kneja, Ruse and Pavlikeni. The trials were sown and harvested manually, in three replications, harvest plot size of 10 m^2 and plant density of 55.000 plants/ha (Table 2). It is noticeable that the yields at Pavlikeni are much lower than those at the other two sites. This is due to the late sowing of the experiment (11-12.05.2020), which was hampered by the complicated situation throughout the country, in relation to the spread of Covid 19, and the scarce rainfall in July (6.6 mm/m^2), when flowering and fertilization of reproductive organs took place. For this reason, a high percentage of infertile plants were recorded during the harvesting trials, which inevitably led to yield reductions. In the ecological variety trials the hybrid exceeded the Kneja 683A standard in yield by 23.1% and was 97.1% to that of Kneja M625.

Table 2. Results from the testing of Kneja 652 hybrid in ecological variety trails (2011)

Year	Grain yield, kg/ha			% the yields to the standart		Grain moisture at harvest, %		
EVT	Kneja 683A	Kneja M625	Kneja 652	Kneja 683A	Kneja M625	Kneja 683A	Kneja M625	Kneja 652
Knezha	656.7	838.2	**830.8**	126.5	99.1	15.6	16.4	**17.1**
Rousse	678.9	751.1	**777.1**	114.5	103.5	16.0	17.0	**17.1**
Pavlikeni	346.2	501.1	**443.8**	128.2	88.6	15.2	15.8	**16.3**

In order to continue testing the productive potential of the hybrid under study, it was included in the country's official variety trial. Testing was carried out under non-irrigated conditions in three locations in the country - Selanovtsi, Brashlen and Radnevo (Table 3). In 2021, Kneja 652 realized a grain yield of 7645 kg/ha, 112.4% of the official standards. The yield in 2022 was 5650 kg/ha - 99.5% towards the standards, where the differences with the average standard are mathematically unreliable. The average yield from the six locations over the two years is 6647.5 kg/ha, with an average exceedance of 106% over the Kneja 683A and Kneja M625 standards. Yields in the official trial were quite low, on one hand because of the climatic conditions at the time of pollination, fertilisation and grain filling and on the other hand because of the inclusion of the Radnevo site, where conditions for maize cultivation are not favourable and low yields are obtained. According to reports from the IACAC, Kneja 652 is resistant to the economically important maize diseases *Helminthosporium turcicum*, *Ustilago zea* and *Fusarium ssr*. The hybrid is recognized after two years of testing by the Executive Agency for Variety Testing, Field Inspection and Seed Control and holds certificate No 11294/25.01.2024 of the Patent Office of the Republic of Bulgaria.

Table 3. Results from official testing of Kneja 652 hybrid in EAVTFISC

Hybrid	Grain yield, kg/h	% average Standart (Kneja M625 and Kneja 683A)	number of days from germination to harvest	Grain moisture at harvest, %
2021				
Kneja 652	764.5	112.4	121	14.9
Kneja M625 and Kneja 683A	684.9	100	121	14.8
2022				
Kneja 652	565	99.5	117	12.8
Kneja M625 and Kneja 683A	567	100	117	13.9

*Executive Agency of Variety Testing, Field Inspection and Seed Control (EAVTFISC)

In the years 2021 and 2023, the hybrid was included under international cooperation for bilateral hybrid testing by the Maize Research Institute - Knezha, Bulgaria with related institutes in Zemun Polje Serbia and Fundula, Romania. In the first year of the trial, the hybrid performed better in Romania (7925 kg/ha) and in Zemun Pole the yield was 7285 kg/ha. In 2023, due to unfavourable conditions (lack of rainfall and high temperatures), the trial in Romania was scrapped. In Serbia, higher yields were obtained in Tovarishevo - 8663 kg/ha and in Zemun Pole - 7792 kg/ha.

The technology of seed production of hybrid Kneja 652 requires simultaneous sowing of the parental components. The sowing scheme can be 6:2, because the panicle of the parent component is very rich and retains its fertilisation capacity 8-10 days. The recommended and optimum sowing densities are: under non-irrigated conditions 55 000 pl/ha and under irrigated conditions 65 000 pl/ha. Seed production of the hybrid is so far on a fertile basis with complete detasseling of the mother rows. A sterile analogue of the maternal form is in the process of being created to switch seed production to the fertility restoration method. This is possible because the paternal component, the XM 9923 line, is a universal restorer, and this in turn will lower the cost of hybrid seed produced. The breeding coefficient of the maternal form - line XM 1617 reaches 3900-4200 kg/ha of standard seed. The hybrid is suitable for inclusion in System Plus with all late hybrids to increase grain yield per unit area.

At the International Agra 2024 exhibition, the Kneja 652 hybrid was awarded a prize for research and development in the innovation competition.

Conclusions

Hybrid Kneja 652 has high productive potential and very good resistance to economically important diseases in maize *Helminthosporium turcicum*, *Ustilago zea* and *Fusarium ssr*.

Once a sterile analogue of line XM 1617 is developed, seed production of the hybrid will be carried out using the fertility restoration method, which will eliminate manual detasseling and increase profit per unit area.

The grain of the hybrid has very good quality indicators: protein content 10.38-10.43%, starch 68.01% and fiber 2.07%.

Abstract

The maize hybrids Kn-442, Kn-509, Kn-511, Kn-M625 and P35F38 of different maturity groups were studied for a period of four years (2014-2015 and 2017-2018). Each hybrid has three variants - 100% fertile; 50% fertile and 50% sterile; 100% sterile plants. Sterility was achieved by means of castration (*detasseling*) before anthesis. The trials were carried out in the field of the Maize Research Institute - Knezha, by the randomized block design, on a 10 m^2 harvest plot, in 3 replications, without irrigated conditions. The results of the three-factor Analysis of Variance (ANOVA) points out significant variances for hybrids, years (environmental conditions) and the interaction between them. The remaining variances, including: variants of the hybrids with percentage of sterility; first-order interactions – hybrids x variants; years x variants, as well as the triple interaction – hybrid x years x variants, are not significant. Significant differences in mean yields between the tested variants (100% fertile, 50:50% and 100% sterile) are observed in some cases at P=5%. The effect of variants with 50% castrated tassels tended to be higher yielding by 0.4 to 12.1% in 2014. With 100% sterile plants, there is a relative excess of yield compared to 100% fertile ones in 4 out of 5 hyrids with a range of 1.3-5.0%. For the period of the study, the highest yield was performed by hybrid Kn-442, followed by P35F38.

Key words: *maize hybrids, percent of detasseling, yield and stability*.

Introduction

According to FAO-data from 2023 worldwide maize production amounts to more than 1.2 *bn/t*, witch mades it the most produce cereal crop on the planet. Maize has good ecological stability and is grown on all five continents from 50°N to 35°S latitude. Mainly used for grain and silage, food for people in developing countries, it is a raw material for the production of over 2,000 products for the food, pharmaceutical and chemical industries (Ranum et al., 2014). Due to its major economic importance, it is the object of constantly increasing scientific and practical interest (FAO Statistical Yearbook, 2023). In recent years, in relation with the global climate changes, the yields of all cultural crops are threatened by yields reduction, including those of maize too. In the Third National Action Plan on Climate Change (Ministry of Environment and Water, Republic of Bulgaria, 2012) it is stated that spring agricultural crops will be increasingly vulnerable to these changes in the future. Increasing the resistance of maize to drought is an extremely important problem not only for Bulgaria, but also for other countries where this crop is grown, due to a significant reduction in yields.

The hybrid is the most important, effective and intensive factor in maize production. The yield obtained and the added value per unit of area largely depends on the correct choice of hybrid, and on the other hand, the choice of correct agricultural techniques. In the last 20-25 years, to deal with this problem, as well as to increase the yield from a unit of area without additional costs for the producers, the so-called "Plus System" has been implemented. It was proposed by Weingartner et al. (2002) and is a mixed crop of two or more maize hybrids of

the same vegetation group, some of them obtained by the mixing method. The expected higher yield results from the combined effect of the higher yielding sterile plants and the higher seed mass obtained from non-exogenous pollination. The combined effect of this system affects two components of the yield – the cytoplasmic male sterility (CMS) leads mainly to an increased number of grains, and the xenic effect increases the 1000 seeds weight (Weider et al., 2010; Vulchinkov et al., 2014). A large part of the newly recognized hybrids of the Maize Research Institute - Knezha have sterile analogues of the maternal component. The use of maternally sterile counterparts in hybrid maize seed production results in greater production efficiency and purity of the resulting hybrid seeds by eliminating hand or machine detasseling. The data on the impact of CMS on yield are contradictory. According to a number of authors (Duvick, 1958; Beckett, 1971; Ilchovska, 1991), the yield of sterile forms is higher than that of their fertile parent lines, due to the weakened competition for assimilates between the ear and the tassel. On the contrary opinion are Valkova (2012) and Vulchinkov et al., (2014), according to which the yield of sterile forms is influenced by the genotype, the year of the study, as well as the genotype-environment interaction. The same thesis has been confirmed by a resent studies by Costa et al., (2019), Ghețe et al., (2020) and Prodanović et al. (2022), as well as the significant importance of the method of detasseling – by hand or mechanized. In some hybrids with sterile counterparts of the maternal form, the paternal component lacks fertility restorer genes. This necessitates the use of a “compromise” mixing scheme (Valkova, 2012). With it, 1/3 of the plants in the mass hybrid are fertile (flowering), which in practice is also a "Plus" system. If at least two hybrids produced according to such a scheme are sown, their sterile plants will cross-pollinate, resulting in a xenia effect.
The aim of the study is to determine the influence of different levels of detasseling on the grain yield of the exanimated hybrids from different vegetation groups over a four-year period.

Materials and Methods

The experiment is conducted in the experimental field of the Maize Research Institute - Knezha during the periods 2014-2015 and 2017-2018. The trails are set in a randomized complete block design with 10,0 m^2 experimental plot size in three replications for each genotype tested; under non-irrigated conditions. Hybrids of different maturity groups were studied - Kneja 442, Kneja 509, Kneja 511, Kneja M 625 and P35F38. Each hybrid is tested in three variants – 100% fertile (1), 50% fertile and 50% sterile (2) and 100% sterile plants (3). Sterility is achieved by hand detasseling the plants immediately after tassel emerging and before anthesis. The grain yield is measured in kg/dka with 14% moisture content at harvest. A three-factor *Analysis of Variance* (ANOVA) on the data is performed. The data processing is done by Microsoft Excel and SPSS 25 Statistical program.

Results and discussion

Of the climatic conditions, rainfall, temperature, and relative humidity are of greatest importance for the growth and development of maize. According to Vulchinkov S., (personal correspondence), a year with a sum of precipitation during the growing season (April-September) higher than 400 ml is defined as favorable for the maize development, and one with less than 300 ml of precipitation can be considered as dry. According to these, two of the years of the study period (2014 and 2018) are considered as favorable with rainfall totals of 627.2 ml and 447.5 ml, respectively. With a more even distribution of rainfall and lower temperatures during pollination, 2014 was the most favorable year during the study period (Fig. 1).

Figure 1. Average mount values of temperatures and precipitation for April-October for the study period (2014-2015, 2017-2018)

The results of the multifactorial Analysis of Variance (ANOVA) show significant differences both between the years of study and between the hybrids and the interaction of environmental conditions and studied genotypes (Table 1). The other factors: the variants of the hybrids with percentage of sterility; hybrid by variants; years by variants, as well as the triple interaction – hybrid, year, variant do not have significant variances.

	(3)	796.1	745.5	878.2	623.7	760.9	623.7	878.2	106.6	14.0
PR 35F38	*(1)*	950.0	811.2	895.1	807.9	866.1	807.9	950.0	69.0	8.0
	(2)	983.1	841.5	783.4	738.3	836.6	738.3	983.1	106.4	12.7
	(3)	894.7	776.6	762.2	816.1	812.4	762.2	894.7	59.4	7.3

(1) 100 % fertile plants; (2) 50 % fertile / 50 % sterile; (3) 100 % sterile plants.
LSD at P=5 % is 102,6 kg

Averaged over the years of the study (Table 2), the highest yield is obtained from hybrid Kn 442 (979.1 kg/ha) under complete detasseling, followed by PR 35F38 (866.1 kg/ha) at 100% flowering plants, Kn 511 (817.3 kg/ha) when 50% of the tassels are removed, Kn M625 (760.9 kg/ha) with 100 % castration and Kn 509 (746.4 kg/ha) in fully flowering plants.
Of the calculated least significant differences at a probability level of 5% for the entire trial is *LSD*=102.6 kg. This means that in hybrid Kn 442 in 2017, the variant with complete detasseling (1190.3 kg/dka) proved to be different from those with partial and no detasseling. This is also the highest yield of all hybrids for the entire research period. Hybrid Kn 509 in 2018, the variant with 50/50 sterility clearly differs from the one with fully fertile plants. A proven difference was also reported in 2018 hybrid Kn 511 for dust 50/ castration, compared to the other variants in the experiment. Differences in the levels of detasseling levels were also observed for Kn M 625 and PR 35F38 in 2017.
Quantitatively, the yield picture is as follows. The sterile variant in hybrid Kn 442 had a higher yield than that of fertile plants by 7.9% on average over the test period and varied from (39.7% in 2017 to 5% in 2014). In the other two years, the yield of the sterile variants is lower than that of the fertile plants by an average of 5%. In the hybrids Kn M625 and Kn 509, higher yields is obtained than the sterile variants in three of the years and in two of those with 50% participation of sterile plants. The excess in yields of sterile variants over that of 100% fertile plants in hybrid Kn M625 varies from 13.6% (2017) to 0.5% (2018), and in Kn 509 from 5.6 (2015) to 1.3 (2014). In hybrid Kn 511, higher yields than the mixed variant ape reported in three of the studied years and in two of 100 % sterile plants. The influence of the number of sterile plants in the crop with the foreign hybrid PR 35F38 is insignificant. Excess in the grain yield from the variants with 50% fertile and 50% sterile plants over that with fertile plants was in 60% of the tested cases. The largest excess is reported for the hybrid Kn 511 with 16% (2018) to 0.4% (2014) for the same hybrid.
The results show that there is relation between the yields of the individual variants and the years of testing in some cases. There is no tendency for a higher yield from the sterile plants in drier conditions, on the contrary, in 2014, the most favorable year, of all the Bulgarian hybrids from the variants with the participation of sterile plants, higher yields are obtained than the variant with 100% fertile plants. These results are in coherency with the results obtained earlier by Valkova. (2012) and contrary to what was demonstrated by Kannenberg (1974) and Hoekstra et al. (1985).

Conclusions

The results of the three-factor Analysis of Variance (ANOVA) points out significant variances for hybrids, years (environmental conditions) and the interaction between them. The remaining variances, including: variants of the hybrids with percentage of sterility; first-order interactions – hybrids x variants; years x variants, as well as the triple interaction – hybrid x years x variants, are not significant. Least significant differences in mean yields between the tested variants (100% fertile, 50:50% and 100% sterile) are observed in some cases at P=5%. The effect of variants with 50% castrated tassels tended to be higher yielding by 0.4 to 12.1% in 2014. With 100% sterile plants, there is a relative excess of yield compared to 100% fertile ones in 4 out of 5 hyrids with a range of 1.3-5.0%. For the period of the study, the highest yield was performed by hybrid Kn-442, followed by P35F38.

Abstract

The phenomenon of heterosis has opened wide perspectives in a number of crops and continues to play a crucial role in the genetic improvement of plants. The heterosis effect is most expressed in cross-pollinated plants, however, they are also the most sensitive to inbreeding depression. Heterosis is less expressed in self-pollinating species, but inbreeding depression is lesser. The crosses in sesame were made in an incomplete diallel pattern. Biometric measurements of major yield elements were made on the parental forms from the working collection of IPGR - Sadovo and the hybrid progeny. Seed mass per plant, number of the branches, total number of boxes per plant were recorded. The mean total parent height (MPH) and heterosis (BPH) were determined. The variation in MPH and BPH among different hybrids was measured. The level of genotypic variance (σ2G) was determined by its components, the levels of additive variance (σ2A), dominance variance (σ2D) and epistasis variance (σ2E). The inheritance coefficients were determined in the broad (H2) and narrow (h2) sense, as a possibility to compare them. Selection success (R) was accounted for by the selection differential (S) and heritability in the broad sense.

Key words: *sesame, heterosis, genotypic and phenotypic variance*.

Introduction

Sesame (*Sesamum indicum* L.) is an oilseed crop that has been cultivated and used by humans since ancient times. It originates from Africa, although India is considered to be the first place of appearance of cultivars. The high nutritional value and health benefits of sesame consumption are undisputed and the interest is growing rapidly (Noureldin S. and Butovchenko A. 2019; Wu 2007). Sesame seed oil is among the most expensive and desirable edible oils in the world. It is one of the healthiest, containing 38.84% oleic acid and 46.26% linoleic acid, which are high in unsaturated fatty acidy. They call it the "Queen" of oils because it reduces the LDL-cholesterol complex, regulates blood sugar, and in addition the antioxidant properties of sesamin, sesamol and sesamolin not only contribute to its high level of resistance against oxidation, but also make it a unique and very high-quality functional food (Oboulbiga et al., 2023)

The production of sesame seed, according to FAO estimates, is 7 706 642 tons in 2020. This is 3.89% more than the previous year and 57.37% more than 10 years ago. In 2019, the 12.8 million hectares used for sesame production resulted in a total of only 6.5 million tons of sesame produced, which must be considered a low yield for such a huge area (FAO statistics database: production, trade, supply. 2019).

Selection for new sesame varieties has focused on several morphological traits and issues related to overcoming biotic and abiotic stress (Teklu et al., 2022). Heterosis in sesame has been reported in a number of works (Disowja et al., 2021; Mishra & Sikarvar, 2021; Chaudhary et al., 2017; Aladji et al., 2014).

The aim of the present study was to determine the heterosis in the inheritance of key morphological traits related to yield, including seed mass per plant, number of branches, and total number of pods.

Material and method

Crosses in sesame were conducted using an incomplete diallel pattern. Biometric measurements of major yield components were taken on both the parental forms and the hybrid progeny, recording seed mass per plant, number of branches, and total number of pods. In the first cross Milena x Sadovo 3959 105 progeny were processed in the F_1 population, in the second Sadovo 3959 x Milena - 83, in the third Sadovo 1 x Sadovo 3959 - 82 and in the fourth Sadovo 3959 x Sadovo 1- 70 progeny. The mean (x), mean error (Sx %), mean square deviation (S %) were determined. Biological characteristics as heterosis - hypothetical and true (%) and heterosis effect (BPH) were analyzed. The type of inheritance of traits in F_1 hybrids was determined by the ratio of the dominant to the additive parameter, d/a (Mather & Jinks, 1971). The heritability coefficients in broad (H^2) and narrow (h^2) sense. The additive variance (σ2A), dominance variance (σ2D) and epistasis variance (σ2E) were calculated. The selection differential (S) was determined - S = Sx defenses in F_2 - Sx in F_1. The (R) was calculated by the formula: $R = S \times H^2$ .The optimal genetic distance (GD) at which the highest heterosis effect is obtained was determined using the quadratic deviation between parents (Nei, 1979).

Results and discussion

The heterosis behaviors of progeny in different hybrid combinations of seed mass per plant are presented in Fig. 1. The average seed mass per plant of F1 progeny in the combination Milena x Sadovo 3959 was 21.50 g. It was 11.70 g in Milena and 7.20 g in Sadovo 3959. Heterozygosity is highly expressed (82.90%) and is manifested by overdominance of the higher yielding parent. Heterosis for seed yield has been reported in a number of studies by Vekaria and Dhadak (2018), Chauhan et al. (2019) and Dela and Sharma (2019). In the reciprocal cross (Sadovo 3959 x Milena), seed mass of a plant is inherited through incomplete dominance of the higher yielding parent, but here heterosis is absent. In a cross with the parents Sadovo 1 x Sadovo 3959, the seed mass per plant for Sadovo 1 is 18.50 g and for Sadovo 3959 is 2.40 g. The resulting average plant mass of the hybrid population was 25.30 g. The observed heterosis effect of 36.60% was due to overdominance of the maternal parent. Daba C., (2019) also found that seed yield, number of capsules and number of tillers are under the influence of dominant gene effects and provide opportunity for heterosis selection in sesame. In the reciprocal cross the seed mass obtained from one plant for Sadovo 3959 was 12.40 g and for Sadovo 1- 45.10 g, and the progeny plants formed a seed mass from one plant of 25.50 g. The indicator d/a has a negative value less than one. Inheritance occurs by incomplete dominance of the lower-yielding parent.

In the combination Milena x Sadovo 3959 variants of additive genes, has a minimum value of 5.1, while dominant and epistatic gene effects have values of 147.7 and 127.1, respectively.

The selection differential (Table 1) has a negative sign, indicating the high degree of depression in F_2 of this trait. In the inheritance of the trait in the reciprocal cross, the variance of additive interactions matters the most.

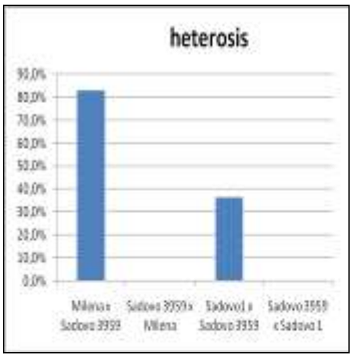

Fig. 1. Heterosis effect by seed yield

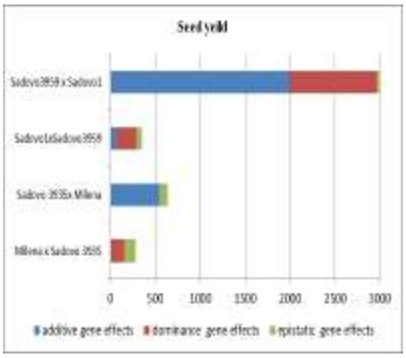

Fig. 2. Gene effects in inheritance by seed yield

This, together with the equalized broad and narrow - sense inheritance coefficients (Table 1), indicate independent genetic control of seed mass per plant in the hybrid population as opposed to epistatic control in the straight cross. Again, the depression in the F_2 generation is strong and the selection differential is negative (-7.78 g). Because of this, selection by phenotype is appropriate and higher yielding progeny can be selected. In the combination Sadovo 1 x Sadovo 3959 the variance of additive and epistatic interaction between genes is almost equal 64.80 - 65.10 with the highest value being the dominant interaction 219.40. This and the higher coefficient of inheritance in a broad sense over that in a narrow sense, make the progeny under consideration suitable for heterosis selection for the trait seed mass per plant. The selection differential was of negative sign (-3.8 g), which was due to inbreeding depression in the F_2 progeny. The epistatic interaction of genes in the reciprocal cross in this trait has the highest score. The selection differential is negative sign (-2.5g) due to inbreeding depression in F_2 progeny. Plant height and number of branches per plant are the bearing surface of capsules and are considered important attributes of biological yield. The heterosis manifestations of progeny in different hybrid combinations are presented in Fig. 3. The number of branches in the hybrid combination Sadovo 1 x Sadovo 3959 was 3.00 for Sadovo 1 and 2.50- Sadovo 3959. In the progeny the average number is 4.00. The dominance (d/a) was 5.00. Inheritance was overdominant, to the parent with the higher number of branches. In this combination, there is a heterosis effect in terms of the number of branches, 33.30%. On this trait, high value heterosis has been reported by Rao (2011), Monpara B.A. and Pawar A.K., (2016). In the reciprocal cross, inheritance of the trait was incompletely dominant, to the parent with fewer branches, the d/a index has a negative value less than one, and heterosis is absent. The values of additive, dominant and epistatic gene interaction in the combination Milena x Sadovo 3959 showed that the highest proportion of epistasis. Inheritance in the broad sense has a higher value than inheritance in the narrow sense, and allelic and non-allelic epistatic interactions were involved in the formation of the number of branches. The selection differential is low and the success of selection by phenotype is unfortunate.

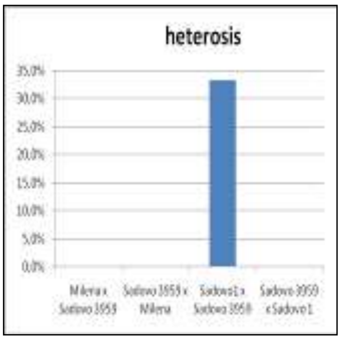

Fig. 3. Heterosis effect by number of branches

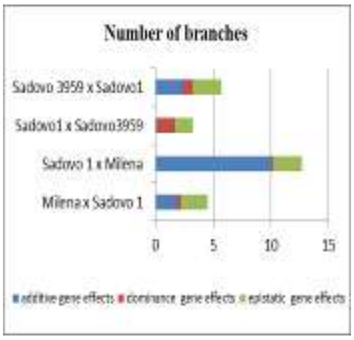

Fig.4. Gene effects in inheritance by number of branches

Additive interactions have the strongest influence on the number of branches in the reciprocal cross. The coefficient of inheritance in the narrow sense, greatly exceeds that in the broad sense. Selection by phenotype for the trait number of branches was successful.
In the combination Sadovo 1 x Sadovo 3959 the highest value were dominant genes effects. The coefficient of inheritance in the broad sense significantly exceeds that in the narrow sense, indicating the interaction of non-allelic and allelic genes. Forms with fewer branches are suitable for mechanized harvesting, the selection differential is negative (-0.27 counts), and the team success is low 5.80. The high value of the inheritance coefficient in a broad sense gives us a reason for successful selection by phenotype. The selection differential is 0.20, and the success of the team has a high value.

In the cross Milena x Sadovo 3959, cultivar Milena formed 92 number of boxes in plant, Sadovo 3959 - 181, and the progeny of F1 population 163.90. The inheritance of the trait was incompletely dominant to the parent with higher number of boxes, and heterosis was absent. In the reciprocal cross, heterosis is again absent, and inheritance of the trait follows the same pattern (fig 5). In the reciprocal cross, the d/a index has a negative value lower than unity inheritance was incomplete to the parent with the lower number of boxes and heterosis was absent. In a study by Rani S., et al. (2015), thirty-three hybrids showed positive heterosis for the number of capsules, while five hybrids showed negative heterosis to the mean parent, supporting our findings.

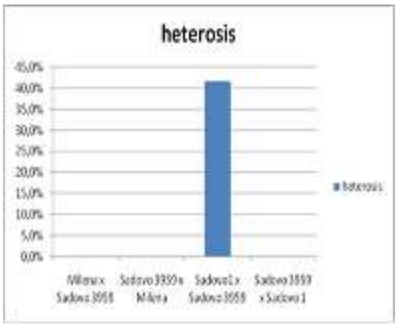

Fig. 5. Heterosis effect by number of boxes

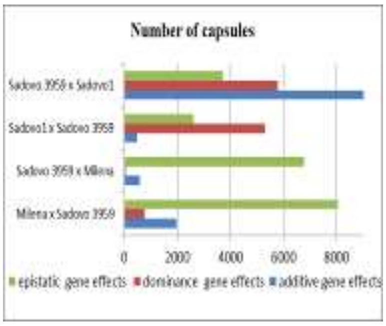

Fig.6. Gene effects in inheritance by number of boxes

Additive gene interactions have the highest proportion in inheritance of this trait in reciprocal cross. This fact combined with the fact that the narrow sense inheritance coefficient has a higher value than the broad sense makes the team in the early generations unsuccessful.

Table. 1 Inheritance coefficients (H^2, h^2) selection differential (S) and team success R

Hybrid combinations	Seeds per plant, g	Nimber of branches	Total number of boxes
♀ *Milena x ♂ Sadovo 3959*

h^2	21,3	1,6	5,8
S	-3,8	-0,27	-11,3
R	-217,7	-5,8	-422,7
♀ Sadovo 3959 x ♂ Sadovo 1			
H^2	89,0	35,0	71,9
h^2	74,8	3,1	84,1
S	-2.5	0,2	-0,1
R	-134.2	141,9	-1,2

Genetic distance and heterosis.
In the inheritance of all yield elements in sesame, the interaction between allelic and non-allelic genes were too complex, and in this case no optimal genetic distance can be established in the parents used to justify obtaining the maximum heterosis effect. The nature of the resulting curve has no direction.

Conclusion

In the incomplete diallel scheme used, the manifestation of heterosis and gene effects depend on the direction of crossing. In combinations with high heritability coefficients, where the influence of gene factors in the overall phenotypic manifestation of traits was greater, effective selection in earlier hybrid generations (F_2 - F_3) is expected. This analysis model confirms the hypotheses of heterosis manifestation (dominance, overdominance or epistasis) and can be used with success in any specific hybrid combination included in breeding programs and in other crops.

Abstract

Twenty Bulgarian maize hybrids (FAO 400-600), including one check – Zp560, are tested in three locations – Zemun Polje, Pancevo and Becej in 2018 and 2019. ANOVA results pointed out a significance of all variances – locations, hybrids and GxE with the first ones’ predomination (51.42%). PC_1 and PC_2 scores occupied 61.6% and 18.2% of the interactions variability. Grain yield stability of hybrids was determined by regression, variation and AMMI analyses. The first three hybrids ranking by grain yield are: Zp-560, Kn-564 and Kn-648. Three hybrids with lowest AMMI stability values (ASV) are Kn-466, Kn-571 and Kn-320, well adapted to all environments. Kn-466 is located almost in the theoretical center of the AMMI-2 biplot – zero point of PC_1 and PC_2. That hybrid also took first rank by ASV. According AMMI-2 analysis five hybrids are unstable – Kn-573, Kn-649, Kn-648, Kn-321 and Kn-572. They had also the biggest values of σ_i^2 – first parameter of Shukla. Ten hybrids (50% from the trial) are located in the more productive zone of AMMI-1 biplot – above grand mean. Five of them are with negative scores of PC_1 including check Zp-560, and the rest five have positive PC_1. A distribution of all hybrids, according yield general mean and mean value (b_i=1.0) of the first stability parameter from Eberhart and Russel model is very similar to AMMi-1 biplot, that confirmed a previous study of ours. Conditions of the three locations in 2018 are better for hybrids performance than in 2019, but Pancevo had biggest PC_1 and PC_2 scores for both years. Vectors of Zp-2018 and Zp-2019 are closest to the center of AMMI-2 biplot.

Key words: *maize hybrids, stability parameters, AMMI, ASV.*

Introduction

The multienvironments testing of maize hybrids is one of the final stages of the breeding process. The main purpose of that testing is the genotypes stability assessment as a result of the genotype-environment (GxE) interaction and determining of the best locations for their zoning as well. A significant GxE interaction has very important consequences for the breeding programs. For such an important quantitative trait as the grain yield, this interaction can seriously limit the efforts in the selection of new genotypes that are important for the final stage of the selection process. The agronomical (phenotype) stability can be defined by means of parametrical methods – most often the regression or variation analysis, or by nonparametrical ones – the rang and cluster analysis (Delic, Stankovic, & Konstantinov, 2009; Branković-Radojčić et al., 2022). Contemporary methods like the AMMI analysis – the Additive Main Effects and Multiplicative Interaction effects model (Zobel et al., 1988) and its modification – the GGE biplot analysis (Yan and Tinker, 2006; Gauch, 2006; Gauch, Piepho and Annicchiarico, 2008) are also applied for determining of the genotype stability and suitable cultivation areas. As hybrid models they use the Analysis of Variance (ANOVA) and the Principle Component Analysis (PCA) with coordinates placement of genotypes and environment in the biplot for a final data interpretation. Purchase et al. (2000) developed the

AMMI Stability Value (ASV) indicator, based on the AMMI-model, in which the ANOVA and the Principal Component Analyses are used simultaneously as a quantitative parameter, in order to the genotypes to be ranked according to the stability of their yields. According to Mitrović et al. (2012) there is not a significant difference between the AMMI and the GGE-biplot analysis and they could be used with equal success for maize hybrids stability evaluation at testing in different environments (locations). Brancovic et al. (2018) make a comparison between linear regression models with the AMMI-analysis in relation to maize hybrids stability. A similarity is observed, but regression models evaluate this stability by one axis – the regression line, while the AMMI-analysis makes rates by two ones – PC_1 and PC_2 (Shojaei et al., 2021). At the prediction of genotype performance and their yield stability in different locations some unpredictable factors may occur – the so-called “noise” (Crossa, 1990; Crossa et al. 1990).
The aim of this study is to evaluate the stability of Bulgarian maize hybrids tested in multi-location field trails in Serbia.

Materials and Methods

Based on a cooperation agreement twenty Bulgarian maize hybrids (FAO 300-600), including one check – Zp560, are evaluated in multi-location field trails in Serbia for a two years’ period (2018-2019). The locations are Zemun Polje (Zp), Pancevo (Pan) and Becej (Be). The climatic conditions of test locations are shown in Figure 1. Combination of years (2018 and 2019) and 3 locations (Zp, Pan and Be) are treated as 6 environments. The trails are set in a randomized complete block design with 7,5 m^2 experimental plot size in two replications for each genotype tested; under non-irrigated conditions. The standard agro-technical practices according to local agro-ecological conditions are applied. The grain yield is measured in kg/ha with 14% moisture at harvest. A two-factor *Analysis of Variance* (ANOVA) on the data is performed. The parameters of stability of genotypes are determined according to the models of *Eberhart* & *Russell* (1966) and first parameter of *Shukla* (1972). *Additive Main Effects and Multiplicative Interaction* effects (AMMI) – according to Zobel at al., (1988) and Gauch (2006); *AMMI Stability Value* – ASV (*Purchase* J. L. et al, 2000) and *Principle Component Analysis* (PCA) with coordinates placement of genotypes and environment in biplot figures for a final data interpretation are applied. The data processing and analyses are done by Microsoft Excel and SPSS 25 Statistical program.

Results and Discussion

The average monthly values of the sum of precipitations and temperatures for a ten-year period (2010-2019), which also includes those of the study (2018-2019), are shown in Figure 1. According to these values, the precipitation in 2019 appears to be average for the period, while 2018 has less rainfall. Rainfall amounts in 2019 at all three locations are over 400 mm (April – October), as follows: ZP (426.6 mm); Pan (460.3) and Be (438.6). In 2018, two of the locations (ZP and Pan) had a lower total rainfall of 313.4 and 344.4 mm, respectively, while Be had 443.3 mm. The results of the ANOVA and AMMI analyses of the trials are shown in Table 1. The variances are significant for all sources of variation – locations, hybrids and their interaction. Locations have the largest variance, followed by genotype (that of hybrids). The genotype-environment interaction has a lesser appearance. In principal components analysis, PC1 accounted for 61.6% of this interaction and PC2 accounted for 18.2%. These results confirm the research of several authors (summarized by Zobel et al., (1988) and Gauch, 2006) on the dominant role of variation in environmental conditions and on PC1 of the genotype-environment interaction.

Table 2 presents the results of the test for grain yield from 6 environmental conditions - two years and three locations. Yields ranged from 8552.1 kg/ha for Kn-M-625 to 12021.8 kg/ha for the ZP-560 standard. A wide range of hybrids by vegetation groups were included in the trial. In the early FAO group (300-400) there are two hybrids; the mid-early FAO group (400-500) – five hybrids; mid-late FAO (500-600) – ten hybrids (including the standard); and in the late FAO (over 600) are three hybrids. This spectrum of hybrids roughly reflects the distribution of Bulgarian hybrids by FAO groups in the official variety list of the Republic of Bulgaria, where the mid-late group are most represented, although not all hybrids from the experiment are included in it. The arrangement by grain yield puts the standard ZP-560 in first place, but as can be seen from the LSD value at P=5%, a total of 8 hybrids do not differ from it significantly. The yield of the ninth ranked Kn-320 is 88.5% of the standard. These nine hybrids represent 45% of the experiment, as from the early group is Kn-320; the middle early group – Kn-466 and Kn-472; the mid-late group – Kn-564, Kn-568 and Kn-572; from the late group – Kn-648 and Kn-649. As a sample, the distribution by vegetation groups is approximately the same as their distribution in the entire experiment. The lack of significant differences between hybrids from different vegetation groups partially confirms the larger study of Videnović et al. (2013) on this matter.

ASV appears as a parametric evaluation of the stability of genotypes, resulting from AMMI-analysis (Purchase et al., 2000). Lower ASV values characterize hybrids as more stable under less favorable conditions. Table 2 shows three groups of this parameter: with values of

ASV<1.0 there are three hybrids; ASV=1.0 to 2.0 are eleven hybrids (the most common group); ASV>2.0 are six hybrids, the last ones can be defined as unstable. The 3 hybrids with ASV<1.0 are Kn-466, Kn-571, Kn-320, which are from three different vegetation groups, and Kn-571 is significantly lower yielding than the standard. There is no overlap between the yield ranking and ASV in the studied hybrids. Hybrids Kn-565 and Kn-569 have a relatively close ranking, the latter is not significantly different from the yield standard.
In the following Table 3, besides the average yield, the variation by hybrids, the stability parameters from the model of Eberhart & Russell (1966) and the first parameter from the model of Shukla (1972) are presented. We commented on the scope of the yield in the previous table, and the variation for the experiment is 8.85%, which defines it as weak. Variation by hybrids ranges from 10.17 to 32.24%, with ten accessions averaging between 10-20% and the other 10 genotypes is over 20 %, which defines it as strong. The first parameter bi according to Eberhard & Russell model has values <1.0 in ten hybrids, which can characterize them as stable under unfavorable conditions. In six hybrids, S2di had negative values that were determined to be zero (according to Russell 1988, personal communication).

*S^2d_i=0

Hybrid Kn-466 has parameters b_i=1.0 and S^2d_i=0, which exactly correspond to the theoretical model. Ten of the hybrids studied had b_i values, including Kn-466, of 1 and above 1, and the rest are below this value. The coefficient of determination R^2, which is taken as an indicator of genetic stability, in four hybrids (Kn-321; Kn-565; Kn-569 and Kn-572) has a value lower than 0.5. The first parameter (σi^2) of Shukla characterizes the stability of genotypes, as a result of their linear interactions with the environmental conditions. Good convergence with the S^2d_i variance from the Eberhart & Russell model is observed. The six hybrids with zero values of this parameter also have low values of σi^2. The results are in good coherency with the study performed by Pavlov et al. (2023) on different stability evaluations in late maize hybrids.

The following **Figure 2** describes the distribution of the studied hybrids by the general mean for grain yield of the trials and the first stability parameter b_i from the model of Eberhart & Russell (1966). In previous research (Vulchinkov., et al., 2021); this distribution was shown to be more correct in characterizing the genotypes in terms of their yield and stability, than the well-known model of Francis & Kannenberg (1978) using mean yield and coefficient of variation. In the figure, half of the hybrids are in the high-yield zone above the general mean of the trials, and also half of them are of the stable type (b_i<1.0). In the most interesting quadrant – higher than average yield and lower value of b_i<1.0, there are five hybrids – Kn-321, Kn-572, Kn-570, Kn-320, Kn-472 plus the standard ZP-560, and Kn-466 with a value of b_i=1.0 can also be added to them. Four hybrids – Kn-568, Kn-564, Kn-648 and Kn-649, which are in the highly productive zone, but of the “responsive” type (b_i >1.0), are also of interest for the selection. The hybrids with low ASV values (see Table 2), four accessions (Kn-320; Kn-466; Kn-472 and Kn-473) falls into the stable zone in Figure 2.

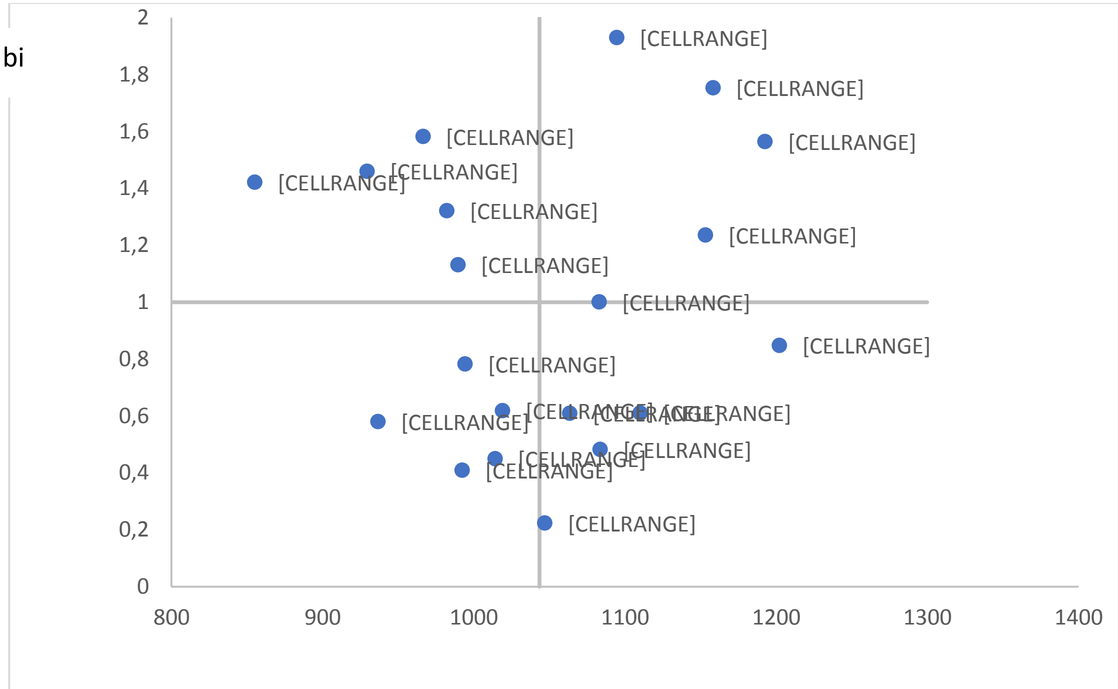

Figure 2. Distribution of 20 hybrids according general means of the grain yield (kg/ha) and first stability parameter (bi) – Eberhart & Russel (1966), tested in 6 locations, 2018-2019.

Figure 3 presents the biplot distribution of AMMI-1 for the grain yield of 20 maize hybrids tested at 6 locations. AMMI-1 operates on the average yield of the hybrids and on the first component of the PCA, that has the largest share of variation, which in this particular case is 61.66%. A high- and low-productivity zone is also observed as in Figure 2. The distribution in the high-productivity zone in terms of the coordinates of the hybrids, relative to their PC1 values, is very similar to the distribution in Figure 2.

The highly productive zone with negative interactions, which we can take as an analogue of the first quadrant (higher than the average yield and bi<1.0) of the Eberhat & Russell model (Fig. 2), practically covers the same hybrids, as only the Kn-466 hybrid (g3) falls in the second quadrant (the zone of positive interactions), in which the remaining four hybrids from

Figure 2 are also distributed. It can be tentatively concluded that good convergence between the yield and stability assessments between the two figures is observed.

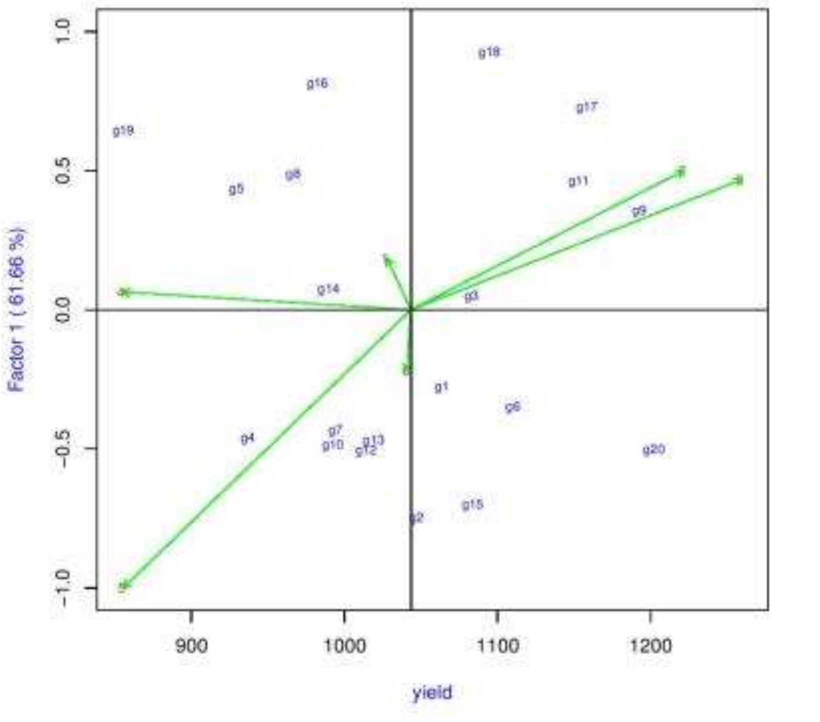

Figure 3. AMMI-1 biplot of grain yield (kg/ha) of 20 maize hybrids, tested in 6 locations, 2018-2019

AMMI-1 also provides additional information on test locations. The Be-2018 (point 2) and Pan-2018 (point 3) of Fig.3 are in the highly productive zone with positive interaction. The remaining locations are in the low-productivity zone, with Pan-2019 being the furthest from the center of AMMI-1.

Figure 4 presents the AMMI-2 biplot, on which the coordinates of the tested hybrids and their locations are plotted, with the corresponding values of their two components (PC1 and PC2). The points at the vertices of the outlined pentagon are the genotypes that are at the greatest distance from the center of the biplot, i.e. with the lowest stability. Clockwise, they are as follows: g2; g16; g18; g 17 and g15 or the hybrids Kn-321; Kn-573; Kn-649; Kn-648 and Kn-572 from Table 2, respectively. These genotypes are from three FAO groups, and their ranking according to ASV values from Table 2 places them in the last five places (from sixteenth to twentieth). Good convergence is observed in the ASV parameter evaluations and the biplot distribution from the AMMI-2 model.

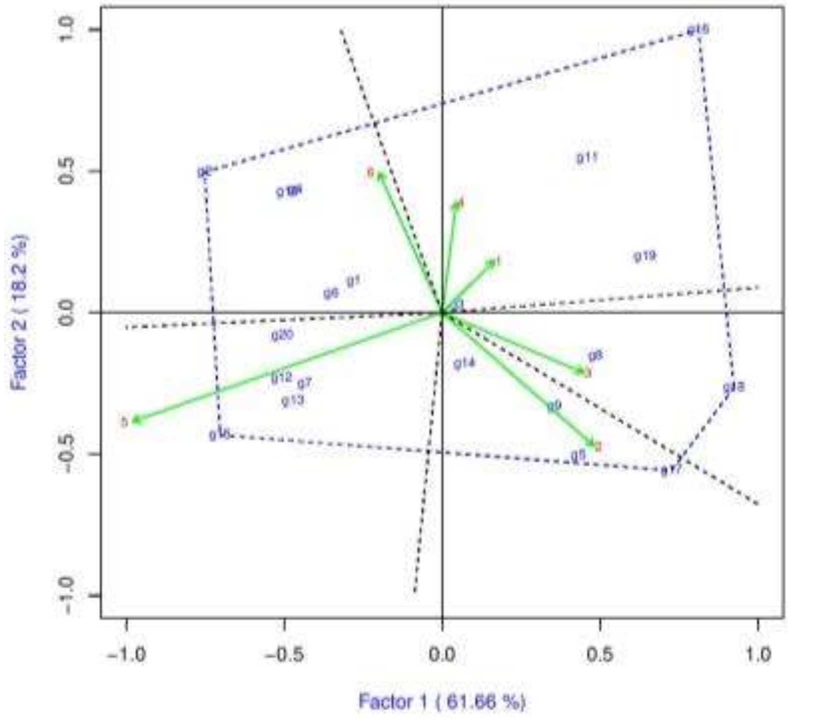

Figure 4. AMMI-2 biplot of grain yield (kg/da) of maize 20 hybrids, tested in 6 locations, 2018-2019

Of the six hybrids (Table 2) with ASV>2.0 values, only Kn-M-625 is not in the periphery of the biplot, but in the quadrant with positive interactions. At the center of the AMMI-2 is a Kn-466 (g3) hybrid, confirming its best stability, also indicated in the other models.
The PC_1 and PC_2 projections of the locations can also be seen on the AMMI-2 biplot. Pancevo has the highest principal component values for both test years. The vectors of Zp-2018 and ZP-2019 are located closest to the center of the biplot, i.e. at this location hybrids with more stable yields may also be presented.

Conclusions

The conducted evaluation of the stability of the studied maize hybrids gives us grounds for the following conclusions:

1. The average productivity of the tested hybrids is over 10 000 kilograms per hectare, and half of them are above it. There are no significant differences between hybrids from different vegetation groups.
2. Half of the studied hybrids are stable under unfavorable conditions (bi<1.0), with 5 varieties in the above-average productivity zone, including standard ZP-560.
3. Three hybrids – Kn-466, Kn-571 and Kn320, are with low ASV values, well adapted to all conditions. The stability of Kn-466 is confirmed by all stability assessment methods in the study applied.
4. A very good convergence between the distribution of the hybrids against the mean values of b_i and grain yield and the AMMI-1 biplot is observed, which is of a confirmatory nature.
5. Test conditions are better in 2018, with principal components at locations Zp-2018 and Zp-2019 being closest to the center of the AMMI-2 biplot.

Acknowledgments

Research team of Maize Research Institute – Knezha render thanks to all colleagues of Maize Research Institute – Zemun polje for the long time cooperation and collaboration.

TRADITIONS OF USING GEORGIAN WHEAT IN GEORGIA

Levan UJMAJURIDZE, Tsotne SAMADASHVILI, Gulnari CHKHUTIASHVILI

Scientific -Research Center of Agriculture, Tbilisi, Georgia
*Corresponding author: samadashvili@agruni.edu.ge

Abstract

Georgia is an ancient country of agriculture and agrarian civilization. The ancient tribes who lived here 8000 years ago, along with the creation of the first dwellings, began to domesticate and cultivate wheat and grape cultures . Georgian vine and wheat still attract great interest: Georgian vine and wine, wheat and bread are the treasures of the country and carriers of national values. Owing to the importance of wheat, people around the world have worked on the improvement of this crop for thousands of years. As a result, up to 40,000 varieties of 22 types of wheat have been created. Today, 14 of the 27 wheat species distributed in the world are grown in Georgia, of which 5 endemic species are widespread in different ethnographic parts of Georgia (Zanduri - *T. timopheevii Zhuk*, Kolkhuri Asli - *T.Karamyschevii Nevski*, Dika - *T. persicum Vav.*,Hexaploid Zanduri - *T. zhukovskyi Men. et Eriz*, Macha-*T. macha Dekapr. et Men.*.). Prominent triticologists confirm the origin and evolution of wheat in Georgia: N. Vavilov, M.Mackay, P. Zhukovsky, M. Yakubtsiner, V. Dorofeev, L. Decaprelevich, V. Menabde, P. Naskidashvili. The center of wheat culture origin is Western Georgia, namely the Kolkhida Plain, Racha-Lechkhumi. History has confirmed that wheat culture played an important role in Georgia's independence. The Georgian people created forms adapted to local conditions, which guaranteed the steady production of crops. That is why the population of Georgia has created such wheat biodiversity, which is unique around the world. Georgian endemic species are characterized by unique properties, therefore they are considered the best genetic source in world breeding. The attention of triticologists of the world is especially attracted by: Chelta Zanduri, Dika and Hexaploid Zanduri (Zhukovsky), characterized by phenomenal complex immunity to fungal diseases; Chelta Zanduri is characterized by high protein content in the grain and high degree of baking ability; the endemic species Kolkhuri Asli is resistant to various types of rust; Macha wheat is characterized by an abundance of leaf mass on the plant and the strength of the stem, well tolerates excess moisture. The native varieties of soft wheat of Georgia are very diverse, which are represented in ecological groups and are characterized by a relatively low, but guaranteed solid yield. They adapt well to dramatically changing soil-climate conditions. Their germplasm carries the necessary characteristics for modern varieties of the intensive type. Wheat traditions in Georgia have survived from the Neolithic period to the present day. The historical experience of the Georgian people in the production of wheat is one of the oldest in the world. At the end of the 19th century, Georgia still produced wheat for export.

Keywords: *wheat, traditions, endemic species, history, evolution.*

Introduction

The attitude of the Georgian people to the wheat culture is exceptional. Historically, Georgia was in a constant war with neighboring countries. From ancient times, the Georgian people were considered permanently residing people and who did not leave their home even in war times. None of the conquerors - Macedonians, Mongols, Iranians, Turks and Russians - were able to destroy Georgia. The high level of agriculture, the love of wheat and viticulture played a large role in the survival of Georgia. The writer Xenophon the First gives us information

that "the Hellenic army, passing through the land of the Muscovites of the Kartvel tribe, robbed houses where they came across a large supply of bread, which, according to the Muscovites, were distributed last year by the will of their ancestors. The freshly cut wheat was bound in sheaves. Especially a lot was "Asli" (Berdzenishvili, 1956; Mikeladze, 1967)
According to ethnographic studies, wheat cultivation in Georgia has been at high level since the ancient times. Endemic elements of material culture have survived to this day, such as "shnakvi" a simple tool for collecting keeled wheat, and a threshing tool "kevri".

Historical data on wheat in ancient times

In the works of ancient Greek historians Herodotus and Xenophon, we come across the information about the distribution of many types of wheat in ancient Georgia. The first monuments of the wheat civilization belong to the Mesolithic period, which is confirmed by archaeological excavations. Several types of wheat have been found in Neolithic settlements - Arukhlo, Khramis Gora, Shulaveris Gora. Among them are hard and soft wheat, whose age dates from 6,000 years BC (Rusishvili et al., 2019). As a result of similar archaeological excavations in a settlement in the village of Digomi, carbonized grains of Zanduri of the late Bronze age were discovered (Maisaia et al., 2005). Archaeological research in the Mtkvari-Araksi Valley revealed the remains of Tavtukhi, dating from the 4th and 3rd millennium BC (Dzidziguri, 2000). According to these materials, the primary wheat species existing in Georgia revealed phylogenesis of the wheat genus and confirmed the diversity of wheat species. Georgian farmers in ancient times gave corresponding names to all this great variety of wheat species. Georgian names for wheat by biological group were "dzveltesli" or autumn, and "akhaltesli" or spring. By species and varieties - Zanduri, Asli, Dika, Tavtukhi, Ipkli, Doli Puri, Khulugo, Khozo, Khotora. By place of origin - Chveneburi, Rachuli, Akhaltsikhe, Kolkhuri, Corbouli. These names give a peculiar folk classification of a wide variety of Georgian wheat varieties. Ecotope is a mesophyte. The distribution area - Racha, Lechkhumi, Chiatura, Sachkhere, Kvemo Svaneti. Varieties: Khulugo, Khotora, Khozo. Later Korboulis Dolis Puri and Ipkli. According to morphological characteristics - Shavtavtava, Shavtavela, Shavpkha, Tsiteli doli, Shavi dika, Tetri dika. These names are a kind of folk classification of a wide variety of of Georgian wheat varieties. According to Ivane Javakhishvili, this is not only the result of observations of farmers, in ancient Georgia there were such writers - agronomists and naturalists as Katon, Varon, Columbella and Plinus. The first information about the biodiversity of Georgian wheat belongs to Sulkhan-Saba Orbeliani (XVII century) and Vakhushti Batonishvili (XVIII century). Foreign naturalists also traveled to Georgia - Guldstadt, Georg and Klaport (18th-19th centuries). In Georgia, even today, it is possible to detect sub-contoured forms resulting from the natural interbreeding of wild and cultural forms. Such forms were discovered in the village Eredvi of Kartli area. Of all the richness of varieties that have been created in Georgia for centuries, autumn varieties of soft wheat with red grains called "Dolis Puri" are especially valuable. These varieties had the most important properties, such as high nutritional value, baking ability, and long-term storage of the baked bread. Based on its meaning, the people called it mother's bread. Thanks to these qualities, wheat played the role of a mother in the history of the Georgian people. Over the centuries, the wheat variety developed following the conditions of historical development. Georgian warriors could take bread with them to the war, which did not got staled or change its taste for two weeks. Thanks to the love of wheat culture, in the highlands of Georgia (Racha-Lechkhumi, Meskhet-Javakheti, Mtatusheti) keeled wheat is still grown today and use old Georgian terms: "Jejili" is a newly sprouted field, "Namja is what is left after harvesting, "Kalo" is a place for threshing ears, "Kevri" is a board for threshing ears, "ulo" means strong binding of wheat stems, "shnakvi" is a tool for collecting wheat.

Traditions of use of wheat in Georgia

Wheat has many uses in Georgia. By the church, it is considered as a holy culture. In the Georgian Orthodox Church from ancient times, flatbreads were made from wheat flour in honor of the holy fathers. In Tusheti, small loaves were baked, which were called “kveri”. In every corner of Georgia, church holidays are celebrated with food made of wheat grains or flour. During the holiday Barbaloba, it is customary to bake “lobiani” (a pie with beans). On Christmas in Guria they bake pies with cheese and boiled eggs. In Kartli-Kakheti, Ertso-Tianeti and Gudamakari is prepared “korkoti” (boiled wheat grains). Church rituals are celebrated in each corner in different way.

Wheat was widely used in folk medicine: pus was squeezed out of a suppurated place with the help of "khavitsi." Stomatitis was treated with roasted wheat grain, into the broth of which alum was added and was prepared infusion for rinsing. Wheat starch is used to treat cough and gastrointestinal diseases. Various ointments are made from wheat flour. Wheat flour porridge is used for gastrointestinal diseases and to eliminate hemorrhoids (wheat grains should be soaked for two days, when it germinates, dried, ground, boiled and mixed with butter and salt). Wheat malt is also used as a laxative for animals. Zanduri is used in Samegrelo to stimulate sweating in patients with fever, and patientswithneurosis are given a boiledgrain broth with honey. Macha seed broth is used to improve vision. In folk medicine, the boiled wheat grains brothis used as a refreshing drink.

Modern achievements of Georgian wheat

The multi-species biodiversity of Georgian wheat has not gone unnoticed by world scientists. Scientists in Japan, Russia, Germany, England, the United States and France are intensively working on Georgian wheat.

It is important that on the basis of endemic species of Georgia, 8 new varieties of wheat were obtained: *Tr. milinae* $2n = 28$, a naked analogue of *Tr. Timopheevii*;*Tr. Miguschovii* $2n = 42$, an immune analogue of hexaploid wheat; *Tr. kiharae* $2n = 42$, wheat spelt homolog; *Tr. Timonovum* $2n = 28$ obtained by Zanduri autopolyploidy; *Tr. fungicidum* 2n=56, obtained by Zhukovsky by crossing Dika and Zanduri;

With the participation of Chelta Zanduri in the USA, Australia, Kenya, Japan, England, many new forms and varieties of wheat were obtained: Melanopus 5, Melanopus 6, Melanopus 7, Steinwedel, Timstein, Mengavi, Lepard, SRPC 67;

The future of the Georgian wheat

The diversity of wheat created by the Georgian people over 8,000 years of activity will allow geneticists and breeders of the world to create new varieties of intensive type of wheat using modern methods. The immunity of Georgian species to fungal diseases is especially important for the future. Chelta Zanduri also has cytoplasmic sterility genes that allow the creation of hybrid wheat.Also a gene, found in Georgian soft wheat Dolis Puri 35-4 allows the restoraton of fertility. The positive characteristics of Georgian wheatspecies and soft wheat varieties are the best source for creating promising varieties and forms using gene modification and nanotechnology. This is confirmed by data from the Institute of Molecular Genetics in Liverpool. According to German researchers, in the future, humanity should consume Zanduri.

Conclusion

The Georgian people are the ancient nation, thanks to their traditions and development, have created a huge biodiversity of the wheat culture over the centuries. These traditions continue today and create new opportunities to provide the world's population with new promising source material for wheat.

Abstract

The perennial plant Hypericum perforatum, commonly referred to as balsam, is renowned for its therapeutic properties, including potent anti-inflammatory and antidepressant effects. This study aimed to evaluate the impact of various biostimulants on both the essential oil content (%) and essential oil yield (ml/ha) of balsam during its initial year of establishment. To achieve this, a field experiment was conducted at the experimental farm of the Agrotechnology Department at the University of Thessaly, located in the Larissa region. The tested factors were three different biostimulant treatments (T1: Control, T2: seaweeds, auxin 1.0 mg/lt and cytokinin 0.031 mg/lt from *Ecklonia maxima*, T3: special formulation containing amino acids 10% w/v, pure protein 11.3% w/v, sucrose 22% w/v, UV filter 10% w/v) in six replicates, for the topaz variety. Harvest took place in late July by hand and samples were dried to constant weight. Distillation was then performed using a lab-modified Clevenger apparatus. It was observed that, in the initial year of establishment, the percentage of essential oil content did not exhibit a statistically significant difference. However, due to the higher dry drogue yield of the control, there was a statistically significant difference in essential oil production compared to the other treatments. Consequently, it appears that the application of biostimulants during the first year of establishment may have an adverse effect. Nonetheless, the results from the second and third years, when the perennial plant will be at the peak of its reproductive phase, are highly anticipated.

Keywords: *Balsam, biostimulants, essential oil, Aromatic-Medicinal plants.*

Introduction

Worldwide, there are more than 480 species of tiny trees, shrubs, and herbs in the family Hypericaceae, which includes the genus Hypericum (Napoli et al., 2018; Becker et al., 2016). It originated in Madeira and is currently found all over the world (Xu et al., 2019; Nürk et al., 2013). It is native to Europe, North Africa, West Asia, India, China, and the Azores. As per Crockett and Robson (2011), several species are well-known for their ability to generate an extensive array of advantageous secondary metabolites, which are often utilized in traditional medicine.

Hypericum perforatum L. is widely utilized in both traditional and modern medicine because of its biological qualities (Ersoy et al., 2020; Sarikurkcu et al., 2020; Butterweck 2003). Nevertheless, the plant's geographic range is restricted to Europe and Asia, even with its extensive therapeutic use (Molins et al., 2014; Morshedloo et al., 2015).

As more is known about the pharmacological activity of St. John's Wort plants and the chemicals that make plant extracts unique, such as hypericin and hyperforin-like substances, interest in these plants is growing. Since then, St. John's Wort has grown to be one of the most sought-after therapeutic herbs over the past 20 years (Russo et al., 2014; Wölfle et al., 2014).

Furthermore, the quality of St. John's Wort can differ according to cultivars or subspecies, the region's geography, and harvest season (Verotta, 2003). St. John's Wort plant chemical composition is also influenced by genotype, environment, or genotypes x environment interactions (Buter et al., 1998). The various populations of St. John's Wort may differ significantly in terms of genotype and phenotype (Walker et al., 2001). Such genetic diversities are defined by morphological and biochemical characterizations (Rahnavrd, 2017).
There is little information available regarding the cultivation and production of Hypericum, even if the medical benefits of its aerial parts are widely documented (Caraci et al., 2011; Saddiqe et al., 2010; Birt et al., 2009).
The perennial shrub St. John's wort (Hypericum perforatum) is 1-3 feet tall and can reproduce both vegetatively and sexually. Important physical characteristics of H. perforatum include its taproot system, woody stems, rhizomes, runners, leaves with pellucid glands everywhere on the lamina, and cyme of yellow flowers that turn into dehiscent capsules that store seeds (Velingkar et al., 2017).
Moreover, as previously noted, St. John's wort is primarily used as a food additive and for medicinal purposes. Therefore, it is important to explore the potential for large-scale production using organic cultivation methods. To this end, biostimulants—biologically derived molecules or microbial products—should be employed. These substances, when applied to plants, enhance their natural processes and growth. (Yakhin et al., 2017).
Seaweed extracts have drawn more attention as a biostimulant category in recent years, partly as a result of studies conducted (du Jardin et al., 2015; Khan et al., 2009). According to Ali et al. (2019), these seaweed-based biostimulants improve crop productivity, root system growth, blooming, stress tolerance, and nitrogen absorption.
The objective of this study was to determine the impact of various biostimulants on the essential oil yield of Hypericum perforatum (Topaz variety) during the initial year of cultivation establishment.

Materials and Methods

On May 18, 2022, a field experiment was initiated at the experimental farm of the Agrotechnology Department at the University of Thessaly, located in the Larissa region. The aim of the experiment was to assess the essential oil yield of balsam plants. Three treatments with six replications were used: T1 was the control, T2 consisted of seaweeds, auxin 1.0 mg/lt and cytokinin 0.031 mg/lt from *Ecklonia maxima*, and T3 was a specific formulation including 10% w/v of amino acids, 11.3% w/v of pure protein, 22% w/v of sucrose, and 10% w/v of UV filter. Harvest took place by hand towards the end of July. The samples were then air-dried to achieve a consistent weight.
All measured and derived variables' collected data were subjected to an analysis of variance (ANOVA) using the statistical program GenStat (7^{th} Edition), where the $LSD_{.05}$ test criterion was used to evaluate the differences between means of the main and/or interaction effects (Steel and Torrie, 1982).

Results and Discussion

The study's findings, presented in Table 1, indicate that treatments 2 and 3 (T2 & T3) and the control treatment (T1) yielded significantly different amounts of essential oil per hectare. Specifically, the control group produced more essential oil—1194 ml per hectare—than treatments 2 and 3, which displayed lower essential oil yields of 699 and 737 ml per hectare, respectively. It is interesting to note that treatment 2, which applied algae together with auxins (11.0 mg/lt) and cytokinins (0.031 mg/lt), had the lowest yield—699 ml per ha.

This outcome contrasts with the literature (Giannoulis et al., 2020; Eisa, 2016; Elansary et al., 2016; Gehan, 2015), which suggests that the application of seaweeds generally enhances the biomass yield of various aromatic and medicinal plants. However, there is limited information available on their effects on balsam yield specifically.

Table 1. Essential Oil Content and Essential Oil Yield of Balsams' inflorescence.

	ES. OIL CONTENT (%)	ES. OIL YIELD (ml/ha)
T1	0,218	1194
T2	0,162	699
T3	0,137	737
$LSD_{.05}$	**ns**	**363,2**
CV (%)	**34,8**	**32,2**

Furthermore, no statistically significant differences were observed among the evaluated components. However, treatments T1 and T2 exhibited a numerical advantage over T3 with respect to the essential oil concentration in the flowers. Thus, it was found that none of the biostimulants increased the concentration of essential oils, contrary to findings commonly reported in the literature (Rasouli et al., 2023; Nassar et al., 2020; Fokom et al., 2019; Gehan, 2015). Consequently, as balsam is a perennial and will promote the growth of its root system in the first year of installation, the effects of the biostimulants on essential oil yield and concentration are anticipated to become more evident in the subsequent year.
Based on existing research, the use of biostimulants in field crops is increasingly prevalent. Seaweed extracts (SWE) represent a novel class of organic fertilizers that compete with growth stimulants and conventional agrochemicals (Elansary et al., 2016; Sharma et al., 2014). Studies suggest that SWE could potentially replace some fertilizers due to their content of both major and minor nutrients (Nassar et al., 2020; Zodape et al., 2010; Hong et al., 2007). The results of this study, which diverge significantly from the literature, suggest that during its establishment year, balsam, being a perennial crop, prioritizes the development of a robust and healthy root system. Therefore, repeating the experiment in the second and third growing years is essential to further investigate these discrepancies and gain a clearer understanding of the effects.

Conclusions

It appears that alternative balsam cultivation methods have yielded substantial amounts of essential oils from the initial year of establishment. However, the use of biostimulants seems to have negatively impacted the outcomes of the first year, with algae extracts demonstrating the lowest performance.
Research is ongoing, as all treatments have been repeated for the second year. Data from this year is currently being processed and analyzed.

Abstract

Lavender (*Lavandula angustifolia*), a common medicinal and aromatic species in the Mediterranean, belongs to the Lamiaceae family. It is one of the most common medicinal and aromatic species cultivated in the Mediterranean Region, including Greece, where the climate is characterized by cool, wet winters and hot, dry summers and its cultivation is preferred to produce dried lavender but also its essential oil. The objective of this study was to determine the lavender flower yield for the 2022-2023 growing season, where lavender was in the second year of its biological cycle, and to evaluate farmer’s profit as well. The experiment was set up on the farm of the University of Thessaly in Greece where the effect of biostimulants on lavender yield and their economic viability was examined. In a field experiment with three replications and six levels of biostimulant application (C: control, A: Ascophyllum nodosum algae extract, S: plant amino acids, A+S: combination of previous two, K: Ecklonia maxima algae extract, PLUS: biostimulant with absorbable calcium), all necessary procedures were conducted for two harvests in June (without irrigation) and September (with irrigation) to assess flower yield. It was observed that biostimulants K and A significantly enhanced productivity, with K exhibiting the highest increase (2599 kg/ha). Formulations A and K resulted in the highest yield. In terms of lavender cultivation economics, K emerged as the most efficient biostimulant (16.5% increase). Algae-based formulations were found to maximize agricultural profitability and flower productivity, which provides long-term promising prospects for lavender cultivation using such biostimulant formulations.

Keywords: *Lavender, biostimulants, yield, dried flowers, profit*.

Introduction

Lamiaceae family includes lavender (Lavandula angustifolia Miller), according to the ITIS (Integrated Taxonomic Information System). The subfamily Nepetoideae, which comprises the lavender species, is one of the seven subfamilies that make up the family Lamiaceae. It is characterized by its square-sectioned stems and opposing and dehiscent leaves (Héral et al., 2021).

Originally from southern Europe and the Mediterranean region, lavender is a plant that is now widely grown throughout the world, with France and Bulgaria being the two primary nations where it is grown the most (Zheljazkov et al., 2012).

The Latin verb lavare, which means "to wash, to clean," is the source of the English name "lavender." This plant, and more especially its flowers, were used in Roman baths to sanitize the body and spirit as well as to give the waters a distinctive scent (Gul et al., 2015).

Lavandula angustifolia Miller is the most widely used species of lavender due to its widespread use, high level of study, and numerous applications for its essential oil. Lavandula angustifolia Mill. is also known by the common names "true lavender," "English lavender,"

and "common lavender" (Pokajewicz et al., 2023). The term "stenofyllis" is synonymous with the plant "angustifolia" (Charles D., 2012).
L. angustifolia is a small, strongly aromatic, erect, herbaceous, perennial shrub that can grow up to 60 cm in height (Pokajewicz et al., 2023). Its leaves are sessile, opposite, linear-lanceolate, narrow, and have spirally curved edges (Fakhriddinova et al., 2020; Héral et al., 2021; Pokajewicz et al., 2023). The root is woody and branched at the top. The structure of the inflorescence is organized in apical dichotomous flower clusters, which means that it consists of a main axis with at least two secondary axes (Héral et al., 2021). The inflorescence spikes of L. angustifolia extend above the leaves and can have a variety of colors. The flowers are densely distributed at the tops of the spikelets and are either purple, blue or purple-blue (Wells et al., 2020).
An important step in the production of lavender is irrigation, which guarantees that the right amount of water is absorbed and that the water movement provides the nutrients the lavender plants need for a healthy growth and development. Furthermore, irrigation helps preserve the distinct, powerful scent associated with lavender farming (Jigău et al., 2022). The significance of irrigation for L. angustifolia yield and quality features has been highlighted by numerous research carried out in a variety of soil and climate conditions (Karamzadeh, 2003).
Although as mentioned above, lavender is drought tolerant, it requires supplemental irrigation for excellent establishment and maximum production (Kimbrough & Swift, 2009). In general, both the yield and the essential oil content of various aromatic plants, including lavender, are affected by the amount of water applied (Aqeel et al., 2023).
Since lavender is a plant with modest requirements for high soil fertility and nutrient concentration, it can grow and perform admirably without fertilizers (Salehi et al., 2018). However, it is well recognized that potassium (K), phosphorus (P), and nitrogen (N) play a major role in the development and production of essential oils in aromatic plants (Chrysargyris et al., 2016). But too much nitrogen can lower lavender's oil yield, making the plant unhealthful and weedy (Salehi et al., 2018).
In order to feed the world's growing population, agriculture heavily relies on the usage of pesticides and fertilizers. High concentrations of chemicals found in the environment, however, pose a major risk to human health, non-target animals, and the ecosystem as a whole because of their harmful effects (Mandal et al., 2023). Because of this, biostimulants are crucial to sustainable agriculture because their application helps to activate a number of physiological processes that improve nutrient use efficiency, promote plant growth, and permit a decrease in fertilizer use (Kunicki et al., 2010). A successful strategy to meet the increasing demand for non-traditional products that have minimal ecological impact, negligible adverse effects on non-target organisms, and biological activity must include biostimulants (Kocira et al., 2020; Lau et al., 2022; Pahalvi et al., 2021).
Any substance or combination of naturally occurring substances or microorganisms that modifies a culture in a beneficial way while having the least detrimental effect on it can be considered a biostimulant (du Jardin, 2015). It is important to note that biostimulants and biofertilizers are not the same thing. Rather than giving crops nutrients directly, the former help them absorb them via altering the rhizosphere and plant metabolism.
This improves crop quality, increases tolerance to abiotic stress, and improves the utilization of nutrients (Drobek et al., 2019). Ultimately, it should be noted that superior agricultural products are not invariably associated with elevated nutrient availability (Bulgari et al., 2015). According to Zamljen et al. (2023), biostimulants have applications in sustainable agriculture and can be utilized to lessen plant stressors.
Greece and the wider region of the Mediterranean basin are distinguished by the extremely beneficial soil and climatic conditions for the growth of lavender, which has led to its widespread popularity. Lavender production can be increased when the right cultivation

methods are used in conjunction with the required formulations. Therefore, the goal of this study is to determine the lavender crop's flower yield in its second year following the application of different biostimulants. Additional goals of this study were to calculate the producer's ultimate profit and evaluate economically the used treatments.

Materials and Methods

Experimental Field

The experiment was conducted University of Thessaly farm in Velestino, Magnesia, at coordinates 39^{o}2' N, 22^{o}45' E. The experimental field's soil is classified as *calcixerollic xerochrept* (USDA, 1975) and its fertility is characterized as sufficient and satisfactory, with the soil being clay-sandy (54% sand, 30% clay and 16% silt), with an alkaline pH (7.82) and the organic matter being ranges from low to moderate levels (2.51%) for Greek data. The experiment took place in the period 2022-2023.

A completely randomized experimental design with one factor and three blocks (replicates) was used. The tested factor was the application of different biostimulants. The biostimulants were applied at 6 levels (C: control, B1: *Ascophyllum nodosum* algae extract, B2: plant amino acids (predominantly glutamic and aspartic acid), B1+B2: combination of the previous two, B3: containing easily digestible calcium, and B4: *Ecklonia maxima* algae extract). For the experiment, lavender cultivation, of the species *Lavandula angustifolia*, of the second year was used. Each trial plot had a 3.15 m^2 area, measuring 2.25 m in width and 1.4 m in length.

Irrigation of the crop started after the first harvest, on 06/21/2023. Until the first cut, the crop was not irrigated. Irrigation was done through drip irrigation system with self-adjusting drippers with a constant supply of 4L/h per plant.

Two harvests took place in total during the experiment: on June 21, 2023, for the non-irrigated crop, and on September 22, 2023, for the irrigated crop.

At harvest, lavender antennae (flowers) were collected manually with a sickle from the inner row of the plot (ground coverage area 0.525m^2). The fresh weight was measured at the farm site, and then, the lavenders from each treatment were placed in paper bags and transported to the Laboratory of Agriculture and Applied Plant Physiology for drying in a hot air dryer at a temperature of 40°C, till constant weight.

The Department of Agriculture, Plant Production and Rural Environment's meteorological station, situated on the University of Thessaly farm in Velestino, provides the meteorological data.

Lastly, an analysis of variance (ANOVA) for all measured and derived variables was carried out on the collected data within the sample durations using the statistical program GenStat (7th Edition). The disparities in the means of the main and/or interaction effects were assessed using the $LSD_{0.05}$ test criteria (Steel and Torrie, 1982). The data could be thoroughly analyzed using statistics, and any differences between the variables under investigation that were discovered would be statistically significant rather than merely accidental.

Finaly, for the financial data of this work were obtained from the supply invoices of the required materials-equipment, and from the average selling price of the dried lavender flowers in the local market.

Results and Discussion

Climatic Data

The meteorological information gathered from the farm's meteorological station in Velestino was recorded and related to the experiment's requirements for the March 2023–September 2023 timeframe. The temperatures (^{o}C) and rainfall (mm) recorded every ten days for the months of March through September of 2023 are displayed in Figure 1. Specifically, the highest recorded temperatures were during the second and third 10 days of July, reaching

38.2°C and 37.8°C, respectively. The maximum temperature rises sharply from the second decade of June to the second decade of July before stabilizing until the third decade of July. Furthermore, the maximum temperature drops sharply. As predicted given the intense weather events that affected the larger region during this time, there is also a noticeable drop in the maximum temperature from the third decade of August to the first decade of September.

Figure 1. Temperature and precipitation (10-days mean values) occurring in studied site during the growing period of lavender in 2023.

In terms of precipitation, Fig. 1 indicates that the first and third 10 days of September get the greatest rainfall. More precisely, because of the flooding phenomenon in the Thessaly region, 416 mm of rain were recorded in the first 10 days of September and 224 mm in the third ten days of September. A week after the second harvest, there was a second wave of terrible weather, with the first wave occurring roughly two weeks before to the second harvest. Furthermore, rain fell during the first and second 10 days of April, with totals of 43.62 mm and 45.17 mm, respectively. This led to the quick growth of weeds in the crop. As the temperature rises, no notable rainfall is seen during the second ten days of May, which also happen to be the times when the biostimulants were applied. Eventually, there was some rainfall with a total height of 23.35mm during the second ten days of June, which is just before the first harvest.

Lavender Flower Dry Yield

Table 1's data shows that there are just numerical variations, not statistically significant differences, between the treatments for the dry weight of the flowers and the first and second cut.

Specifically, treatments B1 and B4 outperform the other treatments quantitatively in the case of the first harvest (Table 1). Upon the second cutting, the B1+B2 and B4 treatments exhibit greater values in comparison to the remaining treatments. As compared to the first and second cuts, the values of the C, B2, and B1+B2 treatments rise; the B1+B2 treatment increases by the greatest amount. By comparison, from the first to the second cutting, the costs of treatments B1, B3, and B4 drop; treatment B1 experiences the greatest value decline.

Table 1. Flower dry yield (kg ha^{-1}).

	1st Harvest	2nd Harvest
C	1081	1145
B1	1439	1055
B2	1177	1196
B1+B2	1032	1331
B3	1212	916
B4	1312	1287
LSD$_{05}$	ns	ns
CV (%)	16,7	20,9

The dry weight of the *L. angustifolia* species ranged from 17.8 to 18.8 g/plant under various phosphorus fertilization conditions, according to a study by Peçanha et al. (2021). As can be observed, the current experiment's conclusions contradict the findings of the previous study. Specifically, it was discovered that the dry weight of flowers varied across treatments in the first cutting, ranging from 25.8 to 36 g/plant, and between 53.2 and 65 g/plant overall.

While the flower dry weight yield in the current work, as indicated in Table 1, ranges from 212.8 to 259.9 g m^{-2}, in another study conducted by Seidler-Lozykowska et al. (2014) in four different lavender organic cultivation locations, the flower dry weight yield in that study was found to be between 7.8 and 38 g m^{-2}. Kucharski (2010) discovered a dry lavender flower yield of 300 to 500 kg ha^{-1} in another study, which is significantly less than what we found. Furthermore, Biesiada et al. (2008) report that during the second year of the experiment, the dry weight yield of lavender flowers under various nitrogen fertilization doses ranged from 1.34 to 1.67 kg m^{-2}. Out of all the studies described above, this one is unique in that the performance in terms of flower dry weight surpasses the results of the current research on flower dry weight across all applied treatments. This could be the outcome of the crop receiving nitrogen treatments in the Biesiada et al. (2008) study.

Finally, Sönmez et al. (2018) reported that the range of the second year's floral dry weight output was 2.90 to 113.30 g/plant. As previously noted, the yield in dry weight of flowers during the first harvest was calculated from 25.8 to 36 g/plant, and in the total number of cuts from 53.2 to 65 g/plant. These results are completely consistent with the findings of the current investigation.

Economic data

The financial data of this work were obtained from the invoices for the supply of the required materials-equipment, from the price databases of the required equipment made available by the University of Thessaly, from the payments of the works and from the calculation-estimation of the cost of personal work for the preparation of the specific experiment. These data are presented in Table 2.

Table 2. Total costs of lavender cultivation.

Establishment Costs	€ ha^{-1}	Annual Costs	€ ha^{-1}
Field preparation	250	Working Cost	600
Basic fertilization	200	Fertilization	150
Weed destruction	100	Irrigation	150
Plants cost	2000	Harvest	300
Establishment Total	**2550**	**Annual Total**	**1200**
Total Costs divided with 7 years of lavenders' life cycle			**1564**

The production in flowers for each of the various biostimulant treatment (C, B1, B2, B1+B2, B3, and B4) is displayed in Table 3. Together with the treatment costs, the gross margin is displayed when the unit sales price was set at 4.14 € kg^{-1}. Gross margin is subtracted from total cost to determine profit per hectare. The final column displays the percentage (%) impact of each treatment in relation to the gain from the control's treatment (C).

Table 3. Biostimulants’ financial

Biostimulants	**Flower yield (kg ha^{-1})**	**Gross Margin (€ ha^{-1})**	**Biostimulant quantity (L ha^{-1})**	**Biostimulant Cost (€ L^{-1})**	**Total Cost (€ ha^{-1})**	**Profit (€ ha^{-1})**	**Value Earnings (%)**
C	2226	9215,6	0	0	0	7651,6	(C-C):C 0
B1	2494	10325,2	1,5	14,5	21,75	8739,4	(A-C):C 11,8
B2	2374	9828,4	1,5	10	15	8249,4	(S-C):C 6,5
B1+B2	2363	9782,8	1,5	24,5	36,75	8182,1	(A+S-C):C 5,8
B3	2128	8809,9	1,0	50	50	7195,9	(P-C):C -4,9
B4	2599	10759,9	1,5	15	22,5	9173,4	(K-C):C 16,5

Table 3 shows that biostimulant B4 (16.5%) has the best return on value, followed by biostimulant B1 (11.8%). It is important to remember that biostimulant B3 has negative value. This finding leads one to the conclusion that it actually decreases medication production rather than increasing it or yielding a higher profit. Applying B3 biostimulant to lavender growing for flowers (dry drogue) may therefore be deemed unnecessary.

In conclusion, B4, or the treatment using the extract of *Ecklonia maxima* species algae, is the biostimulant that produces the best results when lavender is grown for flowers (dry drogue) while simultaneously increasing profit. The formulations containing algae (either the *Ecklonia maxima* species in the case of the B4 biostimulant or the *Ascophyllum nodosum* species in the case of the B1 biostimulant) appear to be the most economically advantageous of all the biostimulant formulations applied to the second-year lavender crop, as they yield the highest production and, consequently, the highest profit in cultivation.

Conclusions

The findings of this study indicate that the most profitable biostimulant formulations for the second-year lavender crop are those that contain algae (either *Ecklonia maxima* species in the case of B4 biostimulant or *Ascophyllum nodosum* species in the case of B1 biostimulant). This is because the algae-containing formulations yield the highest production, which translates into the highest profit in cultivation.

In lavender cultivation, biostimulant B1 is less effective (final product increase of 11.8%) than biostimulant B4 (final product increase of 16.5%). The biostimulants B2 (from plant amino acids, dominantly glutamic and aspartic acid), B1+B2, and B3 (containing readily digestible calcium) follow in descending order of return on value.

Using the previously mentioned biostimulant formulations containing algae appears to have a positive impact on the lavender's yield per hectare. Additionally, it maximizes the lavender crop's overall profit, making it a profitable crop with long-term potential for the Greek economy.

Abstract

Faba bean is an important annual crop and by far the most economically important species of the genus *Vicia.* Faba beans in developing countries are mainly used for human consumption, because of its high feeding value. Faba beans are of high interest to our country as well, mainly for animal feed. However, there are some problems, concerning the disease resistance, the abiotic stress tolerance, seed quality etc., that should be solved, before faba beans can be cultivated in large areas.The interspecific hybrid between faba beans (*Vicia faba*L.) and one of the closest relatives *V. narbonensis* could improve faba beans breeding, because it is an efficient way to introduce desirable traits to faba beans. Efforts to obtain the interspecific hybrid were attempted by many researchers but they did not result in the successful cross.The double fertilization in both reciprocal crosses was held, but the interspecific embryo was aborted at a very young stage because of post-zygotic barriers. In this case crossing the most compatible genotypes of the two species and the development of an embryo rescue technique for the young embryos of both species was the only way to get this hybrid.Itwas concluded that crossing the F_1 intraspecific *V. narbonensis* hybrids with *V. faba*genotypes or the *V. narbonensis* genotypes with F_1 intraspecific*V. faba* hybrids, and then culturing the pods of a 4-day-old hybrid *V. narbonensis*x *V. faba* in large numbers promised a successful hybrid in the future.

Key words: *fababean, human consumption, stress resistance, hybridization.*

Introduction

Faba beans is an important annual crop and by far the most economically important species of the genus *Vicia.* Faba beans in developing countries are mainly used for human consumption, because of its high feeding value, contributing to food protein. Faba beans (*Vicia faba*L.) is of high interest to our country as well, mainly for animal feed. However, there are some problems that should be solved before faba beans can be cultivated in large areas. Thus, the main targets in faba bean breeding except yield, are disease resistance, abiotic stress tolerance, seed quality and other agronomic traits (Gnanasambandam et al. 2012). *V. narbonensis* is a wild legume, and is one of the closest wild relatives of *Vicia faba* (Cubero, 1982), despite their differences in nuclear DNA content (Kew Science's data and resources, 2017). Furthermore, *V. narbonensis* carries many useful agronomic characteristics, such as disease resistance, winter hardiness, resistance to black aphids (*Aphis fabae*) and chocolate spot disease caused by *Botrytis fabae* (Maalouf et al, 2018), drought resistance and generally resistance to adverse environmental conditions (Lazaridou and Roupakias 1993). In addition, a gene that makes proteins rich in certain amino acids has been transferred to *V. narbonensis* (Pickardt et al., 1995*).* For all these reasons, the interspecific hybrid between the two species could help faba bean breeding (Roupakias, 1986). Efforts to obtain the interspecific hybrid were attempted by many researchers who did not succeed to cross the two species (Caracuta et al., 2016) as it was the case of other legume crops, and tried to identify the causes that did not allow the successful cross (Ramsay et al. 1984).The double fertilization in both reciprocal

crosses was held, but the interspecific embryo was aborted, at a very young stage (Roupakias and Tai 1986). In this case the development of an embryo rescue technique for the young embryos of both species is the only way in order to take this hybrid (Lazaridou and Roupakias 1993).
In this review the various efforts to obtain the interspecific hybrid between *Vicia faba* and *Vicia narbonensis* as well as the future prospects are underlined.

Interspecific hybrids between *Vicia faba* (L.) and *Vicia narbonensis* (L.)

Attempts to cross the two species began in 1974 when Van Cruchten observed that although the pollen of one species was germinated on the stigma of the other in the reciprocal crosses, it could not reach the embryosac. Pickersgillet al. (1983) reported that the fertilization occurred in a very low numbers, especially when *Vicia faba* was used as female parent. Crosses between the two species made by Roupakias and Tai (1986) in a controlled environment resulted in double fertilization in both reciprocal crosses, but the interspecific hybrid embryo sac was aborted few days later, at a very young stage. Thus, it would be useful to identify the causes that did not allow the successful cross between the above mentioned species. In addition, it was reported by Roupakias (1986) that the endosperm development of *Vicia narbonensis* was faster than the respective of *Vicia faba*. The genotypes of the two species used in the reciprocal crosses were Polycarpi (*V. faba*) and cv. A-201 (*V. narbonensis*). It was known from previous reports that there was interspecific variability in the endosperm cell cycle time of the two species *(V. faba* and *V. narbonensis*). In order to obtain the hybrid, someone must find out first if there are more compatible genotypes in either species regarding the growth rate of the endosperm. Since cultivars Polycarpi (*V. faba*) and A-201 (*V. narbonensis*) were used in the reciprocal crosses, a study of the endosperm development of *V. narbonensis* was attempted in order to indentify genotypes of *V. narbonensis* with a slower growth rate than the population A-201. To achieve this goal, seven populations of *V. narbonensis* (A-174, A-194, A-201, A-202, A-203, A-205, and A-206) were studied, in a controlled environment with day-night temperature regime 23^{o}C / 16^{o}C respectively. It was found in this work that there was intraspecific variability in endosperm cell cycle time. Additionally it was found that the populations A-174 and A-202 compared to population A-201 were more compatible with *V. faba* cultivar Polycarpi (Lazaridou and Roupakias, 1993).
In order to obtain the interspecific hybrid between *V. faba* and *V. narbonensis*, Lazaridou and Roupakias (1991) studied the embryo sac development of two varieties of *V. faba* (A-108 and A-151).The plants were grown in a controlled environment with day-night temperature regime of 23^{o}C and 16^{o}C respectively. The results revealed that both species (*V. faba* and *V. narbonensis*) followed the same model of endosperm growth but they were different in the growth rate, which is higher in *V. narbonensis*. The identification of the aforementioned populations of *Vicia narbonensis* (A-202 and A-174), possessing a lower growth rate than the respective of A-201compelled us to look for *V. faba* genotypes with an endosperm growth rate higher than that of Polycarpi. Thus, the growth rate of the embryo sac was studied in seven *V. faba* varieties (A-90, A-58, A151, Polycarpi, Tanagra, A-108, A-107) grown in a controlled environment and differences in endosperm growth rate were revealed between the genotypes studied (Lazaridou and Roupakias, 1993). It was also found that cultivar Tanagra had an endosperm growth rate higher than that of Polycarpi. This indicated that Tanagra could be more compatible with the population of *Vicia narbonensis* compared to Polycarpi. All the aforementioned data give evidence that the most compatible genotypes in terms of endosperm growth rate are A-202 and Tanagra. For this, five different crosses of *Vicia faba* x *V. narbonensis* and the reciprocal ones were done, using genotypes with smaller and larger

differences in endosperm cell cycle time (Lazaridou and Roupakias, 1993).The success of V. *faba* x *V. narbonensis* crosses ranged from 9 to 59% while the reciprocal ones ranged from 12 to 30%. The results showed that the crosses between genotypes of the two species with small differences in endosperm cell cycle time did not result in either higher fertilization rates or larger hybrid embryos. Therefore, in order to obtain the interspecific hybrid a new embryo rescue technique, applicable to young embryos of both species should be developed and this was attempted by Lazaridou et al. 1993.This attempt resulted in the rescue of 4-day-old *V. narbonensis* embryos and 11-day-old *V. faba* embryos. Results support the view that cultivation of pods of the 4-day-old hybrid *V. narbonensis* x *V. faba* in large numbers and the simultaneous isolation of more compatible genotypes in both species promises a successful hybrid production in the future (Lazaridou et al. 1993). It was found that the genotypes of *Vicia narbonensis* A-205, A-211, A-194 and A-175 responded better to embryo culture (Lazaridou et al. 1993) but did not produce higher percentages of successful interspecific crosses with *V. faba*. On the contrary, the A-201 population crossed successfully with *V. faba* but had little response to embryo culture. It was found that the intraspecific hybrids A-201 x A-205, A-201 x A-211, A-201 x A-194 and A-201 x A-175 exhibited a better response to embryo culture compared to their common parent (A-201) and a similar response to the second parent (A-175, A-194, A-205, A- 211; Lazaridou and Roupakias 1995). However, when one of the male parents was used as the maternal plant, the embryo culture response of the hybrid was higher than the one of the best parent. If these hybrids revealed good compatibility with *V. faba*, then they could be successfully used in interspecific crosses with *V. faba.* Subsequently interspecific crosses between *Vicia faba* and *Vicia narbonensis* and interspecific crosses between F_1 *V. faba* and *V. narbonensis* intraspecific hybrids were carried out (Zamani unpublished data, 1997). Four interspecific embryos were obtained, three of them from the cross (A-201 x A-194) x (A-107 x A-90) and one from the cross (A-201 x A194) x Polycarpi. However, only one of them was rescued. Besides, in faba bean, techniques such as *in vitro* culture and genetic manipulation were still very difficult to be applied compared to the same effort in many other crops (Pickardt et al. 2004).

Other researchers tried to obtain the hybrid using protoplast fusion. For this to be done Pickardt et al. (1989) tried to regenerate plants from calluses of *Vicia narbonensis* using *in vitro* culture techniques. Somatic embryos derived from calluses but the produced plants that obtained from this could not reach the maturity. A few years later, Tegeder et al. (1995) studied the regeneration capacity of ten *V. faba* cultivars. Calluses derived from protoplast fusion did not manage to induce embryogenesis but the addition of thidiazuron in the culture medium resulted in shoot development of one *Vicia faba* cultivar (Mythos). An increased content of thidiazuron with the presence of naphthalene acetic acid in culture medium affected positively the regeneration frequency of the species (Tegeder et al. 1995). Regarding the regeneration capacity of *Vicia narbonensis,* Tegeder et al. (1996) reported the positive effect of thidiazuron and the production of mature plants from somatic embryos derived from *Vicia narbonensis* protoplasts. Zenkteler et al. (1998) studied the crossability between *Vicia faba* and *Vicia narbonensis*. Several genotypes were used but only a very small percentage (78/5320) of *Vicia narbonensis* flowers pollinated *in vivo* and *in vitro* produced globular hybrid embryos. In addition only a small proportion (124/3860) of *Vicia faba* flowers, pollinated *in vivo* and *in vitro*, produced globular hybrid embryos. One *Vicia faba* line was more compatible with some *Vicia narbonensis* lines. However, the attempt to obtain the interspecific hybrid between the two species had been unsuccessful, due to disturbances in the cells of embryos and endosperm, noticed at earlier stages (Zenkteler et al. 1998). In order this procedure to become successful, more efforts are required and larger number of plants and crosses have to be involved. It should be mentioned that since 1998, due to many unsuccessful attempts, the breeders have stopped dealing with these interspesific hybrids and turned their interest to other breeding methods. However, later results encourage scientists to devote further research to this plant species known to be very recalcitrant to manipulate *in vitro* (Pickardt et al. 2004).

Conclusion and perspectives

The interspecific hybrid between *Vicia faba* and *Vicia narbonensis* could assist faba beans breeding, because it is an efficient way to introgress desirable traits to faba beans. However post-zygotic barriers may prevent the development of interspecific embryos. The various published results indicate that using more compatible genotypes of the two species in the crosses may give larger embryos that could be cultured *in vitro*. More precisely, the existing results indicate that crossing the F_1 intraspecific *V. narbonensis* hybrids with *V. faba* genotypes or by crossing *V. narbonensis* genotypes with F_1 intraspecific *V. faba* hybrids, and then culturing the pods of 4-day-old hybrids of *V. narbonensis* x *V. faba* in large numbers, could contribute to the production of a successful hybrid in the future.

Abstract

Nowadays, the role of nature conservation and animal husbandry has increased drastically due to the effects of climate change. Formerly, wood-pastures were a characteristic farming type in the Pannonian region. In the current work, we studied wood-pastures in the North Hungarian Mountain Range and in the Transdanubian Central Mountain of Hungary. Our purpose was to find out the nature conservation values and grassland management values of wood-pastures grazed by different animals. Among the sample areas of North Hungarian Mountain Range, the sample area of Cserépfalu was grazed by Hungarian Grey Cattle, while the Szurdokpüspöki was grazed by domestic water buffalo. The sample areas of Transdanubian Central Mountain were grazed by water buffalo and Hungarian Racka Sheep. Coenological surveys were between 1994 and 2024 in the main vegetation period according to the method of Braun-Blanquet. We applied the diversity and grassland management value to evaluate the state of the vegetation. Grazing of the studied livestock produced different results among the areas. Based on the results, cattle grazing resulted in a variable, mosaic-like, shrubby area with high cover values, sheep grazing resulted in vegetation with higher grassland management values and buffalo grazing resulted in a variable and nutrient rich area with optimal diversity and grassland management values. Hence, grazing by cattle provides adequate solution to create and conserve wood-pasture habitats. However, grazing by sheep forms valuable grassland with better grassland management values. Nevertheless, grazing by buffalo is probably proper for nature conservation and grassland management values as well.

Introduction

Wood pastures are one of the oldest land-use types in Europe, where livestock graze in mosaic habitats characterised by grasslands with different tree and shrub species. Over the centuries, wood pastures have been important traditional elements in Carpathian-basin as one of the dominant farming types of the country (Moreno *et al*., 2018; Burgess and Rosati, 2018) (Figure 1). The importance of wood-pasture habitats has increased significantly because of the current global climate change issues, as shrinking grasslands lead to potential for animal husbandry in areas that were formerly not considered of high management relevance.

Öllerer *et al.* (2019) provided a complex review of the effects of domestic livestock grazing on temperate forest vegetation. They concluded that successful wood-pasture conservation depends on the choice of grazing animal species and that the lack of grazing can negatively affect biodiversity and forest management. It needs to be taken into account when treating wood-pastures as semi-natural habitats (Bernes *et al.*, 2018; Burrascano *et al.*, 2013).

Figure 1. Location of Hungary (Carpathian-basin) in the map of Europe

Large herbivores have essential role in the formation of forests, shrublands and grasslands (Mitchell, 2005). Therefore, grazing livestock can contribute to the current forest-grassland mosaic (Varga *et al.*, 2020). Different native and introduced livestock such as cattle, sheep and horses can provide a substitute for wildlife activity (Póti *et al.*, 2007). The grazing type influences the vegetation structure and the yield of grassland (Naveh, and Whittaker, 1980, Török *et al.*, 2018).
There were also some investigations on the effects of grazing animal choice in Hungary. Most of the research confirms the traditional nature conservation management that cattle grazing is suitable for habitat conservation (Török *et al.*, 2014; Turcsányi-Járdi *et al.*, 2022; Penksza *et al.*, 2022). Penksza *et al.* (2024) confirmed that grey cattle grazing is a suitable practice for wood-pasture conservation. However, in this study, it was also reported that sheep also have similar grazing characteristics in mountain wood-pasture conditions.
In addition, Fűrész *et al.* (2023) studied a domestic water buffalo grazed shrubland in a mountain with a similar feature to wood-pasture. In this study found that the domestic water buffalo could be a more effective animal for habitat formation and conservation than the grey cattle because it has better digestibility (Mihailou and Massaro, 2021; Escarcha *et al.*, 2018; Warriach *et al.*, 2015).
In the current work, our aim was to study a wood-pasture from Transdanubian Central Mountain (Balatoncsicsó), which is grazed by sheep and domestic water buffalo.

Materials and methods

Data collection and surveyed areas

In the present study, authors took into account two previous studies conducted in the North Hungarian Mountain Range, which focused on the effects of domestic water buffalo, grey cattle and sheep grazing (Fűrész *et al.*, 2023; Penksza *et al.*, 2024). The current work was carried out in Balatoncsicsó (Figure 2) which belongs to the Transdanubian Central Mountain of Hungary where grazing is by domestic water buffalo and sheep. Authors conducted ten

Figure 2. Wood-pasture sample area in Balatoncsicsó

coenological surveys of the woody sample areas, ten in the grassland sample areas in 1994, 2009 and 2024 and ten in the control, untreated grassland sample area in 2024 in the vegetation period (May and June) based on the Braun-Blanquet method (1964) in 2 × 2 m quadrats. The coverage was estimated by percentage for each present species. The name of the species was recorded based on the nomenclature of Király (2009).

Statistical analysis

To evaluate data, the non-parametric statistical method was used to analyze the cover values of species of different sample areas, as these variables were not normally distributed according to the Shapiro–Wilk test ($p < 0.05$). Accordingly, the non-parametric Kruskal–Wallis test (= 0.05) was used, and the non-parametric Dunn’s test with Bonferroni correction was used for multiple pairwise comparisons (Addinsoft XSTAT, 2016).

Results and discussion

Based on the results (Figure 3), it can be seen that the wood-pasture sample areas in Balatoncsicsó have different grazing impacts in terms of changes in cover values.
Compared to the cover results of the control, untreated area, no significant results were found for several sample areas. The results of the control area were significantly different only from the data of the grassland coverage of the survey in 2009. The results of woody areas clearly show that there has been no significant change over 30 years, although the records from 1994 show less similarity with the other records. The results of grassland areas unequivocally show that there has been no significant change over 30 years, however, the records from 2009 show more similarity with the other data. The results of the woody sample area survey from 1994 were statistically significantly different from the mean cover values of grassland. Whereas the mean cover value from 2009 grassland area was significantly different from the cover values of the control area and the woody sample area. The mean cover of the control area was most similar to the data from under the trees of 2009 and 2024.

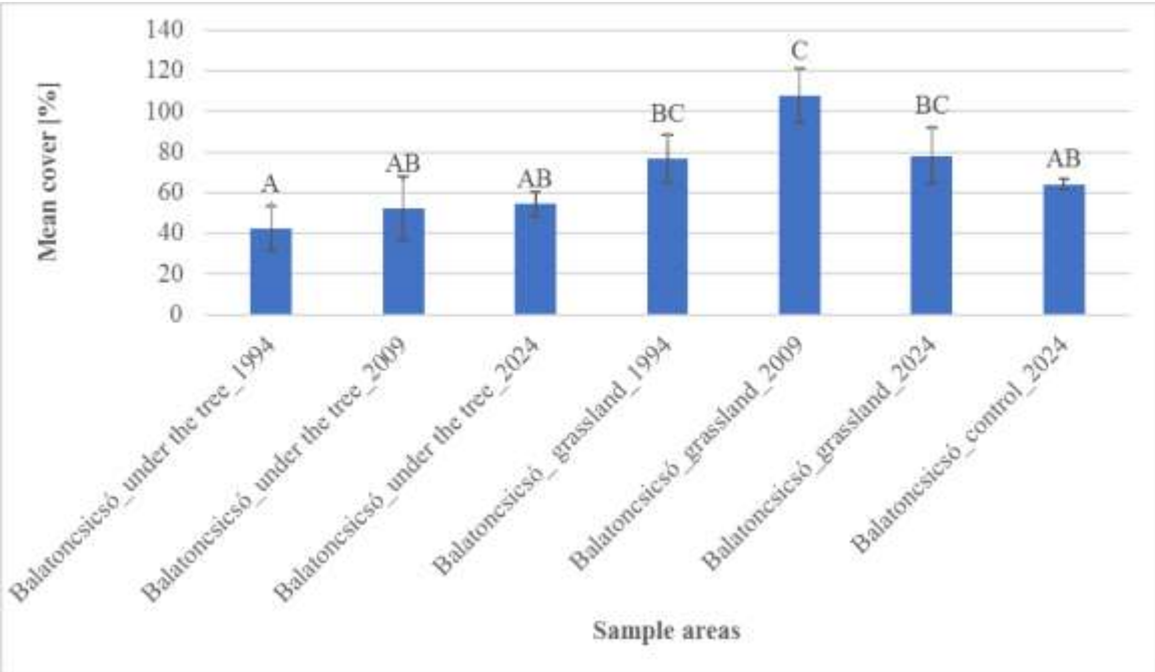

Figure 3. Cover (mean, standard deviation) in the sample areas. Based on the Kruskal–Wallis and Dunn's post hoc tests with Bonferroni correction. Bonferroni-corrected significance level: 0.005. Stand-alone letters indicate homogeneous groups (A or B or C) that significantly differ from each other. When heterogeneous groups have at least two different letters, they are not significantly different from groups with a common letter.

Conclusion

The literature review highlights the outstanding nature conservation and farming values of wood-pastures. To sustain wood-pasture, grazing is essential, but it requires the adequate choice of animal. Preliminary studies have confirmed that cattle are suitable for wood-pasture habitat conservation and biodiversity maintenance, while sheep grazing produces similar vegetation with more beneficial grassland management value. In addition, domestic water buffalo grazing, which has not been practiced in dry grasslands before, may be a more appropriate method to conserve habitat, maintain biodiversity and increase the proportion of plants with high grassland management value.

Consequently, based on the literature reviewed and the results described, it can be concluded clearly that cattle, sheep and domestic water buffalo are capable of sustaining and conserving wood-pasture biodiversity.

Nevertheless, the present work has only investigated the mean cover values, and in the future, it would be useful to carry out a Pignatti life-form data processing and the grassland management values of this sample area to obtain a more complex overview of the impact of grazing.

Abstract

The spinach *(Spinacia oleracea* L.) is an important crop in most regions of the world which is native to Iran. For evaluation of its biological diversity, sixteen landraces collected from different geographical regions of Iran and some quantitative traits remeasured as leaf length (LL), leaf width (LW), petiole length (PL), petiole diameter (PD), leaf area (LA), leaf numbers in flowering (LN), days to flowering (DF), female plants percent (FP), fresh yield (FY) and dry yield (DY). The landraces showed high variability in the morphological characteristics according to analysis of variance. Accession Arak had the high amounts of dry yield, fresh yield, leaf area and leaf numbers and regarding the importance of yield and low properties of petiole length and diameter, accession Arak followed by accessions Karaj and Birjand were identified Dendrogram analysis of a cluster constructed from genotypic distance matrices showed that sixteen landraces could be grouped into three clusters. The number of clusters was confirmed by multivariate analysis using the Wilks lambda statistic test of variance. Accessions Arak, Karaj, Rahnan, Birjand and Sirjan were grouped in cluster-I, accessions Ardestan, Zabol, Bojnord, Esfahan and Shiraz were grouped in cluster-II, accessions Brojerd, Drood, Langrood, Maragheh, Salmas and Tabriz were grouped in cluster-III. The accessions the cluster-I were useful for yield performance while the accessions the cluster-III were useful for improving the quality of spinach.

Keywords: *biological diversity, morphological variation, multivariate analysis.*

Introduction

The spinach *(Spinacia oleracea* L.) is an edible, annual vegetable plant that grows quickly and can survive mild winters. It is native to Southwest Asia and is generally thought to have originated in Iran (Swiader and Ware 2002) and was first mentioned by the Chinese as a Persian herb. It was first cultivated in North Africa, reached Northern Europe through Spain, was documented in Germany, and then was a common garden plant in England and France before 1500 (Decoteau 2000). It is versatile, used as a salad, as a cooked vegetable or as part of many other cooked meat and vegetable dishes which is rich in beta-carotene and folate and is also a good source of vitamin C, calcium, iron phosphorus, sodium and potassium. Spinach, as a dioecious species of male and female plants, is an herbaceous leafy vegetable of the Amaranthaceae family and its leaves are alternate, simple, oval to lanceolate, with larger leaves at the base of the plant and smaller leaves higher on the flowering stem.

Since Iran is the center of genetic diversity of many crops such as wheat, alfalfa, spinach, etc., it is important to conserve these important natural resources. Most *Spinacia oleracea* L. species are cultivars that are highly adapted to specific environmental conditions and are useful sources of genetic variation. However, exploiting the genetic potential of different germplasms requires detailed knowledge of their gene collections, including characterization, evaluation and classification (Lopez-Velasco et al. 2013). Multivariate procedures are useful for characterizing, evaluating, and classifying germplasm collections when a large number of accessions must be evaluated for multiple traits. The usefulness of multivariate methods in dealing with morphological variability in plant genetic resources has been demonstrated for many plants. The aim of this study was to determine the distribution structure of morphological variation for some traits in a collection of 16 original Iranian *Spinacia oleracea* L. germplasm taken from a wide geographical area of Iran and to identify groups with similar traits.

Table 1. Geographical properties of the 16 locations which spinach landraces are collected

No.	Name	Longitude	Latitude	Altitude (meter)	No.	Name	Longitude	Latitude	Altitude (meter)
1	Arak	49° 41′ E	34° 05′ N	1755	9	Langrood	50° 14 ′ E	37° 19′ N	-25
2	Ardestan	52° 22′ E	33° 23′ N	1205	10	Maragheh	46° 16 ′ E	37° 21′ N	1477

Materials and methods

Sixteen native Iranian *Spinacia oleracea* L. germplasm collections were collected and evaluated in the field in a randomized complete block design with replicated four repetitions. The geographical properties of the 16 sites of the collected *Spinacia oleracea* L. landraces are given in Table 1. Sowing was done manually in plots contained six rows and plot size was 4.5 m^2. Control by hand weeding was carried out twice when the weed density was high, in the pre-flowering and post-flowering stages. Several quantitative traits consist on leaf length (LL), leaf width (LW), petiole length (PL), petiole diameter (PD), leaf area (LA), leaf numbers in flowering (LN), days to flowering (DF), female plants percent (FP), fresh yield (FY) and dry yield (DY) were measured based on descriptors developed by Bioversity International. The obtained datasets were first tested for normality by Anderson and Darling normality test and analysis of variance was performed to evaluate differences among measured traits. The 16 *Spinacia oleracea* L. accessions were clustered via the measure of dissimilarity was Euclidean distance and the clustering method was un-weighted pair group method using Ward method. The number of clusters was determined using multivariate analysis of variance through Wilks' lambda statistics via SPSS.

Zabol	173.5	2418.1	58.7	24546.5	61.6	18.2	11.2	7.4	11.0	9.4

LL, Leaf length (cm); LW, Leaf width (cm); PL, Petiole length (cm); PD, Petiole diameter (mm); LA, Leaf area (cm^2); LN, Leaf numbers in flowering; DF, Days to flowering; FP, Female plants percent; FY, Fresh yield (kg ha^{-1}); DY, Dry yield (kg ha^{-1}).

Results and discussion

Accession Arak had the high amounts of dry yield, fresh yield, leaf area and leaf numbers in flowering while Ardestan accession showed the largest values for female plants percent, petiole length, and leaf width (Table 1). Accession Birjand had the high magnitudes of petiole length, dry yield, and leaf numbers in flowering while Rahnan accession indicated the high mean for petiole diameter, days to flowering fresh yield and dry yield. Finally, accession Shiraz was better in days to flowering, leaf area, leaf length and petiole diameter. However, the other accessions consist on Bojnord, Brojerd, Drood, Langrood, Maragheh, Salmas, Sirjan, Tabriz, Zabol were not the best in any of the measured traits. Regarding the importance of dry yield and decreeing the magnitudes of petiole length and petiole diameter for remove the high amount of nitrite content (Shi et al. 2016) as well as days to flowering to cover early maturing, accession Arak followed by accessions Karaj and Birjand were the best ones.

Agglomerative hierarchical clustering methods use the elements of a proximity matrix to generate a tree diagram or dendrogram. The dendrogram generated from accessions distance matrices showed to clear grouping pattern (Fig. 1). In a distance of cutoff point, the examined 16 spinach accessions could be agglomerated into three clusters. The number of clusters was verified by multivariate analysis of variance test through Wilks' Lambda statistics (data not shown). In cluster-I, accessions Arak, Karaj, Rahnan, Birjand and Sirjan were grouped with each other, thus they are similar in the measured traits while in cluster-II, accessions Ardestan, Zabol, Bojnord, Esfahan and Shiraz were grouped with each other, thus they are similar in the measured traits. Finally, in cluster-III, accessions Brojerd, Drood, Langrood, Maragheh, Salmas and Tabriz were grouped with each other, thus they are similar in the measured traits. Regarding the most favorable accessions (Arak followed by Karaj and Birjand), it seems that the all of the accessions of cluster-I are useful for economic targets. The long petiole length is essential for machinery harvesting and genetic improving for having long petiole length is one of the breeding targets of spinach (Sabaghnia et al. 2014). Also, the relative length of petiole is a commercial factor for the producing of spinach canner. The small petiole diameters were observed in the Langrood and Salmas were located in the cluster-III while the short petiole lengths were found in the Salmas, Tabriz and Drood were located in the cluster-III, thus the accessions of this cluster can be used for improving the quality of spinach.

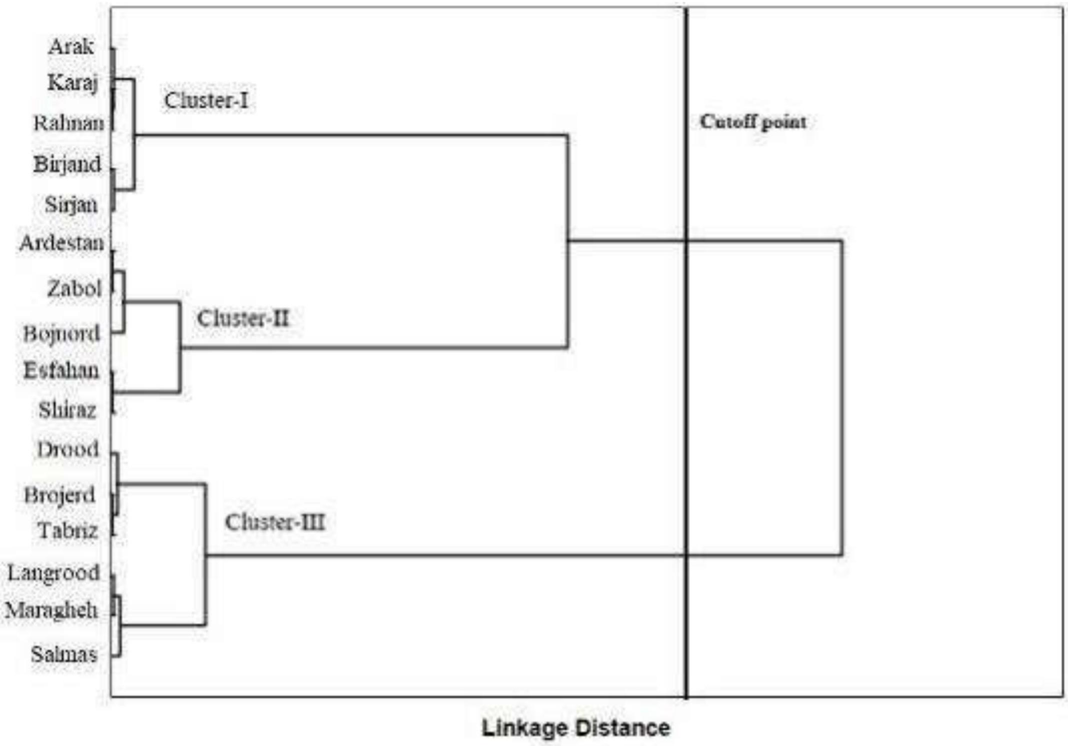

Fig. 1. Hierarchical cluster analysis of the 16 spinach genotypes based on Ward's method

Conclusion

A total of 16 *Spinacia oleracea* L. landraces were collected from different geographical regions of Iran which provided morphological data for the landraces. The dendrogram of cluster analysis for the dataset showed three groups. This investigation provided suitable information that may be useful to breeders who wish to find the most distinct spinach landraces. In conclusion, it was seen that characterization of spinach landraces based on the morphological traits was suitable to assess the diversity among collected spinach landraces. However, a high variability was observed for most measured traits and obtaining more diverse collections especially exotic germplasm is not needed for future preservation of *Spinacia oleracea* L.

Abstract

Lepidium sativum L. is one of native vegetable crops from origin of Iran which is a fast-growing edible herb. A study was conducted using 81 genotypes (77 accessions of genebank Department of Leibniz Institute of Plant Genetics and Crop Plant Research (IPK) in Gatersleben, Germany and four local varieties from different geographical areas of Iran) which were evaluated for phenological and plant structural traits. The genotype× trait (GT) biplot analysis was applied and shoed that the first two principal components of the site regression model accounted for 70% of the total interaction. The vertex accessions were G23, G59, G61, G51, G6 and G12 while important traits consist on seed and biological yield were favorable in sectors of G32 and G12 and these vertex accessions were fell in same sectors. Based on seed yield performance, accession G6 was the best genotype, followed by accessions G29, G32, G48 and G50. The results showed that the studied germplasm may be an important material for improving yield and some yield components which can be used to design efficient breeding strategies in *Lepidium sativum*. By applying GT biplot to our garden cress trials, interrelationships among the garden cress traits were clearly shown, providing more information on these relationships Our results indicated that biological diversity of *Lepidium sativum* L., may be an important source for improving some components such as number of siliques per plant, number of seeds of silique per plant and 1000-seed weight.

Keywords: *accessions, biological variation, germplasm, traits association.*

Introduction

Garden cress (*Lepidium sativum* L.) is an annual herbaceous from Iran origin, fast-growing and edible plant belonging to the Brassicaceae family. It is a plant from Southwest Asia and probably Iran that spread around the world centuries ago. The seeds and leaves are economically important; However, the crop is mostly grown for seed. It is an important green vegetable plant eaten by humans, mostly as a leafy vegetable (Sabaghnia et al. 2015). However, leaves of garden cress are mostly eaten raw in salads, but they have also been cooked with vegetable curries and used as a garnish in some centuries, for example in India (Wadhwa et al., 2012). Garden cress is a cool season annual that is grown as a salad around the world for its long leaves at the base of the stem and small bright green feathers. It can be harvested throughout the year, either indoors or outdoors, and grows abundantly in well-cultivated and well-drained soils (Sharma and Agarwal, 2011). Garden cress grows quickly and can be harvested at seed in many areas; and needs moist soil and some shade in the summer, so that the heat does not flow directly to the seeds. Little is known about the trait relationships between garden cress genotypes, so this study aimed to investigate the biologic diversity of garden cress and reveal their interrelationships and compare genotypes based on multiple traits using GGE biplot methodology that may be candidates for future programs.

Material and methods

A collection of 81 accessions, while 77 accessions were obtained from the Genome Division of the Leibniz Institute for Plant Genetics and Plant Research (IPK) in Gatersleben, Germany, and four of them were Iranian accessions named Birjand, Tabriz, Kerman and Shiraz in Iran, collected. from different geographical regions of Iran. each plot used a 9 × 9 simple grid design with four replicates, consisting of six rows spaced 0.30 m apart, 2 m long, and a plot size of 3.6 m2. Sowing was done in the first week of May, which is the optimal time for sowing garden cress. The following plant traits were at 10 random competing points per plot: height of first branch (HFB), height of first silique (HFS), length of main axis (MAL), number of lateral branches (NLB), number of cylinders per lateral branch (NSL), number of wings on main axis (NSM), number of wings per plant (NSP), number of seeds per lateral branch slice (SLB), number of seeds per main axis silique (SMA), number of silique seeds per plant (NSSP) and plant height (PH). Where possible, days to germination (DE), percent emergence (EP), days to flowering (DF), flowering period (FP) and days to maturity (DM) were also recorded. Flowering days were recorded when 50% of the plants in the experimental area had at least one open flower. A subsample of seeds harvested from each plot was measured for thousand-seed weight (TSW). Four intermediate rows were harvested to determine biological yield and seed yield. The GT biplot method was used to show genotype per trait through the first two principal components retained in the model, which is generally best for extracting structure and rejecting noise from the data. All biplots were generated using GGEbiplot software (Yan, 2001).

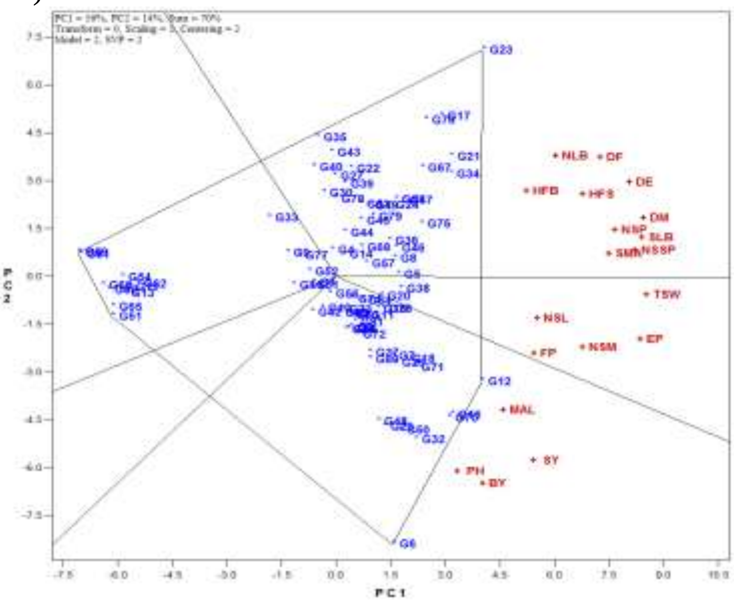

Fig. 1. Polygon-view of GT biplot representing the "which-won-where pattern of traits and genotypes.

Results and Discussion

There were highly significant differences among accessions of *Lepidium sativum* L. and the GT biplot explained 70 of the total variation of the standardized data. This percentage reflects the complexity of the relationships among the measured traits of *Lepidium sativum* L. The fundamental structures among the traits should be captured by the biplots (Sabaghnia et al. 2015). The polygon-view of the GT biplot is the best way to visualize the structure of relations between genotypes and traits. Fig. 1 represents the mentioned biplot generated from data on morphologic traits of *Lepidium sativum* L. accessions in experimental. The following information can be seen from this figure are: the vertex accessions are G23, G59, G61, G51, G6 and G12, and the trait fell into the sectors of G23 and G12. Therefore, accession G12 had the highest values of PH, MAL, SY and BY traits; and accession G23 had the highest values of the other remained traits. Therefore, there are two vertex accessions which were favorable for some traits but the rest of them (four vertex accessions) were not favorable for any *Lepidium sativum* L. traits. In the testing of different interactions for significance, one of the common practices is the tendency to apply multiple mean comparisons while these comparisons do not give extra information about the nature of interactions such as positive or negative interactions. Therefore, the GT biplot procedure, gives the same information as ANOVA as well as additional information of multiple mean comparisons (Bedassa et al. 2013). However, accessions G12, G20, G23, G32 and G53 as the vertex accessions were the most favorable accessions in the most important studied traits of *Lepidium sativum* L. On the other hand, GT biplot explained most of the variation (due to 81 *Lepidium sativum* L. genotypes main effects plus genotype × trait (GT) interaction effects. It can be said that almost all information contained ANOVA and multiple comparisons of genotype means is graphically displayed in a GT biplot. Sabaghnia et al. (2015) in *Lepidium sativum* L., also reported similar findings in the studying of effects of genotype, environment, treatment, trait and their interactions.

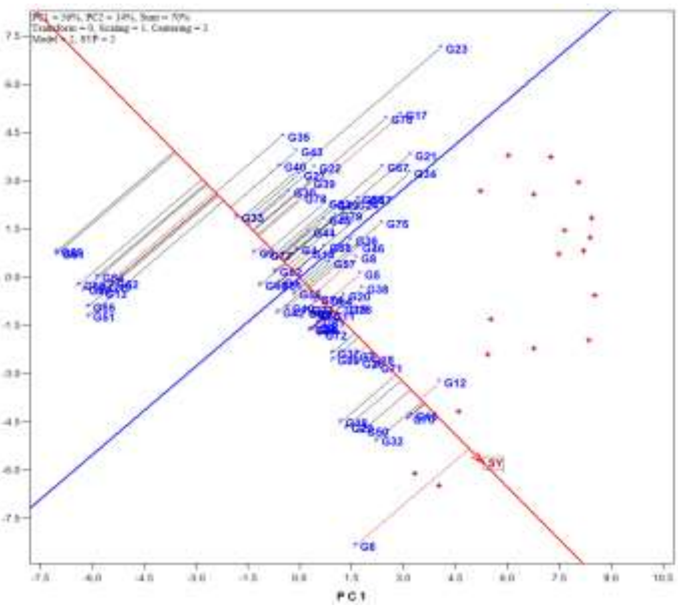

Fig. 2. The GT biplot representing ranking of genotypes based on seed yield.

For accession evaluation based on individual trait which is allows ranking of accessions based on a single trait, the seed yield trait is selected. A line as trait axis is drawn that passes through the biplot origin and the marker of the trait, and the precise position of the marker is at its left end, and the arrow on the selected axis points to increasing trait value. A perpendicular line is drawn that also passes through the origin and is perpendicular to the trait axis. Based on seed yield in year 2012 (Fig. 2) accession G6 is the best genotype, followed by genotypes G29, G32, G48 and G50. All these genotypes had above-average seed yield. Seed yield is forms via number of siliques per plant, number of seeds of silique per plant and 1000-seed weight of *Lepidium sativum* L., and biological diversity in its accessions is very important breeding objectives. Although the GGE biplot was proposed for the analysis of experiments involving multiple environments, it is applicable to any bidirectional set, such as a genotype × trait bidirectional data set. Different features have different units, and the units must be eliminated by standardization before biplot analysis. There is no doubt that the biplot of the first two principal components is more effective than conventional analysis methods if their calculated variance was appropriate. In addition, a biplot shows a graphical representation of the genotype × trait bidirectional pattern, and visualization of the data set is easy with GGEbiplot (Yan and Rajcan, 2002). The two-plot shows a complete picture of the relationships between genotypes and traits. For the above reasons, we recommend using the GGE biplot model to analyze the garden cress dataset. Similar reports showed that GT biplots were an excellent tool for visualizing genotype × trait data and revealing relationships between traits.

Conclusion

Our results indicated that biological diversity of *Lepidium sativum* L., may be an important source for improving some components such as number of siliques per plant, number of seeds of silique per plant and 1000-seed weight. By applying GT biplot to our garden cress trials, interrelationships among the garden cress traits were clearly shown, providing more information on these relationships. Given the importance of biological diversity regarding to seed yield, the high yielding accessions will need to be selected in *Lepidium sativum* L. programs.

GRAPHIC ANALYSIS OF GENOTYPE BY TRAIT INTERACTION IN SAFFLOWER USING BIPLOT METHOD

Naser SABAGHNIA*, Mohsen JANMOHAMMADI

Faculty of Agriculture, University of Maragheh, Maragheh, Iran
*Corresponding author: sabaghnia@yahoo.com

Abstract

Safflower is a neglected crop with many traditional and industrial uses form high quality edible oil to cheaper substitute for saffron. In this study, 81 safflower genotypes were evaluated in a 9×9 simple lattice design for number of plants per plot (NPP), plant height (PH), height of the first lateral branch (HFL), height of the first lateral capitulum (HFC), stem diameter (SD), number of lateral branches per plant (NLB), number of main branches per plant (NMB), number of capitula per plant (NCP), number of seeds per main capitulum (SMC), number of seeds per lateral capitulum (SLC), seed yield (SY) and thousand seed weight (TSW). The genotype by trait (G×T) interaction biplot model was used to indicate the pattern of G×T interaction two-way interaction data in a graph and showed that the first principal component effect explained 49%, and the second principal component, 24%, of the total mean squares interaction. The vector-view displayed that NCP with NMB, and SMC with SY were positively associated while there was a negative association between HFC with TSW, and between NLB with NPP. The polygon-view graph is divided into eleven sectors, and the sector of genotype G80 was winner for most traits. Genotype G58 followed by genotypes G30, G33 and G72, were the most favorable genotypes in the regard of SY while regarding this trait as a reference, SMC was identified as most related trait which is followed by SLC, SD. Applying G×T biplot to the safflower multiple trait data demonstrated that this model graphically displayed the interrelationships among seed yield with number of seeds per main and lateral capitula followed by number of capitula per plant and thousand seed weight, and facilitated visual genotype comparisons and selection. It was found that selection for seed yield alone was not only dependent to number of seeds per main and lateral capitula, but also related to the other traits in safflower breeding.

Keywords: *Yield components, seed yield, principal component analysis.*

Introduction

Safflower (*Carthamus tinctorius* L.) as an oilseed crop from Asteraceae family is a diploid (2n=24) annual herbaceous crop, is originated in the Middle East and cultivated since thousands years ago. The genus *Carthamus* has 25 species and is well adapted to hot and dry climate conditions of arid and semi-arid environments while only C. tinctorius is cultivated as crop worldwide (Rathnakumar and Sujatha, 2022). However, safflower is a drought tolerant crop and can be well adopted in rain-fed agriculture system. Kazakhstan is the largest safflower producer (35%), following to Russian Federation (24%) and United States (10%) in the world with the highest acreage (43%) to Russian Federation (28%) and United States (6%) and seed yield is for the vegetable oil market (FAOSTAT, 2021). According to statistics of FAOSTAT (2021), the highest mean yield performance is belonging to United States (5463 kg ha^{-1}), India (4647 kg ha^{-1}) and Mexico (3110 kg ha^{-1}). Safflower is cultivated on 3700 hectares in Iran, average yielding 1320 kg ha^{-1} and quantity 4889 ton (FAOSTAT, 2021). Regarding the global average seed yield of safflower (1600 kg ha^{-1}), the performance of this

crop is low (about 20% lower) in Iran, and considering the highest mean yield in the world, is very low (about 75% lower), thus it must be improved through a strong breeding program.
Safflower is a good valuable crop which contains flavonoids, lignins, triterpene alcohols and polysaccharides as well as anticoagulant, antioxidant and neuroprotective (Adeleke and Babalola, 2020). It is rich in magnitudes of oleic acid as well as linoleic acid and is very similar to olive oil, and is considered as one of the most ancient important oilseed crops worldwide (Joshan *et al.,* 2019). The press cake or oil cake after industrial oil extraction has good protein content that is used as animal feed while its seed oil yield is about 40% similar to sunflower and olive oil yield performance. Safflower is a multipurpose crop and its products are used as bird feed seed, medicinal plant with special uses, livestock forage, instead of saffron in foods, teabags, or as ornamental cut flowers. In most plant breeding programs, the germplasm is measured to identify the most important lines and the efficiency of a selection project depends on the magnitudes of genetic diversity. Therefore, the genetic variation is evaluated through measuring some characteristics like morphological traits (Gholami *et al.*, 2018). Safflower shows high genetic variation across various environments of the world and there is only a limited researches assessing its genetic variation according to agronomic as well as morphological traits.
Khan *et al.* (2009) assessed genetic variation for 193 safflower accessions from forty countries and eight geographical regions and showed that cluster analysis as well as and principal component analysis demonstrated wide genetic diversity in germplasm and a considerable potential for improving this crop for both agronomic and quality traits. Shinwari *et al.* (2014) evaluated 122 safflower genotypes collected from various eco-geographical regions of the world and indicated that the largest variation was belonged for number of capsules per plant, number of seeds per capsule, seed yield per plant, plant height, days to flowering initiation and days to maturity. They showed that principal component analysis displayed that the traits that mainly distinguish the germplasm were, capsule diameter, number of capsules per plant, number of seeds per capsule, days to maturity, plant height and time of flowering. Gholami *et al.* (2018), studied sixty-four safflower genotypes based on twenty traits and reported high variation for the number of wizened seeds per lateral capitulum, seed weight of lateral capitulum, number of lateral branches, number of capitula per lateral branches, diameter of main capitulum, yield of single plant, thousand seed weight and seed yield. They categorized these safflower genotypes into five clusters but they are not separated based on their geographical origins. This study encompassing 81 various germplasm of safflower from various agro-climatic regions of the world using some of agronomic and morphologic traits will add good information for knowledge of safflower breeders and aid them in future projects.

Material and Methods

In growing season 2021, 81 safflower genotypes from different eco-geographical were cultivated in experimental field in University of Maragheh (37°23′N; 46°14′E), where average rainfall is 322 mm with 12.5 °C annual temperature. It is a highland semiarid zone and the soil texture was sandy loam type with 1.6% organic matter. The trial was carried out in a 9×9 simple lattice design and the size of each experimental plots was 1.0 × 2.0 m^2 with 4 lines per genotype and row width 0.25 m. Hand drill sowing following to thinning was carried out and crop was grown under rainfed circumstances with two supplemental irrigations in the reproductive stage. Number of plants per plot (NPP), plant height (PH), height of the first lateral branch (HFL), height of the first lateral capitulum (HFC), stem diameter (SD), number of lateral branches per plant (NLB), number of main branches per plant (NMB), number of capitula per plant (NCP), number of seeds per main capitulum (SMC), and number of seeds per lateral capitulum (SLC) were measured from ten randomly selected plants from each plant based on safflower (*Carthamus tinctorius* L.) Standard Descriptor of International Board of Plant Genetic Resources (IBPGR), FAO, Rome, Italy. Seed yield (SY) was recorded at physiological maturity and adjusted to 12.5% seed moisture content and then thousand seed weight (TSW) was measured using three random sub-samples of the seed yield from each plot. The dataset was tested for normality by the Anderson and Darling normality test using Minitab version 14.0 (2005) statistical software and phenotypic linear correlation coefficients were calculated for all possible comparisons using the Pearson correlation coefficient to all the measured traits. The genotype by trait (G×T) interaction biplot model (Yan and Frégeau-Reid, 2018) was used to indicate the pattern of G×T interaction two-way interaction data in a graph based on the following formula:

$$\frac{Y_{ij}-\mu_j}{\sigma_j}=\sum_{n=1}^{2}\lambda_n\xi_{in}\eta_{jn}+\varepsilon_{ij}=\sum_{n=1}^{2}\xi_{in}^{*}\eta_{jn}^{*}+\varepsilon_{ij}$$

where Y_{ij} is the mean of genotype i for trait j, μ_j is the mean of all genotypes in trait j, σ_j is the standard deviation of trait j among genotypes, λ_n is the singular value for principal component n (PC_n), ξ_{in} and η_{jn} are scores for genotype i and trait j on PC_n, respectively, and ε_{ij} is the residual value of model related with genotype i in trait j. To obtain symmetric scaling in the scores of the genotypes and traits, the singular value λ_n has to be absorbed by their singular vectors (ξ_{in} and η_{jn}) as the adjusted ones; $\xi_{in}^{*}=\sqrt{\lambda_n}\xi_{in}$ and $\eta_{jn}^{*}=\sqrt{\lambda_n}\eta$. The G×T interaction biplot graphs are drawn by plotting the symmetric scaled scores of the genotypes as well as traits, so that each genotype (entry) or trait (tester) is shown by a special marker in each generated graph. For more details about G×T interaction biplot model and other types and applications of biplots for two-way structures, see Yan and Frégeau-Reid (2018). The ordinary statistical analyses were carried out using IBM-SPSS version 23.0 (IBM-SPSS, 2015) and G×T interaction biplot graphs were generated by GGEbiplot software (Yan, 2001).

Results and Discussion

The genotype by trait (G×T) interaction biplot model indicates that the first principal component effect explained 49%, and the second principal component, 24%, of the total mean squares interaction. The G×T biplot model can evaluate and explore the nature and structure of genotype by trait interaction effect, effectively. Results of analysis of variance is a perquisite option to decide whether a trait has to proceed for t the G×T biplot model or not (Yan *et al.*, 2011), thus in case of significant differences between interaction of main factors i.e. genotypes and traits, one should go for the G×T biplot model while in case of non-significant interaction use of the G×T biplot model is of no use. Analysis of variance for various traits of safflower (results are not shown) verified to proceed for the G×T biplot model as there were highly significant variations among genotypes and traits effects for all safflower genotypes. The vector-view of the G×T biplot model (Fig. 1A), displays the interrelationships among measured traits of safflower whereas the rays connecting the traits to the biplot origin are showed as trait vectors and the associations between traits are estimated by the cosine of the angle between their vectors. Two traits are associated positively if the angle between their vectors is less than 90°, associated negatively if the angle is more than 90°, independent if the angle is 90°, whereas, traits with longer vectors are significant and more responsive while traits with shorter vectors are less significant and responsive as well as those located at the graph origin are not correlated with the other traits or not-responsive (Yan and Fregeau-Reid, 2018). Fig. 1A, shows that the number of capitula per plant (NCP) and number of main branches per plant (NMB) were positively associated as indicated by the small acute angles between their vectors. Also, number of seeds per main capitulum (SMC) and seed yield (SY) were positively correlated as shown by the small acute angles between their vectors. On the other hand, there was a negative association between height of the first lateral capitulum (HFC) with thousand seeds weight (TSW), and between number of lateral branches per plant (NLB) with number of plants per plot (NPP) as shown by the large obtuse angles between their vectors (Fig. 1A). Also, there was a near zero association between TSW with NPP, between HFC with NPP, and between PH with NLB because their near perpendicular vectors. Most of above results are good consistent with those reported by Pearson’s correlation matrix (Table 1), whereas the predictions of the G×T biplot model for traits’ associations can be confirmed from this matrix but some are not consistent because the model described only 73% rather than 100% of the observed mean squares.

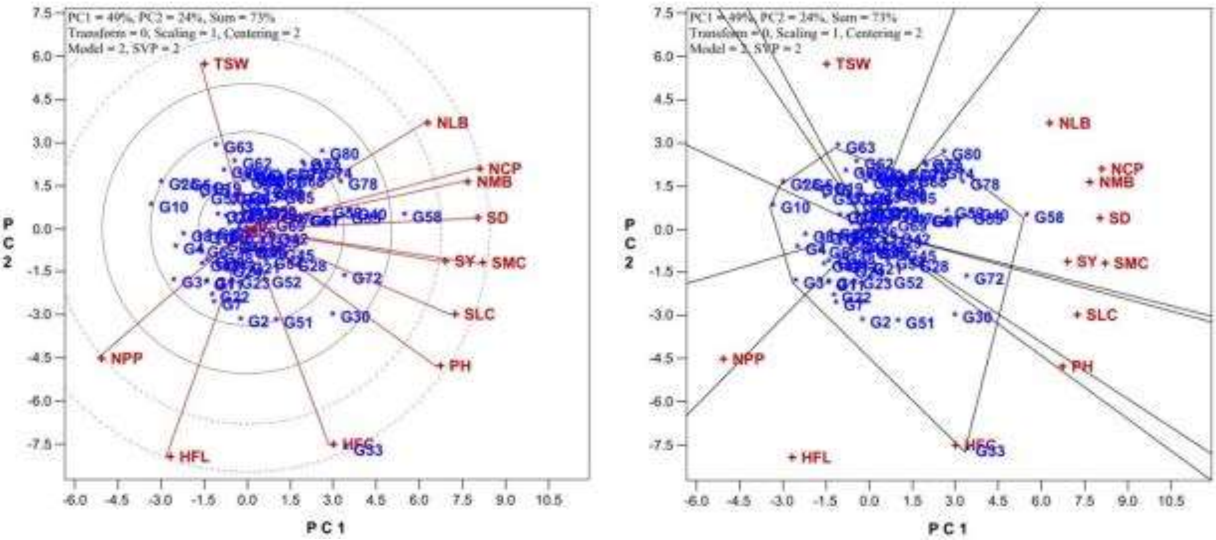

Figure 1. (A) Vector-view of G×T biplot showing interrelationships among traits and (B) Polygon-view of G×T biplot indicating the which-won-where pattern for safflower genotypes.

Among different options of the G×T biplot model, the polygon view provides detection of genotypes with the highest magnitudes for one or more traits and helps to find the best way for graphic interpretation the G×T interaction statures among traits and genotypes. For this purpose, the farthest genotypes from the graph origin are lined with straight lines and a polygon is generated with other genotypes contained within the vertex genotypes. The vertex entries (genotypes) are the most responsive ones as the best or the poorest in some or all of the measured traits while the perpendicular lines are drawn from the graph origin for categorizing the graph into several sections, each having a special vertex entry. In the G×T biplot model, the polygon-view graph (Fig. 1B) is divided into eleven sectors, and the sector contains genotype G80 on the polygon vertex winner for most traits consist on number of lateral branches per plant (NLB), number of main branches per plant (NMB), number of capitula per plant (NCP), number of seeds per main capitulum (SMC), stem diameter (SD), seed yield (SY). While genotype G33 is situated on the vertex of another sector with height related traits as plant height (PH), height of the first lateral branch (HFL) and height of the first lateral capitulum (HFC) (Fig. 1B). Genotype G3 is situated on the vertex of another sector with number of plants per plot (NPP) while genotype G63 is situated on the vertex of another sector with thousand seeds weight (TSW), and genotype G58 is situated on the vertex of another sector with number of seeds per lateral capitulum (SLC). The identified vertex genotypes in each section gave the highest performance for the traits that fall within that section while the other vertex genotypes did not give the highest performance in any of the traits and were the poorest genotypes in some or all of the traits.

The center of the circles in Fig. 2A indicates the position of an ideal entry, which is determined by a projection on to the section axis that is equivalent to the largest vector of the entries that had grater performance than mean and by a low projection on to the vertical axis while a genotype is more desirable if it is closer to this position. Thus, genotypes G72 and G30 following to genotypes G58 and G33 were more desirable than other genotypes while the low desirable genotypes were G10 and G21 because they were far away from the position of ideal entry. An ideal tester should be differentiating of the genotypes and representative of the main goal trait and regarding that the testers or traits are representative items of the main goal trait, the ideal tester should be on the mean traits coordinate axis. The center of the circles shows the ideal tester, which has the largest vector of the traits that had positive projections onto the mean traits coordinate axis (Fig. 2B). A measured trait is more desirable if it is closer to the ideal tester, therefore, number of seeds per lateral capitulum (SLC) was desirable trait followed by number of seeds per main capitulum (SMC) and seed yield (SY). In the next step, plant height (PH) and stem diameter (SD) were relatively desirable traits, whereas thousand seeds weight (TSW) and number of plants per plot (NPP), were relatively undesirable traits.
We found highly significant association between seed yield with number of seeds per main and lateral capitula as well as number of capitula per plant which are in agreement with report of Shinwari *et al.*, (2014) and Gholami *et al.*, (2018), who recorded that number of seeds per capitulum had highly significant positive contribution with seed yield performance. To improve yield, number of seeds per capitulum and number of capitula per plant are important traits following to thousand seeds weight based on report of Ahmadzadeh *et al.* (2012). The higher seed production of safflower was mostly associated with number of capitula per plant and number of seeds per capitulum (Johnson *et al.*, 2012). In our study high branching and more capitula or more seeds per capitulum were found as the most influencing traits on yield performance. However, it seems that for improving seed yield performance in safflower, it is better to focus on more number of seeds per capitulum and then try to increase number of capitula per plant and thousand seeds weight. Also, we found genotype G80 following to genotype G58 as the best for most traits especially number of main and lateral branches, number of capitula per plant, number of seeds per capitulum and seed yield while genotype G63 is a good source for high thousand seeds weight. We found that, seed yield, number of seeds per main and lateral capitula and plant height had the high discriminating potential as well as the high representative ability based on ideal trait biplot. Thus, the mentioned traits indicated both properties and can be advised for screening of genotypes reliably in a large scale, because it was good representative of all measured traits and cold discriminated studied genotypes (Sabaghnia *et al.*, 2016).

Conclusions

Although, the genotype (G) plus genotype by environment interaction (G×E), GGE, biplot methodology was originally used for multi-environment trials interpretation, but it is applicable to two-way type as an entry by tester pattern, such as a genotype by trait (G×T) two-way matrix. The main difference between two above procedures is that in GT data, various traits have different units, so a standardization is needed before analyze. Successful safflower genotypes need to be improved based on effective selection indices in order to ensure their yield performance and economic profitability. It is clear that the G×T biplot method is an excellent procedure for graphic analysis. Compared with common methods, the G×T biplot method has some advantages, including graphical presentation, increase breeders' ability to understand the data pattern, interpretative potential of the G×T biplot method, facilitating pair-wise genotype comparisons, ranking genotypes based on the target trait, and identification of possible groups of genotypes as well as traits.

MECHANICAL PEAR HARVESTING WITH THE "MULTIBASKET" SYSTEM

Roberto TOMASONE*, Carla CEDROLA, Mauro PAGANO

CREA Research Centre for Engineering and Agro-Food Processing, Italy
Via della Pascolare 16, 00016 Monterotondo (RM), Italy
*Corresponding author: roberto.tomasone@crea.gov.it

Abstract

Modern fruit growing requires technical innovations to ensure sustainability, reduce labor costs and overcome lack of skilled harvest employees. To solve these issues, CREA-IT researchers designed an innovative plant-machine system for mechanical fruit harvesting, both for fresh market or processing. The “Multibasket” prototype was developed for harvesting apples and pears from narrow, 45° inclined, “X” shaped trellises. The self-propelled machine has a harvesting frame equipped with multiple baskets to catch the fruits detached by means of four impact rods from the fruit-bearing surface. A soft-roller conveyor belt carries the fruit to the rear end with an automatic bin-filler to store the fruits. This paper presents the results obtained by the prototype in mechanized pear harvesting on an experimental field. Yield and quality parameters of the crop were measured. The machine operating parameters and work quality were evaluated by establishing detachment efficiency, fruit losses and fruit damage. The innovative prototype design proved to be efficient, including the self-propelled frame and the hydraulic system to move the mechanical parts. The rods for detaching the fruit were effective and damage to branches was negligible. The automatic controls allowed for an optimal alignment of the vehicle to the rows and to the fruit-bearing surface. The "Multibasket" prototype showed good harvest efficiency, achieving detachment rates higher than 85%. However, recorded fruit losses to the ground were high (24%), requiring the need to optimize the design of the “multi-basket” intercepting frame. Fruit damage was acceptable and lower than approximately 20%.

Keywords: *orchard mechanization, harvest quality, fruit damage, picking efficiency.*

Introduction

Modern fruit growing requires continuous technical-economic innovations to rationalize farm management, improving production and revenue. Profits can be increased both by improving fruit quality and thereby increasing the price of the product, even if restrained by the global market competition, and by reducing cultivation costs. In economically advanced countries, however, it is necessary to limit fruit production costs, in particular by reducing the use of labor, which, in addition to accounting for up to 50% of cultivation costs, is often difficult to find, especially in the peak harvesting season. To achieve this goal, CREA-IT has long since proposed an integrated plant-machine system for a fully mechanized harvesting of fruit for processing and in some cases, depending on the species and variety, also appropriate for fruit proposed for fresh market (Colorio, 1993).
The *Multibasket* prototype, which was designed, built and tested in CREA's experimental fields for several years, especially for apple harvesting, demonstrated optimal interaction with 45º inclined fruit-bearing trellises. In order to achieve these inclined walls, Y- and X-shaped training forms were proposed and tested (fig. 1 and 2), specially designed for this integrated plant-machine production system (Colorio, 1986). With a first innovative prototype, hereafter referred to as *Multibasket 1*, promising results were obtained and the indications from numerous experimental harvesting trials made it possible to design a second prototype,

referred to as *Multibasket 2*, in order to increase the efficiency of the system. This new machine (Multibasket 2) was later constructed in order to improve the efficiency of the integrated harvesting system. A further opportunity to expand the field of use of the Multibasket system arose from the experimental harvesting trials with pears of *cv.* Decana del Comizio and *cv.* Williams, destined for the agro-food industry. However, it was possible to establish that the quality of the work carried out in the harvest trials by both machines, which are compared in the present paper, allows for a product that is also suitable for the fresh-consumption market (Colorio *et al*, 1994).
The aim of the present paper was to evaluate the operative performance of the two prototypes, carrying out mechanical harvesting trials in the experimental pear orchard established at CREA-IT Extension Field. In particular, the purpose was to assess the improvements achieved with the second prototype, to confirm the validity of the design modifications.

Figure 2. "Y" shaped trellis

Materials and Methods

Based on tests carried out over several years of research and development, the study was set up to increase the efficiency of the integrated machine-crop system with the adoption of improved modifications to the Multibasket prototype (Colorio and Beni, 1995b).
Compared to the Multibasket 1, the Multibasket 2 model has undergone modifications in the following components: self-propelled frame with integral hydraulic drive; hydraulic system for operating the various mechanisms of the harvesting machine; automatic system for approaching and positioning the Multibasket interceptor frame to the trees (with associated detachment rods and harvesting devices); innovative system for detaching the fruit by means of a dynamic impulse at the base of the rod (for each of the 4 horizontal rods); conveyor belt system for transferring the fruit to the storage bins located at the rear of the machine; automatic system for filling the plastic pallet bins with fruit (fig 3 and 4) (Colorio and Tomasone, 2002).

Figure 3. side view of Multibasket 1

Figure 4. side view of Multibasket 2

Particularly significant innovations were made to improve the functionality and efficiency of four systems that had shown limitations in the first design. Each innovation realized is analyzed and described below.

A first important improvement was made to the design of the fruit detachment system, allowing a reduction in the level of damage to the branches, which had been observed in the harvest trials with the first prototype. The fruit detachment system consists of four rods mounted on the multi-basket frame. Each rod is kept in contact with the fruit-bearing wall surface at all times by means of a spring mechanism. Fruit detachment is achieved using dynamic impulses produced by a beating mass inserted at the base of each rod (fig. 5 beater schematic). This mass is loaded by a spring mechanism, accumulating elastic potential energy which, when released, imparts a strike to the base of the rod itself.

This operating mode makes it possible to indirectly transfer acceleration (via the interposed rod) to the fruit walls without a direct impact on the vegetation, thus avoiding injuries to the branches and twigs that occurred with the first prototype in which the rod directly struck the inclined fruit wall.

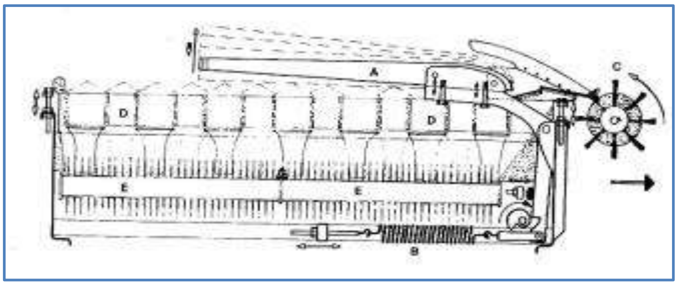

Figure 5. schematic of rod mechanism: A) impact rod; B) spring; C) brush roller; D) intercepting frame; E) roller conveyer

A second change to the prototype regarded the arrangement of the line of conveyor belts, which carry out the transfer of the detached and intercepted fruit from the inclined 'multi-basket' frame to the rear bins filler.

This system of conveyor belts, equipped with soft rollers, is divided into two contiguous sectors. The first sector is placed underneath the 'multibasket' frame, and intercepts the fruit released from the baskets and consists of three transversal belts placed side by side.

Figure 6.: a) transversal belts; b) longitudinal belt.

Figure 7. Rear view Multibasket 2

This first group of three side-by-side conveyer belts (fig. 6a) allow the fruit to be transferred and discharged evenly onto a subsequent longitudinal belt, mounted on the opposite side of the inclined frame (fig. 6b). In the first machine model, the transversal belt was a single belt as wide as the intercepting frame and the fruit was discharged onto the central area of the longitudinal belt. This solution caused the accumulation of fruit along the center line of the longitudinal belt, resulting in subsequent unevenness in the filling of the bin. The subdivision into three belts, with attachment in three different zones of the longitudinal belt, avoids the accumulation of fruit in the central part, which is unfavourable for optimal bin filling. The second belt arranged longitudinally with respect to the machine, transports the harvested fruit towards the rear of the machine, where the automatic palletized bin filler is mounted (fig. 7). The latter is equipped with a

series of pairs of counter-rotating rollers that gently accompany the fruit into the box, which is simultaneously moved forwards and backwards on two rear forks, aligned parallel to the longitudinal axis of the machine. The filling mechanism lowers the bin as it fills, for depositing the fruit in stratified layers (Colorio and Beni, 1995a).
Compared to the first prototype, the system for automating the alignment of the multi-basket intercepting frame to the inclined fruit-bearing surface has also been optimized. The system was implemented using three contact-rods mounted on the frame, which control its movement automatically. The first rod controls the lateral distance of the frame from the fruit wall, the second controls the height of the frame from the ground, and the third controls the angle of inclination of the frame so that it is perfectly aligned with the inclined fruiting surface (fig. 8).
Harvest trials were conducted in an experimental field with two pear cultivars, *cv.* Williams and *cv.* Decana del Comizio, trained in the X shape trellis, inclined at 45º, planted in 2010 at CREA-IT Research Centre (Monterotondo, Italy). The characteristics of the pear orchard are shown in Table 1. A new "X-shaped" support system was designed to hold an inclined fruit-bearing surface, utilizing freely jointed iron bars (Fig. 9). The special joint allows for a certain independent freedom of movement of the opposite bars, so that the impact applied by the rods on one side is not transmitted to the opposite side. The lower rigidity of the support structure improves the shaking action of the rods. Instead, the previous trellis designs where not optimal, because the action of the machine on one side caused fruits to fall on the opposite side to a certain degree.

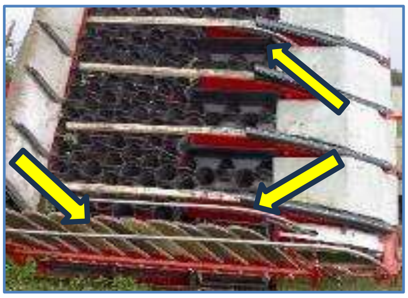

Figure 8. Three contact-rods (arrows)

Figure 9. Joint between trellis beams

In 2019, mechanical harvesting trials were carried out using both Multibasket prototypes, to harvest *cv.* Williams in August and *cv.* Decana del Comizio in September. In the harvesting trials, production and harvesting parameters, operational performance and the quality of the work done by the prototypes were measured. The detachment efficiency, fruit interception capacity, fruit plant and ground losses, and the extent and type of fruit damage were measured. Unfortunately, the small size of the orchard did not allow changes in forward speed during the tests of the two machines.
The comparison of the machines in the harvesting trials made it possible to assess the mechanical efficiency and validity of the modifications made to the new prototype

Table 1 Characteristics of the pear orchard studied for the field tests

Characteristics	units	*cv.* Williams	*cv.* Decana del Comizio
Trellis form	--	X	X
plant distribution	--	binary rows	binary rows
planting spacing	m	5 x 1.5 (0.75 x 0.75)	5 x 1 (0.50 x 0.50)
trunk section area	cm^2	41.0	37.1
maximum tree height	m	2.93	2.87
trees/hectare	n°	2222	3333

Results and Discussion

All the modifications of the new prototype were found to be an improvement on the previous machine. The self-propelled machine and the hydraulic system for the motion of the mechanical parts are more efficient and allow for better machine maneuvering. The 4 impact rods for detaching the fruit are kept properly in contact with the fruit-bearing surface at all times, and the new impact mechanism enables more effective fruit detachment while reducing damage to branches. The modified conveyor belts are more effective in transferring the fruit, although the solution adopted of dividing the sector under the multi-basket frame into three transverse belts instead of one whole belt resulted in a higher loss of fruit due to falling between the gaps.
The new contact-rod automatisms allow the optimum alignment of the machine to the row and the alignment of the multi-basket frame to the inclined fruiting surface. In the X-trellised pear orchard, the *cv.* Williams showed very good productivity, while the *cv.* Decana del Comizio was quite good (Tab 2). The new support structure for the X-shaped training system made it possible to independently harvest the fruit wall on the side of the machine without transferring the impacts to the opposite side. This arrangement reduces the fall of fruit from the branches on the opposite side of the row.

Table 2. Experimental pear orchards yield characteristics

Characteristics	units	*cv.* Williams	*cv.* Decana de1 Comizio
yield	kg/plant	23.34	7.72
average fruit weight	g	153	270
fruit detachment force	kg	4.0	4.6
pulp consistency	kg	8.7	7.7
Sugars	°Brix	13.3	16.3
Production/hectare (theoretic)	t/ha	51.778	25.725

In the field trials, using an equal 1 km/h forward speed for both prototypes, the Multibasket 2 showed a higher production efficiency in comparison to Multibasket 1, for both cultivars harvested (Tables 3 and 4). The new impact-rods detached more than 96% of the pears from the branches as compared to only 82% with the previous prototype. Both machines detached the fruit of cv. Decana del Comizio, with larger fruit mass, more easily than those of cv. Williams. Most of the un-detached fruit remaining on the plant were placed near the trellis support beams, which absorb and attenuate the impacts of the rods, reducing their effectiveness. The fruit loss on the ground appeared significantly lower with Multibasket 1 with respect to Multibasket 2, due to the partially ineffective protection for the gaps between the 3 transversal belts in the second model. Finally, fruit damage observed for both prototypes (Table 5) was very small and characterized by small holes caused mainly by broken fruit peduncles. However, the new prototype proved to be gentler on the fruit than the first one. In fact, the greater efficiency in detaching the fruit decreased the danger of reciprocal impacts with the branches, together with the delicacy of the conveyor belts, reduced damage by about 20%.

Table 3. Prototype efficiency during *cv.* Williams pear harvest

Prototype	Multibasket 1		Multibasket 2	
units of measure	kg/tree	%	kg/tree	%
detached fruits	14.89	67.4	23.73	96.5
fruits left in plant	7.20	32.6	0.86	3.5
fruits stored in bins	12.46	56.4	20.51	83.4
fruits fallen to the ground	2.43	11.0	3.22	13.1
total production	22.09	100.0	24.59	100.0

Table 4. Prototype efficiency during *cv.* Decana del Comizio pear harvest

prototype	Multibasket 1		Multibasket 2	
units of measure	kg/tree	%	kg/tree	%
detached fruits	6.55	81.6	7.18	96.9
fruits left on plant	1.48	18.4	0.23	3.1
fruits stored in bins	5.77	71.9	5.79	78.1
fruits fallen to the ground	0.78	9.7	1.39	18.8
total production	8.03	100.0	7.41	100.0

Table 5. Fruit quality characteristics picked with the two harvesters

Cultivar	*cv.* Williams		*cv.* Decana del Comizio	
prototype	Multibasket 1 %	Multibasket 2 %	Multibasket 1 %	Multibasket 2 %
fruits with peduncle	63.2	73.9	47.8	50.7
fruits without a peduncle	36.8	26.1	52.2	49.3
healthy fruits	75.9	93.5	54.9	76.8
fruits with minor damage	22.4	6.0	31.4	27.7
fruits with severe damage	1.7	0.5	13.7	5.5

Conclusion

Although the Multibasket 2 prototype needs to be fully completed and fine-tuned, it has shown a significant technical and operating improvement in comparison to the previous Multibasket 1 prototype. Interesting results are expected from the next trials on apricot, plum and peach orchards provided with the new X-shaped training structure. Eventually, more extensive orchard trials need to be carried out to determine the limits of the machine's operating performance. However, the Multibasket system is presented as a viable alternative to conventional orchard cultivation for industry food-processing, with estimated savings in harvesting costs of over 80%.

Abstract

The agriculture sector in Jordan faces significant challenges related to water scarcity and resource management. In the arid climate of the Jordan Valley, and varying temperatures between summer and winter, efficient farming practices are essential for sustainable crop production. To address this, we propose a smart greenhouse system that utilizes artificial intelligence (AI) and sensor technology to optimize water usage and enhance productivity. Our smart greenhouse integrates a suitable number of four types of sensors placed at several places. These are moisture sensors to continuously measure soil moisture content, temperature sensors to monitor ambient temperature both inside and outside the greenhouse, a humidity sensor to monitor humidity inside the greenhouse to adjust ventilation and irrigation to maintain an ideal environment, and a luminosity sensor to assess light intensity, allowing precise control of shading and artificial lighting if needed. Our system uses the Decision Tree (DT) machine learning algorithm. Trained on historical sensor data, the DT model predicts irrigation needs based on real-time inputs. By dynamically adjusting irrigation schedules and environmental parameters, our system achieves remarkable water efficiency and crop yield improvements. Our research contributes to sustainable agriculture practices in water-scarce areas like the Jordan Valley. The integration of AI and sensor technology holds promise for optimizing resource utilization and enhancing greenhouse productivity. This study shows that our DT algorithm produced a simulation of a smart greenhouse with a 94.76% overall system accuracy of correct system reactions to different surrounding circumstances.

Keywords: *Smart greenhouse, Decision tree algorithm, Sustainable Agriculture, Water management, Ventilation controller.*

Introduction

The Jordan Valley faces several agricultural challenges such as water scarcity, soil salinity, climate variability, land degradation, and limited arable land. Addressing these challenges requires comprehensive strategies encompassing sustainable water management practices, soil conservation measures, climate-resilient agricultural techniques, land-use planning, and infrastructure development (Al-Ghussain, 2017). Building smart greenhouses in the Jordan Valley presents a promising solution to address some of these challenges. The Jordan Valley, characterized by its arid climate and water scarcity, poses significant constraints to traditional farming practices. However, with advancements in technology and agricultural innovation, smart greenhouse systems offer viable pathways towards efficient resource utilization and optimized crop production (Qatarneh, 2018).
Despite formidable challenges, agriculture remains crucial to the Jordan Valley's economy, providing substantial employment and significantly contributing to food security. The government is committed to enhancing the agricultural sector through initiatives focused on improving water management and productivity (Jordanian Agricultural Statistics, 2019). The Jordan Valley, producing about 40% of the nation's agricultural output, primarily cultivates

tomatoes, cucumbers, eggplants, melons, bananas, and citrus fruits, alongside extensive dairy, and poultry farming. Water scarcity is a major challenge, prompting government efforts to develop efficient irrigation and water conservation measures. Additionally, there is a strong push towards sustainable agricultural practices, reflecting a commitment to long-term environmental stewardship and resilience (Jordanian Agricultural Statistics, 2019)
A smart greenhouse integrates various cutting-edge technologies such as sensor networks, automated climate control systems, precision irrigation, and data analytics to create an optimal growing environment for plants. By employing these technologies, farmers can mitigate the adverse effects of environmental factors, maximize crop yields, and minimize resource wastage. The key components of a smart greenhouse are climate control systems, precision irrigation, remote monitoring and control, and crop management and automation (Badji, 2022).
The Ritchie et al. (2022) article on "Crop Yields," published online at OurWorldInData.org, offers a comprehensive exploration of global crop production and yield trends. By analyzing data from various sources, including national agricultural statistics and research studies, the authors provided insights into the variability of crop yields across different regions and crops (Hannah, 2022). Using the Offered "Crop Yields" tool, Figure 1 gives an insight into potato and tomato crops respectively in several regions. the cultivation of potato, tomato, and cucumber crops in Jordan plays a crucial role in meeting dietary needs, supporting rural livelihoods, and contributing to the country's agricultural economy. This research focuses on tomato, potato, and cucumber crops which are integral to the food security and nutritional well-being of the population, underscoring their significance within Jordan's agricultural sector.

Figure 1. Potato and Tomato Yields measured in tones/hectare. (Hannah, 2022)

Smart greenhouse technology has seen notable advancements recently, focusing on enhancing agricultural productivity and sustainability. Alpay and Erdem (2018) pioneered the use of fuzzy logic-based control systems integrated with wireless sensor networks for efficient environmental monitoring and management in greenhouses. Kumar et al. (2020) expanded on this foundation by reviewing sensor network technology in greenhouse farming, emphasizing real-time data collection, automated decision-making, and resource optimization. Karanisa et al. (2022) explored smart greenhouse technology's role in precision agriculture within the food-energy-water nexus, particularly in Qatar, highlighting its potential to optimize resource use, improve yields, and address food security in arid regions. Viswanathan et al. (2024) examined IoT technology's application for real-time monitoring, predictive analysis, and automated control in greenhouses. Collectively, these studies illustrate the evolution of smart

greenhouse technology, emphasizing its innovative solutions for agricultural production, resource management, and environmental sustainability.
These interconnected studies demonstrate samples of the development of smart greenhouse technology and its increasing significance in modern agriculture. From the utilization of fuzzy logic and wireless sensor networks to the integration of IoT technology for real-time monitoring and control, smart greenhouses offer innovative solutions to address key challenges in agricultural production, resource management, and environmental sustainability.
Our research proposed the first attempt to implement a smart greenhouse project in the Jordan Valley. This project aims to propose a smart greenhouse system that utilizes artificial intelligence (AI) and sensor technology to optimize water usage and enhance productivity. A Decision Tree (DT) machine learning algorithm was developed to control smart greenhouses. It was trained on historical sensor data; the DT model predicts irrigation needs based on real-time inputs. Decision Tree is considered a small-scale software, and it can be used on mobile phones other than fuzzy Logic. DT models following AI principles were more suitable than IoT to manage large scale greenhouses.

Materials and methods

Decision trees

The Decision-making algorithm was implemented in this research. Most common algorithms for decision making include **the Decision Trees algorithm** which is a type of supervised learning algorithm that can be used to classify data or make predictions. They work by dividing the data into smaller and smaller groups until each group can be classified with a single decision. Where **Random Forests algorithm** provides an ensemble learning algorithm that combines multiple decision trees to make a more accurate prediction. They work by training multiple decision trees on different subsets of the data and then averaging the predictions of the trees. Also, **Support Vector machines** (SVMs) are types of supervised learning algorithms that can be used for classification or regression. They work by finding the hyperplane that best separates the data into two classes. In addition, **Neural networks** are examples of machine learning algorithms that can be used to learn complex relationships between data. They work by simulating the human brain's neural network. **Bayesian networks**, which represent a probabilistic graphical model that can be used to represent uncertainty in data, work by modeling the relationships between variables and their probabilities (Wikipedia, 2024).
The best algorithm for a specific problem will be controlled by the following factors: size and complexity of the data set, the number of possible decisions, the degree of uncertainty in the data, the desired accuracy of the decision (Zharmagambetov, 2022).
The best decision-making algorithm for a farmer depends on the factors involved, such as climate, soil, and the degree of uncertainty in weather. For decisions with high uncertainty, a Bayesian network might be suitable. For decisions with large amounts of data, a decision tree or random forest could be effective. Experimenting with different algorithms can help determine the best fit. In conclusion, **Decision Trees (DT)** are often ideal due to their simplicity, low uncertainty, and minimal parameter requirements. The DT are a popular choice for smart greenhouse climate control due to several advantages that make them well-suited for this application: **Interpretability:** Unlike some machine learning models, decision trees are inherently interpretable. The tree structure clearly shows the decision-making process, making it easy to understand how the model arrives at a specific control action (e.g., increasing ventilation or adjusting irrigation). This transparency is crucial in greenhouses where growers need to be confident in the system's logic, especially when unexpected situations arise. Also, **Real-time decision making:** Decision trees are efficient algorithms

that can make predictions quickly based on sensor data. This is essential in greenhouse environments where prompt adjustments to temperature, humidity, or irrigation are necessary to maintain optimal growing conditions. In addition, **handling multiple sensor inputs:** Greenhouses rely on various sensors to monitor factors like temperature, humidity, light intensity, and soil moisture. Decision trees can effectively handle these multiple inputs and create rules based on their combined influence. And **adaptability to new data:** As growers gain experience and collect more data, decision trees can be easily updated by incorporating the new information. This allows the model to continuously improve its performance and adapt to changing environmental conditions or crop requirements. Finally, **it works well with missing data:** Sensor readings in a WSN (Wireless Sensor Network) can sometimes be missing due to various reasons. Decision trees are relatively robust to the missing data provided by input and can still make predictions using the available information (Zharmagambetov, 2022).

Technical features

Temperature and air humidity Sensors (four of each) were placed 2 meters away from each other, while the single luminosity sensor was placed at the center of the greenhouse. Two soil moisture sensors were placed at the center and one end of the greenhouse. The prototype (Figure 2) of the simulated model was for a greenhouse 10 meters long and 3 meters wide.
Drip irrigation pipes were placed on the soil, about 30 cm away from the roots and stem of the plants. Heating fans were placed at each end of the greenhouse while motors were connected to the ventilators on the sides to allow air flow and lower the internal heat inside the greenhouse, and motors were placed on top panels to allow more sunlight (during the day) to enter the greenhouse for optimal luminosity for optimum plant growth. Using an Artificial Intelligence (AI) tool by Figma (2024), an edit to a generated sketch map of the suggested greenhouse is shown in Figure 2.

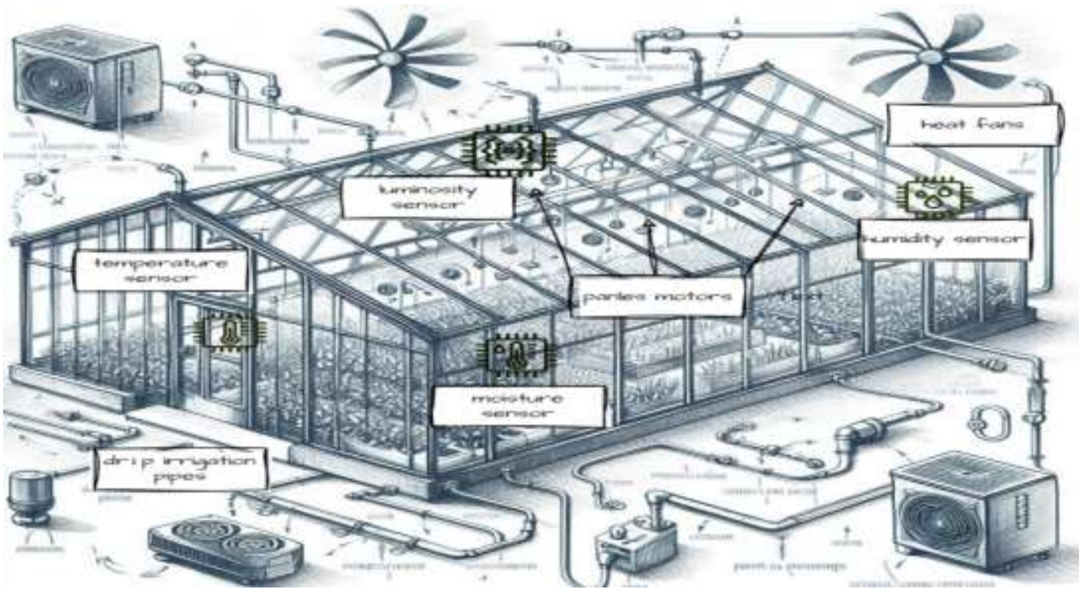

Figure 2. Edited AI generated WSN in the greenhouse under study. (Figma, 2024)

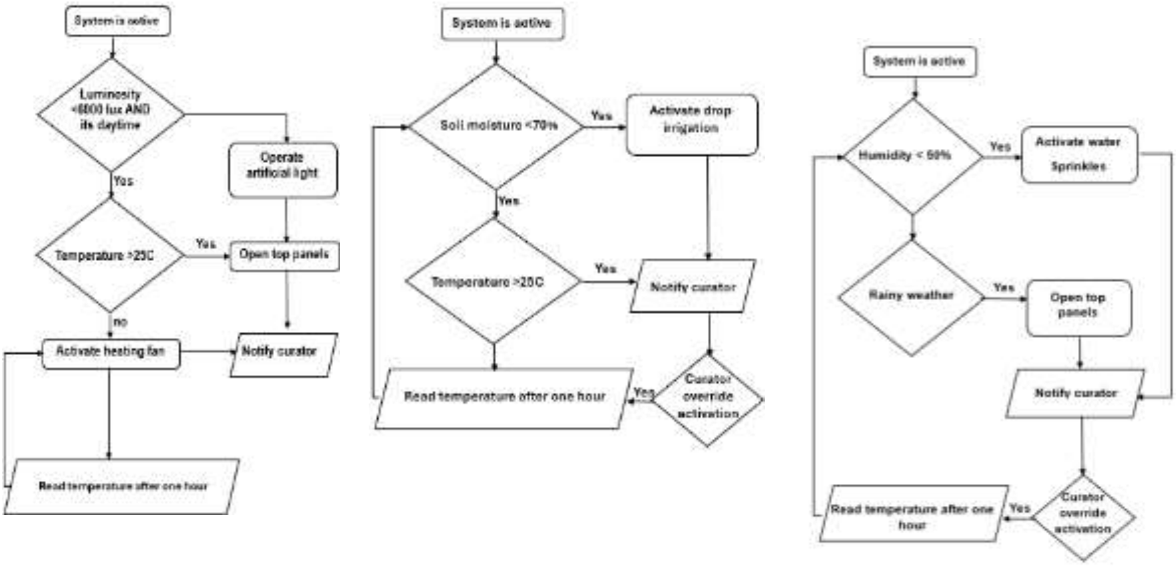
The workflow of actions was taken depending on readings from sensors. Each sensor triggers a certain action to create the optimal environment inside the greenhouse. Figure 3 demonstrates the flow of all sensor types used. Figure 3a shows the flowchart for readings from luminosity and temperature sensors, while Figure 3b shows the flowchart of actions for soil moisture sensors, and finally, Figure 3c the flowchart of actions for humidity sensors.

The DT program was implemented using ***Python*** programming language 3.0 in anaconda ***JupyterLab*** (Project Jupyter, 2024) which is recently considered the most suitable programming language for machine learning and artificial intelligence especially in Mobile Phones Applications, because ***Python*** is flexible and it has simple and readable syntax, a variety of libraries to implement AI, and it is considered an independent platform (Python Land, 2024). The DT program was trained on simulated data that generated random values for all 4 types of sensors twice a day: 10:00AM and 10:00PM. The program used a random library to simulate sensor readings and ***NumPy***, which is a ***Python*** library used for working with arrays, for the DT work. Actions according to the workflow mentioned earlier were added manually to facilitate the training and testing process.



a. b. c.

Figure 3. Flowchart of different types of sensors used in simulation.

Results and discussion

The simulator produced data from **2 moisture sensors, 1 luminosity sensor, 4 humidity sensors, and 4 temperature sensors**. Weather forecast data for the next day was also added to help the decision-making process on the action to be taken. The data set was divided into 80:20 training ratios; where 80% of the data was used for training the decision tree, and the remaining 20% was used for testing the system. The system will aim to maintain a good balance of moisture, humidity, luminosity, and temperature to make crop yields better, and avoid loss, while providing sustainability of the greenhouse's resources (water and electricity mainly).

According to this research, optimal humidity ranges for tomato, cucumber, and potato crops were set between **50% to 70%**, while the temperature to keep the crops in good growth were specified between **18° C – 26**° C. Best soil moisture levels were set between **70% - 80%** for the crops at the fruit stage, and between 75% - 90% at the seeding stage, according to Ministry of Agriculture (Jordanian Agricultural Statistics, 2019). A data set was simulated for the entire month of March in 2024 which is known for weather fluctuations in Jordan. Results were collected for 31 days twice a day resulting in a total of 62 records. Table 1 shows the obtained results, with an overall system accuracy equaling 94.76%.

Table 1. Applications of the developed DT algorithm in 62 trials and their accuracy percent.

Actual action	Predicted action				**Total number of trials**	Accuracy
	Open air ventilation	Turn on heating fans	Turn on drip irrigation	Turn on sprinklers		
Open air ventilation	58	2	1	1	**62**	0.935484
Turn on heating fans	2	59	0	1	**62**	0.951613
Turn on drip irrigation	0	0	61	1	**62**	0.983871
Turn on sprinklers	2	1	2	57	**62**	0.919355

We developed an android mobile application as a **Mobile controller** named **<u>S</u>mart<u>G</u>reen<u>H</u>ouse App** (SGH). It was built to give the farmer the chance to monitor his greenhouse and control all its aspects. This app offers the following services: action taken with an override button, Remaining energy for each sensor (map of sensors with energy for each sensor, alert time to change (or charge batteries), and History of sensors' readings every day.

Conclusion

Luminosity values vary according to the plant's growth stage; while plants at seedling and Vegetative stages require less sunlight, in the flowering and fruit production they need more. We are focused in this research on the fruit production stage, where the most suitable luminosity values vary between **6000–9000** lux for tomatoes and cucumber crops. As at night there is no sunshine, in future, the greenhouse could be improved to install light panels that are activated during short-day months, and the plants don't get enough sunshine. An additional feasibility study needs to be conducted to evaluate the cost in terms of energy consumption to crop yields and find the optimal conditions to incorporate light panels.

APPROACHES TO ASSESSING THE ENERGY POTENTIAL OF BIOMASS OBTAINED FROM CROP RESIDUE IN REPUBLIC OF NORTH MACEDONIA

Igor ILJOVSKI*, Zoran DIMOV, Zlatko ARSOV, Ile CANEV

Ss. Cyril and Methodius University in Skopje, Faculty of Agricultural Sciences and Food, Skopje, Republic of North Macedonia
*Corresponding author: igoriljovski@gmail.com

Abstract

The energy potential of plant residues (leaf, stem) from field crops (wheat, barley, maize, rice, sunflower, rye, tobacco and oats) is the basis for a different focus on biomass in plant production in our country, now as a source of energy. For this purpose, we used statistical data for the period 2014-2023 (total arable and sown area ha, total production t, kt/y, kg/ha), literature data (residue product ratio - RPR, higher calorific value - CV, dry matter - DM), and the basic mathematical and biomass energy potential estimation method (BEP) for obtaining energy potential for crop residues. From the average total arable area (515983 ha), the field crops were represented at 34.9% (180229 ha), of which the most represented were wheat (14.1%), barley (8.6%), maize (6.1%), and tobacco (3.1%), and the rest of the crops were represented below 1%. The total amount of biomass from the studied crops was estimated at 722 kt/y, or from 291.2 kt/y for wheat to 8.3 kt/y for oats, on the sown areas. The total energy potential of all crops according to the basic mathematical model showed 12 081 GJ and was correspondingly higher than the BEP method (10 622 GJ) by 12%, where DM was also included in the assessment. The energy potential of the crops corresponding to the sown areas was realized for wheat at 4926 GJ according to the basic mathematical model, or 4335 GJ according to the biomass energy potential estimation method.

Keywords: *residual biomass, energy potential, field crops.*

Introduction

The global economy is mainly based on fossil fuels, which account for 81% of the total primary energy supply, nuclear energy for 5% and renewable energy sources for 14%, of which biomass is represented at around 70% (Popp et al., 2021). Historically, this was already visible in 2018 when the share of bioenergy exceeded 13.5% (Havrysh et al., 2021). The EU Renewable Energy Directive (2018/2001/EU) of December 2018, as part of the “Clean Energy for All Europeans” package, set a new binding renewable energy target for the EU of at least 32% for 2030, revision in 2023, raises the target to 42.5% (https://energy.ec.europa.eu). Agriculture has optimal conditions for the use as renewable energy sources, with great demand for low-temperature energy sources, relatively low atmospheric pollution, and a large energy potential of renewable energy sources, especially biomass resources (Pabis et. al., 2015). Biomass from agricultural production is provided as crop residues from field crops (stalk, straw, husk, cob, boll, shell and pod) can be used as by-products - residues from agricultural production (Ertugrul et al., 2024). On the other hand, plantation biomass - energy crops (sugarcane, switch grass, sorghum, eucalyptus, poplar, and oil palm) refers to grown whole plants through traditional agricultural practices (Gravalos et al., 2016). The advantage of using crop residues compared to energy crops is that their use leads to minimal impacts on land use change (Batidzirai et al., 2016). Besides the differences, at community level, farmers can cultivate energy crops that fetch more income while meeting their food needs (Dimov et al., 2018). Bioenergy is an important component of the bioeconomy. EU concept who includes economic activities concerning the use of biomass, with strategy focused on the balance of environmental, social, and economic benefits through the sustainable use of renewable resources, for realization of jobs and profit as a goal (Havrysh et al., 2021). Enhancing renewable energy portfolios is crucial to ensure the sustainability of energy since renewables are set to remain in forward thinking of energy security (Ertugrul et al., 2024). Having in mind above mentioned, the primary aim of this research is to assess agricultural residual biomass and its energy potential in the Republic of North Macedonia, using two different approaches for evaluating renewable energy resources.

Material and methods

The accurate assessment of biomass energy potential is crucial for initial evaluations of agricultural residue from field crops. To determine this two different approaches for potential assessments were adapted from studies by Guzmán-Bello et al., (2023), and Batista et al., (2023). These were incorporated into a mathematical procedure essential and the BEP method. The first formula used is: $E = m\times CV$, where: E - energy potential (J or MJ), m - mass of the biomass (kg or t), and CV - calorific value of the biomass (MJ/kg). The second equation is Biomass Energy Potential Estimation Method (BEP), which determines the theoretical energy potential of biomass: $BEP=\sum i=1(Mi\times RRPi\times HHVi\times DMCi)$ where: BEP - the Biomass Energy Potential, expressed in MJ or GJ; n - the total number of agricultural products; M - the annual production; RRP - the residue ratio for the product; HHV - the value of higher calorific value; DMC - the dry matter content (%). Data for total arable and sown areas, total production, and yields from: wheat, barley, maize, rice, sunflower, rye, tobacco and oat from the period 2014 - 2023 were utilized from the Macedonian Statistical Office (https://makstat.stat.gov.mk). Data sets from the literature for crop residue ratio (RPR), calorific value (CV) of biomass conversion and dry matter content (DMC) were also used. The results from the two methods were compared using ANOVA and the LSD test, with a significance level of $p>0.05$.

Results and discussion

In following tables, the literature datasets are presented for factors such: residue-to-crop production ratio (Table 1), biomass calorific value (Table 2), and dry matter content (Table 3).

* Wirsenius (2000); Ronzon et al. (2015); Drackley et al. (1985)

In assessing the distribution of total arable land nationwide (515983 ha) from 2014 to 2023, field crops constitute 34,9%. This significant portion of arable land represents potential biomass derived from eight primary field crops, with wheat accounting for 14,1%, barley 8,6%, maize 6,1%, and tobacco 3,1%, being the most prominent among them (Tab 4). The biomass should be considered as biological, technical, economic and available potential. The assessment of biomass potential in the energy sector focuses primarily on available potential represents the biomass energy stream that can be utilized for the energy purposes (Piskier, 2017). The energy content of the above-ground biomass was significantly by the species and year (Fuksa et al., 2013), and includes harvestable crop residue, primary economy yield part, non-harvestable crop residue, and below ground biomass (Kishore et al., 2021; García-Condado et al., 2017). The minimum quantity of above-ground biomass required for soil function is 2,5t/ha above-ground of not harvestable biomass and roots (Cativa et al., 2024). According our investigation, the mean yearly total above-ground harvestable biomass from examined field crops during the period 2014 - 2023 was 721924 t. Among these, wheat contributed the highest biomass production at 291155 t, while oats production yielded the lowest at 8305 t (Table 4).

Table 4. Total biomass production, yield and % of sum

x̄ 2014 - 2023	Wheat	Barley	Maize	Rice	Sunflower	Rye	Tobacco	Oats	Sum

*Source: https://makstat.stat.gov.mk and literature datasets for RPR residue to crop production ratios

The distribution of biomass production is highest in wheat (40.3%), followed by barley (24.4%), and maize (20.8%), while oats, sunflower, and rye contribute the lowest percentages - 1.2%, 1.9%, and 2.1% respectively from total biomass production and total arable land. Conversely, rice (4.4%) and tobacco (4.9%) are inversely proportional to total arable land. Regarding biomass yield relative to production, rice achieves the highest percentage at 25.8%, followed by wheat at 14.4%. In contrast, oats account for 9.2% and tobacco for 6.6%, representing the lowest percentages in this regard. To accurately assess the biomass potential, it was essential to include both the caloric value and dry matter content. In our research, the net CV for all examined field crops has amounts of 16.6 Mj/kg (Table 5). The caloric value of fresh straw for wheat range between 12.9 - 14.9 MJ/kg for barley 12.0 - 13.9 MJ/kg and 3.3 - 7.2 MJ/kg for maize, and the CV of dry straw is 15 - 17 MJ/kg (Tymiński 1997, Piskier 2017). Jóvér et al., (2018), confirmed CV of wheat at 16.55 MJ/kg, corn at 17.51 MJ/kg and sunflower at 14.39 MJ/kg respectively. For comparision, the caloric value of bio-oil, which is approximately 50-55% of that of diesel oil is 16-18 MJ/kg (Bal and Piechocki, 2006). Wood harvested annually has a CV of 18.55 MJ/kg, and wood harvested every three years has a value 19.56 MJ/kg (Szczukowski et al., 2006). The gross CV of different agroforestry species and bio-based industry residues range from 14.3 - 25.4 MJ/kg (Gravalos et.al, 2016). The second measurement point used in energy potential estimation method are dry matter content, whose average value for the eight field crops is 87%. DM content directly affecting combustion efficiency, and is chosen instead of ash content or chemical composition due to direct impact on extractable energy from biomass (Guzmán-Bello, et al., 2023).

* Literature datasets for CV and DM (Tab 2,3), biomass potential from used approaches (Guzmán-Bello et al., 2023; Batista et al., 2023), differences between approaches and LSD test at level of $p>0.05$.

The theoretical energy potential of the biomass from the examined field crops, shows a total potencial of 12081GJ in the first approach and whare dry matter contet is includ in the assessment the potential is lower at 10622 GJ. The difference in the mesure sum of total energy production between first and secund aproach was 1495 GJ. The energy potential of individual field crops varies based on the amount of total arable land (Tab. 4). Wheat, grown on 72606 ha total arable land, has energy potential of 4926 GJ in first and 4335 GJ in second approach, resulting in a differences of 591 GJ. The other two most common field crops, barleys and maize, achieve energy potential of 2896 and 2578 GJ in first, and 2548 GJ and 2269 GJ in

second approach, with 347 GJ i.e. 309 GJ respectively. Comparing two approaches at a level of 0.05, significant differences were only found in wheat, barley, and maize, or crops that are grown on larger arable land (wheat, barley) and produce higher biomass (Table 5).
Significant amounts of agricultural residues contributing to bioenergy production are available at EU level (1,530 PJ), with the largest quantities available in Germany, Romania, France, Spain and Italy (Bădan et al., 2020). The amount of electrical energy calculated per capita is about 70 GJ per year, which is equivalent to 2.5 t of coal or 1.6 t of crude oil (Pabis et al., 2015). In our case this energy requirement can be met from the annual harvest of maize which provides 71.8 GJ, and rice 118.1 GJ (Table 5).

Conclusion

The potential of the biomass from the primary field crops represented in Macedonia, which some of them are used in the livestock sector as fodder, can also be analyzed from another perspective as a significant energy potential. By applying and comparing two different approaches, we estimated a theoretical energy potential of 12,081 GJ in the first and 10,622 GJ in the second approach. The significant difference of 1495 GJ between the approaches, and at wheat, barley and maize, highlights the greater relevance of the BEP Method, for measuring the energy potential of field crops based on total biomass production.

Abstract

Germination and seedling development are essential phases in a plant life cycle that are significantly influenced by non-optimal temperatures. This study aimed to examine the bio-morphological traits of various corn hybrids in the initial growth phase, the seeds of which were exposed to non-optimal temperatures. Some of the seeds of super sweet corn (P300), semi-flint corn (P402) and popcorn (P398) were germinated for seven days at +10^0 C (cold-test), after which they were transferred to optimal conditions, and some of the seeds were kept for 30 minutes at +50^0 C before germination. The bio-morphological traits, such as overall seed germination, root and shoot length, root and shoot biomass, root and shoot vigor and metabolic efficiency of tested seeds were compared with those of control seeds, which germinated in optimal conditions. An assessment of the relationship between metabolic efficiency and other traits to predetermine the limits of corn resistance to abiotic factors, especially to non-optimal temperature was carried out. Metabolic efficiency was strongly correlated with overall germination (0.8609-0.9603), root and shoot length (0.8392-0.9131), root and shoot biomass (0.9131-0.9911) of control seeds germinated in optimal conditions. The metabolism of seeds exposed to non-optimal temperatures before germination changes significantly. The correlation coefficients decreased, and the correlation in the P402 cold-test and P300 high temperature experiments became inverse. Metabolic efficiency of semi-flint corn P402, seeds exposed to +50^0 C was highly correlated with root and shoot length (0.9305-0.9883); and root and shoot vigor (0.8118-0.9696). The data obtained make it possible to differentiate corn hybrids according to their resistance to temperature.

Keywords: *corn, seed, germination, bio-morphological traits, correlation.*

Introduction

Each varieties of corn has the ability to adapt to changing environmental conditions within limits determined by his genotype. The most cultivated high-yielding corn hybrids with a tooth-shaped and flinty endosperm structure, from which is produced flour, alcohol and animal feed, less demanding on temperature and humidity, than hybrids of popcorn and sweet corn. Popcorn, which is used in the production of flakes and other similar products, is the most sensible type of corn and is characterized by lower biological adaptability to various growing conditions. Sweet corn is a vegetable crop that uses in the canning industry and needs irrigation for growing like all vegetable crops. Many breeders make special efforts to find corn lines and hybrids characterized by more vigorous germination, more powerful seedlings, high initial growth rate in cold and wet soils and normal growth at relatively low and high temperatures (Miedaner and Juroszek, 2021; Khaeim *et al.*, 2022). The abiotic stress hazards seriously affect the yield of corn; however, the genetic basis of temperature adaptation, especially to low temperature, in corn is still poorly understood (Jiao *et al*., 2022).
The higher ability to produce metabolic substances necessary for plant life under stress, the wider the reaction norm of a given plant and the better its capacity to adapt (Borovskij, 2013;

Gupta *et al*., 2013). This property is especially important for edible corn hybrids, since they are more demanding on growing conditions. Changes in corn traits due to temperature stress should be used for diagnostic purposes to realize the potential of plant resistance. Among the variety of physiological traits, the intensity of growth reactions as an integral indicator of the metabolic activity of plants at extreme temperatures is most closely related to the general resistance of plants to stress and is methodically accessible for determination.
Knowledge of interactions between features related to physiological traits and yield is very important in the breeding and cultivation of corn to determine the degree of influence of growing conditions on them (Jayakumar *et al*., 2007; Amin *et al*. 2013). Early it was reported (Kinfe *et al*., 2015; Sharma et al., 2021) that the grain yield of the corn hybrids was significantly positively correlated with yield attributing traits (cob diameter, number of kernels per row, number of kernel rows per cob, etc.). Establishing correlations between highly heritable valuable traits of hybrids for a more complete analysis of their resistance to temperature conditions of germination and development could be powerful for increasing the efficiency of technological methods. This study aimed to determine the bio-morphological traits and examine their relationships in the initial growth phase of various corn hybrids seeds exposed to non-optimal temperatures.

Materials and methods

The studies were carried out in 2024 in the Institute of Genetics, Physiology and Plant Protection (IGFPP), Moldova State University, Republic of Moldova.
Corn seeds of hybrids: Porumbeni 300 sh-2 (P300), super sweet corn, FAO 300, mid ripening; Porumbeni 398 (P398), popcorn FAO 400, mid-late-ripening; and Porumbeni 402 (P402), semi-flint corn, FAO 400, mid-late-ripening were generously contributed by the National Center of Research and Seed Production (Institute of Crop Science „Porumbeni”).
Laboratory testing. Seeds pre-soaked in water for 24 hours were subjected to heat stress at 50°C for 30 minutes (heat test). Germination of intact (control) and heated seeds was carried out in accordance with the provisions of international rules (ISTA. 2017). To conduct the cold test, seeds were germinated for seven days at temperature of 10°C, and then 4 days at 25°C (Goggi *et al.*, 2009; Zhao *et al.*, 2022). After germination, the overall seed germination, root and shoot length, root and shoot biomass, root and shoot vigor and metabolic efficiency of tested seeds was assessed. The biomass of reserve substances that was spent for respiration during seed germination was calculated (Dascaliuc *et al.*, 2020; Borovskaia *et al.*, 2023).
Statistical analysis. Pearson correlation coefficients of relationships between studied traits were determined by Excel and Statistica 7 software.

Results and discussion

The seeds of tested hybrids germinated in optimal conditions (control) demonstrated the highest positive correlation (≥0.8609) between different traits, conjoint of which were seed germination -metabolic efficiency; root length – shoot length; and root vigor – shoot vigor (Table 1). At the same time, other strong relationships between the traits of each individual hybrid in initial growth phase were identified. The number of positive correlated relationships (≥ 0.6029) varied depending on the corn hybrid: in super sweet P300, correlation was observed for 17 traits, popcorn P398 for 8 traits, semi-flint P402 for 16 traits (Table 1). Strong correlation (≥ 0.9297) between root biomass and its length was evaluated for super sweet corn (P300) and semi-flint corn (P402); and between shoot biomass and its length – only for semi-flint corn. The metabolic efficiency of corn seeds had a direct dependence on the root biomass accumulated during germination under optimal conditions and a strong negative dependence on the biomass of seed reserve substances spent on respiration (Table 1).

The metabolism of seeds exposed to non-optimal temperatures before germination changes significantly. The relationships between traits were modified both qualitatively and quantitatively (Table 2). Correlation coefficients for traits of corn development in the initial phase of growth from seeds exposed to $+50^0$ C before germination decreased. However, popcorn (P398) and semi flint (P402) hybrids showed a high positive correlation between root length and dry biomass (0.6660-0.7791), as well as between root and shoot vigor (0.8686-0.9673). The number of traits which had strong positive relationships (coefficients of correlation $\geq$0.75) diminished by 4 times for P300, 1.6 times for P398 and 2.3 times for P402 compared to control corn (Table 1, 2). Considering that the metabolic efficiency of the P402 hybrid was strong correlated with root/shoot length and root biomass at the level of control seeds, it can be assumed that this hybrid is thermotolerant. Therefore, acceleration of root and shoot growth of semi flint corn after heat stress was predermined by high metabolic efficiency of its seeds. Seeds of the P300 corn were more sensitive to heat stress. The metabolic efficiency of super sweet corn exposed to heat stress was negatively correlated with all studied traits (Table 2).

It should be noted that in all tested hybrids, both control (Table 1) and those exposed to heat/cold stress (Table 2, 3), metabolic efficiency had a strong correlation with the biomass of reserve substances spent on respiration during seed germination (r = 0.9572-0.9999). The shoot vigor and root vigor correlated positively for all studied hybrids: control, heat and cold tested seeds.

The relationship between the traits of corn exposed to cold germination was significantly different from that of the control and heat-treated corn. Common to all cold-tested hybrids was a positive correlation between root/shoot vigor and their biomass, which was not found for control and heat-stressed corn seeds (Table 3). The root/shoot vigor of the P300 and P 398 hydrides, seeds of which were germinated in cold conditions, strong correlated with their root/shoot length and biomass (0.7902-0.9749). In addition, root/shoot vigor of these hybrids had the good correlation with all studied traits. The strong correlation (0.8470-0.9848) was also established between shoot vigor and shoot length/biomass of hybrid P402 (Table 3). Since the cold test is considered most important for the vigor of corn seed (Sena *et al.*, 2017), it can be concluded that the seeds of the P300 and P398 hybrids were more resistant to cold treatment compared to the P402 hybrid. The resistance to temperature stress is controlled by the corn’s own genetic constitution, ambient temperature and their interaction. Zhao *et al.* (2022) showed that the low temperature imposed higher influences on growth and yield traits of corn. Thus, according changes in traits relationships of corn in the initial growth phase under influence non-optimal temperatures, the P300 super sweet corn was the most sensible to heat stress and P402 semi-flint – to cold stress.

Conclusions

Based on the results of correlation analysis, it was established that the strong relationship between the metabolic efficiency of corn seeds and other traits of its development in the initial phase depends on both the temperature conditions of germination and type of corn hybrid. Our results confirmed the possibility of using corn seeds growth traits and their relationships to study the characteristics of the reaction of seeds during germination and for a comparative assessment of the resistance of corn hybrids to non-optimal temperature.

Abstract

Strawberries are a popular fruit valued for the outstanding flavor and nutritious composition. The current climate in the area where the runners are grown has a major impact on the productivity of strawberry nurseries. The climate in Azad Jammu and Kashmir is suitable for growing superior strawberry runners; nevertheless, uniform standards on site selection and growth techniques for various cultivars are required. In order to close this gap, we conducted three separate studies in the Poonch district to evaluate the runner health of three different strawberry cultivars: ‘Chandler’, ‘Sea Scape’, and ‘Tribute’. During this study the performance of these cultivars was assessed at Chotta Galla, Khai Galla, and Hajira (Azad Jammu & Kashmir) using a randomized complete block design (RCBD). Our results showed that temperature affected the number of runners produced; cooler climates encouraged vigorous runner growth, while warmer climates were associated with larger yields and higher fruit quality. Furthermore, differences in flower and yields among cultivars were recorded; some showed fruit yields that were limited, which was directly related to the ratio of fruit to leaf. All in all, our research highlights the significance of taking site-specific factors into account while growing strawberries, with a focus on how temperature affects the dynamics of runners and yield. These discoveries aid in the creation of customized plans for maximizing strawberry yield under various climate scenarios.

Introduction

Strawberry (*Fragaria* × *ananassa* Duch.) is a member of the *Rosaceae* family. It is among the sweetest and tastiest fruits. Strawberry has a unique place among all berries due to its charming red colour and its nutritive value. Though, it is a fruit of temperate region, but it can be grown in tropical and sub-tropical regions as well. Botanically, it is a highly perishable aggregate fruit. According to Finn and Strike (2008), in temperate climates, the plants exhibit the characteristics of a small perennial herb with a shallow root system, but in sub-tropical climates, they behave more like annuals. It is one of the delicious fruit due to its flavor, aroma and nutritional properties. It possesses a unique place among all the berry fruits due to its charming red color. This small berry fruit is fully loaded with phytochemical, volatile compounds, sugars and acids. Additionally, they contain high concentrations of phenolic compounds, including as phenolic acids, hydrolyzable tannins, and anthocyanins. The fruit has a lot of nutrients and vitamins. The two main components of strawberries are water (91%) and carbohydrates (7.7%). They have a negligible 0.7% fat content. Less than 50 calories are found in one cup (150 g) of whole strawberries. Less than 6 g of digestible carbohydrates are included in every 100 g of strawberries. Fruit's flavor is primarily influenced by three types of components: sugars, acids, and aromatic compounds. The fruit of the strawberry has 0.5%

total sugar and between 0.90% and 1.85% organic acids, with citric and malic acids predominating.
There are more than 20 species and 600 varieties of strawberries in the world (Mondal, 2010). All these varieties vary in their nutritional composition, size, flavor and color. The world production of strawberry is around 9.2 million tons (FAO, 2017). The largest producer of strawberries in the world is China with annual production of 3.7 million tons followed by USA and Mexico (FAO, 2017). Strawberry production in Pakistan is very low as compared to other areas of the world as Pakistan produced 609 t strawberries per year. This less yield of strawberry is mainly due to lack of research, improper cultivation practices and dependence on only one variety 'Chandler' (Aziz et al., 2018).
Since last few years, area under strawberry production is increasing rapidly in sub-continent countries (Singh et al., 2007). However, its production in Pakistan is limited due to certain environmental factors and lack of knowledge. Our preliminary investigation has revealed that at least eight cultivars 'Chandler', 'Sequoia', 'Camino Real', 'Sea Scape', 'Tribute', 'Corona', 'Stuff' and 'Mark' are available in Pakistan. However, it has been reported that 'Chandler' is the only cultivar which is grown commercially throughout the country (Anwar *et al*., 2018). This might be due to the lack of quality runners which only produced in Mangora and Dir districts, and supposed to be the main which hinders strawberry production (Rajwana et al., 2016).
The climate of Rawalakot suits the nursery production of strawberry and provides good quality runners of different strawberry cultivars. Rawalakot, located at 33°51'32.18"N latitude, 73° 45'34.93"E longitude and 1638 m altitude, is a small town of district Poonch, which seems an ideal place for growth and production of strawberry crop (Hayat et al., 2022). However, till-to-date no trial for nursery production of strawberry has been conducted at different locations of district Poonch. Exploring different areas for strawberry runner production may not only provide multi-sourcing opportunities for farmers/suppliers but may also ensure sustainable supply of healthy runners of different cultivars. Considering the above facts, the present work has been designed to evaluate the runner health of three strawberry cultivars 'Chandler', 'Sea Scape' and 'Tribute' in different areas of Poonch district.

Materials and Methods

Study area

This study was performed at three different locations: Chota Galla (Latitude: 33° 48' 59.21"; Longitude: 73° 49' 19.74" ˚E; 1918 m.a.s.l.), Khai Galla (Latitude: 33° 84' 65" N; Longitude: 73° 82' 87" E; 1736 m a.s.l.) and Hajira (Latitude: 33° 46' 18.12" N; Longitude: 73° 53' 45.96" E; Elevation 3168 m a.s.l.) of Azad Jammu and Kashmir in three different strawberry varieties ('Chandler, 'Sea Scape', 'Tribute'). The study was carried out during consecutive seasons of year 2022 and 2023. Land was prepared according to standard management practices and soil analysis was conducted before the start of experiment. Beds (30 cm above soil level) were prepared. Width of each bed was 45 cm having two strawberry rows and distance between plants was30 cm. Bed to bed distance was maintained at 45 cm.
For runner production, diseased-free mother plants were planted at a distance of 30.48 cm and runners were harvested and propagated. After plug plant production, these plants were planted in field for fruit yield and quality.

Number of runners per plant

Numbers of runner per plant were counted and their average was recorded.

Leaf area (cm2)

With the aid of a leaf area meter, the leaf area of three fully developed leaves from each plant was measured and data were showed in . After that, average leaf area per plant was calculated.

Number of flowers per plant
Flowers per plant were counted from selected plants of each cultivar from first flower opening to full bloom.

Number of fruits per plant
From randomly chosen plants, the number of fruits per plant was counted.

Statistical Analysis
Three treatments and three replications were used in the randomized complete block design (RCBD) experiment setup. SAS software was used to do statistical analysis utilizing the analysis of variance (ANOVA) technique. The Least Significant Difference (LSD) test was used to examine treatment mean differences at a 5% probability level.

Results and Discussion

Number of runners per plant
It was observed that results regarding number of runners per plant were significantly different among cultivars and locations (Table 1). The highest number of runners per plant was found in strawberry ‘Chandler’ (8.55) which was followed by strawberry ‘Sea Scape’ (6.00), while the lowest number of runners per plant was noted in strawberry ‘Tribute’ (2.55). Whereas, the strawberry plants transplanted at Chotta Galla location showed the highest number of runners per plant (9.77) which was followed by Khai Galla location (6.44), while the lowest number of runners per plant were recorded at Hajira location (0.88) . Current study revealed that runner production is high in the areas where temperature is low and flower and fruit production is more in the areas where temperature is high. Our results are in line with the previous findings that runners, are high in the area (Chotta Galla) where flower and fruit production is low. However, it was observed that flowering and runner production in strawberry depends on the temperature of the cropping year (Sønsteby et al., 2022).

Table 1. Effect of different locations on number of runners per plant of three strawberry cultivars.

Cultivar	**Locations**			**Means**
	Chotta Galla	Khai Galla	Hajira	
‘Chandler’	15.0 a	9.00 bc	1.66 e	**8.55 A**
‘Sea Scape’	11.0 ab	6.33 cd	0.66 e	**6.00 B**
‘Tribute’	3.30 de	4.00 de	0.33 e	**2.55 C**
Means	**9.77 A**	**6.44** B?	**0.88 C**	

* different lettering indicate statistically differences at $P < 0.05\%$.

Leaf area
It was observed that results regarding leaf area were significantly different among cultivars and locations under study (Table 2). The maximum leaf area was found in strawberry ‘Chandler’ (144.51 cm^2) which was followed by strawberry ‘Sea Scape’ (119.90 cm^2), while the minimum leaf area was noted in strawberry ‘Tribute’ (89.40 cm^2). Whereas, the strawberry plants transplanted at Hajira location showed the maximum leaf area (125.33 cm^2) which was followed by Khai Galla location (115.46 cm^2), while the minimum leaf area were recorded at Chotta Galla location (113.02 cm^2). It was reported that in some strawberry cultivars flower and fruit production is source limited and is directly proportional to leaf area (Sønsteby et al., 2021). These findings are notably evident that high temperature and low rainfall at Hajira location increased microbial activity in the soils results in availability of

nitrogen to plants helps in increased leaf area (Purbajanti et al., 2019). In our results, highest leaf area was obtained at Hajira location, with high temperature and less rainfall than Chotta Galla nad Khai Galla location which is helpful in increased microbial activities.

Table 2. Effect of different locations on leaf area (cm^2) of three strawberry cultivars.

Cultivar	**Locations**			**Means**
	Chotta Galla	Khai Galla	Hajira	
‘Chandler’	139.2 ab	136.0 b	158.3 a	**144.51 A**
‘Sea Scape’	110.4 cd	127.2 bc	122.0 bc	**119.90 B**
‘Tribute’	89.4 de	83.1 e	95.6 de	**89.40 C**
Means	**113.02 B**	**115.46 B**	**125.33 A**	

* Different lettering indicate significant statistically differences at $P < 0.05\%$.

Number of flowers per plant

It was observed that results regarding number of flowers per plant were different among cultivars and locations (Table 3). The highest number of flowers per plant was found in strawberry ‘Chandler’ (11.9) followed by strawberry ‘Sea Scape’ (7.8), while the lowest number of flowers per plant was noted in strawberry ‘Tribute’ (5.7). Whereas, the strawberry plants transplanted at Hajira location showed the highest number of flowers per plant (11.3) which was followed by Chota Galla (7.2), while the lowest number of flowers per plant were recorded at Khai Galla (6.8). High temperatures cause the organic matter in the soil to decompose, increasing the amount of nutrients available and stimulating microbial activity in the soil (Broadbent, 2015). Plant growth patterns are enhanced by this nutrient availability (Mohamed et al., 2021). Consequently, plants growing in the Hajira location have the greatest number of flowers and fruits, which may be related to the amount of N, P, K, and other hormones in the soil. These were essential for the synthesis of gibberellic acid in the roots, which broke the dormant state of the buds. This led to a rise in flowering sites, an increase in bud development, and an early commencement of the reproductive stage (Kumar et al., 2018).

Table 3. Effect of different locations on number of flowers per plant of three strawberry cultivars.

Cultivar	**Locations**			**Means**
	Chotta Galla	Khai Galla	Hajira	
‘Chandler’	11.3 ab	10.37 ab	14.0 a	**11.9 A**
‘Sea Scape’	5.7 cd	6.07 cd	11.6 ab	**7.8 B**
‘Tribute’	4.7 cd	4.07 d	8.3 bc	**5.7 C**
Means	**7.27 B**	**6.8 B**	**11.3 A**	

* Different lettering indicate significantly statistically differences at $P < 0.05\%$.

Number of fruits per plant

It was observed that results regarding number of fruits per plant were significantly different among cultivars and locations (Table 4). The highest number of fruits per plant was found in strawberry ‘Chandler’ (8.9) followed by. ‘Sea Scape’ (4.8), while the lowest number of fruits per plant was noted in strawberry ‘Tribute’ (2.8). Whereas, the strawberry plants transplanted at Hajira location showed the highest number of fruits per plant (7.4) followed by Chota Galla (4.8), while the lowest number of flowers per plant were recorded at Khai Galla (4.3). According to Broadbent (2015), elevated temperatures cause microbial activity in the soil to rise, which in turn breaks down organic matter in the soil and makes nutrients available. Plants develop more efficiently when these nutrients are available (Mohamed et al., 2021). The abundance of N, P, K, and other hormones in the soil may be the reason why plants cultivated in the Hajira area bear the most blooms and fruits. These were essential for the synthesis of gibberellic acid in the roots, which broke the dormant state of the buds. This brought about a rise in flowering sites, an early commencement of the reproductive stage, and an increase in bud production (Kumar et al., 2018). Thus the increased bud production and increased flowering sites results in increased yield. Nevertheless, yield might be cultivar and species specific (Mardanluo et al., 2018).

Table 4. Effect of different locations on fruits per plant of three strawberry cultivars.

Cultivars	**Locations**			**Means**
	Chotta Galla	Khai Galla	Hajira	
'Chandler'	8.7 ab	7.0 bc	11.0 a	**8.8 A**
'Sea Scape'	3.6 d	3.6 d	7.3 b	**4.8 B**
'Tribute'	2.0 d	2.3 d	4.0 cd	**2.7 C**
Means	**4.77 B**	**4.33 B**	**7.44 A**	

* Different lettering indicate significantly statistically differences at P < 0.05%

Conclusions

The findings of this study indicate that strawberry plants transplanted in cooler locations exhibit a higher capacity for producing abundant and robust runners. On the other hand, plants transplanted in slightly warmer locations demonstrated superior performance in terms of fruit production.

Acknowledgements

The authors would like to express their gratitude to the Higher Education Commission (HEC), Islamabad, Pakistan, for providing funding for this study under NRPU Project No. (NRPU-20-16975). The Pakistan Science Foundation is greatly appreciated by the author for granting a travel grant so author could attend this conference and share this work.

Abstract

A more accurate assessment of apple quality is paramount for various industries, notably in agriculture and food sectors, ensuring economic efficiency and consumer satisfaction. The conventional assessment methods encounter obstacles related to labor intensity, speed, and maintaining quality control standards. This paper presents an alternative perspective, focusing on anomaly detection employing autoencoder techniques to enhance apple quality assessment in a cost-effective manner. Autoencoders are trained on a dataset comprising over 2700 images of healthy apples, offering an economical means of learning representations of healthy apples. These autoencoders proficiently identify anomalies, particularly those indicative of spoiled or damaged apples, streamlining their removal from the sorting process. Additionally, compared to typical CNN architectures, autoencoders provide the advantage of unsupervised learning, as they do notn't require labeled data for training, making them more versatile and adaptable to various datasets and scenarios. The study explores a range of autoencoder architectures and hyperparameter configurations to optimize anomaly detection performance. Initial findings indicate promising results in leveraging autoencoders for identifying spoiled apples, offering potential improvements in sorting efficiency, decreased labor costs, and strengthened quality control procedures.

Keywords: *autoencoder, fruit sorting, deep learning, neural network, convolutional network.*

Introduction

Autoencoders are neural networks designed to learn a compressed representation of input data through an encoder-decoder architecture. The encoder compresses the input into a latent space representation, while the decoder reconstructs the input from this representation. By learning to accurately reconstruct the original images, the autoencoder develops a robust understanding of typical fruit characteristics, including color, texture, and shape. Consequently, when presented with anomalous or spoiled fruit images during inference, the reconstructed outputs deviate significantly from the original inputs, thereby signaling potential defects.
Compared to conventional Convolutional Neural Networks (CNNs) typically utilized for image classification tasks (Taner *et al.*, 2024), autoencoders offer several advantages in the context of fruit quality detection. Firstly, autoencoders operate in an unsupervised manner, eliminating the need for labeled data during training, which can be costly and time-consuming to acquire. Secondly, autoencoders inherently prioritize feature extraction and representation learning, focusing on capturing the most important aspects of the input data (Ventura *et al.*, 2022).

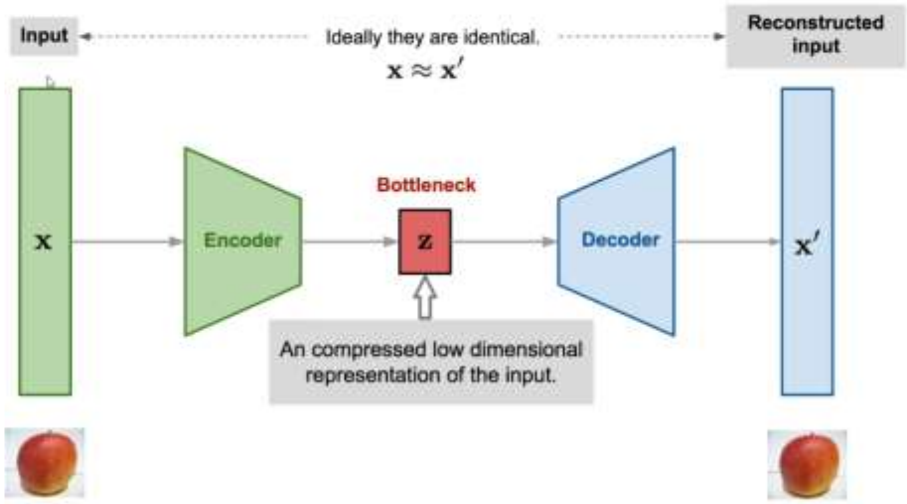

Figure 1: Autoencoder model architecture
(adapted from https://lilianweng.github.io/posts/2018-08-12-vae - Weng, 2024)

Moreover, the compact latent space representation learned by autoencoders facilitates efficient storage and inference, making them suitable for deployment in resource-constrained environments such as agricultural facilities or mobile inspection units. When an apple image deviates significantly from this learned representation - indicative of potential defects or poor quality - the autoencoder's output will exhibit greater reconstruction errors. These errors can then be quantified to flag substandard apples efficiently (Adari *et al.*, 2024).
In this article, we explore the advantages offered by autoencoders and present experimental results demonstrating the efficacy of autoencoder-based models in real-world fruit quality inspection scenarios.
Previous researches have demonstrated the effectiveness of CNNs, especially in classification and sorting operations, and similarly highlighted the potential of autoencoders.
Xue *et al.* (2020) detail the development of a novel deep learning framework specifically designed for the classification of fruit images. This framework, named CAE-ADN, integrates a convolution autoencoder (CAE) and an attention-based densely connected convolutional network (DenseNet) to effectively pre-train and classify fruit images, enhancing operational efficiency across various stages of the fresh produce supply chain. The model achieved an impressive classification accuracy of 95.86% on the Fruit 26 dataset and 93.78% on the Fruit 15 dataset.
Aiadi *et al.* (2022) introduce an advanced approach for categorizing date fruits, a prominent agricultural commodity in the Middle East.Recognizing the nutritional benefits of dates and their role in disease prevention, the authors emphasize the need for efficient sorting methods in the date industry, which is traditionally labor-intensive and costly.
Chen *et al.* (2021) describe a vision system tailored for the citrus industry to address the significant inefficiencies observed in traditional manual sorting processes. The proposed system offers a high-tech solution that integrates advanced deep learning techniques to optimize sorting on a citrus processing line. By analyzing the historical tracking data, the system is able to accurately determine the true categories of the citrus fruits, achieving a high detection precision reported at 93.6%.
The research conducted by Liu *et al.* (2024) critically examines the application of deep learning algorithms, particularly Convolutional Neural Networks (CNNs), in this sector. Their study conducts an extensive evaluation of several popular CNN architectures such as DenseNet, InceptionV3, ResNet, VGGNet, Xception, MobileNet, NASNet, EfficientNet, and

SqueezeNet. The paper tests these models against key performance indicators like sensitivity, specificity, and accuracy, providing a detailed analysis of their capabilities and shortcomings.

Materials and methods

In our research, we explored the following types of autoencoders to enhance the apple sorting process by analyzing and improving image data:

1. Basic Convolutional Autoencoder is the simplest form of this architecture, comprising an encoder and a decoder. The encoder reduces the dimensionality of the input images, extracting essential features, while the decoder reconstructs the images from these features.
2. Deep Convolutional Autoencoder consists of multiple layers, allowing it to learn more complex features. This architecture is more capable of capturing subtle anomalies in apple quality, providing a deeper understanding of intricate patterns within the image data.
3. Variational Autoencoder (VAE) introduces a probabilistic approach, where the encoder outputs mean and variance for the latent space. This helps in capturing more generalized features and improving robustness to variations.
4. Denoising Autoencoder is designed to reconstruct the input from a corrupted version, enhancing its ability to identify anomalies by focusing on key features and disregarding noise. This type of autoencoder is beneficial for improving the quality of images with imperfections, making it easier to detect defects in apples.
5. Contractive Autoencoder (CAE) includes a regularization term that penalizes the norm of the Jacobian matrix of the encoder's activations. This results in more robust feature learning, making the model less sensitive to small changes in input. CAEs are useful for creating stable and reliable representations of apple features, ensuring consistency in quality assessment.

For the purpose of training we utilized a dataset consisting of 2,782 images of apples, all classified as being in good condition. These images were sourced to train the model on recognizing the characteristics of high-quality apples. Each image was resized to a uniform dimension of 128x128 pixels to maintain consistency and improve computational efficiency during model training. The images were preprocessed using the class ImageDataGenerator from the Keras library, which included rescaling the pixel values to a range of 0 to 1 to facilitate model training by normalizing the data.

The authors researched the five type of autoencoder described above. Each type is characterized by its specific encoder and decoder architectures, latent space, and key features:

1. Basic Convolutional Autoencoder - encoder: Conv2D (32 filters, 3x3, ReLU) → MaxPooling2D (2x2) → Conv2D (64 filters, 3x3, ReLU) → MaxPooling2D (2x2); latent space: Dense layer with 128 units; decoder: Conv2DTranspose (64 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (32 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (1 filter, 3x3, Sigmoid); key features: simplest architecture, basic feature extraction.
2. Deep Convolutional Autoencoder - encoder: Conv2D (32 filters, 3x3, ReLU) → MaxPooling2D (2x2) → Conv2D (64 filters, 3x3, ReLU) → MaxPooling2D (2x2) → Conv2D (128 filters, 3x3, ReLU) → MaxPooling2D (2x2); latent space: Dense layer with 256 units; decoder: Conv2DTranspose (128 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (64 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (32 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (1 filter, 3x3, Sigmoid); key features: deeper architecture, captures more complex features

3. Variational Autoencoder (VAE) - encoder: Conv2D (32 filters, 3x3, ReLU) → MaxPooling2D (2x2) → Conv2D (64 filters, 3x3, ReLU) → MaxPooling2D (2x2); latent space: Dense layers for mean and variance with 128 units each; decoder Architecture: Conv2DTranspose (64 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (32 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (1 filter, 3x3, Sigmoid); key features: probabilistic approach, captures generalized features.
4. Denoising Autoencoder - encoder: Conv2D (32 filters, 3x3, ReLU) → MaxPooling2D (2x2) → Conv2D (64 filters, 3x3, ReLU) → MaxPooling2D (2x2); latent space: Dense layer with 128 units; decoder: Conv2DTranspose (64 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (32 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (1 filter, 3x3, Sigmoid); key features: reconstructs from corrupted input, focuses on key features.
5. Contractive Autoencoder (CAE) - encoder: Conv2D (32 filters, 3x3, ReLU) → MaxPooling2D (2x2) → Conv2D (64 filters, 3x3, ReLU) → MaxPooling2D (2x2); latent space: Dense layer with 128 units with contraction penalty; decoder: Conv2DTranspose (64 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (32 filters, 3x3, ReLU) → UpSampling2D (2x2) → Conv2DTranspose (1 filter, 3x3, Sigmoid); key features: regularization for robust feature learning, less sensitive to small input changes.

These architectures have been evaluated for their effectiveness in improving apple quality assessment. For training and testing the autoencoder models, we utilized Python scripts with TensorFlow and Keras.

The autoencoders were compiled with the Adam optimizer and mean squared error (MSE) loss function, which quantifies the difference between the original and reconstructed images. The final models were trained for 120 epochs using a batch size of 8. The validation was performed using a separate set of images to monitor the model's performance and avoid overfitting. During training, the loss and validation loss were recorded for each epoch to track the models' learning progress. The trained autoencoders were employed to differentiate between normal apples and anomalies. This was achieved by comparing the reconstruction error between the input and output images. Images with higher reconstruction errors were flagged as potential anomalies, indicative of defects or diseases. To automate the detection process, thresholds for density and reconstruction error were empirically set based on the distribution of these metrics across known good and anomalous samples. These thresholds help in distinguishing normal apples from those with defects (Sayed, 2023).

The effectiveness of the model in identifying anomalies was assessed by evaluating it on a separate dataset specifically curated to contain anomalous apple images. The models’ performance metrics, such as reconstruction error and density estimates from a Kernel Density Estimator (KDE), were calculated and compared against the set thresholds to determine the presence of anomalies.

Results and discussion

In assessing the performance of various autoencoder models for our apple quality assessment project, key performance indicators were utilized. These metrics provided insights into the models' abilities to reconstruct images and identify anomalies effectively.

The evaluation criteria included (Sayed, 2023):

1. Low Reconstruction Error - a measure of reconstruction quality for normal apples.
2. High Anomaly Detection Accuracy - reflecting the model's capability to identify defects accurately.

3. Balanced Precision and Recall - ensuring unbiased performance in distinguishing between normal and anomalous apples.
4. High F1 Score and AUC-ROC - indicating overall effectiveness in classifying normal and anomalous apples.

Based on the results presented in Table 1, which outlines the performance of various autoencoder models, the Contractive Autoencoder (CAE) emerges as the optimal architecture for our project. Its superior performance across multiple metrics suggests its suitability for a more accurate apple quality assessment.

Table 1. The performance of various autoencoder models

Model	**Reconstruction Error (Mean ± SD)**	**Anomaly Detection Accuracy**	**Precision**	**Recall**	**F1 Score**	**AUC-ROC**
Basic Convolutional Autoencoder	0.05 ± 0.02	0.85	0.80	0.75	0.77	0.82
Deep Convolutional Autoencoder	0.04 ± 0.01	0.88	0.83	0.78	0.80	0.85
Variational Autoencoder (VAE)	0.06 ± 0.02	0.82	0.78	0.70	0.74	0.80
Denoising Autoencoder	0.05 ± 0.02	0.87	0.82	0.76	0.79	0.84
Contractive Autoencoder (CAE)	0.04 ± 0.01	0.89	0.85	0.79	0.82	0.87

Conclusions

The Contractive Autoencoder (CAE) emerges as a standout performer in enhancing apple quality assessment through anomaly detection. It demonstrates a very good reconstruction accuracy with one of the lowest reconstruction errors (0.04 ± 0.01), indicative of its superior ability to faithfully reconstruct normal apples. Moreover, the CAE exhibits remarkable efficacy in detecting anomalies, achieving the highest accuracy (0.89) among all evaluated models. Its precision (0.85) and recall (0.79) values underscore its capability to accurately identify anomalies while minimizing false positives. Furthermore, the CAE achieves a high F1 score (0.82), reflecting a balanced performance between precision and recall. With the highest AUC-ROC value (0.87), the CAE showcases its proficiency in effectively distinguishing between normal and anomalous apples.

In analyzing the outcomes of alternative autoencoder models, the following observations are evident in comparison to the performance of the Contractive Autoencoder (CAE), acknowledged for its better efficacy:

- the Deep Convolutional Autoencoder (DCAE) and CAE demonstrate the lowest mean reconstruction error (0.04 ± 0.01), closely followed by the Basic Convolutional Autoencoder (BCAE) and Denoising Autoencoder (DAE). The Variational Autoencoder (VAE) exhibits a slightly higher reconstruction error at 0.06 ± 0.02.
- while the DCAE closely approaches with an accuracy of 0.88, the CAE achieves the highest anomaly detection accuracy of 0.89, surpassing all other models. BCAE, DAE, and VAE have accuracies ranging from 0.82 to 0.87.

- CAE demonstrates the highest precision (0.85) and commendable recall (0.79), indicating its superior ability to accurately identify anomalies while minimizing false positives. DCAE also displays competitive precision and recall values. In comparison, BCAE, DAE, and VAE present slightly lower precision and recall values.
- CAE attains the highest F1 score (0.82), indicating a well-balanced performance between precision and recall. The next closest is DCAE with an F1 score of 0.80, while BCAE, DAE, and VAE have slightly lower F1 scores.
- CAE demonstrates the highest AUC-ROC (0.87), signifying its superior capability in distinguishing between normal and anomalous apples. DCAE also exhibits a high AUC-ROC value of 0.85, while the other models have AUC-ROC values ranging from 0.80 to 0.84.

In conclusion, while all autoencoder models exhibit competitive performance metrics, the Contractive Autoencoder (CAE) stands out in its effectiveness in apple quality assessment through anomaly detection, consistently outperforming other models across various evaluation metrics.

Abstract

Building upon previous research in the domain of corn pest detection from some species of insects (Coleoptera Order) using Convolutional Neural Networks (CNNs), this study investigates the impact of a higher input resolution on the performance of the MobileNet-SSD neural network architecture. Our initial study focused on optimizing a deep-learning model for low-power mobile devices to detect various corn pests while preserving beneficial species. In order to further improve the detection capabilities of MobileNet-SSD, the present research explores the effect of a higher resolution of 512x512 pixels, as input for the MobileNet-SSD-v1 and v2-Lite models. These adjustment aimed to provide a more detailed input representation to facilitate enhanced detection performance. The evaluation metrics include average accuracy per class and mean average precision (mAP), as used in the previous study, to ensure consistency in performance assessment. Our findings indicate that training the networks on the augmented dataset at a higher resolution resulted in improved detection performance, with both models demonstrating enhanced mAP scores (MobileNet SSD v1: mAP = 0.912; MobileNet SSD v2 Lite: mAP = 0.919). Additionally, MobileNet SSD v2 Lite consistently outperformed MobileNet SSD v1 in terms of mAP across both training phases. This research contributes to a broader understanding of the relationship between input resolution and detection performance in CNNs, providing valuable insights on refining the approach to further enhance the precision and efficiency of modern pest detection systems in agricultural contexts.

Keywords: *Pest control, insects, Coleoptera, smart agriculture, neural network.*

Introduction

The demand for effective pest management solutions in agriculture is an important objective alongside the need for sustainable and eco-friendly practices. Traditional methods relying heavily on chemical pesticides face environmental concerns and diminishing effectiveness over time. As a response, there has been a shift towards integrating artificial intelligence (AI) technologies into agricultural practices, offering innovative solutions for pest detection and management.

Previous research has demonstrated the potential of AI-driven techniques in various agricultural domains, including disease management in sunflower crops (Gulzar *et al.*, 2023), fruit classification in horticulture (Gulzar, 2023), and citrus fruit disease detection (Dhiman *et al.*, 2023). These studies showed the effectiveness of advanced algorithms, particularly neural networks, in addressing diverse agricultural challenges.

Insect pest detection and identification have been particularly emphasized in recent research, with studies employing a range of neural network models and methodologies. The most popular object detection algorithm was YOLO, followed by Faster R-CNN and VGG16 (Maican *et al.*, 2023). In terms of mean average precision (mAP), some of the most notable results are presented in Table 1.

Table 1. Ranking of some insect identification neural networks by maximum mAP

Model	Dataset	Maximum mAP
YOLOv5m	Dataset from Maryland Biodiversity Project (Sava *et al.*, 2022)	99.2%
YOLOv5-X	7046 images, 23 pest classes (Ahmad *et al.*, 2022)	98.3% (mAP@0.5)
YOLOv7	4865 images of coccinellids, seven classes (Wang *et al.*, 2023)	Up to 97.31% (AP@0.50)
Faster R-CNN	36,000 images of harmful and non-harmful beetles (Butera *et al.*, 2022)	92.66%
YOLOv5	100,000 annotated images of small insects (Kranthi *et al.*, 2002)	92.4% (mAP@0.50)
Improved Faster R-CNN	AgriPest21 dataset: 21 pest classes, 25,000 images (Wang *et al.*, 2021)	78.7%
AgriPest-YOLO	Pest24 dataset: 25,000 images of small pests (Zhang *et al.*, 2022)	71.3% (mAP@0.50)

However, most existing research faces challenges when applied to low-power agricultural mobile systems, which require lightweight neural networks both to conserve battery life and to accommodate their limited processing capabilities. In this context, MobileNet networks have received limited attention despite their potential advantages in resource-constrained environments.

Our previous research (Maican *et al.*, 2023) focused on developing optimized MobileNet SSD networks, for crop pest detection. Utilizing a two-step transfer learning approach, we aimed to enhance the accuracy of these networks, particularly MobileNet-SSD-v1 and MobileNet-SSD-v2-Lite. Despite the reduced size of the training set (2648 images), both models demonstrated similar and good overall accuracies (MobileNet-SSD-v2-Lite: mAP = 0.8923; MobileNet-SSD-v1: mAP = 0.908), highlighting their potential for real-time pest control.

Building upon these findings, the main objective of our current study is to investigate the impact of input image resolution on the performance of MobileNet-SSD networks for crop pest detection. By increasing the input resolution from 300 to 512 pixels, we seek to assess whether higher-resolution images yield improved accuracy in pest identification. This adjustment aimed to provide a more detailed input representation to facilitate enhanced detection performance.

Materials and methods

In this study, we modified the MobileNet SSD v1 and MobileNet SSD v2 Lite networks to process images with a resolution of 512x512 pixels. This adaptation aimed to enhance the networks' ability to detect and classify objects with finer details, ultimately improving their performance. The training process was conducted on the Nvidia Jetson AGX Orin platform using PyTorch 2.0.0 for JetPack 5.1.1. Additionally, we utilized Nvidia TensorRT for real-time inference optimization on Nvidia GPUs.

The training dataset comprised 2648 images after augmentation, sourced from the iNaturalist web portal (iNaturalist, 2023). These images represented four beetle species that are pests known to cause substantial damage to crops such as corn, wheat, sunflower, and beans (*Anoxia villosa*, *Diabrotica virgifera virgifera*, *Opatrum sabulosum*, and *Zabrus tenebrioides*). In addition to pest species, the dataset includes images of the beneficial *Coccinella* sp., which is an aphid predator in agricultural ecosystems, in order to test the ability of the network to distinguish it from pest species.

The training process involved both a common transfer learning procedure, as well as a novel two-step transfer learning procedure, which consisted of the following steps:

- Initial Transfer Learning: in the first step, we performed transfer learning using the Open Images dataset to recalibrate the pre-trained MobileNet-SSD models for insect detection task. This involved retraining the models on an Open Images subset of 2605 images, containing only two classes: Beetle and Ladybug.
- Refinement Transfer Learning: in the second step, we further refined the pre-trained models using our custom dataset, organized according to the Pascal VOC format. This dataset included images of the five insect species mentioned earlier, allowing the models to learn specific features relevant to our pest detection task.

The training and evaluation procedures were conducted using two PyTorch scripts: 'train_ssd.py' and 'eval_ssd.py', respectively. These scripts were used for model training, validation, and performance evaluation, including metrics such as mean average precision (mAP). Further optimization for real-time inference was achieved using Nvidia TensorRT and detectNet – an object detection framework that performs optimized real-time inferencing on Nvidia Jetson GPUs. Detailed information on the training and evaluation procedures can be found in our previously published work (Maican *et al.*, 2023).

To summarize, in order to ensure consistency in performance assessment between the results obtained by increasing the image resolution and those from our previous research, experiments were conducted under identical conditions:

- The same two MobileNet-SSD models (MobileNet-SSD-v1 and MobileNet-SSD-v2-Lite) were trained, but modified to process images with resolutions of 512x512 pixels;
- Both models were trained on the same dataset, with the same images in the training, validation, and test sets;
- Identical values were employed for hyperparameters such as batch size, number of workers, and epochs;
- The same evaluation metrics were employed (average accuracy per class, and mAP@.50).

Results and discussion

In our previous work, we demonstrated that training the MobileNet-SSD-v1 and MobileNet-SSD-v2-Lite networks on the unaugmented dataset yielded inferior results compared to training on the augmented dataset. Therefore, in this research, all training was conducted on the augmented dataset. For experimentation, we downloaded pre-trained versions of the two neural networks: MobileNet-SSD-v1 pre-trained on the PASCAL-VOC dataset, and MobileNet-SSD-v2-Lite pre-trained on the COCO dataset. We conducted the following experiments (Figure 1):

1. Single transfer learning training:
   - 1.1. Training the downloaded MobileNet-SSD-v1 and MobileNet-SSD-v2-Lite directly on the augmented dataset (5 classes, 2648 images, input resolution: 512x512 pixels);
   - 1.2. Comparing the results from step 1.1 with the results obtained through the same procedure in the previous research, but with an input resolution of 300x300 pixels;
2. Two successive transfer learning trainings, as described in the Materials and Methods section (Two-step Transfer Learning):
   - 2.1. Training the downloaded MobileNet-SSD-v1 and MobileNet-SSD-v2-Lite on the Open Images subset of 2605 images (2 classes: Beetle and Ladybug, input resolution: 512x512 pixels);
   - 2.2. Training the MobileNet-SSD-v1 and SSD-v2-Lite networks pretrained at 2.1. on the augmented dataset (5 classes, 2648 images, input resolution: 512x512 pixels);

2.3. Comparing the results from 2.2. with the results obtained through the same procedure in the previous research, where the input resolution was 300x300 pixels.

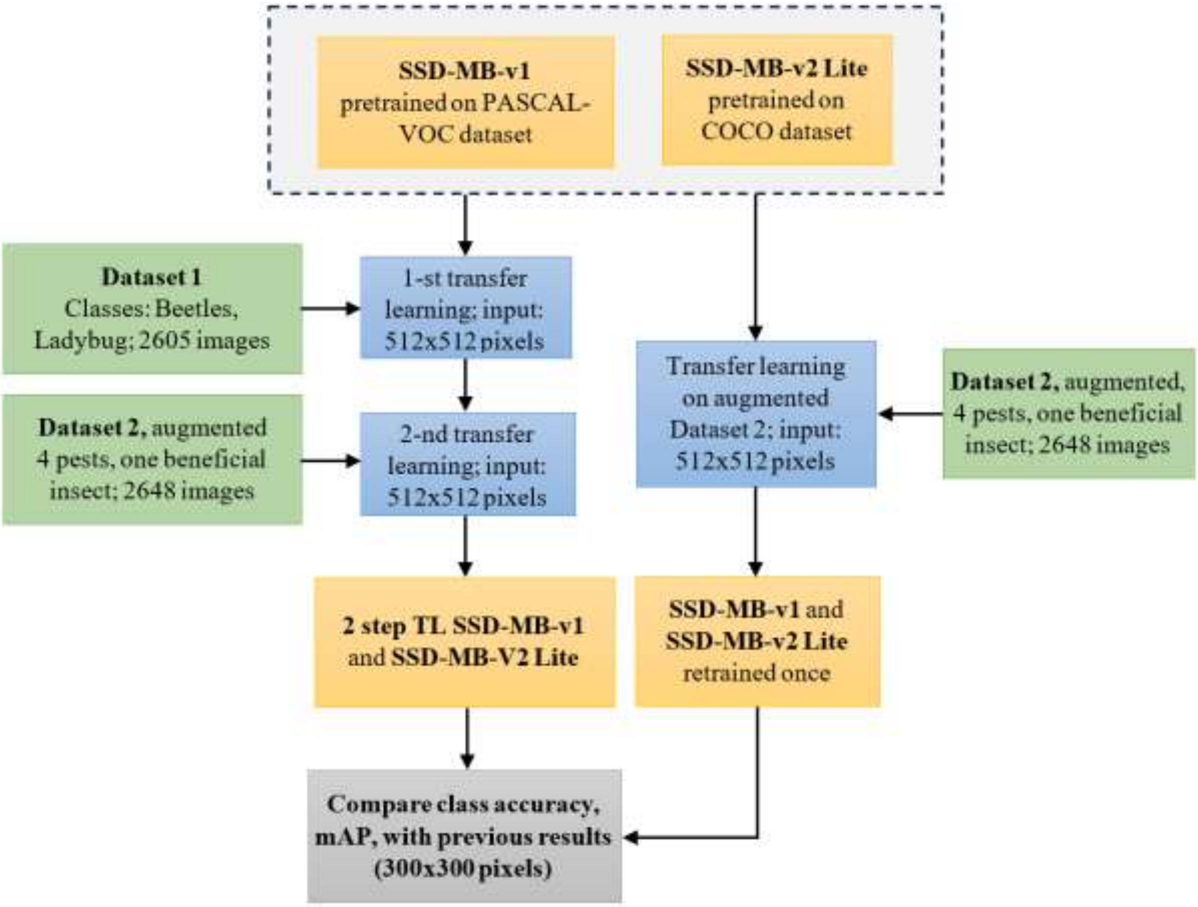

Figure 1. Schematic representation of the training and performance evaluation procedures; 2 step TL: two-step transfer learning; color scheme: orange - neural network models; blue - training procedures; green - datasets; grey - evaluation (adapted from Maican *et al.*, 2023)

To compare the results obtained from the experiments conducted in the current work, using a resolution of 512x512 pixels, with those from the previous work, where a resolution of 300x300 pixels was employed, we analysed the mean average precision (mAP), and the accuracy per class, for both MobileNet SSD v1 and MobileNet SSD v2 Lite.
The mAP metric provides an overall measure of the performance of the object detection models across all classes, capturing their ability to detect objects accurately and localize them within the image.
Conversely, the accuracy per class is a measure of the performance of the object detection neural networks for each individual class, showing their ability to differentiate between various pest species, thus allowing for a nuanced evaluation of their capabilities across different categories.
In case of the Single Transfer Learning training at the resolution of 512x512 pixels, both MobileNet SSD v1 and MobileNet SSD v2 Lite achieved higher mAP values compared to the previous work at 300x300 pixels (Table 2). Specifically, for MobileNet SSD v1, the mAP increased from 0.887 in the previous work to 0.912 in the current work. Similarly, for MobileNet SSD v2 Lite, the mAP increased from 0.884 to 0.891. This indicates that training the networks on the augmented dataset at a higher resolution improved detection performance.

Table 2. Average accuracy per class and mAP for single transfer learning training

Resolution: 512 x 512 (current work)				Resolution 300 x 300 (previous work)			
Mobilenet SSD v1		**Mobilenet SSD v2 Lite**		**Mobilenet SSD v1**		**Mobilenet SSD v2 Lite**	
Anoxia	0.998	Anoxia	0.977	Anoxia	0.987	Anoxia	0.991
Diabrotica	0.768	Diabrotica	0.766	Diabrotica	0.726	Diabrotica	0.727
Ladybug	0.977	Ladybug	0.909	Ladybug	0.874	Ladybug	0.891
Opatrum	0.909	Opatrum	0.909	Opatrum	0.924	Opatrum	0.909
Zabrus	0.909	Zabrus	0.895	Zabrus	0.947	Zabrus	0.903
mAP	0.912	mAP	0.891	mAP	0.887	mAP	0.884

Examining the results from the Two-step Transfer Learning training pipeline, at the resolution of 512x512 pixels, both networks showed better performance compared to the previous work (Table 3). The mAP values increased from 0.908 to 0.915 for MobileNet SSD v1 and from 0.892 to 0.919 for MobileNet SSD v2 Lite. This further confirms the advantage of using the augmented dataset at a higher resolution for training.

Table 3. Average accuracy per class and mAP for two-step transfer learning training

Resolution: 512 x 512 (current work)				Resolution 300 x 300 (previous work)			
Mobilenet SSD v1		**Mobilenet SSD v2 Lite**		**Mobilenet SSD v1**		**Mobilenet SSD v2 Lite**	
Anoxia	0.989	Anoxia	0.986	Anoxia	0.907	Anoxia	0.985
Diabrotica	0.787	Diabrotica	0.795	Diabrotica	0.777	Diabrotica	0.807
Ladybug	0.988	Ladybug	0.998	Ladybug	0.944	Ladybug	0.894
Opatrum	0.909	Opatrum	0.906	Opatrum	0.906	Opatrum	0.951
Zabrus	0.902	Zabrus	0.907	Zabrus	0.903	Zabrus	0.905
mAP	0.915	mAP	0.919	mAP	0.908	mAP	0.892

Comparing the performance of the two networks at the resolution of 512x512 pixels, one can notice that MobileNet SSD v2 Lite consistently outperformed MobileNet SSD v1 in terms of mAP. This suggests that MobileNet SSD v2 Lite is more effective in handling object detection tasks at the higher resolution. The accuracy per class analysis demonstrates consistent improvements in detection performance when using higher input resolutions. MobileNet SSD v2 Lite generally has slightly higher accuracies compared to MobileNet SSD v1, particularly at 512 pixels, indicating its suitability for object detection tasks in agricultural environments.

Conclusions

This study investigated the impact of input resolution on the performance of two MobileNet-SSD neural network architectures for crop pest detection, focusing on the Coleoptera order. By increasing the input resolution from 300x300 to 512x512 pixels, we aimed to assess whether higher-resolution images would yield improved accuracy in pest identification. Our findings suggest several key conclusions:

1. Both MobileNet SSD v1 and MobileNet SSD v2 Lite demonstrated enhanced mAP scores when trained on datasets with a resolution of 512x512 pixels compared to 300x300 pixels. This improvement indicates that higher-resolution images provide more detailed input representations, facilitating better detection performance.
2. The use of a two-step transfer learning approach resulted in improved detection performance for both MobileNet SSD v1 and SSD v2 Lite at the higher resolution.

3. Most of the time, MobileNet SSD v2 Lite slightly outperformed MobileNet SSD v1 in terms of mAP across both training phases at the resolution of 512x512 pixels.
4. The findings of this study have practical implications for pest control in agriculture. By using higher-resolution images on neural networks for limited-power devices such as MobileNet SSD, farmers and agricultural professionals can benefit from more accurate and efficient pest detection systems, leading to improved crop management practices and reduced environmental impact.

Overall, this research contributes to a deeper understanding of the relationship between input resolution and detection performance in convolutional neural networks, offering valuable insights for optimizing pest detection systems in agricultural contexts. Future studies may explore additional factors such as dataset size, augmentation techniques, and model architecture modifications to further enhance the precision and efficiency of crop pest detection systems.

Abstract

It is known that plowing remains a task difficult to replace with other alternative soil processing works, due to its importance. At the same time, plowing remains work that involves the highest fuel consumption. On the other hand, it is known that the physical and mechanical characteristics of the processed soil can vary greatly from one plot to another, and the plow intended for plowing work must be properly adjusted so that the tractor operating in aggregate works under optimal conditions. Variable plowing width prove to be the most suitable for adapting to soil conditions and tractor traction performance. For large agricultural operations, the use of high-power tractors is recommended to ensure that work is carried out with a minimum number of passes. In this paper, the results obtained from experimental trials conducted in Romania using a variable width plow equipped with five moldboards and powered by a 200 HP tractor are presented. The trials have been conducted for different working widths/moldboards (30, 35, 40, 45 cm), different working depths (20, 25, 30 cm), and different working speeds, which allowed, on one hand, the determination of qualitative work indices, and on the other hand, obtaining the energy indices of the tractor-plough unit (fuel consumption, working capacity, slippage, specific fuel consumption, etc.), which are very useful for those who operate such equipment, as well as for agricultural tractor dealers.

Keywords: *Plow, Agricultural tractor, Experimental testing, Quality indices, Energy indices.*

Introduction

Plowing is an essential, yet fuel-intensive agricultural task that requires careful adjustment of the plough to match the varying physical and mechanical characteristics of the soil across different plots, with variable plowing width and high-power tractors being recommended to optimize the adaptation to soil conditions and minimize the number of passes needed for large-scale operations. Enhancing the traction performance and power transfer efficiency of farm tractors during cultivation can lead to optimized energy utilization and reduced fuel consumption and greenhouse gas emissions (Md-Tahir, H., et. al., 2021), (Lekavičienė, K., 2019). Over the years, there have been numerous attempts to develop mathematical models that quantify the influence of the constructive and functional parameters of the plough on soil processing performance, considering its varying physical properties (Ghereș, M.I., 2013), (Gheorghiță, N.E., et. al., 2022), (Meca, V.A., 2012), (Augustin, K., 2019). Soil-machine interaction studies aim to provide scientific insights into how tillage tools and traction devices interact with the terrain, investigating variables such as pulling or pushing forces, vertical and lateral forces, soil failure patterns, displacement of soil particles, interface force between wheel and soil, wheel slippage, rolling resistance, estimation of wheel contact area, and soil stress at various depths. Soil bin facilities serve as ideal laboratories for tillage and traction

experiments, comprising components such as a soil bin simulating the ground, a mobile tool carrier representing tool frames, soil-engaging devices simulating tillage tools or traction elements, a power source and drive system emulating prime movers, soil conditioning equipment for soil preparation, motion control systems for component movement, measurement and data acquisition systems for real-time analysis, and a lifting system for heavy component handling (Ani, O. A., 2018), (Kheiralla, A.F., 2004), (Varani, M., 2023).The operational performance of the plough and the aggregate formed by it with a high-power tractor can be quantified in terms of qualitative and energetic indices, which are as follows (Gill, W.R., Vanden Berg, G.E., 1968):
The average working depth:

$$a_m=\frac{\sum_1^n a_i}{n} \quad [\text{cm}] \tag{1}$$

where: a_i -represents the measured working depth, (cm); n -the number of measurements.
Squared average deviation of working depth:

$$\sigma_a=\pm\sqrt{\frac{\sum_1^n (a_i-a_m)^2}{n-1}} \quad [\text{cm}] \tag{2}$$

The working depth variation index:

$$V_a=\frac{\sigma_a}{a_m}100 \quad [\%] \tag{3}$$

The average working width:

$$B_m=\frac{\sum_1^n B_i}{n} \quad [\text{m}] \tag{4}$$

where: B_i - is the measured working width, (m); n -the number of measurements.
Squared average deviation of working width:

$$\sigma_B=\pm\sqrt{\frac{\sum_1^n (B_i-B_m)^2}{n-1}} \quad [\text{cm}] \tag{5}$$

The working width variation index:

$$V_B=\frac{\sigma_B}{B_m}100 \quad [\%] \tag{6}$$

The degree of crop residue coverage: It is determined by the ratio, expressed as a percentage, between the amount of plant material remaining on the soil surface and the plant mass present on the field surface before the passage of the implement, using the following relationship:

$$G_v=\frac{\sum_1^n \frac{G_{ti}-G_{Si}}{G_{ti}}}{n}\times 100 \quad [\%] \tag{7}$$

where: G_{Si} - is the measured mass of plant residues remaining on the soil surface, on the sample taken, after the passage of the machinery, (g); G_{ti}- is the total measured mass of plant residues on the soil surface before the passage of the machinery, (g); *n* - the number of measurements.
The degree of soil pulverization: It represents the weight proportion of soil fractions with satisfactory fragmentation, namely with clod sizes of maximum 100 mm, relative to the total mass of the soil sample. It is calculated using the following relationship:

$$G_{ms}=\frac{\sum_1^n \frac{M_{ci}}{M_{ti}}}{n}\times 100 \quad [\%] \tag{8}$$

where: M_{ci} - the measured mass of soil clods with dimensions smaller than 100 mm, (kg); M_{ti} - the measured weight of the entire soil sample, (kg); *n* - the number of measurements.
Viteza de lucru:

$$v_e=\frac{3{,}6\cdot s}{t} \quad [\text{km/h}] \tag{9}$$

where: *s* - linear distance traveled, (m); *t* - time taken to traverse the distance, (s).
Fuel consumption:

$$Q=\frac{V}{3{,}6t} \quad [\text{l/h}] \tag{10}$$

where: V -is the volume of fuel recorded by the consumption device, (ml); t -sampling time, (s).
Fuel consumption per hectare:

$$q=\frac{Q}{W_{ef}} \quad [1/\text{ha}] \tag{11}$$

where: Q -hourly fuel consumption, (l/h); W_{ef} -hourly effective working capacity, (ha/h).
The hourly working capacity during actual time:

$$W_{ef}=0{,}1\cdot B_m \cdot v \quad [\text{ha/h}] \tag{12}$$

where: B_m -is the average working width, (m); v -is the actual working speed, (km/h).

Material and Methods

The variable-plowing width for high-power tractors is designed to perform plowing on flat or sloping terrain of up to 6°, on all types of soil, at a maximum working depth of 30 cm. The plough operates in conjunction with 180-240 HP wheel tractors equipped with Category III SR ISO 730-1+C1 suspension mechanism. Field trials, under operating conditions, of the PP5VM plough in combination with a "Zimbru" type tractor with 195 HP (Fig. 1), were conducted in August 2022, on the lands of a family farm in Argeș County (Romania). The experimental field tests were carried out under the following conditions:

- soil type: brownish red with loamy-clay texture;
- previous crop: mechanically harvested wheat, with straw baled and transported immediately after harvesting; height of crop residues: 15 cm;
- mass of crop residues: 70 g/m²;
- soil moisture at a depth of 25-30 cm: 18%.
- The main characteristics of the plough used for experimental trials are: number of bodies: 5; diameter of the metal wheel: 500 mm; working width per body: 30-45 cm; distance between bodies in the forward direction: 830 mm; clearance under the frame: 780 mm; length: 4815 mm; width: 2670 mm; height: 1425 mm; constructive weight: 1400 kg.
- The main functional characteristics of the plough are: maximum working depth: 30 cm; clearance in transport: 600 mm; working speed: 4.5-9 km/h; transport speed: max 10 km/h. The constructive characteristics of the body are: share type: helical; maximum working depth: 30 cm; angle formed by the share edge with the furrow wall: 44^0 ; minimum angle of the generatrices with the furrow wall: 29^0 ; maximum angle of the generatrices with the furrow wall: 46^0 ; maximum height of the share above the furrow edge: 435 mm.

Fig. 1. The 195 HP ”Zimbru” tractor and the plough with variable working width with 5 mouldboards.

Results and Discussion

In Table 1, the performance indicators of the aggregate consisting of the T195 tractor and the PP5VM plow are presented for plowing work at a depth of 30 cm and a furrow width of 40 cm on brown-red soil with average moisture of 18% in the plowed layer. In Table 2 and in Figure 2, qualitative indices of the plowing work performed with the aggregate consisting of tractor T195 and plough PP5VM on brown-reddish soil with an average moisture content of 18% in the plowed layer are presented. The meaning of the terms in the table is as follows: Working width on the mouldboard b_t(cm); Effective working speed v_e(km/h); Average working depth a_m(cm); Maximum deviation from $a_m \pm \Delta_a$(cm); Standard deviation σ_a(cm); Depth working inconsistency V_a(%); Average working width B_m(cm); Standard deviation σ_B(cm); Width working inconsistency V_B(%); Soil fragmentation degree G_{ms}(%); Vegetative residue coverage degree G_v(%).

	25.3	241	14.3	6.17	33.75	1.487	22.69
	29.6	234	15.5	5.14	34.55	1.203	28.72

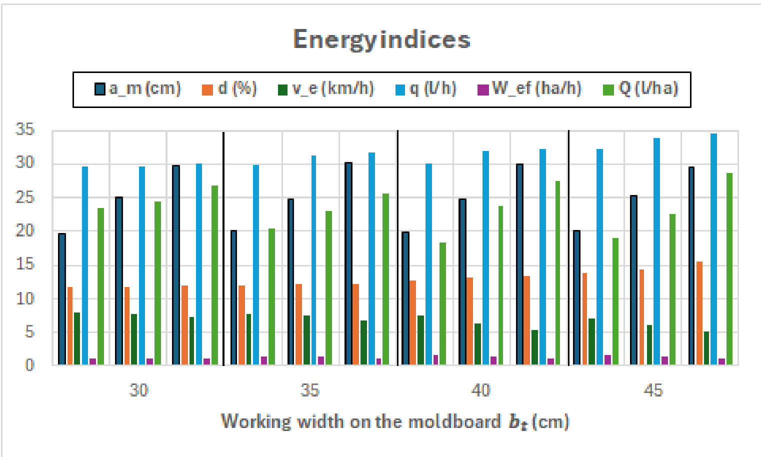

Fig. 3. The variation of energy indices depending on the width of the mouldboard

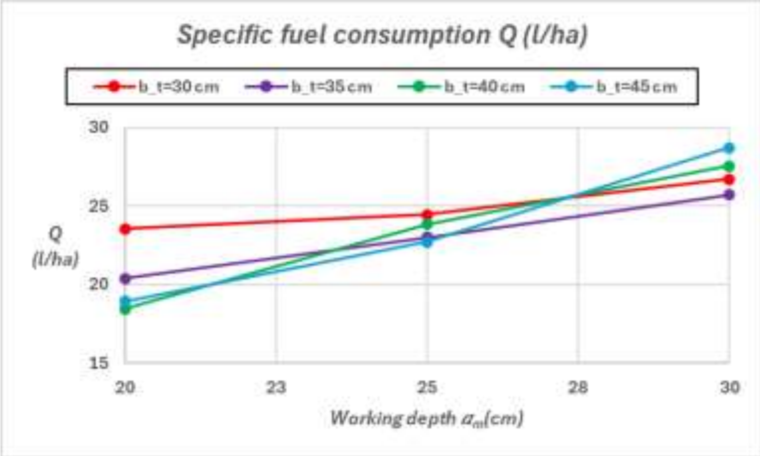

Fig. 4. The variation of specific fuel consumption depending on the working depth

In Figure 4, the graph shows the variation of specific fuel consumption as a function of plowing depth and adjusted working width for a single mouldboard. It can be observed that, as expected, the greatest variation in specific fuel consumption occurs when the working width on the mouldboard is the largest, i.e., b_t=45 cm. This variation is significantly smaller when the plough is adjusted so that the working width on the plow body is 30 cm. However, as indicated in Table 3 and Figure 3, the adjustments made to the plough and operating conditions allow for plowing work to be carried out such that wheel slip remains reasonable (within the range of 11-15%).

Conclusions

This paper emphasizes the essential role of plowing in agriculture, highlighting its irreplaceable nature due to high fuel consumption compared to other tillage methods. The effectiveness of variable plowing width is underscored, adapting efficiently to varying soil physical and mechanical characteristics and tractor traction performance. It recommends high-power tractors to minimize passes over fields, enhancing operational efficiency. Results from experimental trials in Romania using a variable plough width attached to a 200 HP tractor provide valuable data on qualitative and energy indices, such as fuel consumption and tractor efficiency, beneficial for equipment operators and agricultural tractor dealers.

DIGITAL TECHNOLOGIES IN AGRARIAN SCIENCE AND EDUCATION

Daniil IAKOVLEV*, Alexandr PCHELNIKOV

Engineering Institute, Novosibirsk State Agrarian University, Novosibirsk, Russia
*Corresponding author: dyagro@yandex.ru

Abstract

The article analyzes statistics on the number of sown areas and cultivated crops in Russia and Siberia, the total sown area being 81.2 and 14.5 million hectares, respectively. The most common crops are grain and leguminous, including corn, occupying 48 and 9.3 million hectares of sown areas in Russia and Siberia, respectively. An analysis of digital technologies in Russian agriculture is provided. Elements of precision farming are used over an area of more than 15,5 million hectares, the main of which include digitization of fields, soil sampling, parallel driving, variable rates of seed sowing and fertilizer application, monitoring the condition of plants using satellite and UAV images, yield mapping and others. Information is provided on the need to develop interdisciplinary specialists in agriculture as part of the digital transformation of society. The need for close participation of agricultural science in the training of personnel for the agricultural industries was noted. Using the example of the experience of the Novosibirsk State Agrarian University, algorithms for the interaction of science, agricultural production and education are reflected. Examples of our own research in the field of precision farming in Siberian conditions are given. The experience of interaction between enterprises producing agricultural machinery and digital services with an educational institution is shown, as well as the experience of introducing elements of precision agriculture into the educational process of a university and the experience of creating educational laboratories that meet all modern requirements of agricultural production in Russia and it`s regions.

Keywords: *Russia, Siberia, digital agriculture, precision planting, digital education.*

Introduction

Currently, agricultural production in Russia is developing quite rapidly, both technically and technologically (Decree of the President of the Russian Federation, 2016). The main constraint on development is the shortage of labor. We are already faced with a shortage of qualified specialists in all areas of agriculture (Pauschinger and Klauser, 2022). The use of digital technologies makes it possible to solve these problems. Following the example of related industries, we see that the introduction of such technologies brings a certain effect. In turn, we come to the conclusion that in the field of agriculture we need completely different specialists. This is not only an agronomist, an engineer, a livestock breeder, a livestock specialist or an information technology specialist. Today, we need a person who will have the basic skills and competencies inherent in all of the listed specialties. Most often, such a vacancy is referred to as a specialist in the implementation of digital technologies in agricultural production. In connection with the current situation, it is necessary to train such specialists within the framework of existing educational programs (Yakushev, 2022). To do this, teachers and researchers need to be at the peak of production, engage in advanced research related to the introduction of digital technologies in agriculture, and then, based on this, develop the material and technical base of universities. Modern equipment and technologies will allow students to master the necessary advanced competencies. In connection with the upcoming transformation of modern universities, this issue is very

relevant. As part of the new formation of educational programs, students will be integrated into scientific activities from the initial courses, which in turn will be based on the established modern laboratories within the framework of the main strategic projects of universities. Such specialists will be sharpened not only by the ability to operate previously developed technical means or apply previously developed technologies. New specialists will be able to independently create fundamentally new solutions based on scientific research. Upon arrival at a new workplace, future graduates will be able to quickly find their bearings and get involved in the production process and benefit the rapidly developing agro-industrial complex.
The aim of this article is to review the state of the agro-industrial complex of the Siberian Federal District of the Russian Federation and the features of training highly qualified personnel capable of introducing digital technologies into agricultural production.

Materials and methods

The article analyzes open data obtained by the Federal State Statistics Service of the Russian Federation on the number of sown areas in the country. An analysis of statistical data from the center for forecasting and monitoring of scientific and technological development of the agro-industrial complex of the Ministry of Agriculture of the Russian Federation in the field of precision farming, automation and robotization was carried out. Research conducted by the Novosibirsk State Agrarian University from Russia is carried out using modern instruments and equipment located both at the university and at partner enterprises. Also, during research and as part of training programs, modern digital services with elements of geoinformation technologies for agriculture, such as ExactFarming, GEOMIR, Cropio, SmartSoil, etc., are used.

Results and discussion

The area of the Russian Federation is 1713 million hectares, which is the first indicator in the world, in turn, the Siberian Federal District, which includes 10 subjects (regions) with a total area of 436 million hectares, is the second largest in the country after the Far Eastern Federal District. The country's cultivated area is 81.2 million hectares, of which 14.5 million hectares are in Siberia. The most common cultivated agricultural crops are grains and legumes, including corn, and occupy 48 and 9.3 million hectares in the country as a whole and in Siberia, respectively (The Federal Service for State Statistics (Rosstat), 2024).

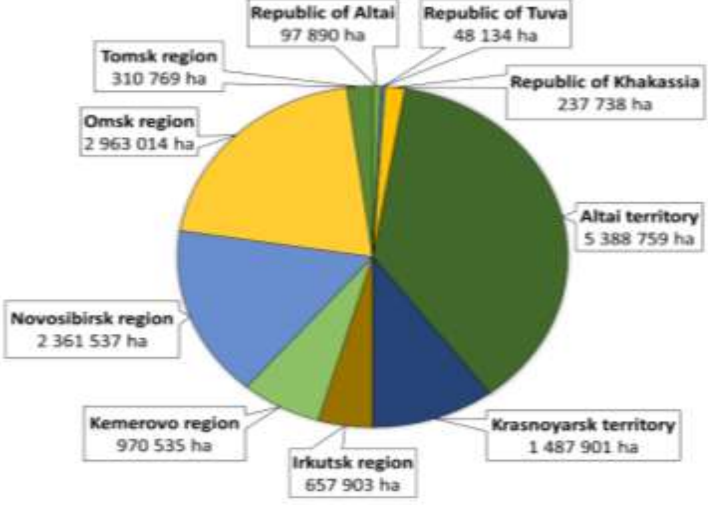

Figure 1. Sown areas of Siberia

From figure 1 it is clear that the territory of Siberia does not have many cultivated areas in relation to a fairly large total area. This fact is due to the fact that most of Siberia is occupied by mountains and forests. Nevertheless, out of 9.3 million hectares, the largest cultivated area is occupied by the Altai Territory with 5.4 million hectares, being the most developed agricultural region of Siberia and one of the leading in Russia, and the Republic of Tuva has the smallest area, due to the fact that it is located mainly in mountainous areas where it borders neighboring Mongolia. It should also be noted that the areas of the Omsk and Novosibirsk regions with 2.9 and 2.4 million hectares of cultivated area, respectively, stand out against the general background.
It goes without saying that in order to increase the economic efficiency of crop production, it is necessary to introduce digital technologies, the basis of which is precision farming, which includes the following elements:
- digitization of fields;
- sampling and tests of soils in the coordinate system;
- parallel driving;
- satellite monitoring of vehicles;
- differentiated spraying/fertilizing/seeding/irrigation/soil cultivation;
- monitoring the condition of crops using remote sensing (UAV, Satellite data);
- yield mapping, etc.

Across the country, one or another of the elements listed above is used on an area of 15.5 million hectares. From Figure 2 it can be seen that in Siberia elements of precision farming are used on an area of 2.9 million hectares (Trufliak, 2020).

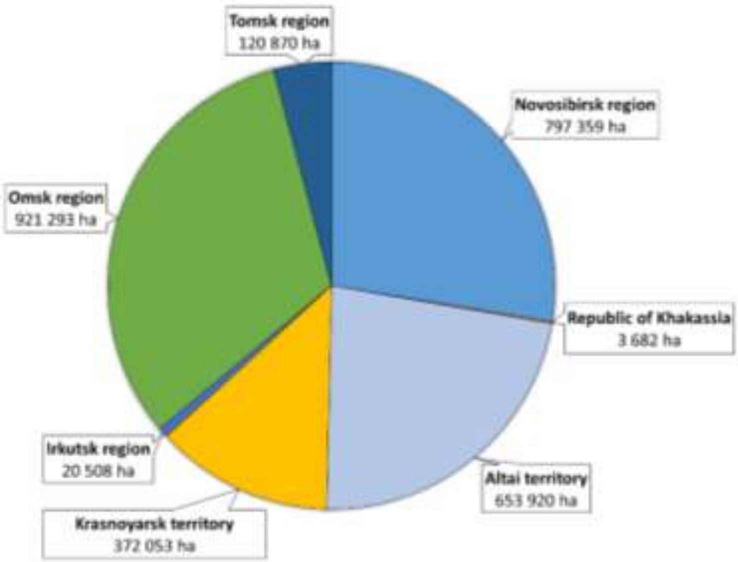

Figure 2. Sown areas cultivated with some elements of precision farming

Having analyzed the areas of Siberia where elements of precision farming are used, we see that the leading regions in the development of modern technologies are the Omsk and Novosibirsk regions with areas of 921.3 and 797.4 thousand hectares. respectively. Elements of precision farming are used on only 30% of the cultivated areas of Siberia, which indicates huge potential for further development.
In turn, the development of modern technologies is impossible without the training of qualified personnel this, in turn, requires practical and scientific experience, which is acquired by the staff of our university in close interaction with agricultural production.

Currently, the main scientific direction of our department is precision agriculture, which, as is known, is based on the concept of an individual approach to each field, and the identification of soil heterogeneities that form depending on many factors (Anfimov et al., 2022; Anfimov, 2022). Subsequently, the calculated areas of heterogeneity are transformed into maps of assignments (prescriptions), using which we can vary the rates of application of seeds, fertilizers, irrigation, and also perform soil cultivation differentiated by depth (Fig. 3). It should also be noted that, taking into account the determined soil differences, it is possible to regulate the operating costs of machine-tractor units when cultivating crops. Since the properties of the soil have a significant impact on such indicators as the traction resistance of implements, and as a result, fuel consumption, and possible disruptions in technological processes that entail losses in yield (Kostić et al., 2014; Iakovlev et al., 2020; Iakovlev, et al., 2023).

Figure 3. Research of soil heterogeneities

We also monitor weather conditions using networks of weather stations (Fig. 4), which allow us to make operational decisions when managing the production cycle (Iakovlev and Polyakov, 2023).

Figure 4. Research of weather conditions

The result of these studies is a reduction in the costs of technological operations, an increase in the yield of cultivated crops and their quality, and as a consequence, an increase in the economic efficiency of agricultural enterprises. And most importantly, our teachers gain enormous practical experience, which they can later pass on to their students, who will soon go to work in agriculture. Modern trends tell us that today's specialists in agriculture must be multidisciplinary, because, firstly, the labor market is experiencing a kind of hunger, and secondly, modern technologies require a specialist to make operational decisions in several areas of specialization. For example, to make decisions in agronomy, a future graduate must have the skills to use geographic information technologies and understand their relationship with engineering technologies. The scientific and industrial experience we have accumulated is reflected in the educational process of our university; in close cooperation with our partners, we successfully introduce elements of agricultural digital technologies into the educational process, modernizing our laboratories, so that our future graduates can master advanced knowledge and skills and apply them in further work (Fig. 5).

Figure 5. Laboratories of the Engineering Institute of NSAU

Conclusion

Agriculture in the Russian Federation and Siberia is currently in a stage of intensive development, as evidenced by constant growth in both technical and technological terms. The total cultivated area in Russia and Siberia is 81.2 and 14.5 million hectares, respectively. The most common crops are grains and leguminous crops, including corn, occupying 48 and 9.3 million hectares of cultivated area in Russia and Siberia, respectively. Elements of precision agriculture are applied over an area of more than 15.5 million hectares, the main of which include field digitization, soil sampling, parallel driving, variable rates of seed sowing and fertilizer application, monitoring of plant health using satellite images and UAVs, yield mapping and others. It is a fact that today it is necessary to train interdisciplinary specialists for agriculture as part of the digital transformation of society. This is possible with the close participation of agricultural science in training personnel for the agricultural industries. Using the example of the experience of the Novosibirsk State Agrarian University, algorithms for the interaction of science, agricultural production and education are reflected. With proper interaction between science, education and agricultural production, the pace will only increase, which is certainly the vector direction of the industry.

Acknowledgement

I express my gratitude to my colleagues from the department of machine and tractor fleet operation and our partner enterprises in the Novosibirsk region and Altai Territory, since everything we do is the merit of each member of our friendly team, working for the benefit of the development of agriculture in our country.

Abstract

With an increase in the cutting height of the corn stalks, the crude protein content increases, and thus the nutritional value of the corn silage. During Treatment I, the highest crude protein content was achieved by silage harvester B (7.18%), and the lowest by harvester C (7.03%). The lowest sensitivity during Treatment I was recorded in harvesters A (b = 0.0451) and B (b = 0.0460), and the highest in harvester C (b = 0.0733). It was found that this dependence was very strong for all types of tested silage harvesters, C (R^2 = 0.9973), B (R^2 = 0.9907), A (R^2 = 0.9847) respectively. In Treatment II, silage harvester B also achieved the maximum crude protein content of 8.17%, and harvester C the minimum (7.97%). The minimum sensitivity during Treatment II was recorded in harvester C (b = 0.0171), and higher in harvesters A (b = 0.0208) and B (b = 0.0213). The R^2 factor values showed a strong dependence in all three cases A (R^2 = 0.9960), B (R^2 = 0.9655) and C (R^2 = 0.9903). The content of crude fiber decreased with the increase in the cutting height of the stems. The maximum values of crude fiber content were achieved by harvester C (24.05% in Treatment I and 21.63% in Treatment II). The lowest crude fiber content was achieved during the operation of harvester B (23.03% in Treatment I and 21.08% in Treatment II). Harvester B showed the lowest sensitivity during Treatment I (b = -0.1705) and during Treatment II (b = -0.1486) compared to other types of silage harvesters.

Introduction

The preparation of silage is one of the most important processes in the preparation of bulk fodder. The main goal of silage preparation is to produce food with high energy content and highly digestible nutrients (Kung et al., 2018). Good digestibility of corn silage is ensured by the high content of carbohydrates, and the lower content of crude protein and crude ash (Szymańska et al., 2018). The nutritional value of ensiled material is the most important factor affecting the quality of silage. The high nutritional value of the corn plant makes it very suitable for ensiling (Neylon and Kung, 2003), and corn silage itself is one of the most important components of forage used in animal nutrition (Khan et al., 2014). During ensiling, the process of anaerobic conservation of the chopped silage mass by lactic acid fermentation takes place. Zicarelli et al., (2023), state that knowledge of the chemical composition of the whole corn plant is important because it enables the preparation of a balanced meal of high nutritional value. The studies of Mandić et al., (2020) and Bumb et al., (2016) showed that the time of the beginning of the harvest and the cutting height significantly affect the quality of the prepared silage. Maize cutting height affects the chemical composition and nutritional value of silage (Aoki et al., 2013). With higher cutting heights, the nutritional value of silage increases because the content of crude proteins increases, and the content of crude ash decreases, which is a consequence of the increased share of grains in corn silage. Due to the increase in the share of grains, the content of starch is increased, and the content of crude fiber is reduced (Horst et al., 2021), which significantly affects the increase in the nutritional value of silage (Diepersloot et al., 2022). Silage with a high crude protein content has a high energy value (Zhang et al., 2018). Zhao et al., (2018), recommend higher cutting heights of high-protein corn varieties because this improves the nutritional value of the prepared silage. Hulse et al., (2017), recommend harvesting corn at 40 cm height. Higher heights are not recommended, and this is proven by the research of Diepersloot et al., (2022), which states that cutting heights of stems over 60 cm result in a decrease in crude protein content in silage. The choice of appropriate machinery for preparing corn silage (silage harvesters) is an important factor that affects the quality of the silage. The production of quality fodder in animal husbandry depends on the efficiency and quality of work of silage harvesters (Valge et al., 2021). A high correlation dependence is observed between the speed of movement of self-propelled silage harvesters and the cutting height of the stalks. As the movement speed increases, the cutting height increases. The goal of our research is to examine the influence of the cutting height of the stalks on the nutritional value of the silage in dry land conditions during the preparation of corn silage, with the use of different types of self-propelled silage harvesters.

Material and methods

Tests on the influence of cutting height on the nutritional value of corn silage were carried out under dry land conditions during 2020 in central Serbia (43º 33' 35.02" N; 21º 29' 55.61" E) in the municipality of Kruševac. The silage is prepared from whole KWS Mikado hybrid corn plants, of high nutritional value. The harvest was carried out on the same plot with three types of tested self-propelled forage harvesters: New Holland FX 28 (Type A), Claas Jaguar 850 (Type B) and John Deere 6810 (Type C), with a theoretical cutting height of 10 cm (Treatment I) and 30 cm (Treatment II). Using the standard chronometric method (Al-Gadi, 2018), by measuring the time interval of the harvester's movement on an experimental track 500 m long, the working speed of the silage harvester was determined. The length of the trail was measured with a PCE LDM 50 laser range finder. Chronometric measurements were made with a digital chronometer TFA Dostman Triple Time XL-Digitaler 3-fach Timer. The working speed and cutting height of corn stalks was determined in three tests (three repetitions within the test). Using the random sample method, each sample was divided into three parts, which constituted a repetition, and the content of crude proteins, crude fiber and crude ash was determined by appropriate laboratory methods. The content of crude proteins (total nitrogen) was determined according to the standard Kjeldahl method (Thiex, 2009), by decomposition of organic matter with concentrated sulfuric acid (H2SO4) in the presence of catalysts (K2SO4 and CuSO4) and titration of the resulting ammonia. The obtained values were multiplied by a coefficient of 6.25. The crude fiber content was determined by the method (Thiex, 2009), which is based on treating the samples with a solution of sulfuric acid and sodium hydroxide. The rest is separated by filtration and weighed after drying. The method for determining of crude ash is based on decomposition of samples by annealing at 550^0C and measurement of residues (Thiex et al., 2012). Experimental data were processed using the free software package R-Statistics. Tukey's multiple range test was used to test the effects of treatment. A linear regression model was used to analyze the influence of the movement speed of the silage harvesters on the cutting height of the stalks and the effect of the cutting height on the content of nutritional elements.

Results and Disscusion

Tests showed that the operating speeds of the investigated silage harvesters influence the cutting height of the corn stalks, which was confirmed by the Tukey test, where a statistically significant difference ($p \leq 0.05$) was found for all the investigated traits except for CP (%) in Treatman II (Table 1). Harvester A achieved the maximum cutting height in the third trial of 13.82 cm at a working speed of 6.60 km h^{-1} in Treatment I and 39.25 cm at a speed of 7.80 km h^{-1} in Treatment II. We recorded the minimum cutting height values with harvester C in the first trial (11.05 cm at a working speed of 3.10 km h^{-1} in Treatment I, i.e. 33.20 cm at a speed of 4.30 km h^{-1} in Treatment II). The achieved results are comparable with the results of Ramm et al., (2023).

Table 1. Results of experimental measurements of silage harvesters (type A, B, C)

Cutting height (cm)		Treatment I				Treatment II			
Param.	Mower	Repetition			$\overline{X}$	Repetition			$\overline{X}$
		1	2	3		1	2	3

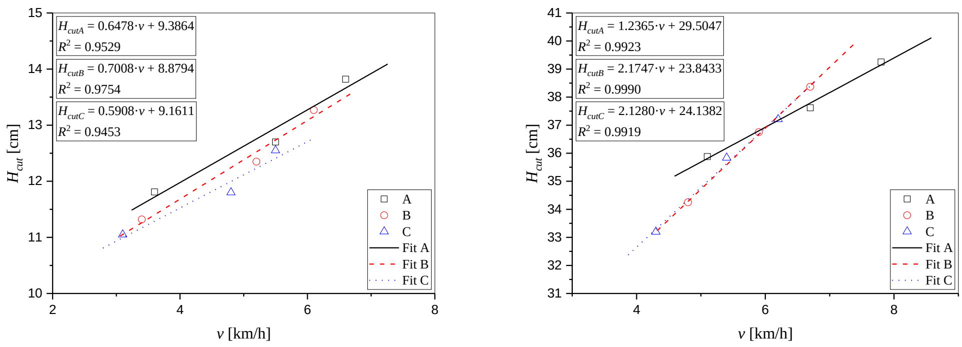
v - working speed; Hcut – achieved cutting heigh; CP – crude protein; CF – crude fiber; CAsh – crude ash; A - New Holland FX 28; B – Claas Jaguar 850; C - John Deere 6810; The Tukey test was applied for the influence of type of harvester (treatment average), significance level $p \leq 0.05$

With the increase in the movement speed of the silage harvesters, the cutting height of the stalks increased linearly (Figure 1).



A B

Figure 1 – Effect of movement speed (v) on cutting height (Hcut): (A) Treatment I, (B) Treatment II

During Treatment I (Fig. 1A), the increase was the largest for the harvester B with a regression slope coefficient b = 0.7008, and the least for the harvester C (b = 0.5908). The R^2 factor values show a strong dependence (B = 0.9754, A = 0.9529, C = 0.9453). In Treatment II (Figure 1B), a very strong sensitivity is observed for the harvesters B (b = 2.1747) and C (b = 2.1280). In this treatment as well, the value of the R^2 factor shows a strong dependence (B = 0.9990, A = 0.9923, C = 0.9919).
The cutting height of the stems affected the content of crude proteins, as their content increased with the cutting height (Figure 2). The highest crude protein content in Treatment I (Fig. 2C) was achieved by the harvester B (7.18% at a cutting height of 13.27 cm), and the lowest by the harvester C (6.92% at a height of 11.05 cm). In Treatment II (Figure 2D), the maximum crude protein content was also achieved by the harvester B (8.17% at a cutting height of 38.37 cm), and the minimum by the harvester C (7.97% at a height of 33.20 cm). The lowest sensitivity during Treatment I (Figure 2C) was recorded by the harvesters A (regression slope coefficient b = 0.0451) and B (b = 0.0460), and the highest by the harvester C (b = 0.0733). It was found that this dependence is very strong for all types of tested silage harvesters, C (R^2 = 0.9973), B (R^2 = 0.9907), A (R^2 = 0.9847) respectively. During Treatment II (Fig. 2D), the minimum sensitivity was observed in the case of the harvester C (b = 0.0171), and higher in the case of the harvesters A (b = 0.0208) and B (b = 0.0213). A very strong dependence was found in all three cases A (R^2 = 0.9960), B (R^2 = 0.9655) and C (R^2 = 0.9903).

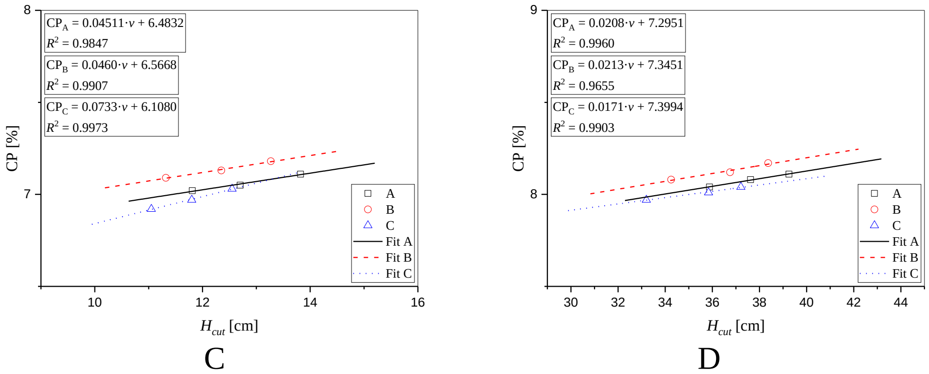


Figure 2 - Effect of cutting height (Hcut) on crude protein content (CP): (C) Treatment I, (D) Treatment II

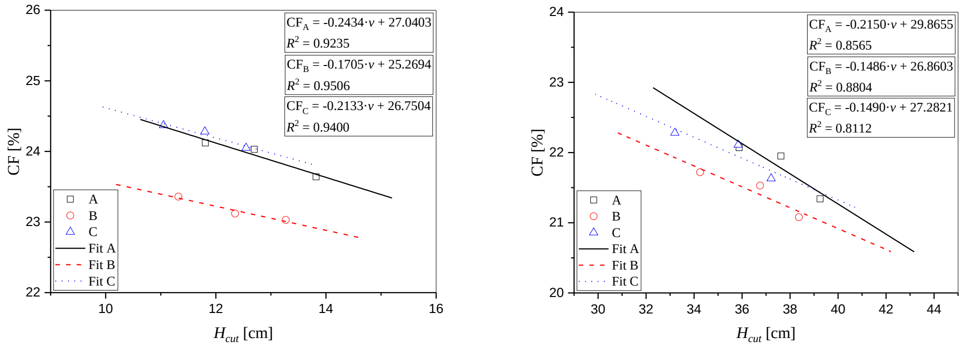
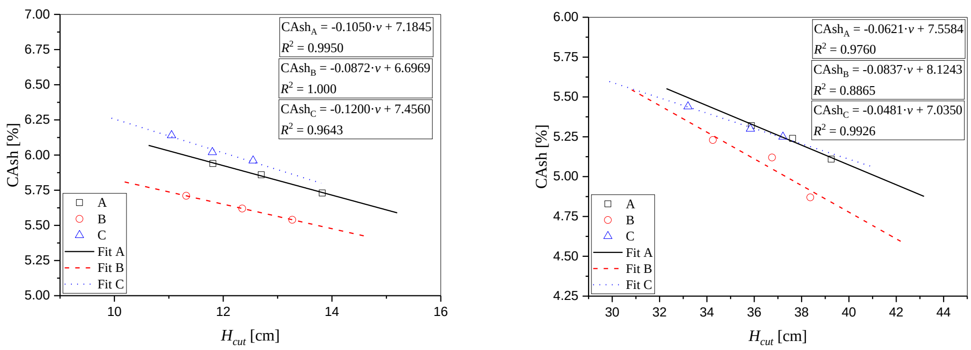
With an increase in the cutting height of the corn stalks, the crude fiber content decreases (Figure 3). The lowest crude fiber content was achieved during the operation of the harvester B (23.03% at a cutting height of 13.27 cm (Treatment I, Figure 3E) and 21.08% at a cutting height of 38.37 cm (Treatment II, Figure 3F).



E F

Figure 3. Effect of cutting height (Hcut) on crude fiber content (CF): (E) Tretman I, (F) Tretman II

The maximum values of crude fiber content were achieved by the harvester C (24.05% at a cutting height of 12.55 cm (Treatment I) and 21.63% at a cutting height of 37.21 cm (Treatment II). The content of crude fiber decreases linearly due to an increase in cutting height. During Treatment I (Figure 3E) the lowest sensitivity was achieved with the harvester B (regression slope coefficient b = -0.1705), and slightly higher with the harvesters A and B (b = 0.2434 and b = 0.2133). The values of the R^2 factor show a strong dependence in all examined silage harvesters A (R^2 = 0.9235), B (R^2 = 0.9506) and C (R^2 = 0.9400). In Treatment II (Figure 3F), harvesters B (with a regression slope of b = -0.1486) and C (b = -1490) recorded the least decline. This relationship was moderately strong for the harvesters A (R^2 = 0.8565) and C (R^2 = 0.8112), and strong for the harvester B (R^2 = 0.8804). The obtained results of crude protein and crude cellulose content are in accordance with previous research (Szymańska et al., 2018; Kung et al., 2008; Kowalik et al., 2013).
The crude ash content did not vary significantly under the influence of the cutting height of the corn stalks (Figure 4). In Treatment I, the concentration ranged from a maximum of 6.14% achieved by the harvester C at a cutting height of 11.05 cm, to a minimum of 5.54% by the harvester B at a cutting height of 13.27 cm (Figure 4G). The decrease is most pronounced during the operation of the harvesters A (regression slope coefficient b = -0.1050) and C (b = -0.1200), and less pronounced with the harvester B (b = -0.0872). The values of the R^2 factor show a very strong dependence in all three cases A (R^2 = 0.9950), B (R^2 = 1.0000) and C (R^2 = 0.9643). In Treatment II (Fig. 4H), we note the lowest sensitivity for the harvester C (b = -0.0481), and the highest for the harvester B (b = -0.0837). A very strong dependence was found for harvesters A (R^2 = 0.9760) and C (R2 = 0.9926) and strong for the harvester B (R^2 = 0.8865).



G H

Figure 4. Effect of cutting height (Hcut) on crude ash content (CAsh): (G) Tretman I, (H) Tretman II

Our research proves that with an increase in the cutting height of the stalks, the crude ash content decreases, which is a consequence of the increase in the share of grains in corn silage and significantly affects the increase in its nutritional value (Diepersloot et al., 2022).

Conclusions

Due to the increase in the cutting height of corn stalks, the crude protein content increases, and thus the nutritional value of corn silage. During Treatment I, the highest crude protein content was achieved by the silage harvester B (7.18%), and the lowest by the harvester C (7.03%). The lowest sensitivity during Treatment I was recorded during the operation of the harvesters A (b = 0.0451) and B (b = 0.0460), and the highest with the harvester C (b = 0.0733). In Treatment II, silage harvester B also achieved the maximum crude protein content of 8.17%, and harvester C the minimum crude protein content (7.97%). The minimum sensitivity during Treatment II was recorded during the testing of the harvester C (b = 0.0171), and higher for the harvesters A (b = 0.0208) and B (b = 0.213). The content of crude fiber decreases with the increase in the cutting height of the stems. Maximum values of crude fiber content were achieved by the harvester C (24.05% in Treatment I and 21.63% in Treatment II). The lowest crude fiber content was achieved during the operation of the harvester B (23.03% in Treatment I and 21.08% in Treatment II). Tukey's test confirmed that a statistically significant difference ($p \leq 0.05$) was found for all investigated traits, except for CP (%) in Treatman II. The results of the comparative test of silage harvesters give an advantage to the harvester B over harvesters A and C.

Abstract

The constant increase in the world population is a trend that also requires the increase in food production, i.e. the increase in crop yields, which represent the main challenge of agricultural production in recent years. This paper aims to provide insight into new trends and technologies necessary for the development of precision agriculture, emphasizing the advantages of integrating smart sensors and innovative technologies. The transition to modern agricultural production enables the increase in yields, a reduction in production costs, and the production of healthier and better quality products. The goal of precision agriculture is to increase yield, efficiency, reduce costs and resources, as well as to minimize the negative impact on the environment. In frames of precision agriculture, there is a trend of introducing sensor detection as a more rational data collection technique. Sensors are devices for detecting, registering and measuring the radiation of electromagnetic energy, its own or reflected. They enable the collection of a larger group of data by applying a simpler technique with minimal costs which can determine the quality of soil and crops. They are also used on a variety of agricultural machinery and robots in order to speed up the data collection process and at the same time prevent the occurrence of malfunctions. The development of precise agricultural production technologies represents a perspective for the improvement of traditional agricultural practices and the transition to modern agricultural production with greater efficiency and sustainability of food provision.

Keywords: *Precision Agriculture, Food production, Data, Innovative technologies.*

Introduction

Agriculture has always been the cornerstone of human civilization, providing a stable source of food and raw materials. However, with a growing world population and limited natural resources, traditional agricultural approaches increasingly show their limitations. In this context, precision agriculture has emerged as an innovative response to the challenges of modern farming, offering sustainable and efficient methods to increase yields and reduce environmental pollution (Yadav & Kumar, 2023).

Precision agriculture relies on advanced technologies to enable accurate and timely management of agricultural processes. One of the key aspects of this practice is the integration of sensors, which collect data on various parameters of the environment and crop conditions. This data allows farmers to make timely decisions, optimize the use of resources such as water, fertilizers, and pesticides, and improve the overall efficiency of agricultural production.

Sensors used in precision agriculture can measure various parameters, including soil moisture, nutrient levels, temperature changes, the presence of pests, and many other factors (Pajić, 2022). These sensors are often linked to systems for remote control and data analysis, allowing real-time monitoring and swift interventions. The use of drones equipped with

cameras and multispectral sensors allows for precise mapping and analysis of large arable land (Dibyajyoti Nath, 2023).
This paper aims to investigate the importance and application of sensors in precision agriculture. It analyzes how these technologies contribute to improving yields, reducing costs, and preserving the environment. The paper will focus on practical examples and case studies of the application of optical sensors, showcasing successful implementations of these technologies in various aspects of agricultural production. Finally, the paper will explore the challenges and future directions of development in this area, which has the potential to transform agricultural production methods.

Sensors

Sensors are devices that can measure various physical quantities such as temperature, humidity, speed, acceleration, position, and light intensity. They provide measurable representations of the measured physical quantity in the form of an electrical signal or changes in the electrical characteristics of an electrical component (Pajić et al., 2022). The purpose of sensors is to detect changes in a given environment and send information to a computer processor. The most commonly used sensors in agriculture are used for measuring meteorological conditions, soil moisture, and plant conditions, as well as for monitoring yield. The sensors are characterized by their ability to register a wider or narrower spectral range, individual spectral lines (rays of one wavelength), or multiple separated spectral lines within one spectral region at once. The fact that sensors are not only used for measurement but also in other areas such as shipbuilding, sports, various sciences, household, medicine, etc. indicates how important sensors are in everyday life.
The sensors can be divided into two types based on the kind of energy they detect: passive or active (Kostić, 2021). Active sensors emit and receive energy, capturing the reflected part from the measured object. They have their light source and can be utilized year-round and throughout the day, regardless of weather conditions and the position of the Sun. Active sensors, unlike passive ones, can send and receive energy. This category includes radars and laser scanners. Active and passive sensor technologies are used in remote sensing to take measurements from a distance or to measure phenomena that are not visible to the naked eye. Passive sensors only detect the energy emitted by the object being observed. Passive multispectral sensors depend on natural light, which can be significantly influenced by factors like sun exposure, cloud cover, architectural structures, and the reflective properties of scanned objects (These variables can impact the consistency of imaging over time, especially when observing a wide area that necessitates prolonged scanning (Fahey et al., 2020; Kostić, 2021). Examples of passive sensor technologies include photographic, thermal, chemical, and infrared sensors. Also, sensors can be classified according to different criteria (Pajić, 2022):

- by the sizes they measure,
- types of signals and interfaces,
- features and characteristics,
- quality class,
- principle of work,
- production technology,
- fields of application,
- values.

The sensor's main features include:
Sensitivity - refers to how the output value changes when the measured value changes, such as in an electrical measuring instrument. If a displacement of 0.1 mm results in a voltage

change of 0.1 V at the output, then the sensor's sensitivity is 1 V/mm. Sensors used to detect small changes must have high sensitivity.
Linearity - ideal sensors are designed to be linear, i.e., the sensor's output signal is linearly proportional to the measured value. Linearity is challenging to achieve, and any deviations from the ideal are called linear tolerances. Linearity is expressed as a percentage of deviation from the linear value. It is the maximum deviation of the output curve from the line that best fits one calibration cycle, and it is related to the accuracy of the sensor.
Accuracy is typically assessed through absolute and relative error. Absolute error is the disparity between the actual value of the measured quantity and the measurement result (sensor output value). Relative error is calculated as the ratio of the absolute error to the actual value. The relative error is often presented as a percentage.
Signal resolution - represents the smallest value change that a sensor can recognize in the measured quantity. Resolution is related to the accuracy of the measurement and represents the sensor's ability to reproduce a certain set of readings within a given accuracy.

Sensors in precision agriculture

The use of sensors in agricultural production has evolved alongside technological advancements. Initially, sensors were complex systems designed to measure temperature or humidity, but today's sensors are modern, precise, and offer a wide range of capabilities. It is expected that sensor applications in agriculture will continue to expand in the future, playing a crucial role in achieving sustainable, efficient, and productive agricultural practices. Modern agricultural systems now integrate various types of sensors, enabling the monitoring and control of numerous parameters, leading to improved efficiency, productivity, and overall sustainability in agricultural production (Saiz-Rubio & Rovira-Más, 2020; Paul et al., 2022).
In precision agriculture, sensors are used on devices to test soil properties, on machines for feeding and protecting crops, and for harvesting crops. These sensors are installed on the machines and connected to the control unit and GPS receiver. The data obtained through these measurements is precise because the measurements are taken during agrotechnical operations. The most well-known system of this kind is OptRx from Ag Leader (https://www.agleader.com/blog/ag-leader-releases-optrx-crop-sensor/). The sensors are calibrated to the machinery (sprayer). What sets it apart is its direct connection to the display, which allows access to sensor readings. The sensor uses a wave that responds even in high-density plant environments. Another widely used approach for assessing soil properties involves the Veris MSP3 sensor system (Jurišić & Plaščak, 2009). These sensors function based on the same principle as the previously mentioned system, offering essential information for soil management. However, unlike the other system, the Veris MSP3 necessitates using processed data alongside a computer program to generate different types of maps that can be applied for agricultural purposes.

Sensory measurement of crop characteristics

Sensory measurement of crop properties is one of the main approaches in modern agricultural production systems. Accurate measurement of plant characteristics is made possible by sensors that have achieved high tracking accuracy through technological progress (Marković et al., 2020). Sensory measurement of crop properties enables optimization of the use of resources such as fertilizers, pesticides and water, thereby reducing production costs. Multispectral sensors used in remote sensing and sensor measurement of crop properties can determine the state of the plant by observing it outside the visible part of the spectrum. Multispectral images have a high resolution and offer the analysis of different wavelengths, which allows identification of plant problems, timely detection of diseases, deficiencies of nutrients, water and other essential elements. The obtained multispectral images enable the calculation of data from different channels based on the absorption and reflection of solar energy. The visible and invisible part of the spectrum of solar electromagnetic radiation is represented by means of bands. So the bands represent parts of the spectrum of different wavelengths and frequencies. Visible spectrum (VIS) refers only to part of solar radiation and represents a wavelength of 400 - 700 nm (Skendžić, 2022). Part of the spectrum with a wavelength of 700 – 2500 nm is called Near infrared (NIR) and it is invisible to the naked eye (Figure 1). The NIR spectrum has two sublevels (I – wavelength range - 1,300 nm, II – wavelength range 1,300 - 2,500), (Wójtowicz et al., 2016; Kostić, 2021).

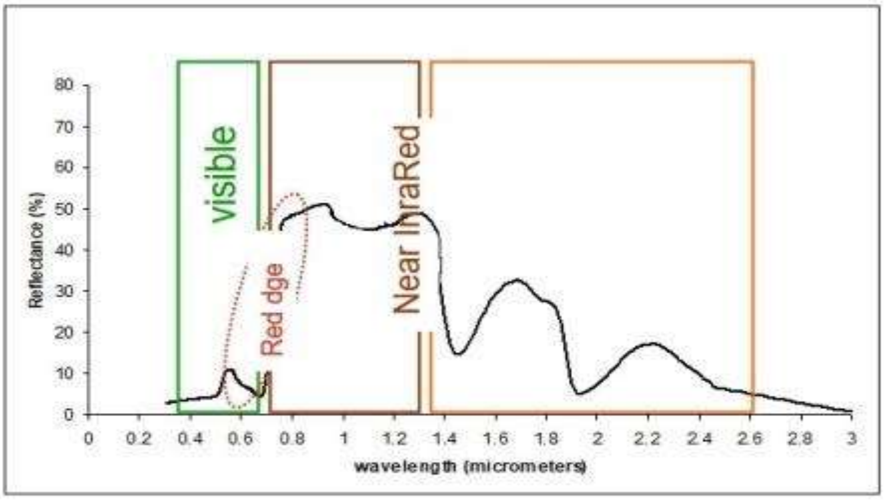

Figure 1. Visible and invisible part of the spectrum

An example of a device for measuring crop characteristics

The Plant-O-Meter device (Figure 2) is a handheld multispectral proximal sensor. This type of sensor belongs to active sensors because it uses its own light source. It has six optical channels: blue (455 nm), green (740 nm), red (657 nm), RedEdge (740 nm), NIR1 (810 nm), NIR2 (940 nm). All information collected in the field can be saved through the application installed on smartphones. Obtaining information from different channels allows the recalculation of over 30 vegetation indices (these indicators make it easier to understand the obtained data).

Figure 2. Plant-O-meter (https://www.plant-o-meter.com/)

Vegetation index values describe crop health in a good way, monitoring growth stages and identifying problems (Xue & Su, 2017). The values obtained by recalculating the amount of solar radiation of different wavelengths make it possible to identify the area and precisely apply the necessary measures in order to respond in a timely manner.

Conclusion

The application of sensors in agriculture has brought many reliefs to agricultural producers. Sustainable and more efficient production using different types of sensors enabled the control of conditions and timely intervention. With further technological progress of the precision agriculture system and the sensors themselves, it is possible to expect improvements in terms of various sensor characteristics and contribute to the creation of a sufficient amount of health-safe food.

Abstract

The nutritional properties of popcorn (*Zea mays* L. *ssp everta* Sturt.) are very attractive to consumers, making it a highly valuable product with excellent functional properties. The increased percentage of consumption of corn with specific properties is a consequence of its quality, because it belongs to gluten-free food, with a high content of fiber and other important components for human nutrition. In some parts of the world, it occupies a significant part in the diet of the population, while in others it represents a healthy snack. Popcorn is a good source of minerals and is low in calories. The paper examined the content of mineral matter (Ca, Zn) in popcorn (hybrid ZPSC 611*k* FAO 600) grown in a sustainable system with the use of cover crops (CC) and biofertilizers (BF). The experiment was set up at the Maize Research Institute "Zemun Polje" during 2013/14-2014/15. Cover crops included variants: T1-winter fodder pea, T2-winter oat, mixture T3 - winter fodder pea + winter oat, and control variant T4 - bare soil. CC were sown in autumn, plowed at the end of April or May, after which 1/2 of the plot was treated with BF, and the main crop in both years was winter wheat. Popcorn was sown in mid-May at a density of 65,000 plants per ha. Cover crops in combination with biofertilizer had a significant effect on increasing the content of the examined parameters in the grain, especially in the second year with more favorable meteorological conditions. By comparing the examined years, we observe that the highest Ca content was achieved on the variant with winter fodder pea (313.75 mg g^{-1}) with the application of BF, while the highest values of Zn (58.94 mg g^{-1}) were recorded on the variant with a mixture of winter fodder pea and winter oat without BF in the second year. The results show that winter fodder pea is a good choice as a cover crop, it produces a large biomass, protects the soil and, in combination with biofertilizer, increases the biomass of popcorn and the concentration of mineral substances in popcorn grains.

Key words: *mineral matter, popcorn, cover crops, sustainable cultivation system.*

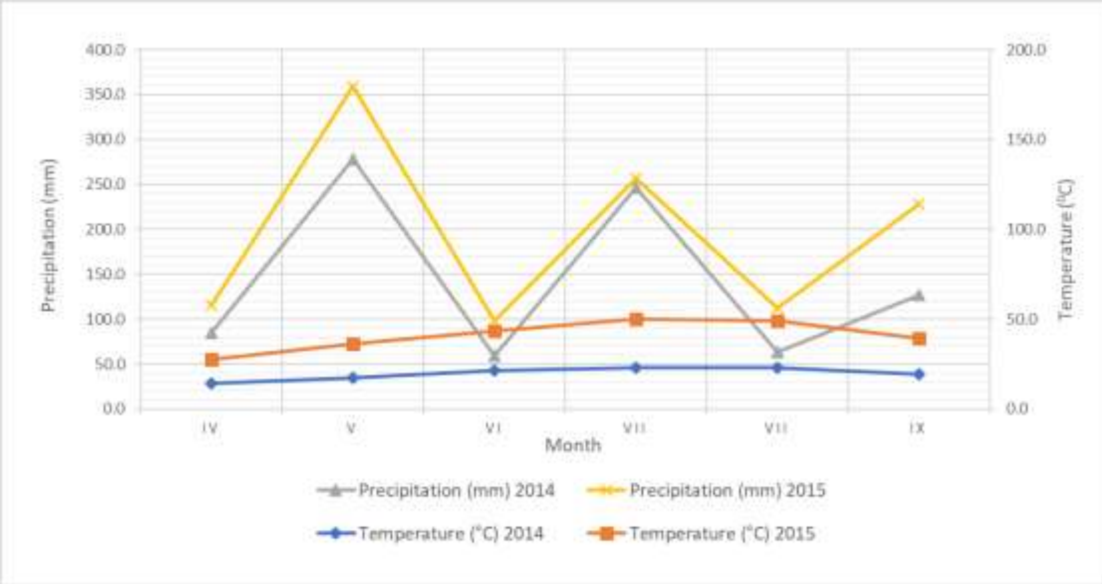
Introduction

Sustainability in agricultural production is largely based on increasing biodiversity and reducing the intake of agrochemicals, especially fertilizers. Revilla et al. (2021) state that a strategy to transition agricultural production with a large investment to a sustainable cropping system is a priority, and some combinations of uses may be more appropriate for sustainable production under different environmental conditions. Cover crops are an important part of sustainable agriculture. This biological measure maintains or increases the level of organic matter in the soil and the main role of the specific crop cultivation system is reflected in the improvement of the physical and mechanical properties of the soil, the water regime, the increase in the content of nutrients, the suppression of weeds and the achievement of higher yields in the main crops (Marcillo and Miguez, 2017. Daryanto et al., 2018; Simic et al., 2020). Microbiological fertilizers play a significant role in maintaining fertility and increasing crop yields (Mahdi et al., 2010). The contribution of microbial fertilizers to the quality of the obtained products has also been confirmed, and a good example is the increase in the content of lycopene and vitamin C in tomato fruit (Verma et al., 2015; Ochoa-Velasco et al., 2016), as well as the increased content of vitamin C and glutathione in maize grain (Dragičević et al., 2013; Dolijanović et al., 2017). To improve the agroecosystem, it is best to grow mixtures of cover crops (Ranaldo et al., 2015). This increases the productivity, stability and efficiency of resource utilization in cultivation systems. The biggest benefit from the use of cover crops in the cultivation of popcorn is their ability to contribute to a higher and better yield, and considering that cover crops contribute to the reduction of weeds, the introduction of cover crops into the cultivation system can represent an alternative use of herbicides (Tardi et al., 2015). The key reason for growing cover crops in a sustainable and organic agricultural production system is to increase soil fertility, reduce the occurrence of weeds, pests and diseases, as well as increase biological diversity (biodiversity) in the agroecosystem (Sturm et al., 2018). The most common crops for green fertilization are mainly plant species from the Fabaceae family (peas, peas, lupins, beans, lentils, clovers and alfalfa), which with the help of nitrogen fixation often provide enough N for their needs, and a significant amount remains on the land and will use it . the next crop (Oljača and Dolijanović, 2013; Blanco-Cankui et al., 2015). The reduction of input and losses of nitrogen in/from the soil by growing legumes due to very efficient mineralization, enables a significant reduction in fossil energy consumption and greenhouse gas emissions (Kocira et al., 2020, White et al., 2017; Abdalla et al., 2019). Leguminous species, which form a large amount of organic matter in a relatively short period of time, are capable of fixing atmospheric nitrogen. For the maize crop, which is a large consumer of nitrogen, legumes are a good choice because they grow quickly in the fall, protect the soil during the winter, and start growing early in the spring, accumulating a large amount of nitrogen-containing organic matter (Cutti et al., 2016; Jabran et al. , 2018). The application of cover crops in the technology of growing plants could achieve direct and indirect economic benefits, which are reflected in the reduction of production costs, primarily of fertilizers, pesticides, etc., as well as the improvement of the agroecosystem, especially the soil (Daryanto et al., 2018; Jacobs et al. al., 2022.). Lesueur et al. (2016) state that biofertilizers must be a priority in such cropping systems, if viewed from the perspective of food security and economic progress. Higher crop productivity and significant improvement of the agroecosystem can be supported by the use of biofertilizers. According to Malusà et al. (2016); Roychowdhury et al. (2017), and Mącik et al. (2020), biofertilizers stand out among the best tools in modern agriculture, which have a low impact on the environment. They represent an indispensable part of the integrated system of nutrient management in the soil and affect the reduction of the intake of mineral fertilizers, thereby ensuring the optimal supply of crops with mineral nutrients (P, Ca, Cu, Zn, etc.). The main feature that distinguishes popcorn from other types of corn is the formation of a large "flake" or "popcorn" after the kernel explodes in response to heating. When the popcorn kernels are heated, the water in the floury endosperm turns into water vapor and the kernel bursts, increasing its volume by 20-30 times. In doing so, the endosperm turns into a white, loose and porous mass. The form and content of mineral substances of popcorn are attractive for consumers and a good choice in nutrition, because it belongs to the group of products with high functional properties. Popcorn is a good source of fiber, Ca, Fe, P, niacin and has low caloric value, especially if it is prepared without oil and other additives, or with a very small amount of oil (Park et al., 2000; Paraginski et al., 2016). Milašinović-Šeremešić et al. (2019) in testing the nutritional quality of corn grains of ten different genotypes observed significant differences between genotypes in the content of starch, protein, oil and cellulose. It was found that corn has a higher content of phenolic acids than many other cereals (Ndolo and Beta,

2014. Fardet et al. (2008) state that corn is the richest source of vitamin E compared to other cereals, including wheat. Dolijanović et al. (2018) state that cover crops, especially leguminous ones, had a significant impact on increasing the protein content of sweet corn grains. Research related to cover crops and the application of biofertilizers, and especially their mutual interaction on popcorn productivity and grain quality when nutritional properties, such as the content of essential elements, are taken into account are few in the literature. The aim of this work is to examine the influence of the application of different cover crops and biofertilizers on the content of mineral substances Ca and Zn in the grain of the tested popcorn hybrid, in order to produce a nutritionally better product for human consumption.

Materials and methods

A two-year trial was set up during 2013/2014. and 2014/2015. in the experimental field of the Maize Institute "Zemun Polje" (44°52′N; 20°20′E), according to the split-plot system in four repetitions. The pre-crop in both years was winter wheat, after which autumn soil preparation was carried out (deep plowing and fine pre-sowing soil preparation), then sowing of cover crops at the end of October/beginning of November. Before sowing, soil samples were taken for agrochemical analyzes at a depth of 0-20 cm and 20-40 cm. Fertilization of cover crops was carried out together with basic tillage. The goal was to provide 120 kg N ha^{-1}, 90 kg P ha^{-1} and 60 kg K ha^{-1} to the main crop. The entire amount of P and K was introduced in the autumn with the fertilizer monopotassium phosphate (0:52:34), while the required amount of N was introduced in the spring, together with the sowing of popcorn, in the form of individual fertilizer Urea, namely 120 kg ha^{-1} N (T2 and T4 variants), 80 kg ha^{-1} N (T1 variant) and 90 kg ha^{-1} of pure feed (T3 variant). The remaining 40 and 30 kg ha^{-1} N, respectively, are considered to be provided by nitrogen fixation. Immediately after plowing the cover crops, the Uniker biofertilizer (mobilizer of nutrient elements) containing strains of proteolytic and cellulolytic bacteria in the amount of 10 l ha^{-1} was applied to the soil on half of the elementary plot, which supported the mineralization of the introduced crop residues and whose application has a favorable effect on increasing soil fertility. Popcorn was sown by hand at the end of May and the crop was grown in a natural water regime. The size of the basic plot was 7x5 m. The sowing density was 65,000 plants per ha, with an inter-row spacing of 70 cm and a distance between plants in a row of 22 cm. Popcorn (*Zea mays* L. *everta* Sturt-fam. Poaceae), hybrid ZPSC 611k (FAO 600) belongs to the mid-late vegetation group. Under optimal conditions, it gives a yield of about 6 t ha^{-1} of dry grain. The bulk volume is from 38 to 40 cm^3 g^{-1}. This hybrid has a yellow-orange pearl type grain. After harvesting, samples were taken for chemical analysis of popcorn kernels in order to determine to what extent the applied sustainable system of cultivation of these crops contributed to the increase in its quality and content of essential elements Ca and Zn, thus recommending the tested technology as useful for growing corn for human consumption. After wet digestion with $HClO_4$ + HNO_3, the concentration of essential mineral elements (Ca and Zn) was determined with inductively coupled plasma-optical emission spectrometry (Spectroflame, 27.12 MHz and 2.5 kW, model P, Spectro Analytical Instruments, Kleve, Germany). The obtained data were processed statistically, using the method of analysis of variance (ANOVA) for three-factor experiments. For individual comparisons, the least significant difference test (LSD test at the significance level 0.05 and 0.01) was used. Meteorological conditions (average monthly air temperature and monthly precipitation) during the vegetation period of the main crop in both years of the study are shown graphically (*Graph* 1).



Graph 1. Climate diagram for the vegetation period of the main crop in the examined years

More favorable meteorological conditions in terms of the amount and distribution of precipitation were measured in the first year of the research. The needs of popcorn for precipitation depend on the stage of development and were less at the beginning of the growing season, and the highest (250-280 mm) in the period of flowering and cob formation. The first year is characterized by the optimal air temperature, which had an impact on grain yield, and which further affected the quality, that is, the content of the tested parameters. Precipitation during the months of June and July in the second examined year was significantly less, while air temperatures recorded higher values, which did not favor popcorn due to the extremely dry period during the summer month.

Results and discussion

The influence of growing cover crops and application of biofertilizers on changes in the chemical composition of popcorn kernels, (Ca and Zn content) , are tabulated for two years of testing (*Tables* 1 and 2). Based on the statistical analysis of the data, it can be seen that the influence of the factors and their interrelation had a statistically significant impact on the examined parameters. The obtained results showed that winter forage pea is an excellent and useful cover crop, especially in combination with biofertilizer, to support the accumulation of popcorn biomass, yield potential and concentration of mineral substances Ca and Zn. The highest Ca values were measured in the second year of the study and amounted to 313.75 mg g^{-1} (*Table* 1). The above results could be attributed to lower air temperatures and optimal amount of precipitation, which had a positive effect on fertilization and grain formation in popcorn. The action of biofertilizers depended to a high degree on meteorological conditions, especially the amount and distribution of precipitation during the corn growing season. Winter fodder peas had the greatest impact as a cover crop, a more robust crop compared to winter oats. In addition, plant residues of winter fodder peas are a good basis in the soil, which encouraged the work of N-fixing bacteria and other soil microorganisms, which had a positive effect on the quality of popcorn kernels and increased content of essential substances. Similar research has shown a good combination for cover crops for the accumulation of essential elements in corn with specific properties, i.e. winter fodder kale and a mixture of vetch + winter oats + BF were achieved in sweet corn grain (Dragicevic et al., 2021). Winter oats and a mixture of legumes and winter oats gave the worst result, especially in the first year of the trial, which was not favorable for the main crop due to the uneven distribution of precipitation and insufficient amounts, followed by elevated temperatures in the summer period. Application of bioferilizers had a positive, but not statistically significant, effect on the content of Zn in popcorn kernels in both investigated years. A mixture of winter fodder peas and winter oats (without the application of biofertilizers) showed a positive effect on the Zn content compared to the control. The mixture variant maintained this trend during both years of testing (*Table* 2), and the highest content was 58.94 mg g^{-1} without BF in the second year.

Thanks to its nutritional value, popcorn is most used as a "healthy snack" around the world. Popcorn corn grain is an excellent source of essential amino acids and mineral elements, such as K (up to 2456 mg kg^{-1}), Na (up to 148 mg kg^{-1}), Mg (up to 387 mg kg^{-1}), Ca (up to 306 mg kg^{-1}) and P (up to 2486 mg kg^{-1}), with lower concentrations of Fe, Mn, Zn, Cu and Cr (Naji et al., 2013; Abebe et al., 2017). The higher nutritional value of popcorn could represent a good basis for its sustainable cultivation system, which includes cover crops and biofertilizers (Ahmed and Hassan, 2021). It is known that microorganisms, and especially actinomycetes, promote the growth and development of legumes (AbdElgawad et al., 2020), it could be assumed that the prolonged influence of plant residues, such as forage peas in the soil, improved the development and activity of actinomycetes, resulting in an increased availability of nutrients matter, and thus the growth of corn and the quality of the grain yield.

Table 2. Zn content (mg g^{-1}) in popcorn kernels for the period 2013/14 - 2014/15.

Year (A)	2013-2014		2014-2015

$p<0.01$ very significant (**); $p<0.05$ significant (*); $p>0.05$ no significant

Ugrenović et al. (2024) in research came to the results, which show that the increased application of plant residues of the mixture of white lettuce + oats as a cover crop in the soil significantly increases the total number of microorganisms and their activity, which contributes to the increase of organic matter in the soil and improved crop production. Ciampitti and Vyn (2013) emphasized a positive correlation between higher amounts of N in maize plants and increased accumulation of Ca, Mg and trace elements in the grain. Dragicevic et al. (2024) stated that higher protein concentration in popcorn kernels was accompanied by greater accumulation of essential mineral elements, such as Ca, Mg, Fe and Zn, which contributed to the nutritional quality of popcorn kernels. In their research, the highest value of Zn (16.71 mg g^{-1}) was achieved in the treatment with winter fodder peas + BF, while good results in terms of Ca content (876.34 mg g^{-1}, i.e. 759.61 mg g^{-1}) were achieved by winter fodder kale with and without BF. Differences in the content of mineral substances existed in the year in which there was a lack of precipitation and high air temperatures, and if the meteorological conditions were more favorable, the content was much higher, both in the variants without and in the variants with the application of biofertilizers.

Conclusions

The combined application of different cover crops and biofertilizers expressed a variable effect on the accumulation of the main grain components (nutrients), from which Ca and Zn were isolated. The most significant statistical influence was shown by cover crops and biofertilizer, as well as their mutual interaction. The best results in Ca content were achieved by the winter forage pea cover crop in combination with biofertilizer, while the highest Zn content was measured on the mixture variant in the second year of testing. The results of this research could contribute to the development of sustainable production of corn with specific properties, all with the aim of improving the quality of popcorn kernels. Sustainable cultivation systems, in addition to the benefits of increasing soil cover and increasing crop yields, can have a positive impact on the nutritional quality of cultivated grains, such as popcorn.

Acknowlegdement

Abstract

The number of seeds in primary spike is a yield characteristic that is related to the degree of pollination and fertilization of spikes. The aim of this work is to investigate the variation of number of seeds in primary spike in wheat grown under different environmental conditions. For this study were used the 10 wheat genotypes which grown in the field experiment on a plot size of 1 m^2 in three replication in two vegetation seasons (2015-2017). The seeds were sown at a distance of 0.10 m in rows of 1.0 m length between which the distance was 0.2 m. At the full maturity stage the 20 plants replication^{-1} were used for the analysis of the number of seeds in primary spike. The analysis of variance was performed by MSTAT C (5.0 version). The results showed significant differences among wheat genotypes in both years, according to number of seeds per primary spike. On average in the first vegetation season the number of seeds per primary spike varied in range from 55.63 in G-3502-5 to 75.10 in G-3501-1 genotype. In the second vegetation season the number of seeds per primary spike varied from the lowest 53.55 in the G-3502-2 genotype to the highest 77.62 in G-3612-4 genotype. The differences in the number of seeds per primary spike were determined due to genotype, environmental factors in vegetation season, and interaction genotype/environment.

Key words: wheat, genotype, number of seed spike^{-1}, environment.

Introduction

Wheat yield is a complex trait which formed as results of interaction of yield components as well as traits of stem, spike and seed. Yield of wheat includes seeds per spike, seed mass and spike per unit square area (Slafer et al., 2014). The number of seeds per spike and the mass of seeds per spike have a large contribution to the formation of the yield, the value of which largely depends on the genetic factors and the environmental factor (Feng et al., 2018; Li et al., 2016; Knežević et al., 2006). Varying the number of seeds per spike depends from developmental stage of spikelets in spike, efficiency of floret fertility (García et al., 2014; Li et al., 2016: Knežević et al., 2024) as well influence of mineral nutrition (Djokić et al, 1998; Sugár et al., 2016). Each wheat spikelet has more than one seed, which indicates their correlation and these represents an essential components in forming of seed yield (Knežević et al., 2021; Zhou et al., 2021; Wolde et al., 2019).The seeds number spike^{-1} is determined by several factors, such as spikelet number per spike, and the fertility of each floret, seed size per

spike (Sreenivasulu and Schnurbusch 2012; Guo et al., 2015; Knežević et al., 2018a) which depends on genotype, environment and interaction of genotype/environment/scientific measures technology growing (Guo and Schnurbusch 2015; Knežević et al., 2018b; Urošević et al., 2023). These traits are determined by genetic factors. Up to nowdays are known genes in wheat genome which associate with increases in number of seed spike^{-1} which contribute to increasing yield. For seeds number per spike identified many candidate genes which located on chromosomes 2A, 2D, 3B, 4A, 5A, and 6D (Mizuno et al., 2021; Glenn et al., 2022). Genotypes flowering earlier tend to have lower spikelets number per spike than those flowering later (Shaw et al., 2013; 2014; González-Navarro et al., 2015). In favorable environments wheat genotypes express their efficiency of floret fertility and seeds survival, better absorption of nutrient, efficient photosynthesis and translocation of photosynthate to seeds (Djokić et al, 1995; Gegas et al., 2010; Guo et al., 2016). During the wheat breeding, the seeds number per spike was changed and increased on the base of increasing translocation of assimilate to developing spikes and seeds, which effects on improving potential of yield (Foulkes et al., 2011; Reynolds et al., 2022).
The aim of this work was to investigate the variability of the number of seeds per primary spike of the divergent winter wheat genotypes growing in different environmental conditions.

Materials and Methods

For this study were used the 10 wheat genotypes which grown in the field experiment on a plot size of 1 m^2 in three replication in two vegetation seasons (2015-2017). The seeds were sown at a distance of 0.10 m in rows of 1.0 m length between which the distance was 0.2 m. At the full maturity stage the 20 plants replication^{-1} (total 60 plants per genotypes) were used for the analysis of the number of seeds in primary spike in each of two vegetation season of experiments. The analysis of variance was performed by MSTAT C (5.0 version) and significant differences were estimated by F-test values and tested by test value of LSD $_{0.05}$ and LSD $_{0.01}$.

Weather conditions

During the both vegetation seasons of experiment were registered different value of temperature variation and dynamics and amount of precipitation. The average temperature 9.96 ^{0}C in the first vegetation season was higher than in the second vegetation season ($\overline{t}$ =8.74 ^{0}C) and than in 10 year periods ($\circ\,\overline{t}$ =8.50). The distribution and average monthly precipitation was different between two vegetation seasons and in the first vegetation season the total amount of precipitation was 651mm and higher than total amount of precipitation 523 mm. In the both vegetation season the total amount of precipitation was higher than in 10 year periods (417 mm). In the both growing season after sowing October-November at the time of seed germination and sprouting plants, the values of temperature and precipitation were similar. However, in period February-April the amount of precipitation in the first vegetation season (250.5 mm) was higher than in the second (174.0 mm), while the distribution of precipitation in second vegetation season was more favorable (Table 1).

Table 1. Average monthly temperature and total monthly precipitation in Kraljevo

	Period	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Xm	Total

Results and Discussion

The number of seeds per primary spike varied in analysed wheat genotypes depends of environment in growing season. In the first vegetation season the lowest number of seeds per primary spike was 55.63 in the genotype G-3502-5 and the highest was 75.10 in the genotype G-3501-1, while the average value for all 10 genotypes was 65.66 seeds spike^{-1}. In the second vegetation season, the number of seeds per primary spike varied in range from the lowest 53.55 in the genotype G-3502-2 to the highest 77.62 in the genotype G-3612-4 with average value 68.06 seeds spike^{-1} for all 10 genotypes. The average number of seeds spike^{-1} for all 10 genotypes in the second vegetation season was 68.06 and higher than the average number of seeds spike^{-1} for all 10 genotypes in the first vegetation season (65.66) table 2.

Table 2. Variability of the number of seeds per primary spike in wheat genotypes

Cultivars	First vegetation season	Second vegetation season	Average
G-3501-1	75.10 ^{abcd}	76.62 ^{bc}	75.86 ^{a}
G-3501-2	69.68 ^{de}	63.85 ^{ef}	66.76 ^{c}
G-3502-1	70.34 ^{bcd}	78.56 ^{a}	74.45 ^{ab}
G-3502-2	59.52 ^{fg}	53.55 ^{h}	56.53 ^{d}
G-3502-3	74.22 ^{abcd}	74.10 ^{abcd}	74.16 ^{ab}
G-3502-4	56.54 ^{fgh}	61.78 ^{fg}	59.16 ^{d}
G-3502-5	55.63 ^{gh}	61.25 ^{fg}	58.44 ^{d}
G-3503-1	56.21 ^{gh}	62.32 ^{fg}	59.26 ^{d}
G-3604-3	70.89 ^{bcd}	70.92 ^{cd}	70.90 ^{b}
G-3612-4	68.54 ^{de}	77.62 ^{ab}	73.08 ^{ab}
Average	**65.66**	**68.06**	**66.84**
LSD	Genotype	Year	Genotype x year
LSD $_{0.05}$	4.569	1.344	6.542
LSD $_{0.01}$	6.612	1.782	9.396

On average for two growing seasons, the number of seeds spike^{-1} was the highest 75.86 in G-3501-1 and the lowest 56.53 in the genotype G-3502-2. The large number of seeds can be explained primarily by rare sowing (low density sowing), which provided optimal conditions for the development of a greater number of spikes and flowers, which resulted in higher average values for the number of seeds per spike. In this study were established significant differences between genotypes for the number of seeds spike^{-1} in both vegetation seasons. Also, number of seeds spike^{-1} in each of genotype was different between vegetation seasons, which indicates the effect of genotype, environment and their interaction in each vegetation season of the experiment (table 2 and 3). Based on the established variation in the number of seeds per spike in varieties and in different growing seasons, it can be concluded that the genotype and environmental conditions have a significant influence on the change in the number of seeds per spike, which is in agreement with the results of other researches (Zečević

et al., 2010; Knezevic et al., 2006; 2012; Branković et al., 2016; Bhutto et al., 2016; Kondić et al., 2017).
In another study of Serbian wheat, the number of seeds spike^{-1} in wheat varied in range from56.00 to 75.10 seeds (Zečević et al., 2010), from 54.56 to 77.83 seeds (Knežević et al., 2012), from 33.52 to 63.82 seeds (Jocković et al., 2014), from 27.9 to 52.73 seeds (Mladenov, 2017), from 37.17 to 66.83 seeds (Šumaruna et al., 2022), from 59.07 to 74.68 seeds (Jocković et al., 2022), from 34.170 to 48.1 seeds (Matković Stojšin et al., 2022). The study of number of seeds spike^{-1} in some Indian genotypes reported variation in range from 42.80 to 56.60 (Arya et al., 2018), in Chinese genotypes from 32.13 to 47.15 (Feng et al., 2018), while in world variety from the German Federal *ex situ* Genebank maintained at the Leibniz Institute of Plant Genetics and Crop Plant Research Gatersleben Genetic number of seeds spike^{-1} varied between 32.97 and 71.31 and in the wheat varieties from Europen and Asia and North America countries the number of seeds spike^{-1} varied between 40.23 and 83.71 (Philipp et al., 2018). These differences of number of seeds spike-1 expressed due to origin of different geographical region and different genetic structure created in different breeding program which enables significant phenotypic variations in different environments in the conducted experimental studies.
The number of seeds spike^{-1} is genetically determined traits in which inheritance included system of minor genes which effect modified in interaction with environmental factors, (Knežević et al., 2006; Würschum et al., 2018; Mizuno, et al., 2021; Wittern et al., 2022). The minor genes and genes associated with seeds spike^{-1} allow expression the significant phenotypic variations under the influence of environmental factors, depends of floret fertility, phenological phase of development (Glenn, et al., 2021). The regime of mineral nutrition, soil moisture and air temperature have influence to developing of spike organs (spikelets, florets fertility, seeds floret^{-1}), photosynthesis efficiency, translocation of assimilate to spike and survival of developing seeds (Kondić et al., 2017; Guo et al., 2018; Wittern et al., 2022). Therefore wheat varieties express different level of susceptibility or tolerance to favourable or stress environmental conditions in in flowering and grain-setting.
The analysis of components of variance established that the differences between the genotypes for the number of seeds spike^{-1} were significant and highly significant. The significant differences among wheat genotypes according to the average values of the number of seeds spike^{-1}, indicate genetic divergence of genotypes. The analysis of components of variance indicates that genetic factors had the highest share (68.95%) in the expression of the number of seeds spike^{-1}, and than interaction genotype/environment (14.59%), while the least share had environment (0,89%) table 3.

Table 3. Analysis of variance for the number of seeds per primary spike in wheat genotypes

Source of variance	Degree of freedom (DF)	Sum of squares (SS)	Mean of Sum of squares (MS)	F -test	Probability	Component of variance	
						σ^2	(%)
Repetitions (R)	2	35.623	17.811	1.3892^{ns}	0.2617	-	-
Genotypes (G)	9	3506.124	389.569	30.3832**	0.0000	56.783	68.95
Year (E)	1	26.934	26.934	2.1006^{ns}	0.1554	0.731	0.89
Genotype x Year (G xE)	9	439.823	48.869	3.8114**	0.0017	12.016	14.59
Error	38	487.230	12.822	-	-	12.822	15.57
Total	59	4495.734	-	-	-	82.352	100.00

In study some Serbian and foreign varieties Zečević et al. (2010) by analysis of phenotypic variance established highly significant F values for varieties, years and their interaction, while

the highest share in the total phenotypic variance belongs to the vegetation season (48.71%), less interaction genotypes/environment (28.88%), and the smallest share had the genetic factors (15.48%).
The number of seeds spike^{-1}, is the result of the degree of flower fertility and is directly dependent on the number of spikelets spike^{-1}, the number of flowers spike^{-1}, and the success of pollination/fertility and seed setting, which is positively related to the number of seed m^{-2}, mass of spike, mass of seeds spike^{-1}, and seed weight m^{-2}, which has a significant contribution to increasing yield (Peltonen-Sainio et al., 2007; Foulkes et al., 2011; Würschum et al., 2018). Variation in the number of seeds spike^{-1}, depends on the genotype, environmental conditions and their interaction (Knežević et al., 2006). Sowing time, regime of nutrition with nitrogen fertilizers, temperature, availability of water in the soil and mineral influence the formation of the number of spikes in a spike, the fertility of flowers and the formation and development of seeds (Hawkesford, 2014; Duan et al., 2018).

Conclusions

In this study were determined significant differences among wheat genotypes according to the number of seeds spike^{-1} in both vegetation seasons. On the base of the results were established differences between two vegetation seasons for the value of number of seeds spike^{-1}, in the same genotype. The variation of the number of seeds spike^{-1} in the same genotype in two vegetation season indicates the genotype's response to different environmental conditions. In the first vegetation season in genotypes G-3501-1 was the highest number of seeds spike^{-1} 75.10 and in the G-3502-5 was the lowest number of seeds - 55.63, while in the second vegetation season in G-3612-4 was the highest number of seeds spike^{-1} (77.62) and in the G-3502-2 was the lowest number 53.55 of seeds spike^{-1}. The differences between genotypes were significant and highly significant for the number of seeds per primary spike. Genetic factors, environmental factors and genotype/environment interaction influenced the expression of the number seeds spike^{-1}. The share of genetic components of variance had the highest (68.95%), than the interaction of genotype/environment (14.59%) and the lowest share had environment (0.89%) in the determination of expression of seeds spike^{-1} in studied ten wheat genotypes.

Abstract

This study examines the impact of climate change on water availability for winter wheat crops in the Toplica region of Serbia, projecting its consequences up to the year 2100. Simulations of precipitation (P), air temperature (T), potential winter wheat evapotranspiration (ETc) and water deficit/surplus were analyzed. The simulations for P and T utilized results from a multi-model ensemble of seven regional climate models from the EURO-CORDEX project. Climate projections were based on the RCP4.5 and RCP8.5 scenarios. Data from three distinct periods were analyzed: the reference period (1971-2000), the near future (2021-2050), and the distant future (2071-2100). The results indicate an expected increase in P, T and ETc during the winter wheat growing season (October–July). At the same level (October-July), the availability of water for the winter wheat crop is projected to remain similar to that of the reference period. Predicted changes range from a surplus of 10 mm (RCP4.5 - near future) to a maximum deficit of 16 mm (RCP8.5 - distant future) compared to the reference period. During the winter months (October-February) a slight increase in the water surplus is expected (maximum 15 mm/month; RCP8.5 - distant future), while during the spring and summer months (March-June) a slight increase in the water deficit is anticipated (maximum 11 mm/month; RCP8.5 - distant future). The conclusion is that climate changes should not have a negative effect on winter wheat production until the end of this century in terms of water supply. An exception is the far future under the RCP8.5 scenario, when an increase in the water deficit is expected in the spring months, which could cause a decrease in the final yield.

Keywords: *climate change, water deficit, winter wheat, Toplica district, Serbia.*

Introduction

The main risks in managing water resources in Europe due to climate change are in the agricultural sector (Iglesias and Garrote, 2015). Southern Europe is one of the most vulnerable regions, due to projected increases in air temperature of up to 5°C and the occurrence of temperature extremes. For the territory of Serbia, an increase in air temperature and a decrease in precipitation during the summer months are projected, which will lead to more frequent droughts (Lalić et al., 2011; Đurđević et al., 2018; Vuković et al., 2018; Tovjanin et al., 2019). The most significant decrease in effective precipitation of 25% can be expected in the southern and southeastern parts of the country, which, accompanied by increased evapotranspiration, will result in reduced water availability for crops during the growing season (Lalić et al., 2013). Estimates suggest that in the territory of northern Serbia, climate change, due to more frequent and severe summer droughts, will have a negative effect on soil water regime (Gregorić et al., 2020), and thus on the final yield of spring crops (Lalić et al., 2011), but will have positive effects on the production of winter crops (Lalić et al., 2011). Therefore, one of the adaptation measures to climate change in southern Europe is precisely the change in crop planting structure in favor of winter crops. The aim of this study is to illustrate the water availability for winter crops in southern Serbia (Toplica district) by the end of the 21st century. Will winter wheat, as the most common plant species in the Toplica region, experience more or less water scarcity during its growing season compared to the period 1971-2000, and in what period of the year? The results of this research will contribute to the development of strategies to combat the negative effects caused by climate change.

Material and method

Simulations of precipitation (P) and air temperature (T) were conducted for the southern region of Serbia, Toplica district, followed by the calculation of potential wheat evapotranspiration (ETc) and water deficit/surplus in the near (2021-2050) and far (2071-2100) futures. The obtained simulations were compared with simulated values in the reference period (1971-2000). The significance of changes was examined using the Mann-Whitney test (MW) ($p=0.05$) (Mann and Whitney, 1947). Water deficit or surplus during the winter wheat growing season (October to June) was calculated as the difference between ETc and effective precipitation (Peff). Effective precipitation was calculated using the expression $0.8 \cdot P$ (Saadi et al., 2015; Stričević, 2007). ETc was calculated as the product of potential evapotranspiration (ETo) and crop coefficient (kc). The crop coefficient was adjusted for the climatic conditions of the Toplica district, following the methodology of FAO 56 (Allen et al., 1998). The modified Hargreaves method was used to calculate ETo (Trajkovic, 2007). The calculation of ETo was based on simulated air temperature (T). Simulations of T as well as precipitation (P) were the result of a multi-model ensemble of 7 regional climate models with a horizontal resolution of 12.5 km from the EURO-CORDEX project (http://www.euro-cordex.net/). Simulations were based on observed daily data on precipitation and maximum and minimum air temperature (Tmax, Tmin) for the period 1971-2000 from meteorological stations in Prokuplje and Kuršumlija. Observed data were obtained from the Republic Hydrometeorological Service of Serbia.

Results and discussion

Simulations of mean daily air temperature (Tmean) during the winter wheat growing season show increased values in the near and distant futures (Table 1). The increase in T ranges from 1.0°C (near future, RCP4.5) to 3.8°C (distant future, RCP8.5).

Table 1. Simulated values and changes in mean temperature (Tmean), effective rainfall (P_{eff}), and potential winter wheat evapotranspiration (ETc), compared to the reference period (1971-2000). Values refer to the period October-July

		(Oct-Jul) 1971-2000	RCP4.5		RCP8.5	
			2021-2050	2071-2100	2021-2050	2071-2100
Prokuplje	Tmean (°C)	9.2	10.3	11.1	10.5	13.0
	Δ Tmean (°C)		1.1	1.9	1.3	3.8
	P_{eff} (mm)	359	384	393	384	402
	Δ P_{eff} (mm)		25	34	25	43
	ETc (mm)	409	423	434	427	459
	Δ ETc (mm)		14	25	18	50
Kuršumlija	Tmean (°C)	8.5	9.5	10.3	9.7	12.2
	Δ Tmean (°C)		1.0	1.8	1.2	3.7
	P_{eff} (mm)	427	448	460	447	463
	Δ P_{eff} (mm)		21	33	20	36
	ETc (mm)	394	408	418	412	446
	Δ ETc (mm)		14	25	19	52

Regarding effective precipitation (P_{eff}) during the wheat growing season, simulation results indicate an expected increase in precipitation in the Prokuplje area, ranging from 25mm (near and far futures, RCP4.5) to 43mm (distant future, RCP8.5), and in the Kuršumlija area, an increase ranging from 20mm (near future, RCP8.5) to 36mm (distant future, RCP 8.5). It should be noted that the increase in precipitation is "attributed" to the increase in P_{eff} during the winter and spring months (October-May), while less precipitation is expected during the summer months (June and July) compared to the reference period (Table 2) (Idrizović, 2023; Koca et al., 2023)

Table 2. Projected changes in average monthly sum of effective precipitation (ΔPeff) and potential winter wheat evapotranspiration (ΔETc) in the near and distant future compared to the reference period (1971-2000). A statistically significant change is shown in bold (Mann-Whitney p=0.05).

The simulated increase in T is reflected in ETc, resulting in an expected increase in winter wheat water demand during the growing season in the future, under both RCP scenarios (Table 1). It is observed that the change in ETc is greater in the distant future compared to the near future under both scenarios. Additionally, the change is greater under the RCP8.5 scenario compared to RCP4.5. The maximum increase in ETc is 50mm (Prokuplje, RCP8.5), and 52mm (Kuršumlija, RCP8.5). The distribution of ETc on a monthly basis shows an increase throughout the growing season in both scenarios and both near and distant futures. The largest increase in ETc is projected in May, reaching 13 mm/month by the end of the century under the RCP8.5 scenario at both locations (Table 2). An increase in potential evapotranspiration in the future has also been observed for maize crops in the same region (Koca et al., 2023).

Mainly due to different rainfall regimes, a water deficit was observed in the reference period in the Prokuplje area (50mm), while Kuršumlija had a surplus (33mm) of water available to winter wheat crops during their growing season. In the future, the projected deficit (Prokuplje) is expected to slightly decrease, while the surplus (Kuršumlija) is expected to slightly increase (Table 3). This pattern is excepted for the distant future period under the RCP8.5 scenario, where Prokuplje is expected to experience a slight increase in water deficit (by 7 mm), and Kuršumlija a decrease in surplus by 16mm.

Table 3. Projected values of winter wheat water surplus/deficit and change (Δ) compared to the reference period (1971-2000). The values refer to the period October-July.

Water deficit		1971-2000	RCP4.5		RCP8.5	
			2021-2050	2071-2100	2021-2050	2071-2100
Prokuplje	(mm)	50	39	41	43	57
	Δ (mm)		-11	-9	-7	7
Kuršumlija	(mm)	-33	-41	-41	-34	-17
	Δ (mm)		-8	-8	-1	16

Intra-seasonal analysis indicates that during the winter wheat growing season in the observed areas, the occurrence of water deficits in the spring and summer months (March-June) is expected, as it was observed in the reference period. Surpluses of water are characteristic of the autumn and winter months (October-February) (Figure 1 (a) and (b)). The maximum values of monthly water deficits are projected in May and range from 84 mm (near future, RCP4.5) to 93mm (distant future, RCP8.5) (Figure 1 (a) and (b)).

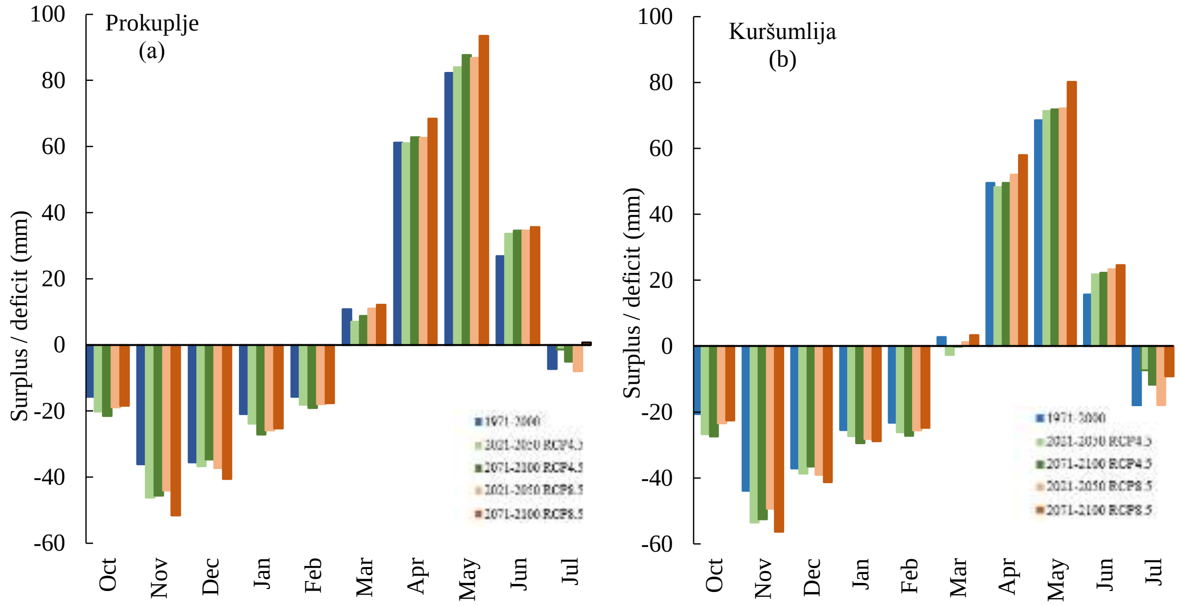

Figure 1. Projected water surplus/deficit for winter wheat in the reference and future periods, for the Prokuplje (a) and Kuršumlija (b) areas. Positive values represent water deficit, while negative values represent water surplus.

In comparison to the reference period, it can be concluded that there won't be significant changes in the near future (2021-2050) under both scenarios. In the winter months, a slight increase in water surplus is expected (maximum 10mm in November - RCP4.5), while in the spring months of April-May, the situation is expected to remain nearly unchanged (changes ranging from -1mm to 4mm) (Table 4). In the distant future period (2071-2100) under the RCP4.5 scenario, significant changes are also not expected. A slight increase in water surplus is anticipated during the winter months (maximum 9mm in November), and almost no change is expected during the spring months (April-May) (changes ranging from 0 to 5mm).

Table 4. Projected change in available water (Δ) of winter wheat compared to the reference period by month. Positive values represent a decrease and negative values an increase in the amount of water. A statistically significant change is shown in bold (Mann-Whitney p=0.05).

Jul	5.9	2.2	-0.7	8	**11.9**	7.5	1.4	**10**

The least favorable prognosis in terms of water availability is provided by the RCP8.5 scenario in the distant future. In the winter months (RCP8.5, distant future), an increase in existing water surplus is predicted (maximum 15mm more water in November), while during April and May, a decrease in water amount is expected (by 8mm in April and by 12mm in May). The period April - May is particularly important from the aspect of winter wheat water supply, because then wheat is in the phase of intensive growth and preparation for the heading phase. Water and nutrient demands are highest during this period, and water shortage during this period could significantly reduce final yields (Jovanović and Stikić, 2012).

Based on the presented results, it can be concluded that in the near future, climate change will not have a negative effect on winter wheat production in terms of water availability. Only in the distant future, under the RCP8.5 scenario, a larger deficit of accessible water is expected in the spring and summer months (compared to the reference period). Similar conclusions were reached by Matović et al. (2021) simulating the parameters of water regime of Zemun chernozem under winter wheat cultivation, based on climate model projection according to the RCP8.5 scenario. They concluded that in the near future (2021/2022-2050/2051), more favorable water regime conditions for wheat production are expected (reduced need for irrigation and lower yield reductions than in the reference period (1970/1971-1999/2000), while in the last three decades of the 21st century, worse water regime conditions, higher irrigation needs, and higher yield reductions are expected. Stričević et al. (2021), based on ensemble projections of climate and AquaCrop models, concluded that in Serbia, high winter wheat yields will be achievable in the future even without irrigation. Similar research conducted in different regions of the world (Central Europe, Eastern England, Azerbaijan, Iran, Iraq) indicates that under climate change conditions in the future, water deficits are expected, and the amount of water needed to replenish wheat and barley will increase, requiring irrigation (Thaler et al., 2012; El Chami and Daccache, 2015; Ashofteh et al., 2015; Mirgol et al., 2020; Salman et al., 2020).

Conclusion

If climate changes in the south of Serbia (Toplica district) occur according to the RCP4.5 scenario, we should not expect a deterioration of the water conditions for winter wheat production until the end of the 21st century. In the winter months, in this case, a small increase in water surplus is expected, while in the spring and summer months, the situation is expected to remain almost unchanged (negligibly small increase in the water deficit). If the CO_2 emissions are higher, leading to climate changes following the RCP8.5 scenario, then in the near future, no changes in winter wheat crop water supply should be expected, but in the distant future, an increase in water deficit is anticipated during the spring months, which could affect the reduction of the final yield.

Abstract

Sweet corn (Zea mays L. var. saccharata Sturt.) is a thermophilic plant species that is sensitive to lack of moisture during the growing season. The experiment was set during 2022 and 2023 in the Velika Plana area on anthropogenic land. Sowing was done in mid-May with an inter-row spacing of 70x22 cm. Three sweet corn hybrids (Enterprise F1, Union F1 and Sweet nougat F1) were included in the experiment. Irrigation was carried out by a drip system with tapes with a capacity of 10 l•m-1•h and three irrigation norms were applied: I – full watering norm (100%), II – 50% of the full norm and III – control treatment under the conditions of a natural wetting regime. This work aimed to examine the effect of watering rate and different hybrids on cob length, cob diameter, total cob weight and grain weight. The length and diameter of the piston were parameters that in the Enterprise F1 hybrid had significantly higher values compared to the other two hybrids. The mass of the piston had values from 174.32 to 322.35 g. The highest values were achieved with the Enterprise F1 hybrid and the differences were statistically significant compared to other variants. Variants with watering showed the same trends, as well as the grain mass parameter per cob, which ranged from 97.60 to 214.50 g. For production practice, the Enterprise F1 hybrid is recommended with a minimum watering rate of 50% compared to the full watering rate.

Key words: *sweet corn, genotype, irrigation rate, production characteristics.*

Introduction

Sweet corn (*Zea mays* L. var. *saccharata* Sturt.) is an extremely important vegetable crop in the world. From a crop grown in temperate regions in the USA and Canada, sweet corn has become a crop produced worldwide (Revilla et al., 2021). In recent years, there has been a great interest in the production of sweet corn in the Republic of Serbia and neighbouring countries. More and more agricultural farms include sweet corn in their production to increase the profitability of their farms (Nastić et al., 2022). The reason for the increase in the area under sweet corn is its agrotechnics, which do not differ to a great extent from the agrotechnics of mercantile corn. The differences are in the specific mechanization for harvesting, while the income per unit of area with the production of sweet corn is significantly increased. Due to its diverse use in fresh or processed forms, more and more significant areas belong to sweet corn. By processing it into syrup, it can be used as a sweetener in soft drinks or as an ingredient in the preparation of salad, as a baked or boiled cob (Ozlem et al., 2014; Uwah & Ogar, 2014). Revilla et al. (2021) state that in the production of sweet corn, it is necessary to apply irrigation and intensive pest control, and its advantage is that it can be produced in different cultivation systems (as a main, secondary or intercrop). As a thermophilic plant species, it is sensitive to low temperatures and lack of moisture during the growing season, but it does not tolerate high soil moisture either (Bekavac, 2012). The same author states that the availability of sufficient amounts of water during the development stages significantly affects the yield and quality of sweet corn. Lack of water negatively affects plant growth, ear diameter and mass and total carotenoid content in grain and leaf surface, Nemeskeri and Helyes (2019) point out in their research. A large number of different sweet corn hybrids present on the market require testing under different production conditions (Soare et al., 2019). The main problem in the production of certain hybrids is the adaptability of crops to the production conditions of the environment, especially to air temperatures and soil moisture. According to that, it is necessary to include hybrids with good production characteristics in research to determine their adaptability to certain climatic conditions (Matei, 2016). This work aimed to examine the effect of watering rate and different hybrids on cob length, cob diameter, total cob weight and grain weight.

Material and Methods

The research was conducted set 2022 and 2023 in the area of the village of Bresje near Velika Plana on anthropogenic land. The experiment was set up according to a randomized block system, in four repetitions. Sowing was done in mid-May with an inter-row spacing of 70x22 cm. Three hybrids of sweet corn (*Enterprise* F_1, *Union* F_1 and *Sweet nougat* F_1) were included in the experiment. Irrigation was carried out by a drip system with tapes with a capacity of 10 l•m-1•h and three irrigation norms were applied: I – full watering norm (100%), II – 50% of the full norm and III – control treatment under the conditions of a natural wetting regime. To maintain the moisture content in the soil at 60% PVK, that is, to determine the full and reduced watering rate, the moisture content in the soil was monitored by placing tensiometers in all variants. The watering rate is calculated using the formula:

$$\mathbf{Nz = 10 \bullet D \bullet (PVK\%\ vol - \theta z) = mm \bullet m^{-2}}$$

Nz - represents the watering rate (mm•m-2), D – the depth of the soil layer (m), PVK% vol – the hydrolimit of the field water capacity in percent by volume, θz - is the soil moisture read from the tensiometer curve at the water holding force read on the tensiometer. The watering duration was calculated from the ratio of the watering rate and the flow rate of the drip irrigation system (10 l•h-1 or 10 mm•h-1). Dividing this watering duration of irrigation in half, we get the duration of irrigation for the reduced amount of watering (50% of the full norm). During the growing season, standard agrotechnical measures were applied in the production of sweet corn. The obtained research results were statistically processed by analysis of variance and tested with the LSD test (Least Significant Difference Test) in the IBM SPSS Statistics program, version 26.0. and are presented tabularly and graphically.

Results and Discussion

Based on the data shown in *Table 1*, we can see that the piston length parameter differed statistically very significantly between the tested hybrids. Variants with irrigation in the *Enterprise* F_1 and *Sweet nougat* F_1 hybrids compared to the natural wetting regime showed statistically significant differences. There was no statistically significant difference between the different irrigation rates. The average value of the length of the piston during the examined period ranged from 19.13 to 22.53 cm. The highest average value for the length of the piston was recorded in the hybrid *Enterprise* F_1 and was 21.94 cm, while the smallest average length of the piston was measured in the hybrid *Sweet nougat* F_1 19.88 cm.

Table 1. Average values of cob length (cm), cob diameter (cm), total cob weight (g) and grain weight (g) of tested sweet corn hybrids

Hybrid (A)	Irrigation (B)	Cob length (cm)	Cob diameter (cm)	Total mass cob (g)	Grain weight (g)
Enterprise F_1	Control	20.91	4.45	255.63	160.70
	Irrigation 50%	22.39	4.84	321.63	212.63
	Irrigation 100%	22.53	4.90	322.35	214.50
	Average	**21.94**	**4.73**	**299.87**	**195.94**

$p<0.01$ very significant (**); $p<0.05$ significant (*); $p>0.05$ no significant

The tested factors, hybrid and irrigation, as well as their mutual interaction, had a statistically significant effect on the diameter of the piston. The difference between irrigation and natural wetting regimes was statistically very significant. The average value of the piston diameter ranged from 4.25 to 4.73 cm. The highest value was recorded with the *Enterprise F_1* hybrid and was 4.90 cm. There was no statistically significant difference between the different irrigation norms (*Figure 1*). Hybrid and irrigation had a statistically very significant effect on total cob mass. The average values of the total mass of the piston ranged from 197.15 to 299.87 g. The highest value was recorded in the *Enterprise F_1* hybrid and is 322.35 g in the full watering norm. The interaction between hybrid and irrigation had a statistically significant effect, while there were no significant differences between different irrigation norms.

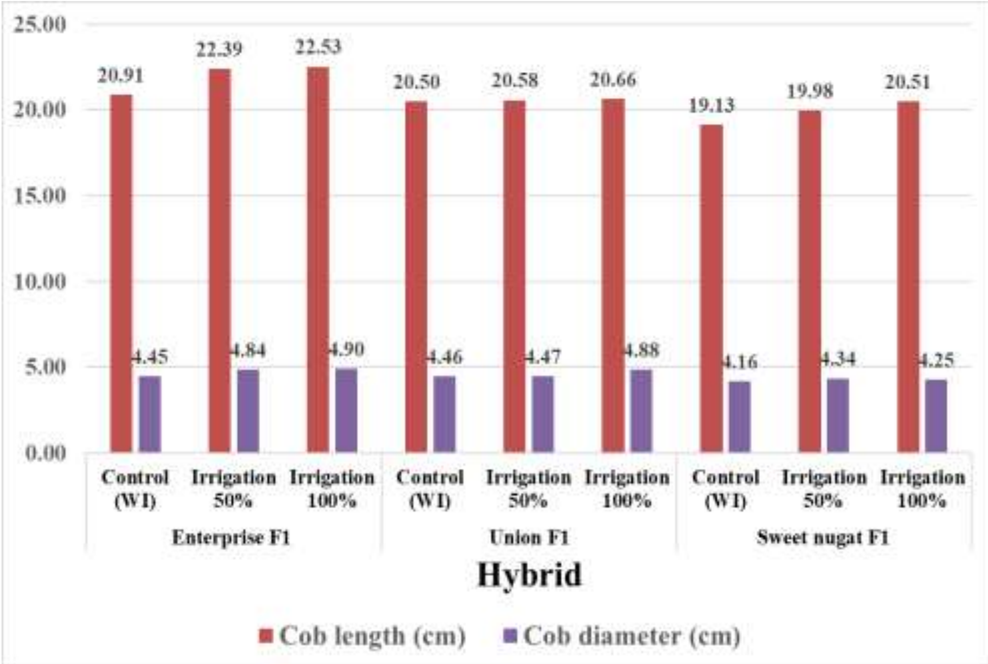

Figure 1. Average values of cob length (cm) and cob diameter (cm) of tested sweet corn hybrids

For the grain weight parameter, the hybrid and irrigation had a statistically significant influence. The grain mass values ranged from 97.60 to 214.50 g. The highest value for the examined trait, total grain mass, was measured in the *Enterprise F_1* hybrid and was 214.50 g in the full watering norm and had no statistically significant difference compared to 50% of the full watering norm, where 212.63 g was measured (*Figure 2*). The highest average value was recorded for the *Enterprise F_1* hybrid and was 195.94 g, while the lowest average value was measured for the *Sweet nougat F_1* hybrid and was 115.02 g. The interaction of hybrids and irrigation was not statistically significant, and there were no significant differences between different irrigation norms. The results of the two-year research are in agreement with the results of the research by Muslimah et al. (2023) who state that drip irrigation is a very effective and economical agrotechnical measure in the production process of sweet corn. They determined that irrigation had an effect on increasing the length, diameter and mass of the cob, and the genotype also had a very significant effect on the examined traits. Siafrudina et al. (2012) state that the manifestation of certain traits in sweet corn is largely influenced by genetic factors in interaction with production conditions. Zainudin (2005) states that different genotypes of sweet corn affect the length and diameter of the cob. Siafrudina et al. (2012) state that the manifestation of certain traits in sweet corn is largely influenced by genetic factors in interaction with production conditions. Zainudin (2005) states that different genotypes of sweet corn affect the length and diameter of the cob.

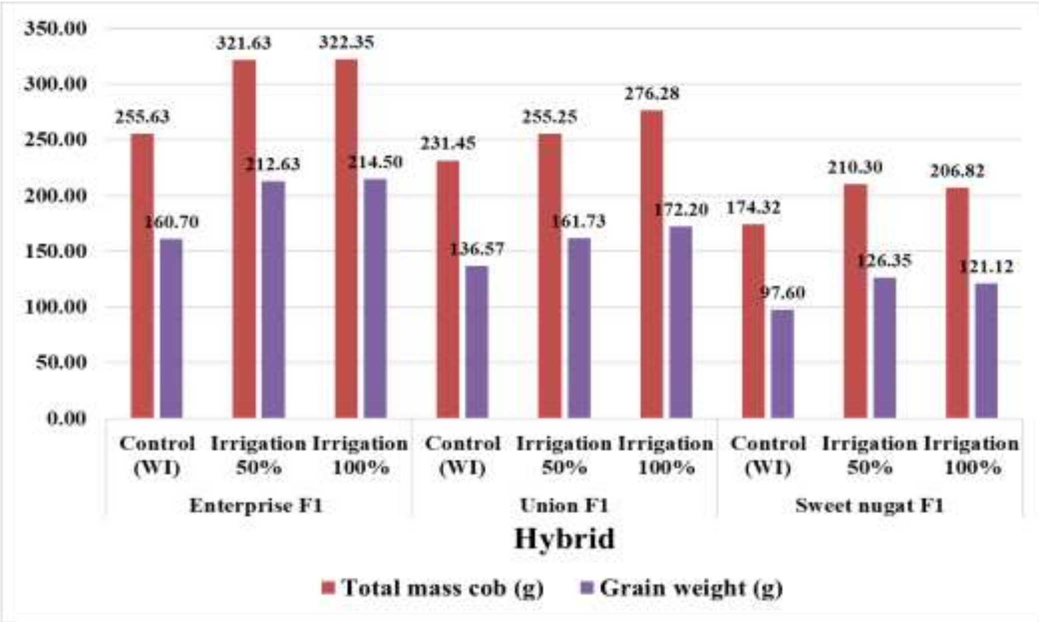

Figure 2. Average values of total cob weight (g) and grain weight (g) of tested sweet corn hybrids

Conclusions

Based on the two-year results of the study on the influence of genotype and irrigation on cob length, cob diameter, total cob weight and sweet corn grain weight, it is concluded that genotype had a statistically significant influence on the tested parameters of sweet corn. In the irrigation conditions, significantly higher parameter values were achieved compared to the control variant. Between the full watering norm and 50% of the full watering norm, no statistical significance was determined for the tested properties. For production practice, the Enterprise F1 hybrid is recommended with a minimum watering rate of 50% compared to the full watering norm.

Abstract

The improvement of β-carotene content (BC) using gene-specific molecular markers is one of the successful examples of marker assisted selection (MAS). Maize genotypes with favourable alleles of *crtRB1* and *lcyE* genes that enhance BC can be used in the biofortification programmes. The *crtRB1* has been predominantly introgressed to develop BC enriched maize. However, given that *crtRB1* and *lcyE* act additively, pyramiding of these genes is desirable to achieve the highest nutritional benefit. This study is a part of the marker assisted breeding program conducted at the Maize Research Institute Zemun Polje with an aim to convert the standard maize to β-carotene rich genotypes adapted to temperate regions. Validation of the multiplex polymerase chain reaction (PCR) assay was done in the backcross-derived population and both donor and recipient parental lines to simultaneously discover the allelic combinations among the segregants. Multiplex-PCR analysis confirmed the results of uniplex assays for both genes. The donor parent carried the favorable allele of *crtRB1* (543 bp) and *lcyE* gene (650 bp) band, while the recurrent parent exhibited the unfavorable *crtRB1* (296 bp) and *lcyE* allele (300 bp). Heterozygous individuals were clearly distinguishable with the fragments of the both favourable alleles, while unfavorable alleles showed a single band due to non-separation of 296 bp (*crtRB1*) and 300 bp (*lcyE*) fragments. Multiplex-PCR assay saved time, money and labor resources and therefore showed the advantage over uniplex assays. Being time and cost effective, multiplex assay confirmed potential to enhance the efficiency of marker assisted selection.

Keywords: *β-carotene, crtRB1 gene, lcyE gene, maize, marker assisted selection.*

Introduction

The World Health Organization has classified vitamin A deficiency (VAD) as a public health problem, the leading cause of preventable night blindness, anaemia, weakened immune system, increased morbidity and mortality (WHO, 2009). Vitamin A cannot be synthesized inside the human body and therefore it must be provided through diet. It can be found in plants as a provitamin β-carotene, the most abundant carotenoid, which can be converted to vitamin A by an oxygenase present in the intestine. Maize is one of the major sources of provitamin A (ProVA) for humans. Thus, the improvement of provitamin A carotenoids in maize varieties through breeding or biofortification is a promising strategy to alleviate VAD (Natesan *et al*., 2020).

The improvement of β-carotene content using gene-specific molecular markers is one of the successful examples of marker assisted selection (MAS). Two genes, *lycopene epsilon cyclase (lcyE)* on chromosome 8 and *beta-carotene hydroxylase1 (crtRB1)* on chromosome 10, have been shown to regulate the accumulation of proA compounds (Babu *et al*., 2013). Downregulation of *lcyE* reduces the ratio of the α-carotene branch to the β-carotene branch (Harjes *et al*., 2008). *CrtRB1* alleles were found to be associated with reduced transcript expression of the gene which correlates with higher β-carotene concentrations in the kernel composition (Yan *et al*., 2010). Maize genes encoding key enzymes in the carotenoid biosynthetic pathway are presented in Figure 1.

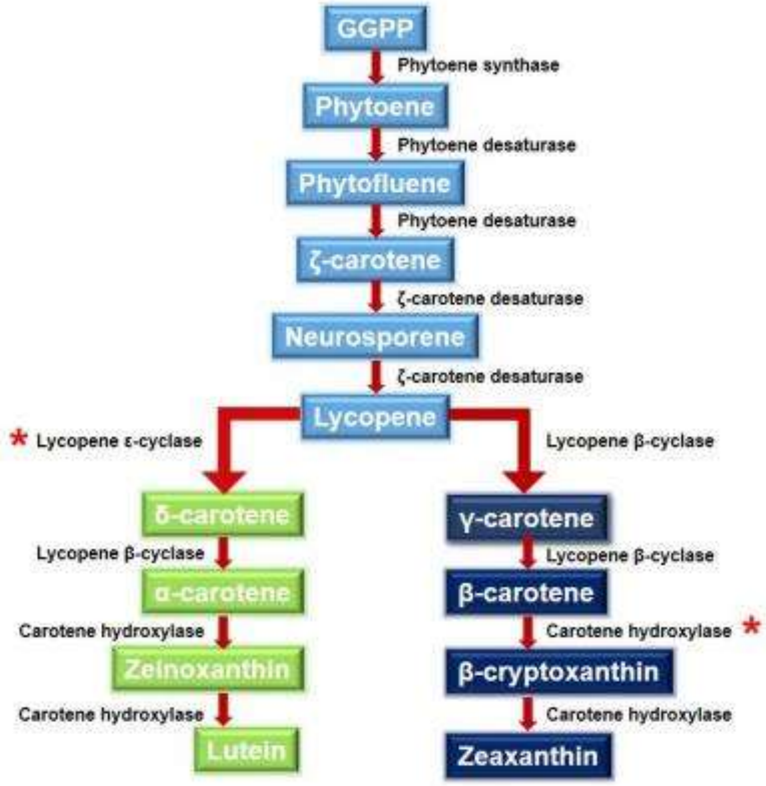

Figure 1. Maize genes encoding key enzymes in the carotenoid biosynthetic pathway

With a much larger effect on proVA concentration, *crtRB1* gene has been predominantly introgressed to develop β-carotene enriched maize (Babu *et al*., 2013). However, given that *crtRB1* and *lcyE* act additively, pyramiding of these genes is desirable to achieve the highest nutritional benefit (Zunjare *et al*., 2018). Regarding the traits controlled by multiple genes, individual genes can be identified and selected at the same time and in the same individuals, and thus marker assisted backcross breeding is particularly suitable for gene pyramiding (Begna, 2020). The process of stacking of two or more genes responsible for traits of interest from single or multiple parents can be accelerated using molecular markers to identify the progeny with homozygous favorable alleles at each generation (Nayak *et al.*, 2017).
This paper is a part of the marker assisted breeding program conducted at the Maize Research Institute Zemun Polje aimed at converting the standard maize to β-carotene rich genotypes adapted to temperate regions. The aim of this research was to validate the multiplex polymerase chain reaction (PCR) assay for simultaneous identification of favorable alleles of *crtRB1* and *lcyE* genes and confirm its effectiveness in the marker assisted breeding program.

Material and methods

The progenies derived by backcrossing in 2021, with both donor and recipient parental maize inbred lines, were used to simultaneously discover the allelic combinations among the segregants. The DNA was extracted from the leaves collected from the four-weeks-old plants applying modified Dorokhov and Klocke protocol (1997). The DNA quantity and quality were analyzed with the bio-spectrometer BioSpetrometer kinetic (Eppendorf, Germany) and diluted to a working concentration of 20 ng/µL for the PCR assay. The set of primers used in this analysis is presented in Table 1. Polymerase chain reaction was carried out in 20 µL reaction volume containing: DreamTaq™ Green PCR Master Mix (2X) (Thermo Scientific™, USA), 0.5 µM primers each and 1 µL DNA template.

Table 1.The set of primers used for multiplex-PCR assay

Gene	Primer	Sequence
crtRB1	*crtRB1*-3′TE-F	5′-ACACCACATGGACAAGTTCG-3′
	crtRB1-3′TE-R1	5′-ACACTCTGGCCCATGAACAC-3′
	crtRB1-3′TE-R2	5′-ACAGCAATACAGGGGACCAG-3′
lcyE	*lcyE*-5′TE-F	5′-AAGCAGGGAAGACATTCCAG-3′
	lcyE-5′TE-R	5′-GAGAGGGAGACGACGAGACAC-3′

Amplifications were performed in thermocycler Biometra TProfessional Standard 96 (Biometra, Germany) with the following program: an initial denaturation at 95 ºC/10 min, followed by 19 cycles each of denaturation at 95 ºC/1 min, annealing at 60 ºC/1 min (-0.5 ºC/cycle) and extension at 72 ºC/1 min; another 19 cycles of 95 ºC/1 min, 55 ºC/ 1min and 72 ºC/1 min, with final extension at 72 °C for 10 min. The amplified fragments were resolved by 8% polyacrylamide gel electrophoresis (Mini Protean Tetra-Cell, BioRad, USA) at 80 V for 1.5 h. After staining with 0.5 µg/µl ethidium bromide, they were visualized under UV transilluminator and documented in gel documentation system BioDocAnalyze (Biometra, Germany). The size of the PCR amplicons was determined relative to the 100 bp molecular weight ladder.

Results and discussion

Maize Research Institute Zemun Polje has a breeding program aimed to create maize enriched with β-carotene, using the integrated conventional and molecular breeding approach. This refers to conversion of commercial inbred lines to their β-carotene enriched counterparts and development of the β-carotene enriched hybrids adapted to temperate climate. The codominant nature of *crtRB1*-3′TE marker has already been confirmed in our previously published papers (Kostadinović *et al*., 2018; Kostadinović *et al*., 2020), enabling its utility in marker assisted introgression of the favorable allele of *crtRB1* into the local maize genotypes. The favorable allele *crtRB1*-3′TE has been proven to increase the β-carotene concentration two to ten times (Babu *et al.*, 2013; Muthusamy *et al.*, 2014). However, *lcyE* and *crtRB1* genes act additively and hence, further enhancement in the proA could be achieved by pyramiding favorable alleles of these genes (Zunjare *et al*., 2018).
Co-dominant and gene-specific molecular markers for both *crtRB1* and *lcyE* genes have been used in marker assisted selection programmes reducing the requirement of evaluation at phenotypic level (Babu et al. 2013). For foreground selection of these two genes, uniplex-PCR assays are being used. Our previous results of the uniplex-PCR analysis (Kostadinović *et al*., 2018; Kostadinović *et al*., 2020) correspond with the findings in several studies (Muthusamy *et al*., 2015; Pitambara and Nagarajan, 2016; Natesan *et al*., 2020). Applying the protocol modified from Zunjare *et al*. (2018), multiplex-PCR assay was used in this research for simultaneous detection of *crtRB1* and *lcyE* favourable alleles. Multiplex-PCR analysis confirmed the results of uniplex assays for both genes, i.e. all the bands detected by uniplex

assays were also present in products of multiplex-PCR analysis. The donor parent (lane 1) carried the favorable allele of *crtRB1* (543 bp) and *lcyE* gene (650 bp) band, while the recurrent parent (lane 2) exhibited the unfavorable *crtRB1* (296 bp) and *lcyE* allele (300 bp). Heterozygous individuals were clearly distinguishable with the fragments of the both favourable alleles, while unfavorable alleles showed a single band due to non-separation of 296 bp (*crtRB1*) and 300 bp (*lcyE*) fragments (lanes 3, 4, 5, 7, 12 and 13). These results are in accordance with Zunjare *et al*. (2018). The gel profile of multiplex-PCR in BC_2F_2 generation is presented in Figure 2.

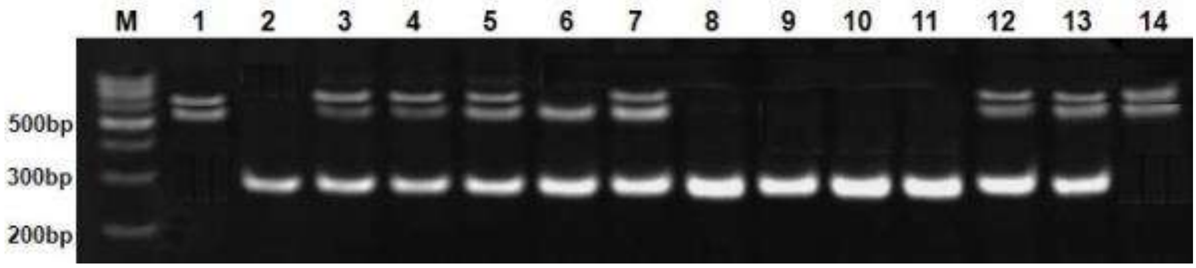

Figure 2. Multiplex PCR assay for *crtRB1* and *lcyE* genes. M:100 bp DNA ladder, 1-donor parent, 2: recipient parent, 3-14: BC_2F_2 individuals.

As the main advantages of multiplex-PCR assay, saving valuable time and money should be emphasized. Zunjare *et al*. (2018) reported a fund savings of 41.09%, as well as a time savings of 50.00%, with one multiplex-PCR for *crtRB1* and *lcyE* genes compared to two uniplex assays. These authors also pointed out the electricity savings, reduced depreciation of thermal cycler and half of the manpower requirements to perform the assay. It could be concluded that multiplex-PCR assay can be effective for marker assisted gene pyramiding of both favorable alleles in a single genetic background.

Conclusions

Multiplex-PCR assay could be effective for pyramiding of *crtRB1* and *lcyE* favorable alleles for maize β-carotene enrichment. Being time and cost effective, multiplex assay confirmed potential to enhance the efficiency of marker assisted selection. Maize genotypes with favorable alleles of *crtRB1* and *lcyE* genes that enhance β-carotene can be used in the biofortification programs alleviating VAD worldwide.

Abstract

This study aimed to examine the effect of cultivar, fertiliser and irrigation, and their combined effect, on different lettuce agronomic parameters and the possible occurrence of tipburn. Two iceberg lettuce cultivars ('Umbrinas' and 'Kavir') were cultivated during summer in the open field, in the black marsh soil containing a wide calcium-to-magnesium ratio. Plants were grown at a density 32×32 cm with regular agricultural practices. Three different levels of magnesium sulfate fertiliser (100 ml, 300 ml, 500 ml solution) were added twice during the growing cycle. Plants were irrigated using a drip irrigation system and sprinklers. After harvest morphological parameters were estimated (head weight, height, diameter, number of leaves, fresh leaf weight, stem height, diameter, and fresh weight). Cultivar 'Umbrinas' showed the highest value of all parameters: head weight (557.15 g), head height (13.91 cm), head diameter (16.90 cm), number of leaves (18.73), fresh leaf weight (527.50 g), stem height (65.73 mm), stem diameter (20.32 mm), and stem fresh weight (29.65 g). Application of all levels of magnesium sulfate fertiliser did not affect observed parameters compared to the control. Drip irrigation led to significantly higher head height, diameter and number of leaves, while sprinkler irrigation significantly enhanced the values of all stem parameters. Tipburn was noticed mainly in the 'Umbrinas' cultivar in the sprinkler irrigation treatment, whereas drip-irrigated plants showed no signs of tipburn. Interaction of all three factors showed a statistically significant impact on head weight, number of leaves, fresh leaf weight, and stem height.

Introduction

Lettuce (*Lactuca sativa*, L.) is an annual leafy vegetable crop from the Asteraceae family. It has wide morphological viability, classified into several types (butterhead, iceberg, leaf, romaine, Batavia, and stem). It is rich in health-beneficial secondary metabolites, mainly phenolic compounds, carotenoids, and folate, even though it has low nutritional value (Ćavar Zeljković et al., 2023). Iceberg lettuce is usually used as a fresh-cut or minimally processed leafy vegetable, with thick leaves, a specific crisp texture, and neutral to a slightly bitter flavour. The advantage of growing lettuce is quick and all-year-round production in different systems (open field, covered systems or hydroponics) with the possibility of multiple growing cycles. It is a cool season crop with optimal temperatures of 21-23 °C (day) and 15-18 °C

(night). During the summer, daily temperatures usually exceed 30 °C which can raise the risk of bolting (Ilić et al., 2017). Early bolting leads to a shortened vegetative phase, decreased biomass, poor head formation, bitter taste, and consequently plants lose marketable value (Lafta et al., 2021). Magnesium (Mg) as a secondary nutrient is important for a wide range of processes in plants such as photosynthesis, nutrient metabolism, cell membrane stability, enzyme activation, and resilience against various stressors (Ahmed et al., 2023). The BCSR (Basic cation saturation ratio) concept is based on the existence of an optimum saturation of the soil cation exchange capacity, particularly cations Ca, Mg, and K, and that optimum ratio will lead to maximum yields (Bear et al., 1945). On the contrary, research by McLean et al. (1983) suggested that for maximum crop yields emphasis should be undertaken on providing adequate levels of each basic cation rather than trying to modulate the optimal ratio. Antagonism between Ca and Mg can occur both on a soil and plant tissue level, and high concentrations of each of the elements can interrupt the acquisition of the other. Calcium (Ca) is considered a relatively immobile element within plant tissue. The transpiration rate usually regulates the uptake and movement of water and Ca where rapidly transpiring outer leaves gain more water and Ca compared to inner leaves. Environmental factors that promote rapid growth, modify the transpiration rate and change the balance of Ca distribution favour the occurrence of tipburn (Sago, 2016). Tipburn is mainly recognised as a calcium-associated physiological disorder visually seen as the browning of leaf margins which reduces the quality and shelf life of fresh and processed products. Proper irrigation management can have an impact on lettuce yield, head size and uniformity, chemical content, and browning-related enzymes (Luna et al., 2012). Drip irrigation has several advantages compared to sprinkler irrigation in a manner that it reduces water usage and loss caused by evaporation, decreases soil erosion, leakage of fertilisers and pesticides, and availability of water for the weeds.
Therefore, this study aimed to examine the effect of cultivar, fertiliser and irrigation, and their combined effect, on different iceberg lettuce agronomic parameters, and the possible occurrence of tipburn during summer production.

Materials and methods

Two iceberg lettuce cultivars were studied 'Umbrinas' (Rijk Zwaan, the Netherlands) and 'Kavir' (Meridiem Seeds, Spain). Lettuce seeds were sown on July 23 in peat cubes size 4 cm in the substrate Potgrond H (Klasmann-Deilmann, Germany) in a glasshouse condition in the company Grow Rasad (Serbia). Plants were cultivated in the summer open-field experiment from August to October 2018 in the company Iceberg Salat Centar (Surčin, Serbia). Seedlings were transplanted on August 11, manually in the black marsh soil. Before the experiment, randomised soil samples were taken at 0-30 cm depth. A pH was determined potentiometrically (SRPS EN ISO 10390, 2022), Ca and Mg using extraction with molar ammonium acetate solution (ISO/TS 22171, 2023), total nitrogen was measured with dry combustion (SRPS ISO 13878, 2005), readily available phosphorus and potassium were determined using AL method (Egnér et al., 1960), and volumetric method for $CaCO_3$ (SRPS ISO 10693, 2005). Regular agricultural measures were applied (weed hoeing, irrigation, and preventive protection against diseases and pests). The experiment was arranged in a complete block design using Mg sulfate fertiliser (Yara Tera KRISTA, MgS, Norway) where 30 g was dissolved in 15 l of water and added twice during the growing cycle. Fertiliser was applied in three different levels (100 ml, 300 ml, 500 ml), and control (without fertilisation). Plants were irrigated using a drip irrigation system (T-Tape 506-10-1350, Rivulis, Israel) and sprinklers (type 501-U, NaanDan Jain, Israel) 11 times during the vegetation period. After transplanting, firstly we used sprinklers, and after successful rooting, plants were irrigated using two systems with the same quantity of water. The dimension of the plots was 1.3 × 2 m, in three replications, the distance between plants was 32 × 32 cm, 50 cm among repetitions, and 100 cm among treatments. Lettuce plants were harvested 55 days after transplanting when heads were fully matured and reached commercial size. Agronomic parameters were measured by taking 6 plants per treatment using a scale, digital caliper, and ruler. The presence of the leaves affected by the tipburn was analysed during the morphological measurements. Statistical analysis was performed using a three-way ANOVA with a Tukey's test for post hoc comparison. All results were calculated at a significance level α of 0.05 using the software SPSS Statistics (Version 25.0.; Armonk, NY, USA: IBM Corp) and Microsoft Office Excel 2019 (Microsoft Corp., USA). During the growing cycle air temperature, air relative humidity, and precipitation were collected using RC-4HC Data Logger (Elitech Technology Inc., USA) and rain gauge (TFA Dostmann GmbH & Co. KG, Germany**)** (Table 1). Plants were exposed to different photoperiods from 14 h 16 min to 11 h 35 min.

Table 1. Climatic data during the iceberg lettuce growing cycle

	Average air temperature (˚C)	**Maximum air temperature (˚C)**	**Minimum air temperature (˚C)**	**Average air humidity (%)**	**Total precipitation (mm)**
August 2018	23.7	34.7	14.2	66.0	19.0
September 2018	19.2	33.5	2.9	62.9	12.1
October 2018	12.4	23.3	3.0	71.2	1.0

Results and discussion

Cultivar showed significant influence on all tested morphological parameters except head diameter (Table 2).

The data show the means (n = 6) ± SE. Values followed by the same letter are not significantly different at the 0.05% level of probability according to Tukey's test. Groups of data within the same parameter and factor with no letters are not different from each other. Asterisks indicate significant differences at * $p \leq 0.05$; ** $p \leq 0.01$; *** $p \leq 0.001$; ns, non-significant.

The results showed the highest value of head weight (557.15 g), head diameter (16.90 cm), head height (13.91 cm), number of leaves (18.73), fresh leaf weight (527.50 g), stem height (65.73 mm), stem diameter (20.32 mm), and stem fresh weight (29.65 g) in cultivar 'Umbrinas'. Head weight is one of the most important traits impacting the lettuce yield. Although 'Umbrinas' was suggested as a cultivar for spring cultivation, during our trial this cultivar exhibited the highest head fresh weight compared to the summer cultivar 'Kavir'. On the other side, 'Kavir' showed lighter and smaller stems, which is a crucial point for the processing industry, by obtaining a higher proportion of edible parts and less waste. Research by Rouphael et al. (2017) showed a significant genotypic influence of different iceberg cultivars on the head fresh mass. Furthermore, in the same study cultivar 'Umbrinas' obtained a lower head fresh weight (485 g) compared to our trial (557.15 g). The head size is a considerable parameter for the consumer's choice since cultivars with longer and larger heads are preferred and recognised as good marketable heads of high quality (Maboko and Du Plooy, 2008). Our results for head diameter are in line with or even higher compared to 25 crisphead lettuce cultivars examined by Lafta et al. (2021). Number of leaves obtained in our experiment was lower compared to trial with iceberg lettuce in hydroponics (Maia et al., 2024).

Stem fresh mass is determined by stem length and diameter in the sense that longer and larger stems are heavier. According to Yuri et al. (2004) stems up to 6 cm are the most favorable for the processing industry, while values up to 9 cm are still acceptable, whereas values higher than that are usually not recommended. Our results for both cultivars showed acceptable values of stem height (3.78; 6.57 cm, Table 2). Cultivar 'Umbrinas' showed 1.7 times longer stem than 'Kavir' which could mean that this cultivar is susceptible to high temperatures during the growing cycle. Likewise, our results for stem diameter are in line with the results of Maia et al. (2024) under hydroponic cultivation in a conventional greenhouse in the summer.

Application of all levels of Mg sulfate fertiliser did not affect any of the observed morphological parameters (Table 2). Nevertheless, the application of 100 ml solution of fertiliser obtained the highest head weight, height and diameter, while 500 ml solution contributed to the highest stem fresh weight and height, and number of leaves but without statistically significant difference. Preciado-Mongui et al. (2023) found an optimal fertilisation formula for lettuce using nitrogen and Mg fertiliser to optimise yield and balanced nutrition. Soil analysis in our experiment showed a neutral to slightly alkaline reaction (pH (H_2O)- 7.6, pH (KCl)- 7.1), very high concentration of Ca 12.375 mg/kg, and high concentration of Mg 726 mg/kg, wide range ratio Ca/Mg (10.23), and adequate levels of macronutrients (total nitrogen-0.19%; readily available phosphorus-26.67 mg/100 g; readily available potassium-18.13 mg/100 g, and 2.82% $CaCO_3$). Results of Ca and Mg, and their ratio, which means Mg ion deficiency, while pH was in the acceptable range for availability of various nutrients (Hazelton and Murphy, 2016). Mg fertiliser was applied twice but possibly with a low dosage of Mg. There is a possibility that with an increased quantity, applied during basic tillage and the vegetation period, continuously, it can be expected to lower the current Ca/Mg ratio to a more balanced level. Literature data are not consistent about the significance of the Ca/Mg ratio. Regression analysis showed no relationship between soybean and corn yields and soil Ca/Mg ratio (Leiva Soto et al., 2023). Research by Zhang (1999) showed that both soil Ca/Mg ratio and plant Ca/Mg ratio affected lettuce yield. The lower critical level of the soil Ca/Mg ratio was 0.5 and within a range from 0.50 to 7.70, no reduction of the yield was observed.

Drip irrigation system led to significantly higher head height and diameter, number of leaves, while irrigation with sprinklers led to significantly higher stem parameters. Type of the irrigation did not influence the head weight. According to Kaniszewski et al. (2017) drip irrigation system gave better results compared to sprinkler irrigation.
Tipburn was noticed mainly in the 'Umbrinas' cultivar in the sprinkler's irrigation treatment, whereas drip-irrigated plants showed no signs of tipburn (Table 3).

Table 3. Number of lettuce plants affected with tipburn after harvest

Cultivar	Umbrinas		Kavir	
Irrigation	Sprinklers	Drip irrigation	Sprinklers	Drip irrigation
Fertiliser	**Number of plants affected by tipburn**			
Control	2	0	0	0
100 ml	1	0	0	0
300 ml	1	0	0	0
500 ml	0	0	1	0

Application of 500 ml solution resulted in no tipburn in the 'Umbrinas', while in the 'Kavir', the same level of solution led to the appearance of tipburn in 1/6 analysed plants. Results of Kuronuma et al. (2022) with tipburn incidence and calcium acquisition in lisianthus showed that tipburn can be significantly decreased with increasing Mg level in two of three cultivars.
Even though the influence of fertilisation was not statistically significant on particular morphology traits, three main factors conjointly affected head weight, number of leaves, fresh leaf weight, and stem height, in a way that cannot be predicted by testing just a single factor.

Conclusion

The presented study showed that the cultivar influenced all tested parameters except head diameter. Cultivar 'Umbrinas' showed the highest value of all morphological parameters. On the other side, 'Kavir' showed more favourable values of the stem measurements compared to the head parameters relation which is important for the processing industry, especially during early and mid-summer cultivation to avoid raw material and economic losses. The application of magnesium sulfate fertiliser did not affect the tested parameters. Drip irrigation led to significantly higher head height, diameter and number of leaves, while sprinkler irrigation significantly enhanced the values of all stem parameters. Tipburn was noticed mainly in the 'Umbrinas' cultivar in the sprinkler's irrigation treatment.The application of 500 ml Mg solution resulted in no tipburn in the 'Umbrinas', while in the 'Kavir', led to the appearance in 1/6 analysed plants. Nevertheless, the interaction of all three factors showed a statistically significant impact on head weight, number of leaves, fresh leaf weight, and stem height.

Abstract

Six Batavia lettuce cultivars ('Tourbillon', 'Champollion', 'Impression', 'Voltron', 'Bataille', and 'Batsun') were grown in the black marsh soil in March-May 2020. 'Tourbillon' is a standard Batavia cultivar, while five others are not registered on the Variety list in Serbia. This study aimed to select the optimal Batavia cultivar according to agronomic parameters, suitable for the fresh market and processed products by applying the WASPAS (Weighted Aggregates Sum Product Assessment) method. The correlation analysis was carried out to reduce the number of criteria having high coefficient values above 0.8 to exclude double influence on the ranking results. The study involved six alternatives (cultivars) and six different criteria regarding agronomic parameters (rosette height, rosette fresh weight, number of leaves, stem diameter, stem fresh weight, and core ratio). According to the expert’s opinion, we depicted morphological traits of interest significant for fresh and processed lettuce products. Thus, according to the selected criteria and both scenarios, the obtained results showed that cultivar A2-'Voltron' was the best-ranked for fresh and processed products, while cultivar A3-'Champollion' showed the least favorable results. A SAW (Simple Additive Weighting) method was applied to verify and confirm the obtained results by the WASPAS method. Therefore, this study showed that the WASPAS method could present an initial step toward decision-making in the selection of novel lettuce cultivars for the fresh market and ready-to-eat salads and highlighted the importance of choosing the adequate cultivar for different purposes to avoid quality and economic losses.

Keywords: *Lettuce, Morphology traits, MCDM methods, WASPAS, SAW.*

Introduction

Lettuce (*Lactuca sativa*, L.) is an annual leafy vegetable crop from the Asteraceae family. Different groups such as butterhead, iceberg, leaf, romaine, Batavia, and stem include numerous cultivars. Batavia lettuces are like iceberg but with loose-filled rosettes containing relatively crisp-textured leaves in light green color. Wide-range viability has been observed among cultivars in morphological traits, fresh mass production and nutritional value. Unlike other cooked or thermally processed vegetables lettuce, provides nutrients since it is eaten raw (Kim et al., 2016). It can be consumed as a fresh vegetable or processed in ready-to-eat products. Leafy vegetable retail has changed in recent decades as a result of changes in living style, consumers' preferences and needs (Sucheta et al., 2020).
From the breeding point of view, genetic diversity is important in selecting the most favorable genotypes to achieve higher yields. Agronomic parameters such as fresh weight, number of leaves, stem length, plant diameter can be important parameters to farmers, producers, and breeders. A decrease in the stem height and the number of old and yellowish leaves enhances

the proportion of edible fresh weight used in processing and avoids losses (Simko et al., 2014). The morphological traits can affect the market price and advanced marketing influence (Mampholo et al., 2016). The decision-making process corresponds to the existence of several criteria, which causes more complexity during the making of final and optimal choices by using different multi-criteria decision-making methods (MCDM). By setting the criteria experts are called to assess the alternatives based on the decision criteria (Gokasar et al., 2022). One of the numerous MCDM methods is the WASPAS method which combines two methods: the weighted sum model (WSM) and the weighted product model (WPM). According to Sorooshian et al. (2022) WASPAS method was widely applied in about 20 different fields, mainly in engineering, computer science, mathematics, business, management, accounting, environmental science, and energy, while in agricultural and biological sciences just several papers. The same authors highlighted the ability of the WASPAS method to be used in combination with other MCDM methods such as AHP, TOPSIS, MOORA, COPRAS, SWARA, Entropy, fuzzy methods, and sensitivity analysis.
Considering several different criteria (quantity, quality, economic) can affect farmer acceptance and consumer choice of the cultivar in the production, the experts in decision-making methods use the appropriate method in the cultivar selection process and make a final decision between several different alternatives (cultivars). This study aimed to choose the most suitable novel Batavia cultivar for the fresh market and processing industry for ready-to-eat products by applying the MCDM methods.

Materials and methods

Six green open-type Batavia lettuce cultivars 'Tourbillon', 'Champollion', 'Impression', 'Voltron' (Rijk Zwaan, the Netherlands), 'Bataille', and 'Batsun' (Nunhems, The Netherlands) were grown in the spring open-field experiment in 2020. Seeds were sown on February 15 in peat cubes in the substrate Potgrond H (Klasmann-Deilmann, Germany) in a glasshouse condition in the company Grow Rasad (Serbia), and seedlings production lasted 25 days. After several days of acclimatisation, plants were transplanted manually in the black marsh soil on March 15. Soil analysis showed adequate levels of macronutrients (total nitrogen-0.21%; readily available phosphorus-25.42 mg/100 g; readily available potassium-22.34 mg/100 g) and humus 4.1%. Regular cultural practices for the lettuce outdoor production were applied (irrigation, weed hoeing, and preventive protection against diseases and pests). The experiment was arranged in a complete block design, the dimension of the plots was 1.3 × 2 m, with three replications, and the distance between plants was 27 × 27 cm. Lettuce plants were harvested on May 28, 74 days after transplanting, when rosettes reached commercial size and fully matured. Morphology parameters were measured by using a scale, ruler, and digital caliper. A one-way ANOVA was used to test the effect of different Batavia cultivars on the morphology traits by using a Tukey test for post hoc comparison. All results were calculated at a significance level α of 0.05. Statistical analysis was performed with the software SPSS Statistics (Version 25.0.; Armonk, NY, USA: IBM Corp) and Microsoft Office Excel 2019 (Microsoft Corp., USA). Data for air temperature, air relative humidity, and total precipitation were collected using RC-4HC Data Logger (Elitech Technology Inc., USA) and rain gauge (TFA Dostmann GmbH & Co. KG, Germany**)** (Table 1). Plants were exposed to different photoperiods, ranging from short to long days, from 11 h 53 min to 15 h 15 min.

Table 1. Climatic data during the lettuce vegetation period

	Average air temperature (°C)	Maximum air temperature (°C)	Minimum air temperature (°C)	Average air humidity (%)	Total precipitation (mm)
March 2020	7.3	21.2	-4.0	59.4	21.2
April 2020	12.1	27.5	-3.1	52.5	9.4
May 2020	15.5	28.2	6.3	66.5	69.3

For the evaluation and selection of the most favorable cultivar for fresh market and food processing, we used the MCDM method-WASPAS (Weighted Aggregates Sum Product Assessment) method (Zavadskas et al., 2012), which is a combination of two previously established multi-criteria decision-making methods: the Weighted Sum method (WS) and the Weighted Product method-(WP). Correlation analysis was applied to test possible linear correlation using the Pearson coefficient among morphological parameters (criteria) to eliminate their double influence on the ranking results. To verify the results obtained by the WASPAS method we used another MCDM method- SAW (Simple Additive Weighting) (MacCrimmon, 1968).

Results and discussion

One-way ANOVA was used to test the effect of the cultivar on different morphological parameters with Tukey’s test for post hoc comparison. Cultivar showed a significant influence on all tested morphological parameters except the number of leaves (Table 2).

Table 2. Effect of Batavia lettuce cultivars on agronomic parameters

	Rosette height (cm)	Rosette diameter (cm)	Rosette fresh weight (g)	Number of leaves	Fresh leaf weight (g)	Stem height (cm)	Stem diameter (cm)	Stem fresh weight (g)	Core ratio
Cultivar

Significance									
Cultivar	***	**	**	ns	*	**	**	**	*

The data show the means (n = 3) ± SE. Values followed by the same letter are not significantly different at the 0.05% level of probability according to Tukey’s test. Groups of data within the same parameter with no letters are not different from each other. Asterisks indicate significant differences at * $p \leq 0.05$; ** $p \leq 0.01$; *** $p \leq 0.001$; ns, non-significant.

Results for a single parameter using ANOVA showed that the cultivar 'Tourbillon' had the highest value of rosette height (21.27 cm), rosette fresh weight (579.00 g), and leaf fresh weight (542.00 g). Cultivar 'Champollion' showed the highest values of rosette (34.90 cm) and stem diameter (2.40 cm), stem fresh weight (27.67 g), core ratio (0.23) as well as 'Impression' core ratio (0.23) and stem height (4.63 cm). Fresh matter is usually considered the most valuable trait due to its contribution to lettuce yield. Additionally, the number of leaves is an important parameter also contributing to the yield. Both consumers and the food industry are interested in cultivars with a larger number of leaves, especially the consumer’s attention is concentrated on the appearance, volume and secondarily the number of leaves (Graciano et al., 2020). Rosette diameter shows the horizontal expansion of the rosette and the progress of its morphology and shape formation. Despite the consumer’s preference for larger and heavier plants, this is not usually a beneficial trait because larger plants can be easily damaged during packaging and transport, and with reduced quality of the final product (Suinaga et al., 2013). Stem length is also a relevant trait in lettuce breeding due to its connection with bolting. According to Yuri et al. (2004) stems between 6-9 cm are favorable for the processing industry. Our results are in line with the desirable stem length (3.10-4,63 cm, Table 2) and all cultivars were suitable for the processing industry, with the highest obtained in cultivar 'Impression'. According to Maboko and Du Plooy (2008) core ratio (stem height to rosette height) should not exceed 0.5. In our experiment, all cultivars showed core ratios between 0.17-0.23 (Table 2) which can be considered as growing within favourable environmental conditions, even though maximum air temperatures in April and May were above 27 °C in the phase of intensive leaf growth (Table 1). A strong positive correlation was found between rosette fresh weight and stem height (0.75^{**}, Table 3) pointing out the importance of the stem height in rosette weight. Our results were in line with the similar linear correlation between these two parameters (0.719) (Madar and Hájos, 2021).

Table 3. Correlation analysis of tested morphological criteria

Criteria	Rosette height	Rosette height	Rosette fresh weight	Number of leaves	Leaf fresh weight	Stem height	Stem diameter	Stem fresh weight	Core ratio
Rosette height	1								
Rosette diameter	0.71^{**}	1							
Rosette fresh weight	0.72^{**}	0.80^{**}	1						
Number of leaves	-0.08	0.21	0.23	1					
Leaf fresh weight	0.67^{**}	0.75^{**}	0.99^{**}	0.28	1				
Stem height	0.60^{**}	0.61^{**}	0.75^{**}	-0.06	0.68^{**}	1			
Stem diameter	0.29	0.70^{**}	0.71^{**}	0.58^{*}	0.70^{**}	0.47	1		
Stem fresh weight	0.63^{**}	0.81^{**}	0.71^{**}	0.39	0.64^{**}	0.71^{**}	0.72^{**}	1	
Core ratio	0.15	0.36	0.52^{*}	0.003	0.46	0.87^{**}	0.42	0.51^{*}	1

Asterisks indicate significant differences at * $p \leq 0.05$; ** $p \leq 0.01$.

One-way ANOVA showed differences between cultivars when one parameter was taken into account, yet in situations when it is needed to include several parameters, we employ MCDM methods. Before starting the WASPAS method the correlation analysis was applied to test possible linear correlation using the Pearson coefficient among morphological parameters (criteria). The criteria rosette diameter, leaf fresh weight and stem height, showed a strong linear relationship with coefficient values (greater than 0.8) and were excluded from the multi-criteria decision-making procedure to eliminate their double influence on the ranking results. Thus, the ranking procedure of the 6 cultivars using the WASPAS method was carried out taking into account 6 different criteria: rosette height (C1), rosette fresh weight (C2), number of leaves (C3), stem diameter (C4), stem fresh weight (C5), and core ratio (C6). The initial 6 × 6 matrix formed in the first step is normalised in the second step in such a way that the benefit criteria (C2 and C3) are normalised by bringing the values of the initial matrix criteria into relation with their optimal value, which is their maximum value, while the cost criteria are normalised by bringing in relation to the optimal value of each criterion with their individual values (Table 4).

Table 4. Normalised matrix

Cultivar (Alternatives)	C1	C2	C3	C4	C5	C6
Tourbillon (A1)	0.82	1.00	0.92	0.85	0.63	0.90
Voltron (A2)	1.00	0.79	0.90	0.91	1.00	0.83
Champollion (A3)	0.89	0.99	1.00	0.72	0.51	0.75
Impression (A4)	0.87	0.95	0.85	0.95	0.68	0.74
Bataille (A5)	0.97	0.67	0.95	1.00	0.91	1.00
Batsun (A6)	0.95	0.81	0.98	0.91	0.79	0.85

Alternatives: A1- 'Tourbillon'; A2- 'Voltron'; A3- 'Champollion'; A4- 'Impression'; A5- 'Bataille'; A6- 'Batsun'; Criteria: C1- rosette height; C2- rosette fresh weight; C3- number of leaves; C4- stem diameter; C5- stem fresh weight; C6- core ratio.

In the next step, based on the data from the normalised matrix, weighted matrices are formed by WS (the product of the normalised values of each criterion and the weighting coefficients for each) and by the WP method (by scaling the normalised values of the criteria with the values of the weighting coefficients for the same). The weight coefficients and the ranking list of cultivars were determined through two scenarios. In the first scenario, the ranking was performed in case cultivars are used for fresh consumption, and the criteria of rosette fresh weight, number of leaves and stem fresh weight were given greater importance compared to the other observed criteria. In the second scenario, the assumption is that the cultivars are for processing and producing ready-to-eat products, and in that case, greater importance is given to the criteria of rosette fresh weight, stem fresh weight and core ratio. The values of the weight coefficients according to the scenarios are given in Table 5.

Table 5. Weight coefficients (w_i) according to the two scenarios

Scenario	C1	C2	C3	C4	C5	C6
S1 w_i	0.056	0.278	0.278	0.056	0.278	0.056
S2 w_i	0.056	0.278	0.056	0.056	0.278	0.278

S1-scenario 1 (for fresh market); S2-scenario 2 (for processed products); W_i- weight coefficients

The relative importance of each alternative is determined by summing the value of the weighted matrix for the same (WS method) as well as by multiplying the value of the weighted matrix for each alternative (WP method). The relative importance of the alternatives in the WS and WP methods, as well as the total relative importance of individual alternatives, under the condition of equal influence of both methods on the obtained solution (λ=0.5), for the first scenario, is given in Table 6.

Table 6. Relative importance, the total relative significance for each alternative and ranking list for scenario 1

Alternatives	WS Q_i	WP Q_i	Q_i	Rank
A1	0.85	0.84	0.842	4
A2	0.90	0.89	0.896	1
A3	0.83	0.79	0.810	6
A4	0.83	0.82	0.825	5
A5	0.87	0.86	0.864	3
A6	0.87	0.86	0.865	2

Q_i-the relative importance; WS- Weighted Sum method; WP-Weighted Product method

According to scenario 1 and fresh lettuce consumption, the best-ranked cultivar is 'Voltron', followed by 'Batsun', while 'Champollion' was the worst-ranked. The ranking list of analysed cultivars for lettuce processing (scenario 2) is given in Table 7.

Table 7. Ranking list of analysed alternatives for scenario 2

Alternative	A1	A2	A3	A4	A5	A6
Rank	3	1	6	5	2	4

Results for scenario 2 showed that the 'Voltron' remained the best-ranked cultivar for processing, as well as the 'Champollion', which remained the worst-ranked in the ranking list. The stability of the obtained ranking list was checked using the SAW method. Ranking results for both scenarios are shown in Table 8.

Table 8. Ranking list of the alternatives for both observed scenarios using the SAW method

Alternatives	A1	A2	A3	A4	A5	A6
Rank (S1)	4	1	6	5	2	3
Rank (S2)	3	1	6	5	2	4

According to the SAW method the best-ranked cultivar 'Voltron'-A2 and the worst-ranked cultivar 'Champollion'-A3 stayed in the same positions for both scenarios which can confirm that the WASPAS method was suitable for solving this kind of decision-making problem in lettuce production. Also, the ranking positions of other cultivars stayed at the same position except for scenario 1 where alternatives 5 and 6 in the SAW method changed their positions. WASPAS method in agriculture included research on the efficiency of agricultural enterprises in Serbia (Lukić et al., 2021), the selection of pear (Nedeljković et al., 2022) and apple varieties in raising orchards (Nedeljković et al., 2023), assessment of nutrient deficiencies in kinnow (Pathania et al., 2023). This research showed that WASPAS and SAW methods can be used as decision-making tools for the selection of lettuce cultivars for different purposes. To the best of our knowledge this is the first experiment regarding the selection of lettuce cultivars using the WASPAS and SAW method and its contribution is to make optimal solution in cases when there are different criteria (traits) that should be taken into account.

Conclusion

Choosing an adequate cultivar is one of the most important steps in lettuce production. This research was conducted on five new cultivars that at the moment of experiments have not been registered in Serbia. Therefore, before involving them in production for the fresh market and/or processed industry, it is necessary to consider more criteria before making a final decision. For the fresh market, experts' opinions depicted several criteria (rosette fresh weight, number of leaves, stem fresh weight), being different for the processing (rosette fresh weight, stem fresh weight, core ratio). Application of WASPAS method derived cultivar 'Voltron' as the best-ranked alternative, while the lowest-ranked was 'Champollion', for both scenarios. To obtain more accurate results, a SAW method was applied. This method confirmed the ranking list for both scenarios obtained by the WASPAS method. Therefore, the presented results suggest that the WASPAS method provided an initial step toward decision-making in the selection of novel lettuce cultivars for the fresh market and ready-to-eat salads and that the cultivar 'Voltron' should be taken into consideration for registering on the variety list in Serbia.

Acknowledgement

This research was funded by the Ministry of Science, Technological Development and Innovation of the Republic of Serbia under Contract No. 451-03-66/2024-03/200053 and Contract No. 451-03-66/2024-03/200011. The authors are thankful to the company Iceberg Salat Centar (Serbia).

Abstract

The aim of this study was to compare irrigation scheduling and planting density in maize and to evaluate yield, water use efficiency (WUE), irrigation water use efficiency (IWUE) and financial efficiency of water use for irrigation (F_{IWUE}). A two-year field experiment was conducted in Vojvodina region (Serbia), and maize was subjected to three irrigation levels (rainfed and supply at 60 and 100% of crop evapotranspiration, ETc) interacting with three planting density (54,900, 64,900 and 75,200 plants ha^{-1}). The results indicate a large year-to-year variability, mainly due to a rainfall event in the first year during the silking stage. A significant irrigation and planting density effect was observed for all variables studied. The results showed that the reduction of irrigation decreased yield and WUE, but improved the IWUE. Increasing the planting density increased yield, IWUE and F_{IWUE}. In addition, increasing planting density increased the WUE, but only in the irrigated treatments. Treatment 100% ETc and 75,200 plants ha^{-1} achieved the highest grain yield (13.098–16.125 Mg ha^{-1}) and a relatively high WUE (2.525–2.958 kg m^{-3}). A significant “D × I” interaction was observed for grain yield and WUE and IWUE. The effect of planting density on grain yield and WUE was strongest at 100% ETc and the highest planting density. The treatment 60% ETc and 75,200 plants ha^{-1} obtained the highest IWUE (2.356 kg m^{-3}) and F_{IWUE} (\$2.543 m^{-3}). Maize can be grown in the Vojvodina environment with acceptable yields while saving irrigation water and increasing planting density. By taking advantage of the positive interaction between these two factors, resource utilization can be maximized.

Keywords: *Sprinkler irrigation, Planting density, Water use efficiency, Economic water productivity.*

Introduction

Maize (*Zea mays* L.) is widely cultivated in Serbia. The area under cultivation is 996,527 hectares and the average grain yield is about 790 g m^{-2}, while in Vojvodina, which is characterized by a temperate continental climate, cultivation covers 569,556 hectares and the average grain yield is about 840 g m^{-2} (Statistical Yearbook of the Republic of Serbia, 2021). However, due to the high variability in precipitation, maize yields in Serbia vary considerably from year to year (Dugalić *et al.*, 2024). According to Pejić *et al*. (2011), most maize crops in Vojvodina are produced under rainfed conditions, however, some areas with this crop are produced under irrigation to stabilize production. Under such water-limited conditions, maize productivity is highly dependent on irrigation, but in many intensive agricultural areas the availability of irrigation water is steadily declining as a result of climate change and increasing consumption. In many areas of southern Europe, irrigation water is becoming an increasingly limited resource (García-Tejero and Durán-Zuazo, 2022), so appropriate irrigation scheduling is required to maximize water use efficiency and profit. Appropriate use of irrigation water and plant density is critical to increase yield and water productivity (Zhang *et al*., 2022).

Evaluating crop response to irrigation in combination with planting density could help determine the best allocation of available resources to crops on the farm to maximize profit and reduce groundwater pollution. Literature on the effects of water and planting density on yield and related parameters such asWUE and IWUE can be found in Zhang *et al*. (2022), Wang *et al*. (2021), Xu *et al*. (2017) and Assefa *et al*. (2016). Irrigation affects maize grain yield, and the highest yield is obtained when crop evapotranspiration is fully restored, although WUE and IWUE generally decrease with an increase in irrigation water.

Djaman and Irmak (2012) found that the IWUE of maize decreased with irrigation amount in the first year of the experiment, which was conducted in a silt loam soil, while they showed the opposite trend in the second year. In a two-year study, Payero *et al*. (2006) evaluated the response of maize to deficit irrigation in the semi-arid environment of the US Great Plains. They found that WUE in this environment did not increase favourably with deficit irrigation, as WUE increased linearly with the ratio of actual crop evapotranspiration to potential plant evapotranspiration. An increase in plant density generally increases the grain yield of maize until an optimum number of plants per unit area is reached (El-Hendawy *et al*., 2008). Hou *et al*. (2020) also reported that higher plant densities in maize lead to higher grain yields. Norwood (2000) concluded that for maize, deficit irrigation combined with adequate plant population is a viable alternative to dryland farming in Kansas, where groundwater resources are declining.

The objectives of this study were: (i) to evaluate the impact of sprinkler irrigation scheduling in interaction with planting density of maize grown in a Vojvodina environment, and (ii) to analyze water use efficiency for maize.

Materials and methods

The field experiments were carried out in 2018 and 2019 in Vojvodina province, Serbia (44°52’ north latitude; 20°20’ east longitude, 81 m above sea level) in the experimental farm of the Maize Research Institute “Zemun Polje”. The soil was a Chernozem on loess (Calcic Chernozems), silty-clay-loam with the following average properties at 0–50 cm depth: clay 31.2%, silt 50.4%, sand 18.4%, pH (water) 7.8, total nitrogen 0.20%, organic matter 3.2%, plant available P_2O_5 13.1 mg per 100 g soil, plant available K_2O, 30.6 mg per 100 g soil, bulk density 1.32 kg dm^{-3}, field capacity water content 0.36 m^3 m^{-3}; permanent wilting point water content 0.17 m^3 m^{-3}, available soil water 190 mm m^{-1}.

Comparisons were made between three irrigation regimes with the restitution of 100 % (I_{100}) and 50 % (I_{60}) of the crop’s evapotranspiration (ETc) and rainfed (I_0) and three planting density (D_1 – 54,900, D_2 – 64,900 and D_3 – 75,200 plants ha^{-1}).

Irrigation was planned on the basis of a water balance calculated as the sum of estimated daily crop evapotranspiration (ETc), subtracting the portion of rainfall and stored soil water. ETc was calculated as suggested by the FAO, where the reference evapotranspiration (ETo) was calculated using the Penman–Monteith model before being modified by a crop coefficient (Allen *et al*., 1998). Irrigation was carried out every 7 days throughout the growing season to cover crop water requirements at a depth of 90 cm. A hand move sprinkler irrigation system was used.

A four replicate split-plot design was used, with irrigation “I” in the main plot and planting density “D” in the subplot. The experimental plots were located within an area planted with maize, and each experimental plot was 5.6 m × 8.0 m, corresponding to eight rows of maize. The individual plots were separated by bufferstrips. The maize hybrid ZP 677 from the Maize Research Institute “Zemun Polje”, FAO class 600, was sown by hand on May 5, 2018 and

April 26, 2019 with a row spacing of 0.7 m. At the time of physiological maturity, a sample area of 11.2 m^2 (the two middle rows of each plot, 8 m long) was harvested by hand and the mass of grains was determined. The grain samples were oven-dried at 65 °C to constant weight. The main details of the experiments are given in Table 1.

Table 1. Maize management during the 2 years of the experiment

Agronomic practices	2018	2019
Sowing date (day of year – DOY)	106	104
Irrigation supply (I_{60} and I_{100})	8–13	7–13
Seasonal irrigation rate (mm) treatments (I_{60} and I_{100})	90–239	94–291
Harvest date (DOY)	270	255
Length of growing season (days)	164	151

Soil water content was measured weekly in all experimental plots at sowing and harvest using the gravimetric method based on conventional dry weight multiplied by bulk density. Soil samples were taken in three points of the central zone of each plot in 10 cm soil layers (0–120 cm depth). Soil bulk density was also measured at the beginning of the growing season.
Seasonal crop water use (WU) was estimated using the following water balance equation (Kresović *et al*., 2016):

$$WU = P + I \pm SWC - D \quad (1)$$

where P is precipitation, I is irrigation,“ΔSWC” is the change in volumetric soil water content in the 0–1.2 m depth layer between sowing and harvest and D is water loss due to deep percolation, all in mm. The term D was calculated according to a water balance approach using the daily values of ETc, precipitation and irrigation and based on the gravimetrically measured soil water content at sowing. In this water balance model, losses due to surface runoff and capillary return flow are considered negligible.
Water use efficiency (WUE, kg m^{-3}) was calculated as the ratio between dry grain yield (in kg ha^{-1}) and seasonal water use (in mm). Irrigation water use efficiency (IWUE, kg m^{-3}) was also calculated as the ratio of the increased yield compared to the rainfed treatment with seasonal irrigation amount. The financial efficiency of water use for irrigation (F_{IWUE}, \$ m^{-3}) was calculated as the ratio of income generated by the application of irrigation and the cost of using irrigation.
Analysis of variance was performed for the 2-year period, considering year as a random effect. Least significant difference (LSD) was used as a test to separate means. Statistical procedures were performed using SAS statistical software (SAS version 9.4, 2016).

Results and discussion

Climate. In both years, the average temperatures (with the exception of September 2018) were always above the long-term average temperatures. In both years, these conditions were generally suitable for the heat requirements of maize, with daily temperatures in the range of 12–25 °C and slightly lower summer temperatures in the first year. The ETc also fluctuated between the two years and was 370–535 mm in 2018 and 304–501 mm in 2019 during the sowing-harvest period.

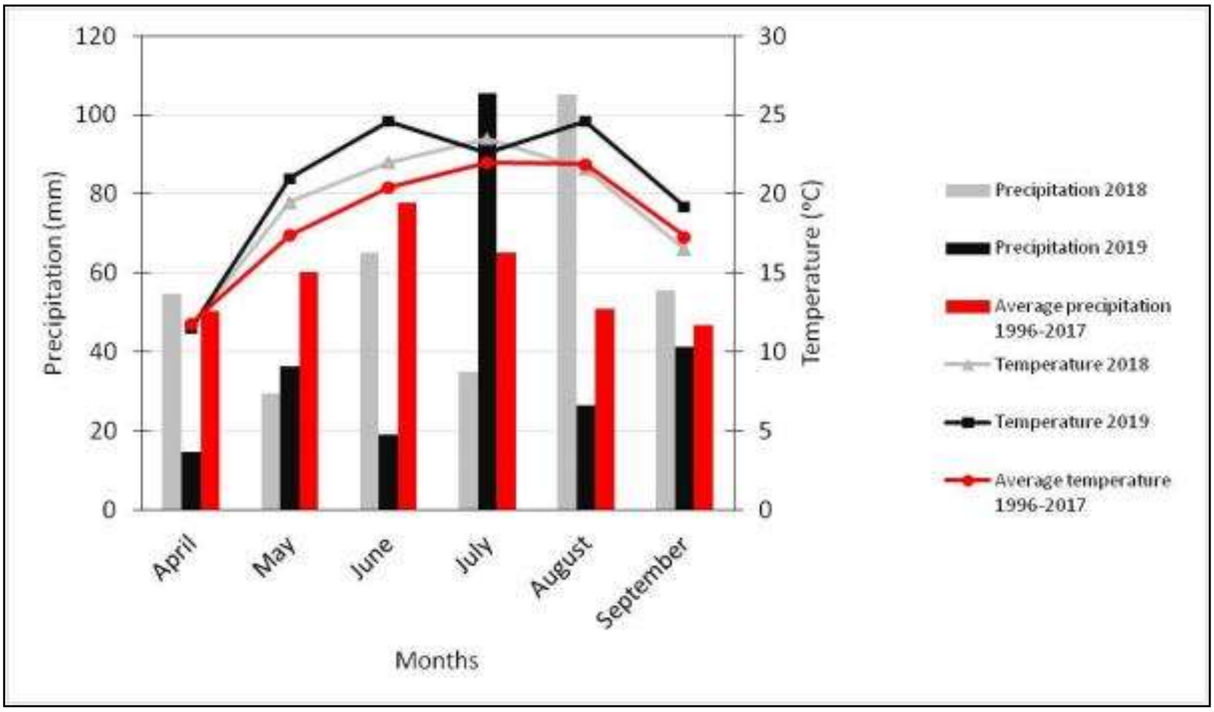

Fig. 1. Monthly climate data in Zemun Polje during the growing season of maize in 2018 and 2019 and the 20-year average.

Total precipitation during the maize cycle amounted to 345 mm in 2018 and 243 mm in 2019, which is below the long-term average (351 mm). In 2018, 18 mm of precipitation fell in the first 10 days of July during the silking maize stage, which was important for both grain yield formation and response to irrigation. In contrast, 40 mm of precipitation fell in the first 10 days of July 2019.

Grain yield production. The grain yield differed significantly between the two years (Table 2). In 2018 the average grain yield was 13.144, in 2019 9.561 Mg ha^{-1}. This can be explained by the climatic conditions, which were more favourable for ear fertility in 2018 (lower temperatures and humid days in the period after anthesis). Maize grain yields differed between irrigation and planting density treatments, but the “D × I” interaction was significant. In fact, irrigation enhanced the effect of plant density and vice versa (Fig. 2).
The differences between planting density treatments for each irrigation regime were small at I_{60} (10.519, 11.218 and 10.833 Mg ha^{-1} for D_1, D_2 and D_3, respectively), while they were considerably larger at I_{100} (13.323, 14.054 and 14.612 Mg ha^{-1}, respectively). This confirms the positive effect of adequate soil irrigation on water availability and the plant’s ability to take up water and plant nutrients simultaneously.
El-Hendawy *et al*. (2008) reported a greater response of maize yield to planting density when soil water was sufficient and a lesser response when water was deficient. They also reported an average yield increase of 63.5 % with sufficient (100 % ET) versus insufficient water supply (60 % ET) and significant yield decreases at 95,000 plants ha^{-1}, averaging 51 and 40 % of the values at 48,000 and 71,00 plants ha^{-1}, respectively, in Ismailia region, Egypt. In our study, yield increases with irrigation water were 66% at I_{100} versus I_0 and 36% at I_{100} versus I_{60}. The response to planting density was less effective; grain yield increases were 8.4% at D3 versus D1 and 0.2% at D3 versus D2. They also reported an average yield increase of 63.5% with sufficient (100% ET) versus deficient water supply (60% ET) and whereas yields at

95,000 plants ha^{-1} showed significant decreases average 51 and 40% of values at 48,000 and 71,00 plants ha^{-1}, respectively.

Relationship between water use and yield. In 2018, WUE was considerably higher than in 2019 (+23%), due to better climatic conditions favouring photosynthesis and carbon assimilation (Table 2). During the study period, the WUE ranged from 2.090 kg m^{-3} (I_0-D3) to 3.085 kg m^{-3} (I_{60}-D2). In this study, increasing the planting density and irrigation amount increases the WUE of maize. This agrees with the results of Zhang *et al*. (2022).

Table 2. Dry grain yield, water use efficiency (WUE), irrigation water use efficiency (IWUE) and financial efficiency of water use for irrigation (F_{IWUE}) of maize as a function of year, irrigation and planting density.

	Grain yield, Mg ha^{-1}	WUE, kg m^{-3}	IWUE, kg m^{-3}	F_{IWUE}, \$ m^{-3}
Year				
2018	13.143	2.878	1.570	1.393
2019	9.560	2.331	2.060	2.429
$LSD_{(0.05)}$	0.342	0.319	0.413	0.336
Irrigation				
I_0	9.186	2.653	–	–
I_{60}	10.873	2.535	1.822	1.943
I_{100}	13.996	2.627	1.808	1.879
$LSD_{(0.05)}$	0.217	0.051	0.279	0.275
Planting density				
D1	11.052	2.546	1.401	1.470
D2	11.606	2.673	1.753	1.838
D3	11.397	2.595	2.291	2.425
$LSD_{(0.05)}$	0.200	0.052	0.389	0.397

Averaged over all planting density, the yield of rainfed maize was very low: 11.342 and 7.032 Mg ha^{-1} in 2018 and 2019, respectively. This is consistent with the results of Kresović *et al*. (2016) for rainfed maize in an area with similar climatic characteristics. In rainfed crop, increasing planting density from 64,900 to 75,200 plants ha^{-1} resulted in significantly lower yields in bout years. These results show how difficult it is to achieve a satisfactory maize yield in these areas without irrigation and confirm that water is crucial and will become increasingly important in the future

Al-Kaisi and Yin (2003) obtained similar results under the agroecological conditions of the Great Plains in the USA. They reported that the highest grain yield was obtained in the maize treatment with full water supply at a density of 69,000 plants ha^{-1}. Increasing the plant density had no significant effect on yield, while significantly lower yields were obtained at lower densities than those mentioned. Under conditions of more or less pronounced irrigation, the maize achieved higher yields at lower sowing densities.

The significant "D × I" interaction of WUE, the relationship between grain yield and water use (ETc), is shown in Fig. 2. Higher values were obtained for D2 at I_0 and I_{60} irrigation. In this case, the yield-limiting factor was water availability in rainfed treatment (I_0) and at an irrigation supply of 60% of ETc, which proved to be sufficient to achieve the maximum WUE value at D2 in rainfed cultivation. On the contrary, the WUE values in I_{100} were better in the D3 treatment than in the D1 and D2 treatments.

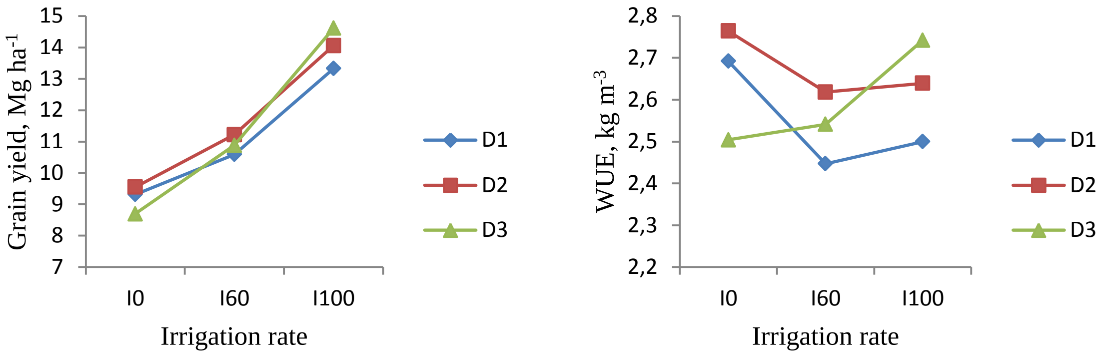

Fig. 2. Significant interaction “planting density” × irrigation for maize grain yield (left) and water use efficiency (right)

The combined effects of irrigation rate and planting density on irrigation water use efficiency (IWUE) were significant in 2019 (dry season) but not significant in 2018 (wet season) (data not shown). In 2018 treatment I_{100}-D3 (2.160 kg m^{-3}) and in 2019 treatment I_{60}-D3 (3.085 kg m^{-3}) had the highest IWUE. On the contrary, in D1, IWUE values were better in I_{100} than in deficit irrigation (I_{60}). On average, the lowest IWUE (1.301 kg m^{-3}) was recorded in I_{60} with 54,900 plants ha^{-1} and the highest IWUE (3.085 kg m^{-3}) in I_{60} with 75,200 plants ha^{-1}. Pejić *et al*. (2011) and Kresović *et al*. (2016) determined similar IWUE values of maize. In contrast to our results, El-Hendawy *et al*. (2008) reported the highest IWUE values for the highest irrigation rate (100% ET) for medium to small densities (48,000 or 71,000 plants ha^{-1}).
In the wet year 2018, no statistically significant differences in financial efficiency of water use for irrigation were found between deficit irrigation (I_{60} – F_{IWUE} = \$1,249 m^{-3}) and full irrigation (I_{100} – F_{IWUE} = \$1,536 m^{-3}). In addition to the water regime, the increased planting density also had a positive effect on the increase in F_{IWUE} values. The interaction between water regime and planting density showed no statistically significant differences. Irrigation resulted in a better F_{IWUE} in the dry year 2019 (Table 2) than in 2018. On average, for all densities, the I_0 treatment had a significantly higher financial efficiency of water use for irrigation (F_{IWUE} = \$2.635 m^{-3}) than the I_{100} treatment (F_{IWUE} = \$2.223 m^{-3}). Also in 2019, the highest F_{IWUE} (\$2.455 m^{-3}) from the application of irrigation was obtained by sowing maize in the highest tested density (D3). Analyzing the interaction between the two factors, it is concluded that the highest F_{IWUE} (\$3.640 m^{-3}) was achieved in the I_{60}-D3 treatment.

Conclusions

Based on these experimental results, an irrigation schedule that provides for partial restoration of crop ETc on a 60% basis allows for water savings (65% – when I_{60} is compared to I_{100}) and ensures a satisfactory maize grain yield level (10.873 Mg ha^{-1}, –22%) in a Vojvodina environment. Irrigation was more effective than planting density in increasing grain yield in both years. Irrigation increases the WUE value at I_{60}. Irrigation water productivity was higher in the I_{60} irrigation regime at higher planting densities, as shown by IWUE values. The maximum F_{IWUE} (\$3.640 m^{-3}) was achieved at I_{60}-D3.
In conclusion, high maize yields and high water use efficiency can be achieved in the Vojvodina region through the use of irrigation and higher planting density, while improving water production efficiency and economic returns.

Abstract

Climate change and the resulting increase in the frequency and severity of drought can have significant impacts on plant production. The use of drought-tolerant crop varieties can significantly improve plant production under drought conditions. Therefore, the goal of this research was to evaluate the drought tolerance of different wheat genotypes using stress resistance indicators. An experiment was conducted with sixteen wheat genotypes in Novi Bečej (Vojvodina) in different growing seasons. The spike weight was used as a phenotypic marker of the effect of drought stress on the plant. Selection based on resistance indicators such as stress tolerance index (STI), mean productivity (MP), and geometric mean productivity (GMP) favors the selection of genotypes Dunavka, Skopjanka, and Fundulea 4, which were characterized by the highest average values of spike weight, especially in favorable growing conditions. However, genotype Fundulea 4 is characterized by the highest stress susceptibility index (SSI) and the lowest yield stability index (YSI), which makes this genotype undesirable for growing under drought conditions. The parameters SSI and YSI favor the selection of the genotype Pitoma, which showed the highest value of spike weight in drought conditions as well as the least reduction in value caused by stress. Genotypes Pitoma, Dunavka, and Skopjanka, characterized by a high yield index (YI), are suitable for cultivation in drought conditions, where they achieved above-average trait values. The most suitable stress resistance indicators for selecting drought-tolerant wheat genotypes are SSI, YSI, and YI.

Key words: *drought stress, stress susceptibility index, stress tolerance index, wheat.*

Introduction

The greatest threats to the availability of food in the present and future are population growth and climate change. Drought is one of the most significant consequences of climate change and can which have a severe impact on agricultural production, especially in arid and semi-arid areas (Cheng et al., 2021). Wheat is the primary food source for around 40% of the world's population and a main source of daily protein and calories for about 2.5 billion people in developing countries (Braun et al., 2010). According to predictions made by Alexandratos et al. (2012), the demand for wheat in developing countries could rise by as much as 60% by 2050. Some of the causes influencing this projected rise in demand include urbanisation, rapid population expansion, and changes in dietary patterns.

According to Darvanto et al. (2016) drought conditions can reduce wheat productivity by 50 to 90% of the crop potential. Drought affects wheat at all growth stages, but it is more severe during the flowering and grain-filling stages, leading to significant yield losses (Sareen et al.,

2023). A worldwide effort to reduce the severity of droughts involves the development of drought-tolerant cultivars. However, progress has been significantly delayed by the complex structure of the drought-tolerance characteristics, which is controlled by a number of genes and greatly influenced by the environment (Pandey et al., 2022). Accordingly, identifying genotypes with tolerant genes is a difficult process (Anwaar et al., 2020). One of the approaches in the identification of drought-tolerant genotypes is the calculation of stress resistance indicators, which compare the value of the yield achieved in drought conditions with the yield in normal conditions (Anwaar et al., 2020, Aksić et al., 2020).
The aim of this study is to identify the wheat genotypes that exhibit the highest drought tolerance in the agro-ecological conditions of the semi-arid climate. Also, the goal is to select the best drought resistance indicator.

Material and Methods

A field experiment was established in Novi Bečej (Banat, AP Vojvodina, Serbia), which includes 16 wheat genotypes (Dukat, Dunavka, Fundulea 4, Iskra, Jedina, Jugoslavija, Kavkaz, Mačvanka 1, Marija, NS 58-04, Pitoma, Poljana, Skopjanka, Tamiš, Vali PKA-7114, and Zvezda). The analysed genotypes were sown according to the randomized block system in three replications with an inter-row spacing of 12 cm, where the size of the basic plot was 2 m^2. The soil type was humogley, which is characterised by a high content of clay. The usual agrotechnics for wheat production were implemented, where monoammonium phosphate (MAP) was used as the basic fertilizer in the amount of 250 kg ha^{-1}, while urea was used in the amount of 250 kg ha^{-1} for crop feeding. In both vegetation seasons, the harvest was performed at the optimal time (the first week of July in 2015/2016 and the last week of June in 2016/2017), when the grain moisture was below 14%. The spike weight was measured in 30 plants for each analysed genotype.
The stress resistance indicators were calculated based on the value of the spike weight under stress conditions (Yd), which characterized the 2016/2017 growing season, and the value of the spike weight in conditions favorable for plant development (Yp), which characterized the 2015/2016 season. The following stress resistance indicators are expressed in this paper:

Stress susceptibility index – SSI (Fisher and Maurer, 1978):

$$SSI = 1-(Yd/Yp)/1-(\bar{Y}d/\bar{Y}p)$$

Mean productivity – MP (Rosielle and Hamblin, 1981)

$$MP = (Yd + Yp)/2$$

Stress tolerance index – STI (Fernandez, 1992)

$$STI = (Yd + Yp)/\bar{Y}^2p$$

Geometric mean productivity – GMP (Fernandez, 1992):

$$GMP = \sqrt{Yd \times Yp}$$

Yield stability index – YSI (Bouslama and Schapaugh Jr, 1984):

$$YSI = Yd/Yp$$

Yield index – YI (Gavuzzi et al., 1997):

$$YI = Yd/\bar{Y}d$$

A cluster analysis was applied according to Ward's method for grain yield per ear and indicators of stress tolerance using the programme IBM SPSS Statistics, Trial Version 22.0

(https://www.ibm.com/). Distances between clusters are expressed as squared Euclidean distances, and the significance of distances was tested by the t-test. The number of cluster groups was identified using a dendrogram, after which a K-means analysis was performed with a predetermined number of cluster groups. After the analyses were carried out, the cluster groups were ranked according to the mean values of the analysed parameters.
During the experiment, large differences were noted regarding the amount of precipitation between the analysed growing seasons. Twice as much precipitation was recorded in the 2015/2016 growing season) compared to 2016/2017 (612 or 300 mm). Because of this, the 2016/2017 season is regarded as dry. In 2015/2016, during the growing season, average monthly temperatures were within the multi-year average, and the amount of precipitation was significantly higher than the multi-year average in almost all months. Heavy rainfall in June (164.0 mm) extended the grain filling period. On the other hand, 2016/2017 growing season was characterised by significantly higher temperatures than the multi-year average and a pronounced deficit of precipitation, especially in the grain-filling phenophase, which caused an earlier harvest of crops in the mentioned season (http://www.hidmet.gov.rs/).

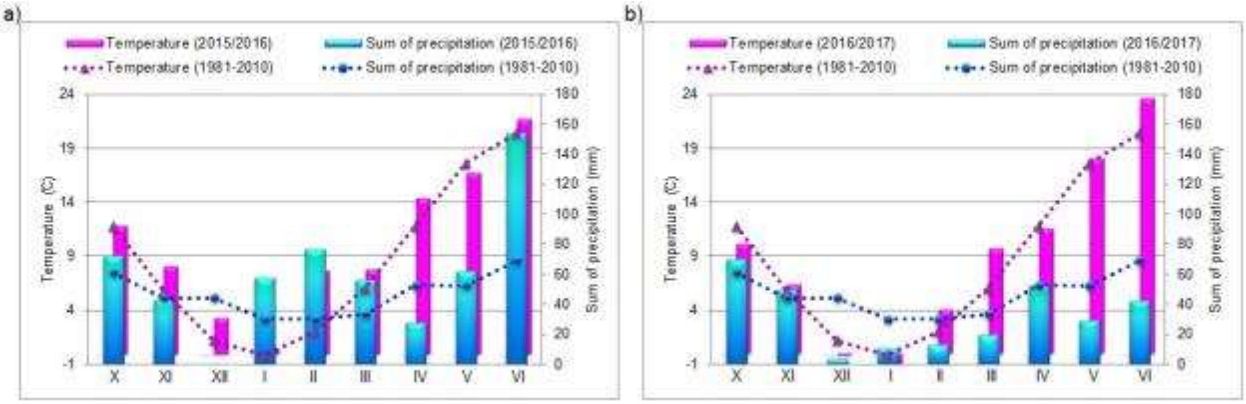

Figure 1. Mean monthly temperatures and sum of precipitation in Novi Bečej locality in 2015/2016 (a) and 2016/2017 (b) vegetation season

Results and Discussion

In this study, it was established that the drought stress conditions in the 2016/2017 vegetation season affected the reduction of the spike weight value in all analysed wheat genotypes, compared to the values achieved in the favourable 2015/2016 vegetation season (Figure 2, a).
The greatest decrease in the spike weight was recorded in the Fundulea 4 genotype (58.0%), while the smallest decrease was observed in the Pitoma genotype (20.2%) (Figure 2, 2). In accordance with the above, spike weight is considered a good phenotypic marker of the impact of drought stress on wheat. Wasaya et al. (2021) also found a decrease in the wheat spike weight under drought stress conditions, which they explained by a reduction in photosynthetic parameters.

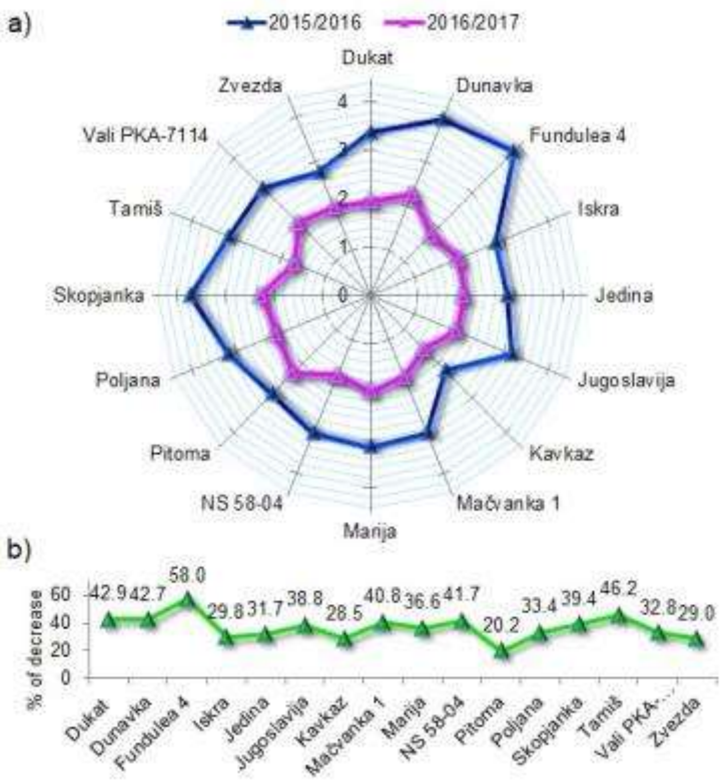

Figure 2. Radar graph of spike weight in examined wheat genotypes grown in drought stress and favorable conditions (a) and decrease (%) in spike weight due to drought stress (b)

The stress resistance indices were calculated, according to the values of spike weight of the analyzed wheat genotypes (Table 1). Indicators of resistance such as mean productivity (MP), stress tolerance index (STI) geometric mean productivity (GMP) take into account the spike weight achieved both in drought and in favorable environmental conditions. Golbashy et al. (2010) noted that STI and GMP are effective in identifying genotypes with high grain yield values in both, non-stress and stress conditions. According to the mentioned stress resistance indicators, the first-ranked cluster group includes the genotypes Dunavka, Skopjanka, and Fundulea 4, which were characterized by the highest average values of spike weight, especially in favorable growing conditions (Table 1, Figure 1,a). Similarly, Aksić et al. (2020) observed that STI, MP, and GMP indicators are positively correlated with grain yield achieved under irrigated conditions. Among the mentioned genotypes, Dunavka and Skopjanka are distinguished by the highest value of the yield index (YI) indicator (1.15), which relates the spike weight of certain genotypes in drought conditions to the average spike weight of all genotypes in drought stress conditions. Although genotype Fundulea 4 has a high value of MP (2.99), STI (0.59), and GMP (2.73), it is characterized by the highest stress susceptibility index (SSI) (1.53), the lowest yield stability index (YSI) (0.42), as well as a low value of the yield index (YI) (0.90). This genotype showed a very high value of spike weight in non-stress conditions, but a low value in drought stress conditions. According to Awnaar et al. (2020), such genotypes are not suitable for growing in wider areas, due to large yield losses under stress conditions. Stress resistance parameters SSI, YSI, and YI favor the selection of the genotype Pitoma, which showed the highest value of spike weight under drought stress conditions, as well as a smaller decrease in value under the influence of drought. Therefore, this genotype is considered the most drought-tolerant. Also, according to the SSI, YSI and YI parameters, the Kavkaz genotype is classified among drought-tolerant genotypes, exhibiting a small decrease in the spike weight under drought. However, according to the MP, STI, GMP and YI indicators, it is classified in the lowest ranked cluster group (4 and 5), characterized by lowest value of spike weight, which makes it an undesirable genotype in breeding programs and for cultivation in semi-arid climate conditions.

Table 1. AMMI analysis of variance for spike weight in 27 wheat genotypes grown in different agro-ecological conditions

Genotypes	SSI	MP	STI	GMP	YSI	YI
Dukat	1.13 (2)	2.66 (2)	0.53 (2)	2.55 (3)	0.57 (4)	0.98 (3)
Dunavka	1.12 (2)	3.12 (1)	0.62 (1)	3.00 (1)	0.57 (4)	1.15 (1)
Fundulea 4	1.53 (1)	2.99 (1)	0.59 (1)	2.73 (2)	0.42 (5)	0.90 (4)
Iskra	0.78 (4)	2.40 (3)	0.48 (3)	2.36 (4)	0.70 (2)	1.01 (3)
Jedina	0.83 (4)	2.39 (3)	0.47 (3)	2.35 (4)	0.68 (2)	0.99 (3)
Jugoslavija	1.02 (3)	2.56 (2)	0.51 (2)	2.48 (3)	0.61 (3)	0.99 (3)
Kavkaz	0.75 (4)	1.90 (4)	0.38 (4)	1.87 (5)	0.71 (2)	0.80 (5)
Mačvanka 1	1.07 (2)	2.48 (3)	0.49 (3)	2.39 (4)	0.59 (3)	0.94 (4)
Marija	0.96 (3)	2.57 (2)	0.51 (2)	2.50 (3)	0.63 (3)	1.01 (3)
NS 58-04	1.10 (2)	2.45 (3)	0.49 (3)	2.36 (4)	0.58 (4)	0.92 (4)
Pitoma	0.53 (5)	2.58 (2)	0.51 (2)	2.56 (3)	0.80 (1)	1.16 (1)
Poljana	0.88 (4)	2.64 (2)	0.52 (2)	2.59 (3)	0.67 (2)	1.07 (2)
Skopjanka	1.04 (3)	3.00 (1)	0.60 (1)	2.90 (1)	0.61 (3)	1.15 (1)
Tamiš	1.22 (2)	2.43 (3)	0.48 (3)	2.32 (4)	0.54 (4)	0.86 (4)
Vali PKA-7114	0.86 (4)	2.63 (2)	0.52 (2)	2.57 (3)	0.67 (2)	1.07 (2)
Zvezda	0.76 (4)	2.36 (3)	0.47 (3)	2.33 (4)	0.71 (2)	1.00 (3)

Note: The numbers in parentheses represent the rank of the cluster group for each resistance indicator, where number 1 is the cluster group with the highest, and number 5 with the lowest mean value of the resistance indicator.

Conclusion

Drought stress affected the reduction of spike weight in all analyzed wheat genotypes, which makes this trait a good phenotypic marker of the impact of drought stress on wheat. Therefore, stress resistance indicators were calculated based on the value of this trait. High values of the MP, STI, and GMP resistance indicators favor the selection of genotypes Dunavka, Fundulea 4, and Skopjanka, characterized by a high average spike weight, especially in non-stressful environmental conditions. Genotype Pitoma characterized by high values of MP, STI, GMP, YSI, YI and low value of SSI is rated as highly drought-tolerant genotype. Also, Dunavka, and Skopjanka are characterised by high YI values and are considered drought-tolerant genotypes. Genotype Fundulea 4, characterised by high values of MP, STI, and GMP and low values of SSI, YSI, and YI, are preferred for cultivation in non-stressful, but not in stressful environmental conditions. The most suitable stress resistance indicators for selecting drought-tolerant wheat genotypes are SSI, YSI, and YI.

Abstract

Throughout the life cycle, plants are exposed to a wide range of environmental factors, some of which may be harmful to their capacity to grow and develop to the fullest extent possible. The ability of a plant to respond rapidly and effectively to stress is one of the most critical aspects in determining its optimal output and survival. Plants have developed a mechanism for communication and signaling throughout their evolutionary history. Plants emit volatile organic compounds (VOCs) into the atmosphere to warn other plants of impending danger. Neighboring plants exposed to volatile organic chemicals develop their own defense systems in response to the stress. The basil plant (Ocimum basilicum) has been subjected to three different salinized water treatments (0, 40, and 80 mM NaCl) in order to investigate plant communication under stress. The main volatile organic compounds (VOCs) found in basil leaves were detected using analytical headspace-gas chromatography/mass spectrometry (HS-GC/MS). In basil, six signaling terpenes and one monoterpenoid were found. Under saline stress, eucalyptol synthesis and emission are intensified. The monoterpenes beta-phellandrene showed a tendency to decline under stress. Interestingly, the concentration of 4-carene is enhanced, while emission of its isomere 3-carene is reduced. In contrast to this, when exposed to stress, the concentrations of pinene, beta-ocimene, and alpha-camphene increased in moderately salinized solutions and decreased in substantially salinized solutions.

Key words: *plants communication, VOC, basil, terpenes, GCMS.*

Introduction

A critical aspect of contemporary agriculture is soil salinization. The production of plants is adversely affected by salinization of agricultural land, which further intensifies soil degradation. Retention of soluble salts in the soil leads to salinization of the soil. It occurs either naturally or as a result of inappropriate human activity, especially farming methods, intense industrialization pressure, and climate changes. In addition to reducing the yield of most crops, salinity affects the physical and chemical characteristics of the soil. There is a noticeable acceleration of the pace of soil salinization. It is anticipated that 50% of agricultural soil will become holomorphic by 2050 (Nachshon, 2018).

During their evolution plants developed a specific mechanism of communication as response to stress. When exposed plants experience stress, stress triggers set off a series of events that include gene expression, signaling cascade reactions, and morphological changes. For stress reactions to be successful or unsuccessful, signal processing time is crucial. Plants can communicate through sophisticated systems of mycorrhizal networks, electrical impulses, and volatile organic molecules released into the atmosphere or soil (Karban, 2008; Sharifi and Ryu, 2021). Volatile organic compounds, or VOCs, emitted by plants exposed to stress, have a particular composition and ratio of compounds. Plants react to messages containing volatile organic compounds (VOCs) by initiating a specific defense mechanism. For instance, the plant may produce specific secondary metabolites to protect itself from a particular kind of stress (Abbas et al., 2021, Rozenkranz et al., 2021).

With nearly sixty varieties, basil is an aromatic member of the *Lamiacea* family. Because of its essential oil concentration and aromatic flavor, basil is utilized extensively in both the culinary and pharmaceutical industry. The predominant aromatic profiles found in each of the species can be used to classify them into chemotypes, plant subspecies that share the same morphological traits but differ in the amounts of chemical compounds they produce in their essential oils (Muráriková et al., 2017). Monoterpenoids, methyleugenol, sesquiterpenoids, and phenylpropanoids fall within this category. Furthermore, there have also been reports of phenolic profiles. The differences in the content of essential oils are caused by factors such as cultivation conditions (temperature, light quality, and quantity), species and cultivar, growth season, leaf position and age, harvesting techniques, and extraction methods (Tangpao et al., 2022). The objective of the present study was to examine the relationship between plant communication and volatile organic compounds (VOCs) emission in limiting settings of saline stress.

Material and methods

The experiment constituted growing plants from seeds in the ecological-climatic conditions of Novi Sad, Serbia (45.2396° N, 19.8227° E). The basil seeds were sown at the beginning of March 2024 into a commercial substrate. When the basil seedling reached 5 cm in plant height, they were transferred to the experimental pots. Without causing any water stress, the seedlings were irrigated by ponding water in each pot until they had grown to an average height of 10-15 cm and had become acclimated to the soil. Following the original harvest of the basil plants in order to establish consistency among the plants, treatments were applied at regular basis. The irrigation interval and saline solution concentration were set at three days and 0, 40, and 80 mM, respectively. After 30 days of exposure to saline stress, basil leaves were harvested and analyzed for qualitative and descriptive composition of VOCs.

Basil varieties grown under stress and under control were analyzed for volatile chemicals using gas chromatography–mass spectrometry (GC/MS, 7890A/ 7694E, Agilent Technologies, USA), in scan mode. The instrument used a 30-m Agilent J&W DB-5MS Ultra Inert column (0.25 mm × 0.25 µm film thickness). For GCMS headspace analysis was used 0.3g of basil samples.

Results and Discussion

In terms of descriptive results, a total of six signaling VOCs were identified in this study (table 1), among which carene exists in isomer forms of 4- and 3-carene. Detailed analysis of the complete volatile compounds profile confirmed that terpenes are essential for stress-related communication. This finding is in line with recent studies. Namely, a thorough examination of the entire profile of volatile molecules highlighted terpenes and terpenoids, the most diverse class of plant secondary metabolites, as critical for stress-related communication (Rozenkranz et al., 2021). Terpenes, which include isoprene, monoterpenes, and sesquiterpenes, make up the greatest group of volatile organic compounds (VOCs) generated by plants under suboptimal growing conditions. Terpenes have the potential to serve as a chemical language for plant communication. Different classes of terpenes are used for warning under specific stress. While in plant-insect interactions, mono-and sesquiterpenes act as communication molecules, isoprene, the smallest and most often released terpene, has a role in abiotic stress resistance (Karban, 2008; Boncan et al., 2021, Abbas et al., 2022;).

In comparison to control plants, there was an increase in the levels of total eucalyptol and 4-carene following exposure to moderate and severe (40 mM and 80 mM NaCl treatment, respectively) saline stress. Specifically, under mild saline stress, the ratio of the cyclic monoterpenoid eucalyptol is raised by 60%. After further exposure to higher concentration of

NaCl, the initial rise declined, however, it remained higher than in the group of reference plants (Table 1). Full gas-mass chromatogram was shown in figure 1.

Table 1. Signaling terpenes emitted by basil leaves exposed to saline stress

Terpene	Ratio T1*/C**	Ratio T2***/C**
Pinene	1.18	0.87
Alpha-camphene	1.19	0.88
Beta-phellandrene	0.90	0.76
Eucalyptol	1.60	1.29
Beta-ocimene	1.11	0.81
Gamma-terpinene	1.41	0.76
4-carene	1.13	1.09
3-carene	0.95	0.58

*T1: treatment of mild salinization of 40mM NaCl solution
**C: control group
***T2: treatment of severe salinization of 80mM NaCl solution

Bicyclic monoterpenes 4-carene showed a similar pattern, with concentrations rising by 13% and 9% under moderate and severe salt stress, respectively. However, during salinization, the levels of the monoterpenes beta-phellandrene and 3-carene decreased in a corresponding manner in comparison to plants cultivated under optimal conditions and not exposed to stress (0.90 and 0.76 and 0.95 and 0.58, respectively, figure 1).

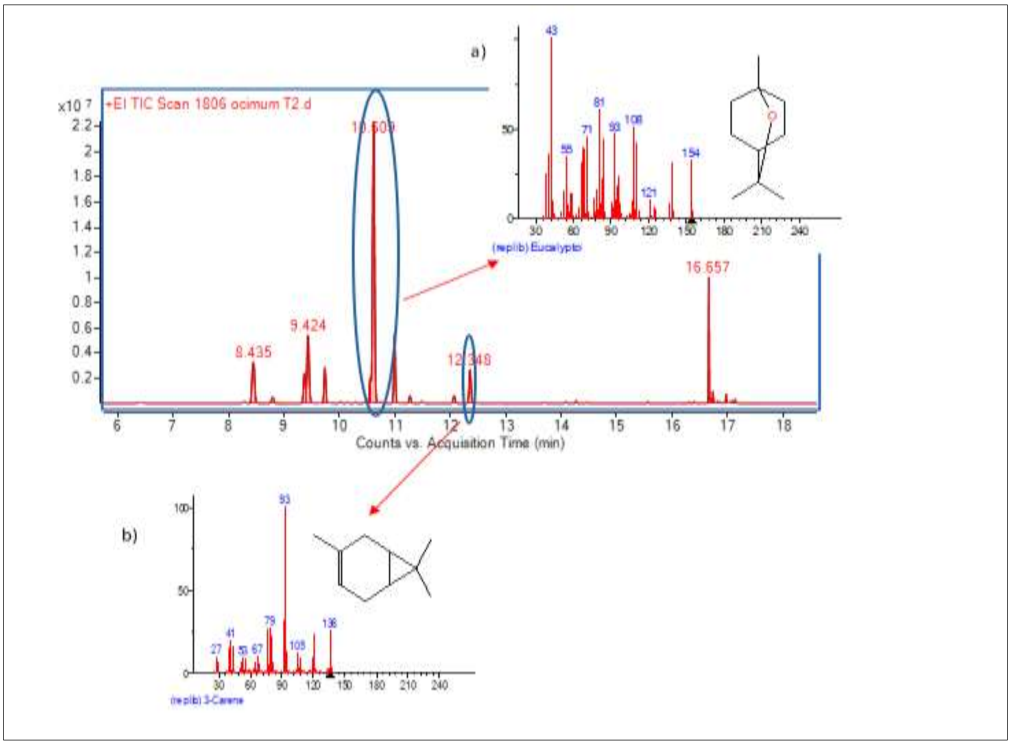

Fig.1 Full GCMS chromatogram in scan mode with mass spectra for a) Eucalyptol and b) 3-Carene

In contrast, the salinization caused decrease of monoterpene beta-phellandrene and 3-carene levels (0.90 and 0.76 and 0.95 and 0.58 compared to plants grown under optimal conditions respectively). Alpha-camphene, beta-ocimene, and pinene release are intensified under mild stress circumstances, however their production is suppressed at 80 mM NaCl concentration.

Compared to abiotic factors, effects of biotic-induced plant-to-plant communication have been studied far more. While the emission of volatile monoterpenoids is triggered by all types of stress, the production of aromatic volatiles appears to be promoted mostly by insect attack.
Additionally, in line with our findings, the volatile monoterpenes, such pinenes and ocimene, are activated by both biotic and abiotic stress (Abbas et al., 2022; Rosenkranz et al., 2021). Moreover, alpha-camphene may serve as a marker for biochemical alterations occurring at infection, whereas pinene, linalool, and ocimene are induced by biotic and abiotic stress (Arimura et al., 2011; Lee et al., 2014, Kleiber et al., 2017, Boncan et al., 2021).
Similar to our findings, several studies have linked the variation in 3-carene concentration to the plant's response to abiotic stress (Lee et al., 2014; Kleiber et al., 2017). Our findings are consistent with Lee et al. (2014), who found terpenine emission in rice under abiotic stress. According to Zebelo et al. (2012) and Kleiber et al. (2017), exposure to biotic and abiotic stress has been shown to cause the emission of gamma-phellandrene in the atmosphere.
Until now, research has not determined a change in beta-ocimene synthesis due to exposure to abiotic factors, but only due to insect invasion (Arimura et al., 2011, Lee et al., 2014). This finding gives room for beta-ocimene to be considered as a candidate for VOCs involved in communication in stressful circumstances, particularly in salinity-related situations.
The alternations in betta-phellandrene synthesis noticed between control and stressed plants can be explained with prior outcomes at gene expression level. Conditions of drought or excessive salinity alter the volatile emission in plants (Fernández-Martínez et al., 2018, Penuelas et al., 2005). A study that cross-referenced the volatile ingredients indicated many alterations in gene expression under constant salt stress. The plant can be protected from abiotic stresses by changes in VOC composition, such as the production of monoterpenes and isoprene. Most of the genes involved in volatile emission were suppressed in tomatoes exposed to salt (Benjamin et al., 2012) and betta-phellandrene synthase was one of these.
Our results demonstrate that concentrations of alpha-camphene, beta-ocimene, and pinene increase after initial exposure to moderate saline stress. Continued exposure to high salt concentrations causes a drop in their levels. This can be explained by the fact that increased salt concentrations are toxic to plants and that metabolic activities of stressed plants are reduced to minimum (Xu and Wu, 2021).

Conclusions

Detailed study of the entire profile of volatile chemicals verified that terpenes are necessary for communication linked to saline stress. For warning under particular stress conditions, different classes of terpenes and their mode/level of synthesis are employed. Upon exposure to moderate and severe salinity stress, there were variations in the amounts of six signaling volatile chemicals compared to control plants. These compounds include alpha-camphene, beta-ocimene, carene (which represents 4-carene 3-carene in two isomer forms), eucalyptol, and beta-phellandrene. The novel aspect is that, up until now, studies have only found that insect invasion causes changes in beta-ocimene production. This result allows beta-ocimene to be taken into consideration as a potential volatile organic compound (VOCs) implicated in stressful situations, especially those including salt. Our findings indicate that following an initial exposure to moderate saline stress, concentrations of alpha-camphene, beta-ocimene, and pinene rise. Their levels decrease with continued exposure to high salt concentrations. This makes sense given that plants are poisonous to higher salt concentrations and that stressed plants have minimal metabolic activity. As a result of initial exposure to moderate saline stress, our data show that concentrations of alpha-camphene, beta-ocimene, and pinene rise. They decrease as a result of prolonged exposure to high salt concentrations. This implies that stressed plants exhibit minimal metabolic activity and higher salt concentrations are toxic to plants.

Abstract

Maize (*Zea mays* L.) is considered one of the most important crops in the world and plays an important role in human food and animal feed. Considering the importance of maize production, as well as significant variability in productivity, biomass and early grain yield evaluation may be significantly important. Crop growth monitoring by remote and proximal sensing based on spectral information could provide promising results in its prediction. In the present study, an active multispectral proximate sensor, namely the Plant-O-Meter (POM) was used in the field trail to provide early yield and biomass estimation in maize crops. The maize crop was grown under field trial conditions with various levels of nitrogen application. This study investigated the contribution of the Normalized Difference Red Edge Index (NDRE) and Normalized Difference Vegetation Index (NDVI) on maize grain yield and biomass estimation during the season. The canopy reflectance was measured between the 4-leaf growth stages (V4) and the end of the tasseling and silking stage (VT/R1) in maize. Pearson's correlation coefficient (r) was applied to determine the correlations between grain yield and biomass with the NDRE and NDVI indices throughout the growing season. Maize grain yield showed a more significant positive relationship with both indices across the V4 stage, while biomass estimation showed the highest correlation at the VT/R1 growth stages. These results imply that NDRE and NDVI indices may be suitable for early yield and biomass estimation, while their accuracy depends on the growth stage of maize.

Key words: *maize, yield, biomass, proximal sensors.*

Introduction

Maize (*Zea mays* L.) is one of the most important cereal crops and has the most notable global production, providing human food, animal feed and feedstock for numerous industrial products and biofuel production (Cardador-Martínez et al., 2011). Despite the genetic improvement and high progress in the selection of new maize genotypes, the grain yield potential of maize is still unpredictable and largely affected by abiotic and biotic factors, as well as by a certain combination of different factors (Ljubičić et al., 2023). In maize cultivation, nitrogen (N) management has a significant impact on yield quantity and quality, and it is required for optimal maize development, photosynthesis, and grain production during the growing season. Since the maize crop requires more nitrogen than the soil can supply, it is common practice to apply nitrogen fertilizer. Still, soil nitrogen availability is not persistent, and its amount depends on various elements, such as water status, soil type and meteorological conditions. Therefore, forecasting yield and yield related traits of maize before harvest is becoming increasingly important in areas where climate uncertainty has become prevalent, as well as to recognize environmental stress and mitigate its negative impact on plant growth. Recent studies showed that remote sensing has been applied quite successfully to monitoring open fields and large areas, which provides rapid data collection over wide field areas (Kostić et al., 2016; Ljubičić et al., 2018). The main characteristic of remote and proximal sensing technology in agriculture is that it presents non-destructive measurements and real-time plant monitoring based on canopy reflectance measurements. Depending on the surface's optical characteristics, light is absorbed, transmitted, or reflected. Plants reflect light emitted during different physiological processes or morphological components, while different sensors can detect the fraction of light that a surface reflects. Advancements in canopy reflectance detection accuracy have led to linking specific wavelengths with specific plant traits, physiological processes, or morphological parameters, as well as yield and biomass estimation (Sarlikioti, 2011). Several studies have been conducted to identify the combinations of reflectance at various wavelengths to properly account of the effect of impacting elements on the relationship between plant reflectance and plant traits. The combinations of the reflectance at different wavelength bands have become known as vegetation indices (VI’s). Vegetation indices, defined as mathematical combinations of spectral bands, commonly assess land surfaces in the visible and near-infrared ranges of the electromagnetic spectrum (Lambin, 2001). Vegetation indices represent quantitative measures used to estimate vegetation activity, the fraction of photosynthetically active radiation absorbed by the vegetation canopy, plant health, growth dynamics, vegetation cover or plant vigor (Wang et al., 2005; Xue and Su, 2017). Over the past years, scientists have developed a number of VIs for qualitatively and quantitatively evaluating vegetative covers using spectral measurements. Among numerous indices, the Normalized Difference Vegetation Index (NDVI), developed by Rouse et al. (1974), is the oldest and most well-known vegetation index used as an indicator of vegetation greenness (Ihuoma and Madramootoo, 2017; Zhao et al., 2015). However, NDVI has certain disadvantages and can be sensitive to certain atmospheric effects and has the tendency to saturate over dense vegetation (Agapiou et al., 2011; Gu et al., 2013). By substituting NDVI’s red band with NDRE’s (The normalized difference red edge index) red edge band it is possible to mitigate the issue of saturation. It has been confirmed that NDRE’s red edge band provides better insight into plants in their later stages and is less prone to saturation in the presence of dense vegetation. Therefore, the objectives of this study were to evaluate the potential of using NDVI and NDRE indices to get accurate results in grain yield of maize and biomass estimation. The second objective was to determine the specific growth stage where the correlation between yield, biomass and NDRE and NDVI indices acquired by a multispectral sensor is highest and therefore most suitable for sensing.

Material and Methods

The present research was conducted in a field trial at Ravno Selo, near Novi Sad, Serbia, on the Chernozem type of soil, throughout the 2021 growing season. In order to examine the variation of maize grain yield traits, maize hybrids (*Zea mays* L.) of different maturity were chosen under different nitrogen applications as pre-plant applications. The field experiment was conducted according to randomized block design with three replications. An active, multispectral optical sensor, namely Plant-O-Meter (POM), recently developed at the Biosense Institute in Serbia, was used to measure plants during vegetation. The Plant-O-Meter device possesses a multispectral source, which integrates six light sources into one optical module. Based on six band combinations (Blue: 455 nm, Green: 528 nm, Red: 657 nm, Red Edge: 740 nm, NIR1: 810 nm and NIR2: 940 nm) it provides reflectance for each band separately, allowing the calculation of more than 30 different VIs. As the sensor provides its own light source, it was designed to block the influence of sunlight in any environment. Sensor readings were recorded throughout the growing season, from V4 (four completely developed leaves) growth stage to VT/R1 (tasselling and silking) growth stage of maize

development. The collection of data with the POM was carried out manually by passing over the canopy 0.5 m above and screening the two centre rows in continuous mode at a frequency of 1 Hz. After processing the data with GIS software, the central part of each measured row, or two middle rows per plot, was selected. Based on the six-band combination obtained by multispectral measurements the vegetation indices NDVI and NDRE were calculated.
The normalized difference red edge index (NDRE) was calculated as follows:
NDRE = (NIR−RED EDGE) / (NIR+RED EDGE), where NIR present near-infra red band (810 nm) and RED EDGE present red edge spectral band (740 nm).
The normalized difference vegetation index (NDVI) was calculated as follows:
NDVI = (NIR – RED) / (NIR + RED), where NIR present near-infra red band (810 nm) and RED present red spectral band (657 nm).
Pearson correlation coefficients were used to determine the relationship between NDRE and NDVI indices, grain yield and biomass of maize. All statistical analyses were carried out with the STATISTICA software version 13 (Stat Soft Inc., Tulsa, OK, USA).

Results and Discussion

In this research, the relationship between two vegetation indices, biomass and overall grain yield of maize has been estimated. Average grain yields, biomass and vegetation indices of the examined maize crop are presented in Table 1. In respect of the mean values of NDRE and NDVI values, it was observed that both indices showed the greatest values at the V4 (four developed leaves) leaf stage of maize. The obtained data indicated that a significantly better condition of the plants was observed at the beginning of the growing season, which is confirmed by the data from the NDVI and NDRE vegetation indices. The lowest mean values were observed in the V8/V9 growth stage for the NDRE with a mean value of 0,088, while the NDVI showed the lowest value at the VT/R1 stage of maize, with a mean value of 0,615 (Table 1).

Table 1. The mean values of biomass, grain yield, NDRE and NDVI throughout the growing season

			Growth stage of maize		
GY[a]	AB[b]	V4	V7	V8/V9	VT/R1
					NDRE[c]
7,460	75,302	0,166	0,164	0,088	0,116
				Growth stage of maize	
		V4	V7	V8/V9	VT/R1
					NDVI[d]
		0,765	0,652	0,738	0,615

[a]GY: Mean grain yield (t ha^{-1}), [b]AB: Mean biomass (t ha^{-1}), [c] NDRE: The normalized difference red edge index, [d]NDVI: The normalized difference vegetation index

The maximum values of NDVI observed during the V4 and V8 stages were expected when photosynthesis was at its highest point and the leaf area was the largest. The NDVI and NDRE of maize crop decreased with the growth process, and through the later growth stages, both NDVI and NDRE values gradually declined, reaching the minimum values at VT/VR1. The obtained results indicated that through the growing season and towards the end of the season, reflectance of visible wavelengths increased, while reflectance of NIR decreased because of senescence and less absorption of visible light in the maize leaves. These results are in accordance with previous findings reported by Reynolds et al. (2012) and Zhao et al.

(2023). In respect to the association between NDRE, NDVI indices and grain yield and biomass of maize the calculated ratios showed that different correlations were found between NDRE, NDVI, grain yield and biomass of maize estimation. Regarding the association between grain yield of maize and NDRE, the result revealed that a highly significant and positive association was observed at the V4 (r=0,348**) and VT/R1 (r=0,318**) growth stages. In respect to the NDVI, highly significant and positive association was observed at V4 (r=0,362**) and VT/VR (r=0,321**) growth stages of maize. The significant and positive association between NDVI and maize biomass was also observed at V7 (r=0,209*), Table 2.

Table 2. Relationship between NDRE and NDVI indices with grain yield of maize throughout the growing season

	Growth stage of maize			
GY[a]	V4	V7	V8/V9	VT/R1
	NDRE[b]			
8,460	0,348**	-0,008	0,031	0,318 **
	Growth stage of maize			
	V4	V7	V8/V9	VT/R1
	NDVI[c]			
	0,362**	0,209**	0,177	0,321**

[a]GY: Grain yield t ha^{-1}, [b]NDRE: The normalized difference red edge index, [c]NDVI: The normalized difference vegetation index, **Correlation significant at the 0,01 level, *Correlation significant at the 0,05 level.

In respect to the association between NDRE, NDVI indices and the biomass of maize, the calculated ratios showed similar correlations. Regarding the association between the biomass of maize and NDRE, the result revealed that a highly significant and positive association was observed at the VT/R1 (r=0,309**) and V4 (r=0,288**) growth stages. In respect to the NDVI a highly significant and positive association was observed at VT/VR (r=0,362**) and V4 growth stage (r=0,334**). The significant and positive association was also observed at the V8/V9 (eight to nine developed leaves) growth stage (r=0,209*), Table 3. The obtained results are expected since, during the tasselling and silking stages of maize development, the plants showed the least uniformity. This is a consequence of the different appearance of plants in the reproductive stage, when they express higher variability in leaf color, varying from dark green to pale brown. Similar findings were observed by Vian et al. (2018), while different results and a significant positive correlation between vegetation indices and maize yield in the filling stage were shown by Zhao et al. (2023).

Table 3. Relationship between NDRE and NDVI indices with grain yield of maize throughout the growing season

			Growth stage of maize	
AB[a]	V4	V7	V8/V9	VT/R1
			NDRE[b]	
75,302	0,288**	0,016	0,052	0,309**
			Growth stage of ma ize	
	V4	V7	V8/V9	VT/R1
			NDVI[c]	
	0,334**	0,177	0,209*	0,362**

[a]AB: Aboveground biomass (t ha^{-1}), [b] NDRE: The normalized difference red edge index, [c]NDVI: The normalized difference vegetation index, **Correlation significant at the 0,01 level, *Correlation significant at the 0,05 level.

Although methods of correction of the NDVI index using the NDRE index should provide more accurate data and a better understanding of the obtained data (Hassan et al., 2019; Voitik et al., 2023), the present results indicated the need to consider more parameters for a better assessment of maize plant states and forecasting their grain yield and biomass. Since several investigations were conducted on wheat plants, there is a need for further investigation and clarification for other crops.

Conclusion

Based on the present findings, it can be concluded that the grain yield and biomass of maize may be estimated with high accuracy using both the NDVI and NDRE indices. The estimation of maize grain yield presents a higher level of accuracy at the appearance stage of the V4 growth stage, while the best estimation for biomass was observed at the V6 growth stage of maize. Despite certain advantages of the NDRE index, the NDVI showed higher accuracy than the NDRE in the estimation of maize biomass and grain yield. In light of the present findings, additional research on various cultivars and fertilisation management techniques has to be done in the future, which will provide more information and clarification for other crops.

Abstract

One of the factors that most severely limits plant production is a rise in salinized soil, which is brought on by a combination of pollution and contemporary farming methods. Arugula (*Eruca sativa*), a green leafy vegetable belonging to the Brassicaceae family, is rich in proteins, fibers, and vitamins A, C, and K. Arugula is a powerful antioxidant and anti-inflammatory because of its biochemical composition. Arugula plants were subjected to 0 mM NaCl (C), 40 mM NaCl (T2), and 80 mM NaCl (T3) solutions for 60 days throughout the 2024 growing season to determine the impact of soil salinity. Indoor growing conditions were provided for the plants in pots. Each treatment was run through three replicates. Temperature was used to estimate the early stress response of the arugula plants. The leaf's progressive reduction in temperature when exposed to salt solution is an indication of a stress reaction. Plant spectral reflectance was measured using the handheld multispectral sensor Plant-O-Meter. The Normalized Difference Vegetation Index (NDVI) and the Enhanced Vegetation Index (EVI) were the two vegetational indices (VI) that were utilized to evaluate the plant response. Significant variations between treatments for both calculated indices are revealed by the calculation of f-ratio values. When ANOVA is used for multiple comparison analysis testing, the NDVI values of T1 and T3, as well as T2 and T3, differ significantly. There are notable variations in EVI values between T1 and T2, as well as T1 and T3 treatments. These findings suggest the possible use of remote sensing tools to forecast stress in arugula by utilizing NDVI and EVI.

Key words: *arugula, NDVI, EVI, salinization, leaf temperature.*

Introduction

In contemporary agriculture, there is a rising gap between the expanding need for food and the corresponding escalating land degradation. Projections of human population show steady growth, while soil degration, of which soil salinization is a major issue, will continue to trend negatively. Contemporary agriculture production, especially irrigation and fertilization management, are one of the major factors which lead to soil salinization. Although anthropogenic influence has a remarkable effect, there are other elements that contribute to soil degradation and subsequent salinization. Salinization is predicted to get worse due to climate change, which will cause more frequent and severe droughts as well as sea level rise (Singh, 2021, Nogacz et al., 2022).

Optimization of agricultural production under salinization is necessary and can be properly implemented if the stress is detected in initial phase and mechanism of action of salt stress on plant as well as its reaction is known. According to recent studies (Nogacz et al., 2022, Vellinga et al., 2021), salinity interferes with nitrogen intake, causing growth inhibition. As a consequence, plant reproduction is halted and normal plant development and productivity are inhibited. Additionally, oxygen exchange is altered during stress. Plants eventually die when the concentration of certain ions, especially chloride, rises because of their toxicity.

Arugula (Eruca sativa), also reffered to as rocket, is green leafy vegetable from Brassicaceae family. Originating in the Mediterranean area, it is very well-liked salad ingredient (Garg & Sharma, 2014). This is supported by the fact that raw arugula has been used in salads in Italy since the Roman era. Usually, the species grows on arid, rugged soil. Traditionally, the plant was gathered from the wild or planted in household gardens alongside other herbs like basil and parsley. Nowadays, arugula is grown commercially in many locations all over the world. Apart from the leaves, edible parts include the blooms, immature seed pods, and mature seeds. Currently, thanks to its content, arugula is used as a garnish for mixed salads, where it lends a pleasant sharpness (Gulfraz et al., 2011, Komeroski et al., 2023).

With only a small quantity of fat, raw arugula reach in proteins, vitamins (A, C, and K), and fibers. It is an abundant source of vitamin folate, while magnesium, calcium, manganese, and vitamin C. Next to the role in nutrition, arugula is recognized as valuable source in medicine and pharmaceutical industry. When used as medicine, the arugula stimulates hair growth and has antibacterial, antidiabetic, antihypertensive, antiplatelet, and antioxidant properties (Gulfraz et al., 2011, Greg and Sharma, 2014).

Vegetation indices (VIs) derived from remote sensing of canopies are straightforward and effective algorithms for quantitative and qualitative assessments of vegetation cover, plant vigor, growth dynamics, and other relevant parameters. More than one hundred vegetation indices have been derived from multispectral imagery (Xue and Su, 2017). These indices facilitate the identification of nutrient deficiencies, water stress, extreme temperatures, soil coverage, diagnosis of biological parameters, and yield estimation (Andrade et al., 2022).

The Normalized Difference Vegetation Index (NDVI) is one of the earliest and most widely used indices for vegetation assessment due to its simplicity and compatibility with any multispectral sensor equipped with visible and near-IR bands (Huang et al., 2021). Mathematically, NDVI is expressed as follows:

$$NDVI = \frac{NIR - RED}{NIR + RED}$$

However, the interaction between soil and atmosphere can complicate the interpretation of NDVI, as reducing the influence of one can amplify the effects of the other. To address this issue, a feedback mechanism was introduced through the development of the Enhanced Vegetation Index (EVI), which simultaneously corrects for both soil and atmospheric effects (Xue and Su, 2017). The EVI is expressed as follows:

$$EVI = 2.5\left(\frac{NIR - RED}{NIR + 2.4RED + 1}\right)$$

The aim of this study was to investigate the early salt stress-induced response in arugula. We summarized the effect of salinization through NDVI and EVI analysis using the portable multispectral optical device Plant-O-Meter, which integrates a multispectral light source consisting of wavelengths at 850, 630, 535, and 465 nm, enabling simultaneous illumination of the entire plant (Kitić et al., 2019).

Material and Methods

The experiment represented growing arugula plants from seeds in indoor conditions in Novi Sad, Serbia (45.2396° N, 19.8227° E). At the beginning of February 2024, the arugula seeds were planted in a commercial substrate. Once the seedlings reached the height of 5 cm, they were transplanted into test pots. The seedlings were irrigated by ponding according to their specific needs until they had grown to an average height of 10 to 15 cm and had become adapted to the conditions. Following the establishment of healthy plant conditions and consistent development, solutions with varying NaCl concentrations were applied to the plants to subject them to saline stress. Treatments were applied regularly; there was an

irrigation interval of three days, while the concentrations of the saline solution were 0 (T1), 40 (T2) and 80 (T3) mM NaCl. After sixty days of exposure to salt stress, vegetation indices NDVI and EVI were evaluated using a multispectral optical device Plant-O-Meter. An infrared thermometer was used to measure the leaf's temperature simultaneously.
All statistical tests were carried out using the Statistical AnalysisSystem Statistica 6.1 version. An overall difference between sample means were tested by one-way ANOVA (for $P<0.05$). whether Tukey's HSD test was used to determine significance between the pairs of treatments.

Results and Discussion

This study investigated how different treatments affected NDVI values in arugula under early salt stress conditions. Analysis of variance revealed significant variations among treatments ($F = 18.47109$, $p < 0.05$, Table 1). Further pairwise comparisons showed that NDVI values did not significantly differ between treatments T2 and T2 ($Q = 0{,}022$, Table 2), suggesting similar responses. In contrast, significant differences were observed between T1 and T2 ($Q = 0.66$), as well as T1 and T3 ($Q=0{,}64$), indicating distinct effects of treatment T3 on vegetation indices. These results underscore NDVI's sensitivity as an indicator of salt-induced stress in arugula, providing valuable insights into treatment-specific physiological responses. Similar results were obtained in Aldakheel (2011) study, where lower NDVI values may correspond to high electrical conductivity of the soils, suggesting that soil salinity impacts vegetation health, similar to the treatment-induced variations in NDVI observed in our study. Indices based on chlorophyll absorption bands and the NIR region, such as NDVI, had a strong relation with soil salinity because these indices are related to the growth of plants, biomass, leaf area and chlorophyll content (Zhang et al., 2011).

Table 1. Summary of one-way analisys of variance performed on parameters NDVI, EVI, and leaf temperature of basil subjected to 0 (T1), 40 (T2) and 80 (T3) mM NaCl solutions ($P < 0.05$)

	One-way ANOVAtesting (df=2)	
Evaluated parameters	F- statistics	p-value
NDVI	18.471	1.85E-07
EVI	34.124	8.13E-10
Leaf temperature	3.985	0.02212

Similarly, the study explored the response of Enhanced Vegetation Index (EVI) values in arugula under various treatments subjected to early salt stress. Analysis of variance revealed significant differences among treatments ($F = 34.124$, $p < 0.05$, Table 1), highlighting diverse effects on EVI across experimental conditions. Pairwise comparisons (Table 2) revealed that treatment T1 exhibited significantly higher EVI values compared to both T2 (mean difference = 0.064, $p < 0.05$) and T3 (mean difference = 0.045, $p < 0.05$), indicating a heightened response to salt stress. Conversely, no significant difference was found between T2 and T3 (mean difference = 0.019), suggesting similar EVI responses under these treatments. These findings underscore EVI's sensitivity in detecting early physiological changes induced by salt stress in arugula, emphasizing its utility in evaluating treatment-specific plant responses in controlled agricultural environments. Lobell et al. (2010) concluded that EVI is a more reliable measure of vegetation condition and, consequently, salinity, compared to NDVI.

Table 2. Difference between means of treatments 0 (T1), 40 (T2) and 80 (T3) mM NaCl tested by multiple comparison test (Tukey HSD test, P < 0.05).

	NDVI		EVI		Leaf temperature	
Pair	Q	p-value	Q	p-value	Q	p-value
T1-T2	0,66	1.52E-07	0.064	8.13E-10	0.66	0.0451
T1-T3	0,64	0.0002126	0.045	1.45E-09	0.67	0.0400
T2-T3	0.022	0.1706	0.019	0.9666	0.01	0.9986

This study analyzed temperature variation among treatments. A total of 90 observations were distributed across three treatments. Mean temperatures were 22.1°C (T1), 21.8°C (T 2), and 21.5°C (T3), with corresponding standard deviations of 0.8909, 0.9852, and 0.7018°C, respectively. Analysis of variance revealed a sum of squares (SS) between treatments of 3.926 with 2 degrees of freedom (df), resulting in a mean square (MS) of 1.963 and an F-ratio of 2.60934 (Table 1). The associated p-value was 0.079335, indicating a trend towards significance at the $p < 0.05$ level. These results suggest potential treatment effects on temperature variation. Tian et al. (2020) concluded in their study that plants subjected to salt stress exhibited significantly higher leaf temperatures compared to the control group. These findings underscore the importance of monitoring leaf temperature as an indicator of plant responses to stressful conditions.

Conclusions

The arugula's early stress response was estimated using temperature. When a leaf is exposed to salt solution, its temperature gradually drops, which is a sign of a stress reaction. Plant-O-Meter, a portable multispectral sensor, was used to detect the spectral reflectance of plants. The two vegetational indices (VI) that were used to assess the plant response were the Enhanced Vegetation Index (EVI) and the Normalized Difference Vegetation Index (NDVI). The F-ratio values computation reveals significant differences between treatments for both derived indices. The ANOVA multiple comparison analysis highlighted significant difference in the NDVI values of T1 and T3, as well as T2 and T3. EVI values differ significantly between T1 and T2, as well as between T1 and T3 treatments. These results imply that NDVI and EVI could be used as remote sensing metrics to predict stress in arugula.

Abstract

The intensification of agriculture and modern breeding activities have reduced biological diversity and led to the nearly-complete elimination of old varieties and local landraces from farms. The aim of this study was to examine the effect of nitrogen application on the main yield components and grain yield of five old, traditional wheat landraces and varieties. The experiment was conducted as a two-factorial trial with a randomized treatment design. The following factors and treatments were examined: five winter wheat varieties - Stara Banatka, Bezostaya 1, Bankut 1205, Crnozrna, and Brkulja 4; and nitrogen fertilization with two treatments: a) control (N_0) and b) nitrogen fertilization in top-dressing based on N-min analysis (N_{109}). For all analyzed traits, the analysis of variance showed that the varieties had the largest contribution to their variability, suggesting significant genetic differences among the varieties, which can be attributed to their different origins and varietal specificity. The Crnozrna variety produced the highest grain mass per spike while the variety Bezostaya 1 had the highest 1000-grain weight. The variety Bezostaya 1 produced the highest grain yield on average. Overall, significantly higher values of yield, and yield components were achieved in the nitrogen fertilization treatment compared to the unfertilized treatment. The yield difference in favor of the fertilized treatment ranged from 2% for the variety Crnozrna to 11% for the variety Bankut 1205.

Keywords: *winter wheat, old varieties, landraces, nitrogen, yield components, yield.*

Introduction

Old, traditional wheat varieties and local landraces are considered significant sources of natural variability in important agronomic and nutritional traits, some of them with good tolerance to abiotic stress factors (Mirosavljević et al., 2021) and good ability to remobilize nutrients to the grain (Mikić et al., 2023). Their diversity can have substantial advantages in unfavorable agroecological conditions and represent an alternative to modern varieties due to better adaptability to extensive production conditions. The value of local landraces and old wheat varieties is recognized primarily from a nutritional perspective. Modern varieties, compared to old varieties and landraces, often have lower protein and mineral element content. The content of carotenoids and micronutrients (Fe and Zn) is particularly low in the grains of modern varieties. Newton et al. (2011) and Aćin et al. (2023) highlighted that local landraces and old varieties are the richest sources of micronutrients, antioxidants, carotenoids, vitamins, and other specific bioactive components, thus playing an important role in the prevention of numerous diseases. Živančev et al. (2023) noted that landraces and old varieties of bread wheat, as well as einkorn, emmer, durum, and spelt wheat, have proven to be excellent sources of tocopherols, Fe, and Zn. Local landraces, old varieties, and varieties intended for organic farming have shown relatively high protein yields under extensive

production conditions and in less favorable agroecological conditions but exhibit low performance in favorable agroecological conditions and intensive production systems (Baresel et al., 2008).
Considering that old wheat varieties and landraces used to be cultivated in farming systems with very little inputs, they could meet the present needs for ecological, sustainable, integrated, and organic production, especially on marginal lands with poor soil fertility, especially in nitrogen, in less favorable agroecological conditions and under extensive production conditions. Especially in the context of climate change and the trend toward more sustainable agricultural production systems, there is a need for the availability and use of a broader collection of genetic resources. According to Newton et al. (2011), old varieties and landraces are a very valuable but underutilized resource in modern crop production. The overall improvement of agriculture, as well as selection and breeding, has led to a constant increase in wheat yields over the years. This has been accompanied by an increased need for higher amounts of mineral nutrients in high-yielding varieties to fully express their genetic potential in intensive farming (Jaćimović et al., 2023). However, the intensification of agriculture, characterized by high chemical application, as well as modern breeding activities, has not only reduced the biological diversity of cultivated species but also led to the near-complete neglect of old, traditional varieties and local landraces. Due to the ongoing trend of reintroduction old wheat varieties and landraces, and reducing the reliance of wheat production on nitrogen fertilizers, it is necessary to re-examine their agro-morphological and productive traits, as well as their response to basic agronomic practices in trials with no and with optimal nitrogen input. Therefore, the aim of this study was to compare performances and examine the effect of nitrogen fertilization omission, as well as its application in top-dressing, on the main yield components and grain yield of five old, traditional winter wheat landraces and varieties.

Material and Methods

The research was conducted as part of the FAO project GRAINEFIT led by the Institute of Field and Vegetable Crops in Novi Sad, Serbia. The project is focused on the conservation and sustainable use of neglected small grains genetic resources in the light of climate change. In addition, the aim of the project is to support small farms in achieving stable production and obtaining safe and high-quality grain products. The experiment was conducted during the 2022/2023 growing season, at the Agricultural school in Bačka Topola (45°47'34"N 19°35'52"E). Agro-ecological conditions are typical for the Pannonian region, with continental climate characterized by considerable temperature variations, and in recent decades, hot summers, more and more often mild winters, irregular rainfall distribution and frequent drought events. The weather data for the growing season 2022/2023 in Bačka Topola were shown on Figure 1.

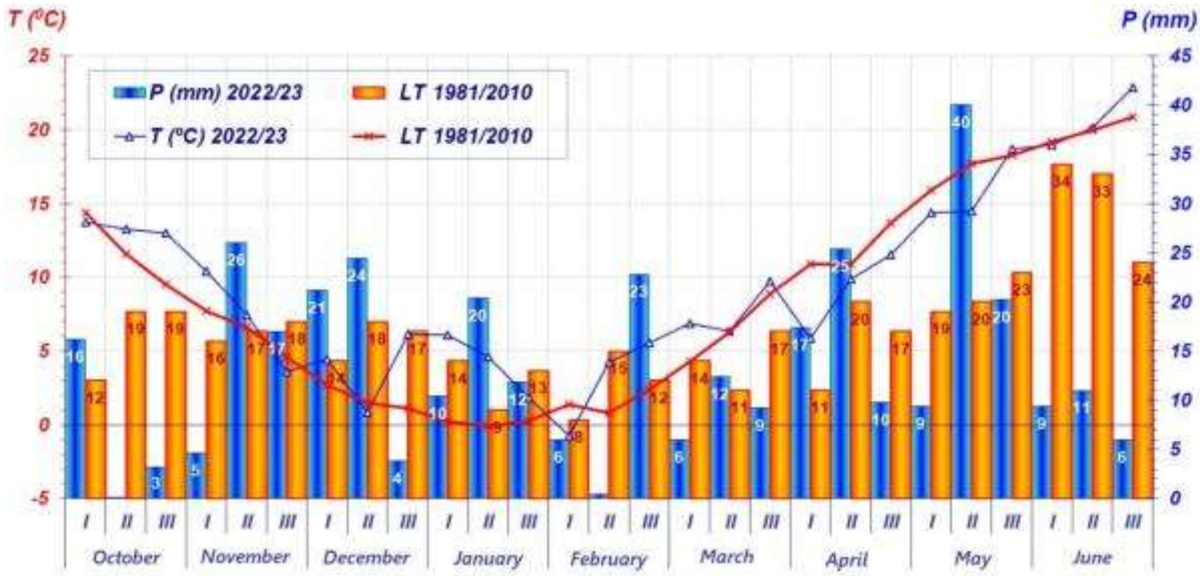

Figure 1. The average temperatures (T) and precipitation (P) compared to their long-term averages (LT) per 10-day periods from October 2022 to June 2023 in Bačka Topola

The field trial area was on meadow soil, which had been cultivated without fertilizers application for years. The soil type on the experimental plot was chernozem, formed on a loess terrace. Agrochemical analyzed determined the soil quality, as well as the mineral nitrogen content by soil profile depth, to determine the fertilization needs for the selected wheat landraces and varieties. Soil analysis for basic agrochemical properties was performed in the fall of 2022 for determination of the necessary amounts of P and K. For determination of the mineral N content in the soil according to the N-min method, soil samples were taken using a manual probe in February 2023 at layers of 0-30 cm, 30-60 cm, and 60-90 cm. Based on the soil analysis results (Table 1), the soil was slightly alkaline. According to the $CaCO_3$ content, the soil belonged to the class of highly calcareous soils, while based on humus and total N content, it was moderately humic and moderately supplied with total N. The content of available P and K was very high, so there was no need for fertilization with these elements.

Table 1. Results of basic agrochemical properties of soil testing

Agrochemical properties of soil							
Depth	**pH**		**$CaCO_3$**	**Humus**	**Total N**	**AL-P_2O_5**	**AL-K_2O**
(cm)	in KCl	in H_2O	(%)	(%)	(%)	(mg/100 g of soil)	
0-30	7.60	8.11	12.89	3.04	0.180	84.84	57.20

The results of the determination of mineral nitrogen content and distribution in the soil according to the N-min method are presented in Table 2. The total amount of mineral N in the 0-90 cm layer was 52.14 kg ha^{-1}, which served as the basis for calculating the required amount of N for top-dressing. Based on the standard calculation, it was determined that 109 kg of active N ha^{-1} was needed for top-dressing wheat on the experimental plot. It was decided to split the calculated amount into two top-dressing applications in a ratio of 70% (basic dose of N): 30% (corrective top-dressing), i.e., 76 : 33 kg of a.m. of N ha^{-1}. Given the very low mineral N content in the surface soil layer (12.90 kg ha^{-1} in the 0-30 cm layer), the top-dressing of wheat was carried out using a fast-release AN fertilizer (34% N).

Table 2. Results of mineral nitrogen (N-min) and soil moisture content analysis

Soil depth	**N-min** (kg N ha^{-1})	**Soil moisture** (%)
0-30 cm	12.90	25.6
30-60 cm	16.93	25.5
60-90 cm	22.31	23.9
Sum:	**52.14**	**75.07**

The experiment was conducted as a two-factorial, using a split-plot design with four replications and a randomized arrangement of treatments. The following factors and treatments were examined: Factor A - winter wheat varieties: S1 - Stara banatka, S2 - Bezostaya 1, S3 - Bankut 1205, S4 - Crnozrna, and S5 - Brkulja 4 (seeds obtained from the collection of the Institute of Field and Vegetable Crops); and Factor B: nitrogen fertilization in top-dressing, with two treatments: a) control treatment without N fertilization (N_0) and b) nitrogen fertilization in top-dressing based on soil N-min analysis (N_{109}).
After primary tillage (plowing to a depth of 25 cm) and pre-sowing soil preparation, sowing of the selected wheat varieties and landraces was performed on October 19, 2022. Sowing was done using a mechanical grain drill with a row spacing of 12.5 cm and a seeding rate of 500 viable seeds per m². Each variety was sown on an area of 30 m² (3 m width × 10 m length), with isolation paths of 1 m between varieties. Each main plot (i.e., variety) was divided lengthwise into two subplots: unfertilized (N_0) and fertilized with nitrogen in top-dressing based on N-min analysis (N_{109}). Each subplot was further divided into four replications, each measuring 1.5 m × 2.5 m. In the treatment planned to examine the effects of N fertilization, top-dressing of all varieties was performed twice: on February 18, 2023, at the tillering stage (base dose; 76 kg N ha^{-1}), and on March 9, 2023, before stem elongation phase (corrective top-dressing; 33 kg N ha^{-1}). The only maintenance measures applied were keeping the isolation paths and manual weed control. Harvesting of all experimental plots was carried out in late June 2023. The yields of dry grain (13% moisture) per plot were converted to t ha^{-1}. The effects of the analyzed factors and their interactions on yield components and grain yield of the examined varieties and landraces were processed using analysis of variance (ANOVA) for a two-factorial experiment conducted in a split-plot design with randomized treatment arrangements (GenStat for Windows 12th ed.). The statistical significance of treatment mean differences was determined by Fisher's Least Significant Difference (LSD) test at a significance level of 5%.

Results and Discussion

The analysis of variance for grain weight per spike, 1000-grain weight, and yield (Table 3) showed that both the analyzed varieties and nitrogen fertilization had a statistically highly significant effect on the total variability of all traits. The interaction effect of varieties and top-dressing was highly significant for grain weight per spike and grain yield, and significant for 1000-grain weight. Analysis of the contribution of individual sources of variation to the total sum of squares revealed that the varieties dominated with the largest share in the variability of all three traits, suggesting that there is a significant difference in the genetic potential for yield among the analyzed varieties, which can be attributed to their different origins and the presence of varietal specificity. The overall contribution of nitrogen fertilization and the interaction of varieties and fertilization was very low but still significant, indicating that N top-dressing also influenced the modification of the examined traits.

Table 3. Key indicators from the analysis of variance for grain weight per spike, 1000-grain weight, and grain yield in the experiment[1]

Sources of variation	d.f.	Grain weight per spike			1000-grain weight			Grain yield

Statistically significant differences in grain weight per spike were recorded among all analyzed varieties (Table 4). The highest value for this trait (1.67 g) was achieved by Crnozrna, while Stara banatka produced the lowest grain weight per spike. On average across varieties, significantly higher grain weight per spike (1.34 g) was obtained with N top-dressing treatment compared to the control treatment (1.23 g). This pattern of variation between N treatments was observed in Bezostaya, Bankut, and Brkulja, while no significant differences were observed between the N_0 and N_{109} treatments in Crnozrna and Stara banatka. On average across both N treatments, the 1000-grain weight was highest in Bezostaya (37.6 g) and significantly higher compared to all other varieties. Brkulja and Crnozrna had lower but statistically similar 1000-grain weights, which were significantly higher compared to Stara banatka and Bankut. Across all analyzed varieties, significantly higher 1000-grain weight (31.1 g) was obtained with N top-dressing treatment compared to the control treatment (29.5 g). Higher 1000-grain weight with N top-dressing treatment was also observed for all individual varieties except for Crnozrna.

The highest grain yield was obtained from Bezostaya (3.66 t ha^{-1}), which was significantly higher compared to the other varieties (Table 4). Specifically, the grain yield of Bezostaya was 39% higher than Stara banatka, 32% higher than Bankut, 16% higher than Crnozrna, and 14% higher than Brkulja. On average across all five analyzed varieties, N-fertilization resulted in a significantly higher grain yield compared to the unfertilized treatment in the trial. The average yield difference in favor of N-fertilization was 0.11 t ha^{-1} (or 4%). Only Stara banatka showed a higher grain yield in the control (N_0) treatment, while for all other varieties, the yield was higher in the N_{109} treatment. The yield increased due to nitrogen application ranged from 2% for Crnozrna to 11% for Bankut.

The treatment means labeled with different letters in the index indicate the presence of statistically significant differences ($p \leq 0.05$; LSD test)

Numerous studies have established that wheat yield depends on several key components: plant density, number of spikes per unit area, number and weight of grains per spike, and thousand grain weight. There are complex relationships among these indicators, as increasing one parameter often leads to a decrease in another (Hristov et al., 2008; Jaćimović et al., 2012). The significance of each of these components in yield formation depends on weather conditions during critical growth stages (especially water stress), as well as on applied agronomic practices, particularly the quantities and ratios of NPK nutrients (Hristov et al., 2011; Jaćimović et al., 2020). Several studies have shown that wheat growth and yield increase with fertilizer application up to a certain level, beyond which additional fertilization generally has no further positive impact, and at very high nutrient levels, yield reduction may occur (Aćin et al., 2016).

Conclusions

Our study revealed that all examined traits of traditional winter wheat landraces and varieties, had the greatest contribution to their variability, suggesting substantial genetic differences among the varieties, attributable to their different origins and specific varietal characteristics. The highest value for grain weight per spike was achieved by Crnozrna, while the lowest was by Stara banatka. On average, the grain weight per spike was significantly higher in the N-fertilized treatment compared to the control treatment. The highest 1000-grain weight was recorded in Bezostaya 1. Overall, for all varieties, a significantly higher thousand grain weight was obtained in the fertilized treatment compared to the unfertilized treatment. The highest grain yield was obtained in Bezostaya 1, and it was significantly higher compared to other varieties. Stara banatka produced the lowest grain yield. On average, across all varieties, N-fertilization resulted in a significantly higher yield compared to the unfertilized treatment.

Abstract

Precise sowing of maize can be done with different technological and technical systems. The quality of the system for precise maize sowing implies that the distance of the seeds in depth, length, and width should be adjusted to the crop being sown since the layer of soil covering the seeds should be uniform, the furrow should be properly prepared and the seeds should be well pressed and covered. Application of the system for precise maize sowing enables a uniform assembly of plants, increased yields, and reduced production costs. Considering the need to respect optimal agrotechnical deadlines, which are also very short, there is often a need to achieve higher work speeds during sowing to achieve better results. However, a large increase in movement speed opens up the possibility of seriously impairing the quality of work. The emphasis on this problem is understandable, especially considering that large farmers have high-quality tractors of higher categories. Three different systems for precise sowing of maize A, B, and C were represented in the tests. The goal of our research was to determine the quality of work of different systems for precise sowing of maize depending on the defined parameters in the production conditions of the observed area. Tests and evaluation of the quality of work of the tested systems were performed according to the DLG method of testing seeders and by the ISO 7256/1 and 7256/2 standards. Based on the obtained results, it was concluded that there is a significant influence of the defined parameters on the quality of the tested systems for precise sowing of maize, which is particularly pronounced in variants A and B, bearing in mind that the values of the QFI index at speeds greater than 10 km h^{-1} were significantly below 90%, while in variant C these values were in the range of 91 - 94% even at higher speeds.

Keywords: *Seeder, Precision sowing, Maize, Quality, Schedule indexes.*

Introduction

Maize represents one of the most important crops and in terms of representation in the structure of crop production, it occupies one of the leading places in the world (Akhiyarov et al., 2021; Banaj et al., 2023). In the Republic of Serbia, maize is grown on 1,324,368 ha with an average yield of 4.55 t ha-1 (Stat. Yearb. Serb. 2023). One of the most important technological operations in the production of maize is sowing since mistakes during sowing cannot be corrected later by other agrotechnical measures. The goal of precise and high-quality sowing is the correct and optimal number of plants per unit area (Loveland *et al.*, 2003; Findura *et al.*, 2009; Yazgi, 2016; Findura *et al.*, 2018). The correct layout and optimal number of plants per unit area are the basic prerequisite for successful sowing and maize production, and numerous field and laboratory methods have been developed to test the properties of seeders (Koller *et al.*, 2014; Narang *et al.*, 2015; Liu *et al.*, 2018). In the case of precise and high-quality maize sowing, a proper layout, sufficient vegetation space, manifestation of production potential, and high yields are achieved (Parish *et al.*, 2003;

Milenkovic *et al*., 2008). Therefore, it is understandable to strengthen the application of appropriate technological and technical systems for the precise sowing of maize. Precision sowing has been a major thrust of agricultural engineering research for many years; however, most of the research and development work has dealt with seeders for agronomic crops (Karayel *et al*., 2004). Precise sowing of maize achieves better use of available land, savings in seed material, avoidance of thinning after emergence, more uniform growth and development, and more uniform and higher yields (Fanigliulo *et al*., 2022; Turan *et al*., 2015). Improving the precision of sowing is impossible without knowing the principles of operation of all parts of the sowing mechanism and all the factors that influence possible sowing errors (Kostić *et al*., 2020). The quality of maize sowing is the most significant factor that affects a high and high-quality yield, and it is expressed as a percentage of the achieved sowing spacing according to ISO 7256/1 and 7256/2 standards (Bozdogan, 2008). The analysis of the operation of seed drills with different concepts of dosing-sowing at increased working speeds (10, 12, and 13 km h^{-1}) showed that these are working speeds that exceed the potential of the seeder (relatively low share of the sowing distance of 0.5 - 1.5 set on the level of 68.89 - 88.57 %). With increasing working speed, the share of empty spaces in the longitudinal distribution of maize seeds increases (up to 25.56%). A comparison of the same seeder at different working speeds (10, 12, and 13 km h^{-1}) showed a statistically significant difference. (Turan *et al*., 2011). The pneumatic seeder with negative pressure achieved a very good quality of maize sowing in field conditions, bearing in mind that in the group of 0.5 - 1.5 required distance, there were 94.34 - 97.64% of plants (QFI index), with values of open distances >1.5 of the theoretical (MISS index) in the range of 1.27 - 2.59 (Banaj *et al*., 2018). The seeder for precise sowing of maize achieved very good results in terms of the quality of sowing and the distribution of seeds in a row, which according to the ISO standard qualifies it to be classified in the group of very good seeders (Barać *et al*., 2023).

Material and Methods

Tests of the quality of work of various technological and technical systems for precision sowing of maize were carried out in production conditions in the vicinity of Pancevo, in 2024. The tests included the assessment of the longitudinal arrangement of maize when sowing with seed drills for precise sowing of maize depending on the defined parameters. A seeding trial was set up with local farmers, and maize was sown with three different types of drills A, B and C. Type A is the overpressure drill Panonija Becker Aeromat II, type B is the underpressure drill PSK 6, while type C is also was a seed drill with overpressure Vaderstad Tempo T6. All three drills were six-row, and the power required for traction of the tested drills was in the range of 45 - 90 kW according to the manufacturer's recommendation. Autumn plowing was carried out at 25 cm, and pre-sowing preparation with a seed drill at a depth of 15 cm for variants A and B, while for variant C plowing was carried out and then harrowing twice with a heavy harrow. Pioneer P9911 maize hybrid seeds with 95% germination were used for sowing so that they met the basic seed conditions in terms of germination and dimensions (Vitázek *et al*., 2006). The planned arrangement was 75,200 (type A), 74,000 (type B), or 73,000 plants ha^{-1} (type C), where the row spacing was 190 and 195 mm, respectively. All tested varieties worked under similar production conditions that were satisfactory, and sowing was done in April in the optimal agrotechnical period. Tests and assessments of the quality of work of the tested systems were performed according to the DLG method of testing seeders, following the ISO 7256/1 and 7256/2 standards. The quality of the work was evaluated based on qualitative indices depending on the work mode, namely: MULT index (multiple index) - represents the percentage share of achieved seed spacings in a row that are $\leq$0.5 cm from the theoretical spacing, QFI index (quality of feed index) -

represents the percentage share of realized seed spacing in a row that are >0.5<1.5 cm from the theoretical and MISS (miss index) which represents the percentage share of realized seed spacings in a row that are ≥1.5 cm larger than the theoretical spacing. Bearing in mind that locating the sown seeds is difficult, requires a lot of time, and that there is a high probability of seed spreading, the quality of sowing is evaluated and calculated only after the crop has sprouted, because the achieved assembly is the main factor of successful and profitable production (Raheman *et al*., 2003). The values of the movement, speed and other indicators were read in the tractor cabin from the display because the tractors were equipped with ISOBUS technology for advanced exploitation of agricultural machines and the autopilot T - TrimblGFX-1060. The objectives of the research was to determine the difference or similarity in the quality of the longitudinal distribution of seeds during sowing depending on the mode of operation and to achieve optimal seed distribution in the row. In the test, no emphasis was placed on the reliability and quality of production of sowing aggregates. All values were read in ten repetitions and the obtained results were processed using the Microsoft Office Excel 2007 package.

Results and Discussion

Tables 1 - 2 show the results of testing the quality of work of various technological and technical systems for precise sowing of maize. The obtained results indicate a significant influence of the defined parameters on the quality of work of the tested varieties, that is, on the longitudinal distribution of seeds in the row. The highest average values of the MULT-index of 5.47% (the share of achieved distances ≤0.5 compared to the theoretical) were recorded in variant B, at the movement speed of the sowing aggregate of 8.23 km h^{-1}, and the lowest of 1.62% in variant C, operating speed of 11.89 km h^{-1}. Analyzing the average achieved values of the MULT index by individual variants, it is noted that those of the type A seeder was in the range of 3.76 - 5.06%, of the type B seeder in the range of 3.54 - 5.47, while the values of this index in the variant C were within the limits of 1.62 - 2.93%, while the working speed regime for all tested variants was 11.89 and 8.23 km h^{-1}, respectively (table 1). Considering the values of the QFI index (range at the level of >0.5<1.5 compared to the theoretically expressed in %), it can also be noted that the defined parameters significantly impact the achieved values of this index.

Table 1. Longitudinal distribution in the rows by tested variants

Tested variant	Working speed [km h^{-1}]	Qualitative indicators of the longitudinal distribution of maize								
		MULT			QFI			MISS		
		≤0.5			>0.5<1.5			≥1.5		
		Mean	Min	Max	Mean	Min	Max	Mean	Min	Max
A	8.23	5.06	4.68	5.59	90.41	87.73	92.51	4.53	2.61	7.1
	10.16	4.64	3.98	5.11	85.91	81.34	90.13	9.45	5.79	14.22
	11.89	3.76	3.37	4.11	84.07	82.19	85.17	12.17	10.95	14.34
B	8.23	5.47	4.49	6.45	90.11	85.67	95.56	4.42	3.81	5.52
	10.16	4.35	2.88	10.16	80.89	79.17	82.44	14.76	12.31	17.95
	11.89	3.54	2.91	4.13	76.64	73.53	79.58	19.82	16.44	22.83
C	8.23	2.93	1.78	4.00	94.11	91.78	96.17	2.96	1.93	4.67
	10.16	2.21	1.69	3.15	92.73	90.77	94.14	5.16	3.82	7.76
	11.89	1.62	1.20	2.11	91.29	90.33	92.11	7.11	6.51	7.54

Thus, the lowest average values of 76.64% were achieved when sowing with a type B seeder at a working speed regime of 11.89 km h^{-1}, and the highest when sowing with a type C seeder averaged 94.11% (working speed of 8.23 km h^{-1}). Observed according to the examined varieties, the average values of QFI were in the range of 84.07 - 90.41% in the type A seeder, i.e. 76.64 - 90.11% in the type B seeder. In the case of the type C seeder, the values of this index were within the limits of 91.29 - 94.11% (table 1).

An important indicator of the quality of seed drills for precise sowing of maize is the MISS index, which represents the share of achieved row spacing at the level of $\geq$1.5 compared to the theoretical one, expressed as a percentage. The lowest values of the mentioned index were achieved with the type C seeder, which amounted to an average of 2.96%. and the highest in type B seeders were on average 19.82%. Evaluating the average values of the MISS index for all variants that were examined, it can be concluded that those of the type A seed drill varied within the limits of 4.53-12.17%, of the type B seeder within the limits of 4.42 - 19.82%, while the values of this index for the seeder type C were in the range of 2.96-7.11% (table 1).

Other authors report similar results in their research (Parish *et al*., 2003; Milenkovic *et al*., 2008; Bozdogan, 2008; Turan *et al*., 2011; Findura *et al*., 2012; Yazgi, 2016; Fanigliulo *et al*., 2022; Banaj *et al*., 2018; Barać *et al*., 2023).

Evaluating the quality of work of the examined variants, it can be stated that during the sowing of maize at increased working speeds, the quality of work is particularly impaired in the case of type A and B seeders, bearing in mind the relatively low values of the QFI coefficient (76.64 - 85.91%), with the high values of the MISS index, which points to the conclusion that operating speeds that are higher than 8 km h-1 exceed the capabilities of these two types of seed drills. For variant C, the QFI values were in the range of 91.29 - 94.11%, with low values of the MISS index, which, according to the ISO standard, qualifies this variant to be included in the group of very good seeders. Table 2 shows the average values of the achieved row spacing and statistical indicators on the influence of the defined parameters on the values of the achieved spacing. With all tested variants, it can be stated that by increasing the speed of movement, the deviations of the achieved distance in the row compared to the theoretical one also increased. Based on the test results shown in Table 2, it can be seen that the average values of the row spacing varied from 196.82 mm (seeder type C, working speed 8.23 km h^{-1}) to 212.26 mm (seeder type B, working speed 11.89 km h^{-1}).

Table 2. Achieved distance according to the investigated variant statistics indicators

Tested variant	Working speed [km h^{-1}]	Theoretical sowing distance [mm]	Achieved sowing distance [mm] Statistical indicators					Lsd	
			Mean	σ	*Cv*	*Min*	*Max*	5%	1%
A	8.23	190	197.55	14.26	4.02	180.51	222.63	4.17	5.75
	10.16	190	201.23	12.38	5.86	189.76	224.14		
	11.89	195	208.01	15.09	7.92	189.52	233.03		
B	8.23	190	198.83	6.26	3.89	191.23	208.14	4.52	6.23
	10.16	190	201.15	8.60	4.87	189.34	214.11		
	11.89	195	212.26	12.81	6.93	196.85	235.19		
C	8.23	190	196.82	5.18	2.63	191.13	204.16	2.75	3.62
	10.16	190	200.68	8.15	4.09	187.56	211.33		
	11.89	195	202.04	3.82	1.91	195.67	207.43		

The increase in the working speed resulted in an increase in the sowing distance with an increase in the standard deviation of all tested varieties, which leads to the conclusion that with an increase in the working speed of the sowing aggregates, the quality of sowing decreases. This is particularly pronounced in the case of variants A and B, bearing in mind that the variations in the average row spacing are more pronounced. In the case of variant C, the variations in the average values of the maize spacings in the row are less pronounced compared to the first two investigated variants (table 2).

The results of our research correlate with the other authors' findings (Findura *et al*., 2009; Turan *et al*., 2011; Narang *et al*., 2015; Turan *et al*., 2015).

Conclusions

Based on the obtained results, it can be concluded that there is a significant influence of the defined parameters on the quality of work of the examined types of seeders, that is, on the longitudinal distribution of maize in the row. The highest average MULT-index values of 5.47% (proportion of achieved gaps $\leq$0.5 compared to the theoretical) were recorded with variant B and the lowest of 1.62% with variant C. The lowest average values of the QFI index (gap in line at the level >0.5<1.5 concerning the theoretical expressed in %) of 76.64% were achieved when sowing maize with type B seeder, and the highest when sowing with type C seeder, on average 94.11%. The lowest values of the MISS index (percentage share of achieved row spacing at the level $\geq$1.5 compared to the theoretical) were achieved with the type C seeder and amounted to an average of 2.96%. and the highest in type B seeders were on average 19.82%. The increase in working speeds led to a deterioration in the quality of work, especially for seed drills type A and B, bearing in mind the relatively low values of the QFI coefficient (76.64 - 85.91%), with high values of the MISS index, which indicates the conclusion that working speeds that are greater than 8 km h^{-1} exceed the capabilities of these two types of seeders. With the type C planter, the QFI values were in the range of 91.29 - 94.11%, with low values of the MISS index, which qualifies this variant according to the ISO standard to be included in the group of very good planters. The average values of the row spacing varied from 196.82 mm for type C seeders to 212.26 mm for type B seeders. An increase in the working speed resulted in an increase in the sowing distance with an increase in the standard deviation.

Abstract

The tomato production sector in Serbia is increasingly shifting towards greenhouse cultivation. This study evaluates the economic viability and sustainability of both open-field and greenhouse tomato production through a comprehensive gross margin analysis, while also considering environmental and food safety implications. Data from 211 tomato farms over four years (2020-2023) showed that greenhouse production achieved significantly higher gross margins (32,227 €/ha) compared to open-field cultivation (24,098 €/ha). In 2023, greenhouse production's gross margin was 44,749 €/ha, while open-field was 15,231 €/ha. However, the economic advantage of greenhouse production is partially offset by environmental concerns, particularly microplastic pollution from greenhouse materials, with mitigation costs ranging from 430 to 850 €/ha annually. Additionally, food safety issues arise from pest and disease management, requiring improved pest management strategies to prevent pest outbreaks and ensure compliance with maximum residue levels (MRLs) for pesticides. This research provides a holistic assessment of tomato production systems in Serbia, integrating economic, environmental, and food safety considerations. The findings suggest that while greenhouse production offers superior economic returns, its long-term sustainability hinges on addressing environmental concerns and optimizing pest management. Future research should focus on developing sustainable greenhouse materials, improving pest management strategies, and conducting long-term profitability analyses that account for fixed costs and environmental impacts. These insights are valuable for policymakers, farmers, and researchers in the agricultural sector.

Keywords: *Tomato production, Gross margin analysis, Greenhouse cultivation, Open-field farming, Microplastic pollution, Integrated pest management.*

Introduction

Tomato production is a crucial component of Serbia's agricultural sector, with both open-field and greenhouse cultivation methods being employed. Recent years have seen a shift towards greenhouse production due to higher yields and extended growing seasons. However, this transition raises questions about economic viability, environmental sustainability, and food safety.

Stanković et al. (2015) and Filipović at al. (2015, 2016, 2017) provided a comprehensive framework for analyzing gross margins in Serbian agriculture, highlighting the importance of this metric in assessing farm profitability. Building on this work, Filipovic et al. (2017) examined the economic efficiency of different vegetable production systems in Serbia, emphasizing the role of technology adoption in improving farm profitability. Krnjajić et al. (2023) and Grujić et al. (2024) further explored the environmental implications of intensive vegetable production, focusing on soil health and the potential for sustainable intensification

in Serbian agriculture. Their work provides valuable insights into the long-term sustainability of different production systems.
Our study aims to:

- Compare the gross margins of open-field and greenhouse tomato production in Serbia.
- Analyze trends in tomato farming economics over the past five years (2020-2023).
- Assess the environmental impact of greenhouse production, particularly regarding microplastic pollution and soil health.
- Evaluate food safety concerns related to tomato pests and diseases.
- Provide recommendations for the sustainable and economically viable development of the sector.

Materials and Methods

Study Design: This study employed a mixed-methods approach combining quantitative economic analysis with qualitative assessment of environmental impacts and food safety considerations. The research was conducted over a five-year period from 2019 to 2023, focusing on tomato production in Serbia's major agricultural regions.

Data Collection
Economic Data

- *Farm-level data*, data were collected from 211 tomato farms over a four-year period (2020-2023) across Serbia, especially in Belgrade, Smederevo, and Leskovac. This included information on variable costs, yields, and market prices.
- *Market data*: Daily wholesale prices of tomatoes were obtained from the three largest agricultural markets in Serbia (Belgrade, Smederevo, and Leskovac).
- *Input costs*: Prices of major inputs (fertilizers, pesticides, seeds, energy) were collected from five leading agricultural supply companies in Serbia.

Environmental Data

- *Microplastic pollution*: Soil samples were collected from 50 greenhouse farms and 50 adjacent non-farm areas.
- *Water quality*: Water samples were collected from irrigation sources and runoff points at 30 greenhouse farms bi-annually.
- *Soil health indicators*: Following the methodology outlined by Grujić et al. (2024), we assessed soil organic matter content, microbial biomass, and enzyme activities in both open-field and greenhouse production systems.

Food Safety Data

- *Pest and disease incidence*: Data were collected through farm surveys and regular monitoring (Krnjajić et al., 2023).
- *Pesticide usage and residue*: Data were obtained through farm records.

Data Analysis
Gross Margin Analysis
Following Filipović at al. (2015, 2016, 2017) approach and incorporating refinements for vegetable production, gross margins were calculated as:

Gross Margin = Total Revenue – Variable Costs

Variable costs included seeds, fertilizers, pesticides, seasonal labor, and energy costs. For greenhouse production, additional costs such as plastic replacement and heating were included.

Environmental Impact Analysis:
Microplastic quantification in soil and water samples was performed using density separation. Soil health indicators were analyzed following Grujić et al. (2024) protocols.

Statistical Analysis:
Time series analysis was used to examine trends in gross margins over the five-year period. Analysis of variance (ANOVA) was employed to compare gross margins between open-field and greenhouse production.

Results and discussion

Gross Margin Analysis

Open-field Production

- *Average yield*: 20 t/ha
- *Average selling price*: 60 RSD/kg
- *Total Revenue*: 1,200,000 RSD/ha
- *Variable Costs*: 500,000 RSD/ha
- *Average Gross Margin*: 700,000 RSD/ha

Greenhouse Production

- *Average yield*: 100 t/ha
- *Average selling price*: 70 RSD/kg
- *Total Revenue*: 7,000,000 RSD/ha
- *Variable Costs*: 3,500,000 RSD/ha
- *Average Gross Margin*: 3,500,000 RSD/ha

Trends (2019-2023)

- Greenhouse gross margins increased by 15% over the five-year period.
- Open-field gross margins decreased by 5% due to rising input costs and climate variability.
- The gap between greenhouse and open-field gross margins widened from 400% in 2019 to 500% in 2023.

Environmental Impact

- Estimated annual microplastic release from greenhouses: 25-50 kg/ha
- Microplastic mitigation costs reduced greenhouse gross margins by approximately 50,000 - 100,000 RSD/ha annually.
- Soil health indicators showed a 15% decrease in soil organic matter and a 20% reduction in microbial biomass in greenhouse soils compared to open-field soils, consistent with findings by Grujić et al. (2024).

Food Safety Concerns

- Major pests identified: *Tuta absoluta, Trialeurodes vaporariorum, Tetranychus urticae*
- Common diseases: Late blight (*Phytophthora infestans*), Early blight (*Alternaria solani*)
- Pesticide residues were generally within acceptable limits, but 5% of samples exceeded maximum residue levels (MRLs) for certain pesticides.

Economic Implications
Our results, consistent with Filipović at al. (2015, 2016, 2017) findings in other agricultural sectors, demonstrate that greenhouse tomato production in Serbia generates significantly higher gross margins compared to open-field cultivation. The 500% difference in gross

margins by 2023 explains the ongoing shift towards greenhouse production. However, it's crucial to note that gross margin analysis does not account for the higher initial investment costs associated with greenhouse construction. Filipović at al. (2015, 2016, 2017) emphasized the importance of considering these fixed costs when evaluating long-term profitability.

Environmental Considerations

The environmental impact of greenhouse production, particularly microplastic pollution, presents a growing challenge. The costs associated with mitigating microplastic pollution (50,000 - 100,000 RSD/ha annually) reduce the gross margin advantage of greenhouse production. This aligns with Filipović at al. (2015, 2016, 2017) observations on the increasing importance of environmental costs in agricultural production. The environmental impact of greenhouse production extends beyond microplastic pollution. Our findings on soil health, corroborating Grujić et al.'s (2024) research, indicate that intensive greenhouse cultivation may lead to soil degradation over time. This poses a long-term sustainability challenge that needs to be addressed through improved soil management practices.

Food Safety Implications

The management of pests and diseases in tomato production has significant implications for both gross margins and food safety. While greenhouse production offers better control over environmental conditions, the intensive use of pesticides poses risks of pesticide residue buildup, which can threaten food safety. Our findings highlight the need for improved integrated pest management (IPM) strategies in greenhouse production to mitigate these risks. Filipović at al. (2015, 2016, 2017) emphasized the importance of maintaining consumer trust through food safety compliance, which is critical for the long-term sustainability of the tomato production sector.

Conclusion

Greenhouse tomato production in Serbia offers substantial economic advantages over open-field cultivation, with higher gross margins and the potential for year-round production. However, these benefits are offset by significant environmental and food safety concerns, particularly related to microplastic pollution and pesticide residue management. Addressing these challenges is essential for the long-term sustainability of greenhouse tomato production in Serbia. Future research should focus on developing sustainable greenhouse materials, improving pest management strategies, and conducting long-term profitability analyses that account for fixed costs and environmental impacts. Policymakers should consider incentivizing environmentally sustainable practices and supporting farmers in transitioning to more sustainable production systems.

Abstract

The Serbian agriculture sector is undergoing a crucial transformation due to global climate change and the demands of European Union (EU) integration. This shift requires comprehensive strategies for climate adaptation and mitigation, aligned with EU agricultural policies, to ensure sustainability, competitiveness, and economic benefits. Serbian agriculture, a significant contributor to employment and GDP, is highly vulnerable to climate variability and extreme weather events, threatening productivity and food security. To address these vulnerabilities, Serbia must adopt sustainable practices, improve regulatory frameworks, and leverage EU support. Aligning with EU standards is essential for mitigating climate risks and meeting the quality and safety standards necessary for market access. Key areas for attention include climate vulnerability, as Serbia faces increasing extreme weather events, and the need for improved agricultural practices, such as advanced technologies and sustainable farming techniques. Additionally, Serbia's regulatory frameworks require significant enhancement to meet EU standards, particularly in sustainability, food safety, and environmental protection. This paper outlines strategies for aligning with EU policies and climate adaptation, emphasizing sustainable agricultural practices like crop diversification, water management, and the use of climate-resilient crops. The benefits of this alignment include improved food security, better resource management, and increased environmental protection, contributing to the long-term sustainability and resilience of the agriculture sector. Key recommendations focus on government support, international cooperation, and sustainable development through innovation and modernization.

Key words: *Agriculture, transformation, climate change, agricultural practices, development.*

Introduction

The agricultural sector in Serbia holds a critical position within the national economy, employing approximately 690,000 individuals, which constitutes about 21% of the total labor force. Agriculture contributes around 11.9% to the GDP and occupies about 66% of Serbia's total land area, with approximately 5 million hectares dedicated to agricultural use. The rural population, which constitutes half of the country's population, depends significantly on agricultural activities. The agricultural landscape in Serbia is characterized by a large number of small farms, with around 400,000 farms, most of which are less than 5 hectares in size. Only about 100,000 of these farms operate on a commercial basis, holding 46% of the arable land. This fragmented land ownership presents challenges for large-scale agricultural productivity and modernization. It is important to emphasize Serbia's agricultural dependency and vulnerability to climate change and importance of aligning with EU regulations and standards to ensure sustainable agricultural practices and market competitiveness. The diverse agro-climatic zones across Serbia significantly influence its agricultural production. The northern region of Vojvodina, known for its fertile soils and large arable plots, primarily produces maize, cereals, sugar beet, and sunflowers, alongside substantial milk and pig farms.

Central Serbia, with its hilly terrain, supports mixed production, including high-value crops like fruits, berries, and vineyards. The southern mountainous areas are more suited for extensive and semi-extensive ruminant production.
However, the Serbian agricultural sector faces numerous challenges. The pressure on natural resources, climate change impacts, and the need for sustainable practices are critical concerns. The EU's Common Agricultural Policy (CAP) has introduced various environmental and sustainability requirements that Serbia, as an EU candidate country, must adopt. This includes the "Nitrates Directive" and "Cross-compliance" measures, which mandate farmers to adhere to environmental protection, food safety, and animal welfare standards to qualify for subsidies.
Climate change poses a significant risk to Serbian agriculture, with increasing incidents of droughts, floods, and extreme weather events causing physical damage and financial losses. Effective management of these risks requires the adoption of advanced agricultural practices, such as improved irrigation systems, sustainable crop rotations, and climate-resilient farming. Furthermore, the introduction of innovations and technologies to enhance resource efficiency and productivity is crucial. In terms of agricultural output, Serbia is a net exporter, with agricultural exports valued at €1.5 billion in 2019, contributing to 20% of the country's total exports. Key export products include fruits (plums, apples, grapes, and berries) and vegetables (such as potatoes, cabbages, melons, peppers, and tomatoes). Despite this, the sector's productivity is hampered by issues: water quality, air pollution, and low irrigation intensity.
To align with EU standards and address climate-related challenges, Serbia's agricultural policies emphasize modernization and sustainability. This includes public spending on research and development, construction of new irrigation systems, adaptation of agricultural technologies, and increased use of renewable energy sources. Additionally, Serbia's biodiversity strategy and the National Action Plan for Biodiversity and Climate Change outline measures to protect vulnerable ecosystems and enhance the resilience of agricultural production to climate shocks. The alignment with EU policies, supported by the Instrument for Pre-Accession Assistance (IPA) and IPARD program, provides financial and technical assistance to Serbian producers, processors, and local communities. These efforts are aimed at achieving sustainable agricultural growth and resilience in the face of global, climate, and EU challenges.

Materials and methods

This paper employs a mixed-methods approach, integrating quantitative and qualitative data to provide a comprehensive analysis of the Serbian agricultural sector’s transformation in response to global, climatic, and EU challenges.
Literature Review and Policy Analysis: A thorough review of relevant literature, policy documents, and strategic plans was conducted to understand the current state and challenges of Serbian agriculture. Key documents analyzed include Serbia's Nationally Determined Contribution (NDC) for 2021-2030, the Stabilization and Association Agreement with the EU, and various national agricultural and environmental policies.
Sectoral Analysis: The agricultural sector was divided into key sub-sectors, including field crops, fruits, vegetables, and livestock. For each sub-sector, production dynamics, risk factors, and climate impacts were examined. This involved analyzing data on crop yields, livestock productivity, and incidences of pests and diseases.
Risk Assessment: A risk assessment framework was developed to evaluate the vulnerability of different agricultural sub-sectors to climate-related risks. This included identifying the most significant risks such as droughts, floods, extreme temperatures, and the emergence of new pests and diseases. The impact of these risks on crop yields, livestock health, and overall agricultural productivity was quantified where possible.

Stakeholder Consultation: Input from key stakeholders, including agricultural producers, policy makers, and researchers, was gathered through interviews and consultations. This provided insights into the practical challenges faced by the agricultural sector and the feasibility of proposed adaptation and mitigation measures. The combined use of these methods provides a robust and multidimensional understanding of the transformative pressures facing Serbian agriculture and the strategies needed to mitigate risks and enhance resilience.

Results and discussion

The results of this paper provide a detailed analysis of the Serbian agricultural sector's vulnerabilities, opportunities, and the necessary measures to align with EU standards, Nationally Determined Contributions (NDCs), Sustainable Development Goals (SDGs), and the EU Green Deal. The findings are organized into three main sections: risks, possibilities, and alignment with international and EU frameworks.

Risks to the Serbian Agricultural Sector

Climate Change Vulnerability - Serbia’s agricultural sector is highly vulnerable to the adverse impacts of climate change. The analysis of historical climate data and future projections reveals several significant risks:

- **Increased Temperature**: Rising temperatures, particularly during the growing season, are expected to negatively impact crop yields. Heat stress can reduce the productivity of both crops and livestock, leading to lower yields and increased mortality rates in animals.
- **Erratic Precipitation Patterns**: Changes in precipitation patterns, including more frequent and intense droughts and floods, pose a severe threat to agricultural productivity. Droughts can lead to water scarcity, affecting both crop and livestock production, while floods can cause soil erosion and damage to infrastructure.
- **Extreme Weather Events**: The frequency and intensity of extreme weather events, such as storms and hail, are projected to increase. These events can cause significant physical damage to crops and agricultural infrastructure, leading to substantial economic losses.
- **Pests and Diseases**: Climate change is likely to alter the distribution and prevalence of agricultural pests and diseases. Warmer temperatures and increased humidity can create favorable conditions for the proliferation of pests and pathogens, further threatening crop and livestock health.

Possibilities for Adaptation and Mitigation

Adoption of Sustainable Practices

To mitigate the risks posed by climate change and align with the EU Green Deal and SDGs, Serbia must adopt sustainable agricultural practices. The following measures are critical:

- **Climate-Smart Agriculture**: Implementing climate-smart agricultural practices, such as crop diversification, agroforestry, and conservation tillage, can enhance resilience and productivity. These practices help to maintain soil health, improve water use efficiency, and reduce greenhouse gas emissions.
- **Improved Irrigation Systems**: Upgrading irrigation infrastructure to more efficient systems, such as drip or sprinkler irrigation, can help to conserve water and ensure more reliable crop production during periods of drought.
- **Soil and Water Management**: Enhancing soil and water management practices, including the use of organic fertilizers and cover crops, can improve soil fertility and structure, increase water retention, and reduce the risk of erosion.

- **Agroecological Practices**: Promoting agroecological approaches, which integrate ecological principles into agricultural systems, can help to increase biodiversity, improve ecosystem services, and enhance the resilience of farming systems to climate change.

Technological Innovations

The integration of technological innovations into agriculture offers significant opportunities for improving productivity and sustainability:

- **Precision Agriculture**: The use of precision agriculture technologies, such as GPS-guided equipment, remote sensing, and data analytics, can optimize inputs like water, fertilizers, and pesticides, leading to increased efficiency and reduced environmental impact.
- **Genetic Improvement**: The development and adoption of climate-resilient crop varieties through traditional breeding and biotechnological methods can enhance tolerance to heat, drought, and pests, ensuring more stable yields under changing climatic conditions.
- **Digital Tools**: The use of digital tools and platforms for monitoring weather patterns, soil conditions, and crop health can provide farmers with real-time information to make informed decisions, improving adaptive capacity and resilience.

Alignment with International and EU Frameworks

Nationally Determined Contributions (NDCs)

Serbia's commitment to its NDCs involves significant efforts to reduce greenhouse gas emissions from the agricultural sector and enhance its capacity to adapt to climate change:

- **Emission Reduction Targets**: Serbia has set ambitious targets to reduce its overall greenhouse gas emissions by 33.3% by 2030 compared to 1990 levels. This includes measures to reduce emissions from agricultural practices through the adoption of sustainable practices and technological innovations.
- **Adaptation Measures**: The NDC outlines various adaptation measures for the agricultural sector, including improving water management, enhancing soil conservation, and promoting the use of climate-resilient crop varieties. These measures are aimed at reducing vulnerability and increasing the resilience of agricultural systems to climate impacts.

Sustainable Development Goals (SDGs) - Alignment with the SDGs is essential for ensuring the long-term sustainability and resilience of Serbia's agricultural sector:

- **SDG 2 (Zero Hunger)**: By adopting sustainable agricultural practices and improving productivity, Serbia aims to ensure food security and promote sustainable agriculture.
- **SDG 13 (Climate Action)**: Implementing measures to mitigate and adapt to climate change aligns with the goals of SDG 13, contributing to the reduction of climate-related risks and enhancing resilience.
- **SDG 15 (Life on Land)**: Sustainable land management practices that prevent land degradation and promote biodiversity conservation are critical for achieving SDG 15.

EU Green Deal: The EU Green Deal provides a framework for Serbia to transition towards a sustainable agricultural sector:

- **Farm to Fork Strategy**: The Farm to Fork Strategy aims to create a fair, healthy, and environmentally-friendly food system. Serbia's alignment with this strategy involves adopting sustainable farming practices, reducing the use of pesticides and fertilizers, and enhancing food safety standards.
- **Biodiversity Strategy**: The EU Biodiversity Strategy aims to restore biodiversity and ensure sustainable use of natural resources. Serbia's efforts to conserve biodiversity, protect natural habitats, and promote sustainable land use practices are essential for alignment with this strategy.

- **Climate Pact and Circular Economy**: The Climate Pact and Circular Economy initiatives under the EU Green Deal emphasize reducing waste, recycling, and promoting the efficient use of resources. Serbia’s adoption of circular economy principles in agriculture can help reduce waste, enhance resource efficiency, and contribute to sustainability goals.

Key Findings

- **Climate Vulnerability**: The Serbian agricultural sector is highly vulnerable to climate change, with significant risks from increased temperatures, erratic precipitation patterns, extreme weather events, and the proliferation of pests and diseases.
- **Sustainable Practices**: Adoption of climate-smart and sustainable agricultural practices, such as improved irrigation systems, soil and water management, and agroecological approaches, is essential for mitigating climate risks and enhancing resilience.
- **Technological Innovations**: Integration of precision agriculture, genetic improvement, and digital tools can optimize resource use, improve productivity, reduce environmental impact.
- **International Alignment**: Aligning with NDCs, SDGs, and the EU Green Deal involves setting emission reduction targets, implementing adaptation measures, and adopting sustainable practices to ensure long-term sustainability and resilience of agricultural sector.

By addressing these risks and seizing opportunities for innovation and sustainable development, Serbia can enhance the resilience and productivity of its agricultural sector, ensuring alignment with international and EU frameworks and securing a sustainable future for its agricultural economy.

The discussion elaborates on the need for Serbia to enhance its legal and regulatory framework to meet EU standards. It stresses the importance of integrating climate adaptation and mitigation measures into agricultural policies. The discussion also covers the economic, social, and environmental benefits of aligning with EU policies, including better access to EU markets, improved food security, and enhanced sustainability.

Aligning Serbia's agricultural practices with EU standards is crucial for its accession process and integration into the European Union.

Conclusions

The conclusions reiterate the necessity for Serbia to adopt comprehensive strategies that align with EU policies and address climate change. It underscores the critical role of government support, financial incentives, and international cooperation in achieving these goals.

Key Points on Serbian Alignment to EU and Climate Needs

- **Legal and Regulatory Alignment**: Serbia needs to align its agricultural policies and regulations with EU standards, focusing on sustainability, food safety, and environmental protection.
- **Climate Adaptation and Mitigation**: Implementing strategies to adapt to climate change is crucial. This includes adopting sustainable agricultural practices, enhancing agrobiodiversity, and investing in climate-resilient infrastructure.
- **Economic and Social Benefits**: Aligning with EU policies will open up access to EU markets, improve food security, and provide economic benefits through subsidies and financial support.
- **Government and International Support**: Strong government policies and international cooperation are essential for successful alignment. This includes financial incentives.

Recommendations for Serbia:

1. **Promoting Climate-Resilient Agriculture:** Encourage the adoption of climate-smart agricultural practices such as agroforestry, conservation agriculture, and precision farming. These practices can enhance productivity, conserve natural resources, and mitigate climate risks.
2. **Enhancing Water and Resource Management:** Invest in irrigation infrastructure, water-saving technologies, and sustainable land management practices. Efficient water use and soil conservation are crucial for mitigating water scarcity and enhancing agricultural resilience.
3. **Supporting Smallholder Farmers:** Provide financial and technical support to smallholder farmers to enhance their adaptive capacity. Training programs on climate-smart practices, access to climate information, and market integration can empower farmers and improve their livelihoods.
4. **Strengthening Policy and Institutional Support:** Align national agricultural policies with EU requirements and climate adaptation goals. Enhance coordination among government agencies, NGOs, and international partners to implement integrated climate resilience strategies.
5. **Fostering International Cooperation:** Collaborate with EU institutions, international organizations, and neighboring countries to access funding, expertise, and knowledge-sharing opportunities. International cooperation can accelerate Serbia's progress towards sustainable agriculture and climate resilience.

Addressing climate change impacts on agriculture and rural poverty in Serbia requires holistic approaches that integrate climate resilience strategies, EU policy alignment, and support for vulnerable rural communities. By prioritizing sustainable agricultural practices, enhancing resource management, and fostering international cooperation, Serbia can mitigate the adverse effects of climate change, protect livelihoods, and achieve sustainable development goals. Continued commitment to climate action and adaptation is essential for building a resilient and prosperous future for rural communities in Serbia and ensuring food security for generations to come. In summary, Serbia's journey towards EU accession offers an opportunity to transform its agricultural sector into a resilient and sustainable engine of economic growth. By embracing EU standards, implementing innovative practices, and empowering rural communities, Serbia can navigate climate challenges and foster a prosperous agricultural sector aligned with global sustainability goals.

Abstract

Maize is rich in genetic and phenotypic variations, yielding a range of diverse secondary metabolites. Biochemical analysis and molecular characterization using SNP markers allowed content of secondary metabolites (carotenoids, tocopherols and phenolic acids) and genetic diversity to be evaluated in 18 maize genotypes, including nine lines from MRI gene bank and nine elite inbred lines. The contents of tocopherols, carotenoids and phenolic acids were determined by the HPLC method. Eighteen inbred lines were analyzed using 25k SNP chip (Infinium Illumina array, TraitGenetics). The elite inbred lines had greater average content of all phenolic acid, excepted gallic acid. The average contents of gamma, alfa, delta tocopherols as well as beta carotene and lutein + zeaxantin were higher in maize lines from MRI gene bank. Line 2 from MRI gene bank had high content of tocopherols and carotenoids, as well as elite inbred line 17 with the highest level of ferulic, p-coumaric, syringic, caffeic and vanillic acid. Genetic diversity parameters were calculated and the data from SNP markers were subjected to population structure analysis by STRUCTURE as well as cluster analysis in Tassel software. According to both analyses three distinct inbred groups were revealed with some discrepancies between analyses in classification of genotypes. A STRUCTURE led to a more consistent classification of genotypes based on their origins. A considerable variation of secondary metabolites observed among inbred lines could be utilized in breeding programs to increase the nutritive value of maize varieties.

Keywords: *maize, carotenoids, phenolic acids, tocopherols. genetic diversity.*

Introduction

Maize is the 3rd most important in the world production of cereal crops and is cultivated in a wide range of agroecological environments. Parallel with world's human population increasing demand for maize production as a source of food, feed, and biofuel is increasing. The main goal of maize breeding programs is to develop genotypes with high yield and little attention was paid to consumers' demands for quality (Holmes *et al*., 2019). By adopting user needs and integrating them into products, breeders will be better utilize resources, increase usage of specific maize genotypes and improve nutrition value of maize kernel (Ekpa *et al*., 2018). So, recently, many efforts have been placed in evaluating and using maize diversity for developing nutritionally-enriched high-yielding varieties.
It is well-known that maize kernels are a good source of important health-relevant phytochemicals such as carotenoids, tocopherols and phenolic acids (Ranilla, 2020). The two most abundant groups of lipid-soluble antioxidants in maize kernels are carotenoids and tochopherols and substantial variation were found among diverse maize germplasm (Chander *et al*, 2008; Drinic et al., 2019) which can be explored for breeding. The genetic variation for various carotenoids among traditional maize inbreds showed zeaxanthin and lutein were the most predominant carotenoids (Chander *et al.* 2008). On the other hand, most maize lines

naturally have a low level of α-tocopherol but are abundant in γ-tocopherol. The level of most important, α-tocopherol is about 20% of total tocopherols in maize (Rocheford *et al*, 2002), and its higher levels can be obtained through either utilization of existing natural variation (Chander *et al*. 2008) or by genetic engineering.
Other secondary metabolites found in maize kernels are the phenolic acids, which are present as soluble and insoluble bound forms. Among them, ferulic and *p*-coumaric acid can act as antioxidants in humans, ferulic acid can improve cardiovascular and kidney functions (Cicero & Gaddi, 2001) and *p*-coumaric acid minimizes the oxidation of low-density lipoprotein. Biochemical evaluation allowed genotypes to have a greater content of carotenoids, tocopherols or phenolic acid to be identified and then evaluated regarding nutritional profile.
Genetic diversity is highly desirable in maize breeding programs since it may represent an important source of genes for breeding applications and development of improved maize genotypes relevant for nutrition and health. It could be managed, maintained and explained by morphological, biochemical and molecular markers. SNP markers, a biallelic and codominant, are widely distributed and the most abundant, highly reproducible and reliable molecular markers, the most commonly used in genetic diversity assessing (Xu *et al*., 2017, Srii *et al*. 2021). Based on present knowledge and experiance, two approaches in breeding maize for increased micronutrient content in grains could be recommended: a) selection of genotypes with increased concentration of particular nutrients and boosting their content through several cycles of selection by creating synthetic populations, and b) development of hybrids from parental lines with enriched grain micronutrient content and with good combining ability (Maqbool *et al*., 2018).
In this study, content of carotenoids, tocopherols and phenolic acids as well as genetic diversity in 18 maize inbred lines were evaluated.

Material and Methods

Eighteen inbred lines, nine from Maize Research Institute Gene bank (MRIGB 1-9) and nine elite inbred lines from breeding collection (ZPL 10-18) were used in this study. The content of tocopherols, carotenoids and phenolic acids was determined by the HPLC method. Approximately 0.2 g of maize grain was used to determine tocopherols and carotenoids content, and approximately 0.5 g of maize grain for free phenolic acid. The extraction of tocopherols was achieved by adding 5 mL of 2-propanol, extraction of free phenolic acids by using 5 mL of 80% methanol, and extraction of carotenoids by adding a mixture of methanol and ethyl acetate (6:4, v/v), 2 × 5 mL. After homogenization on the digital shaker, IKA (30 min at 25 ºC) for all analyses, the extracts were centrifuged, filtered (0.45 μm nylon membrane syringe filter), and injected into the HPLC system equipped with diode array (DAD) and fluorescence detector (FLD). Carotenoid extracts before injection were evaporated to dryness under a stream of nitrogen and redissolved in the mobile phase. The same analytical column, mobile phase, and wavelengths for separation and detection of carotenoids, tocopherols, and free phenolic acids were the same as described in the study of Mesarovic *et al*., 2019. Agglomerative Hierarchical Cluster Analysis (HCA) was performed by using the PLS Toolbox software package within MATLAB (R2011a).
Using a 25k SNP chip (Infinium Illumina array, TraitGenetics), a chosen set of eighteen inbred lines from various origins was analyzed. Following the exclusion of SNPs with a missing rate and heterozygosity >10% and SNPs with minor allele frequency (MAF) <0.05 using Tassel 5 software, a total of 15289 SNPs were retained for further analysis. The same software was applied for constructing dendrogram using neighbor-joining (NJ) method. Genetic diversity parameters (minor allele frequency, observed and expected heterozigosity) were calculated using Plink 1.9 software. Utilizing the STRUCTURE v2.3.4 software

(Pritchard *et al.*, 2000), the population structure was examined. The burn-in period and MCMC length were both set at 10,000 iterations. The model was executed by changing the number of clusters (K) from 1 to 10, with 5 alterations for each K.

Results and Disscusion

Significant variation was observed in carotenoids, tocopherols and phenolic acids (Table 1). The content of Lutein+Zeaxantin varied from 22.22 to 41.57 µg/g dry weight (d.w.), with an average of 30.83 µg/g d.w. Beta-carotene ranged from 0.55 µg/g d.w. to 3.70 µg/g d.w., average 1.35 µg/g d.w. The content of β-carotene in normal yellow maize ranges from 0.3 to 4.7µg/g d.w. (Menkr *et al*. 2008). Chander *et al*., (2008) in 87 inbred lines from China revealed β-carotene content in a range of 0.016-1.726 µg/g dw,, which is lower than obtained in our study.

Table 1. Content of carotenoids and tocopherols in maize inbred lines (µg/g d.w.)

Inbred lines	Lutein+zeaxantin	β-caroten	β+γ-tocopherol	α- tocopherol	δ-tocopherol

ZPL17	26,06	0,78	32,76	15,23	1,25
ZPL18	26,76	0,55	43,63	9,01	3,77

Among cereals, maize grain has the highest content of tocopherols and the two predominant isomers are γ-tocopherol and α-tocopherol (Rocheford *et al.,* 2002). In our study the content of α- tocopherol varied from 1.62 µg/g d.w. to 17.84 µg/g d.w., average 7.50 µg/g d.w., as well as β+γ-tocopherol from 19.52 µg/g d.w. to 85.92 µg/g d.w., average 52.09 µg/g d.w. Several studies have shown significant differences among maize inbreds for tocopherol levels. A similar range of variation inα-tocopherol content in maize kernel has been reported by Muzhingi *et al.* (2016) but Li *et al*. (2012) reported the much higher range of variation for α-tocopherol. Drinic *et al.* (2020) obtained higher average values for β + γ and α-tocopherol in study of variation of tocopherols in 120 maize inbred lines with standard (yellow and orange) kernel type as well as sweetcorn and popcorn.

The average contents of tested tocopherols as well as tested carotenoids were higher in maize lines from MRI gene bank (51.86, 8.81, 3.97, 1.72 and 33.46 µg/g d.w., respectively) than elite inbred lines (51.38, 6.18, 2.98, 0.98 and 28.20 µg/g d.w., respectively).

The content of ferulic acid varied from 0.62 µg/g d.w. to 6.91 µg/g d.w., average 2.68 µg/g d.w.and p-coumaric acid from 0.38 µg/g d.w. to 4.23 µg/g d.w., average 1.83 µg/g d.w., (Table 2). The elite inbred lines had greater average content of all phenolic acids, excepted gallic acid. Muzhingi *et al*., (2016) obtained similar results for ferulic acid distribution (between 0.23 and 6.90 µg/g d.w.) in 923 inbred lines grown in three different locations. On the other hand, higher content of *p*-coumaric acid (2.51 to 6.07 μg/g DW) was reported by Cuevas-Montilla *et al*. (2011) in nine Bolivian purple maize varieties.

Line 2 from MRI gene bank had the highest content of carotenoids and high content of tocopherols, as well as elite inbred line 17 with the highest level of ferulic, p-coumaric, syringic, caffeic and vanillic acid. Inbred lines MRIGB 4 (85.92 μg/g d.w.) and elite inbred line ZP16 (80.14 μg/g d.w.) have the highest level of β+γ-tocopherol and MRIGB 1 (17.84 μg/g d.w.) and elite inbred line ZP17 (15.23 μg/g d.w.) of α- tocopherol.

Table 2. Content of phenolic acids in maize inbred lines (μg/g d.w.)

Inbred lines	Gallic	Protocatechuic	vanillic	Caffeic	Syringic	Sinapic	P - Coumaric	Ferulic	Cinnamic

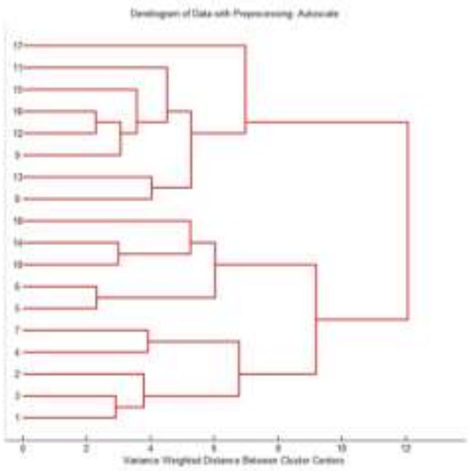

Figure 1. Dendrogram based on tested biochemical parameters in maize inbred lines

Based on the content of secondary metabolites (carotenoids, tocopherols and phenolic acids) cluster analysis was done (Figure 1). Inbred lines were grouped in two clusters at the level of similarity of approximately 10 %. Cluster I comprise two subclusters: subcluster 1. grouped five MRIGB inbred lines and subcluster 2. two MRIGB inbred lines as well three elite inbred lines grouped together. Cluster II consist of two subclasters with mixed inbred lines both from MRI gene bank and elite lines (six elite inbred lines and two inbred lines from MRIGB).

Genetic diversity parameters were calculated and the data from SNP markers were subjected to population structure analysis by STRUCTURE software as well as cluster analysis in Tassel software. Plink 1.9 software was used for calculating genetic diversity prameters. Minor allele frequency was in a range from 0.0 to 0.5 with an average of 0.29. The smallest

value for observed heterozygosity was 0 and the highest 0.06, while the average was 0.03. Expected heterozygosity was in the range from 0.11 to 0.5, with an average of 0.37. The low average value of observed heterozygosity close to zero is expected for inbred lines. Comparable, but greater average heterozygoisty (0.08) is reported in Semagn *et al*., (2012).
Cluster analysis based on SNP markers divaded inbred lines in three main groups (Figure 2). Group I consisted of five elite inbred lines and one inbred from MRIGB. Group II comprised two MRIGB inbred lines and one elite and group III formed two subgroups (A and B). Subgroup A was formed -by five inbred lines from MRIGB and subgroup B –formed by three elite inbred lines and one inbred line from MRIGB.

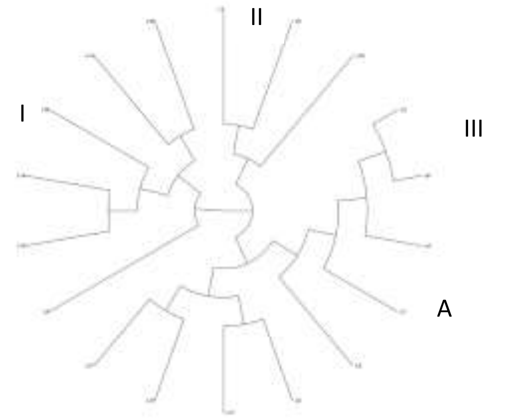

Figure 2 Cluster analysis of maize inbred lines

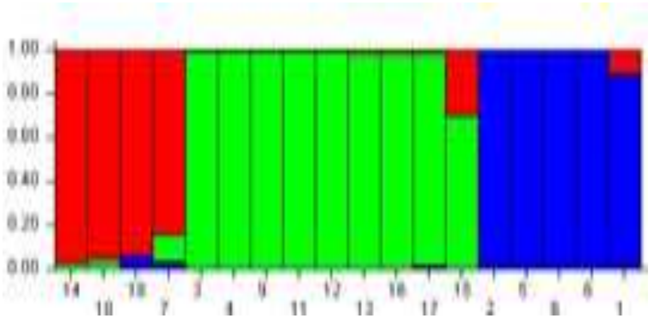

Figure 3. STRUCTURE analysis of inbred lines

Lines were subdivided into genetic clusters using a model-based approach with the package STRUCTURE (Pritchard *et al.* 2000). STRUCTURE analysis (Graf 3.), grouped inbred lines in three groups: Group 1. was formed -by three elite inbred lines and one from MRIGB, group 2. -contained nine inbred lines (3 form MRIGB and 6 elite inbred lines), and group 3. -contained five MRIGB inbred lines.
According to both analyses three distinct inbred groups were revealed with some discrepancies between analyses in classification of genotypes. A STRUCTURE led to a more consistent classification of genotypes based on their origins.

Conclusion

The presence of extensive genetic variability represents a valuable source of micronutrients, and genotypes with enhanced grain content could be used in improving of maize breeding programms. Biochemical evaluation allowed inbred lines having greater content of β carotene (MRIGB 2), L+Z (MRIGB 2 and MRIGB3), α (ZPL17) and β+γ-tocopherols (MRIGB 4 and ZPL16) to be identified and used as potential source of micronutritient for the development of nutritionally enriched maize genotypes. Significant genetical divergence among the studed~~y~~ inbred lines was determined. Inbred lines belonging to Group I after STRUCTURE analysis have the highest average level of γ-tocopherols, and inbred lines in Group III were found to be promising for β carotene, Lutein+Zeaxantin and α tocopherols, since they had high mean values for these traits. Inbred lines belonging to group II have the highest value of ferulic and p-cumarin acid. The molecular characterisation allows genetic variability to be estimated and it can be a useful tool for supporting genetic improvement when combined with biochemical traits of interest.

Abstract

Ribwort plantain (*Plantago lanceolata* L.) is a widespread perennial herbaceous plant species, usually found in pastures and grasslands, rarely in arable lands. It is used as a medicinal plant from ancient times because of high concentration of various secondary metabolites in leaves. But plantain also excretes many phytochemicals into its rhizosphere soil which are then used by different microbes, plant growth promoting bacteria (PGPB) among others. PGPB can enhance plant growth through different modes of action. The most important are nutrient availability improvement, control of pathogenic microorganisms, and production of plant hormones. Bacteria of genus *Pseudomonas, Bacillus, Azotobacter* and *Streptomyces* were isolated from the rhizosphere of plantain. They were fully characterized based on their morphological, physiological, biochemical and PGP traits. Out of total 12 bacterial isolates, four demonstrated production of indol acetic acid (IAA), and seven were good producer of hydrogen cyanide (HCN). Significant number of isolates showed the ability to mineralize organic phosphorus (P) compounds (six isolates) as well as to mobilize water insoluble tertiary phosphates (five isolates). *Streptomyces* isolates showed the best PGP potential, especially the isolate S4/1 with four out of five investigated PGP traits. Also, important isolates with significant PGP traits were K3/2 and K5/1 (*Pseudomonas* sp.), M3/1 (*Bacillus* sp.), and F1/2 (*Azotobacter* sp.). Further investigation of these isolates is necessary before they could be used as a potential base in creation of a bacteria based formulation(s).

Keywords: *PGP bacteria, Ribwort plantain, rhizosphere, Streptomyces.*

Introduction

Ribwort plantain (*Plantago lanceolata* L.) is a widespread perennial herbaceous plant species, usually found in pastures and grasslands, rarely in arable lands. It is used as a medicinal plant from ancient times because of high concentration of various secondary metabolites in leaves. Plantain excretes many phytochemicals into its rhizosphere soil which are then used by different microbes, including plant growth promoting bacteria (PGPB).

Rhizosphere bacteria play a principal role to plant growth and root development. These microorganisms are very diverse with numerous genus including *Azotobacter*, *Azospirillum, Rhizobium*, *Pseudomonas, Bacillus, Streptomyces, Micromonospora*, *Frankia* ect. (Bello and Utang, 2011). They growth and metabolytic activity is heavily influenced by temperature, pH, salinity, water content, as the most important abiotic factors, as well as by biotic interactions (Al-Maqtari et al., 2019).

Production of enzymes, phytohormones, vitamins, siderophores etc. by bacteria are considered as plant growth promoting (PGP) traits (Stamenov et al., 2021). Many studies proved PGP activities of bacterial isolates (Bjelić et al., 2015; Niyonzima, 2019; Krishna Samal et al., 2020; Stamenov et al., 2020). *Azotobacter* species are known as phosphate-solubilizing microorganisms because it can convert insoluble (Ca_3PO_4, $AlPO_4$, Fe_3PO_4) to available forms of phosphate (Aasfar et al., 2021). Results of Bjelić et al., (2015) showed intense indole-3-acetic acid, hydrogen cyanide and siderophores production of *Azotobacter*

sp. isolates. *Bacillus* species are known to produce protease, amylase, lipase (Al-Maqtari et al., 2019) phytase, keratinase, cellulase and pectinase (Niyonzima, 2019). The microorganisms belonging to *Pseudomonas* sp. are known to secrete cellulase and amylase (Sethi et al., 2013; Niyonzima, 2019). *Streptomyces* species produce enzyme amylase (Niyonzima, 2019), cellulase, lipase, urease, gelatinase and IAA (Stamenov et al., 2016).
Bacteria of genus *Pseudomonas, Bacillus, Azotobacter* and *Streptomyces* were isolated from the rhizosphere soil of plantain. The main aim of this research was to assess the isolates PGP traits. Prior to that, full characterization based on their morphological, physiological, and biochemical traits were performed.

Materials and methods

Bacteria were isolated from rhizospheric soil of plantain, in Trapisti, municipality Banja Luka, Bosnia and Herzegovina. Morphological identification and chemotaxonomic analyses of purified isolates were identified to genus level. Direct microscopic observation (at 1000x magnification) of the vegetative and aerial mycelium was used according to Bergey's manual of determinative bacteriology (Holt et al. 1994). Spherical thick-walled, Gram-negative cells were selected as *Azotobacter*. Rod-shaped, Gram-positive cells with endospores were chosen as *Bacillus*. Isolates which were established as gram-negative, rod-shaped cell and produced pigment fluorescein were selected as *Pseudomonas* isolates. Filamentous and Gram-positive cells were chosen as *Streptomyces* isolates.
The isolates of *Azotobacter*, *Bacillus*, *Pseudomonas* and *Streptomyces* were inoculated on F-agar, tripton soya agar (TSA), King's B and synthetic medium, respectively (Stamenov et al., 2021). Growth conditions were tested at different temperatures (5, 28 and 45°C), salt concentrations (3, 5 and 7%) and pH levels (5, 7 and 9) for 2-5 days. The width of the colony was measured and compared to the control.
Utilization of carbon sources was determined by using Hugh-Leifson medium (peptone 2 g/L, K_2HPO_4 0.3 g/L, NaCl 5 g/L, 10 g/L of carbon sources (glucose, galactose, xylose, saccharose, lactose or fructose) bromtimol blue 0.03 g/L and agar 3 g/L) (Stamenov i sar., 2020). Change of colony colour from greenish to yellow was proof of a positive reaction (Hugh and Leifson, 1953).
According to Frey-Klett et al. (2005), bacterial cultures were streaked on tryptic soy agar with glycine. To test hydrogen cyanide (HCN) production, a sterile filter paper soaked in 2% Na_2CO_3 and 0.5% picric acid (2,4,6-trinitrophenol) solution was placed in each Petri dish. Dishes were sealed with parafilm and incubated at 28°C. Development of color from yellow to dark brown indicated HCN production. Production of indol-3-acetic acid (IAA) by bacterial isolates was examined according to the Etesami et al. (2015). Development of pink color in tubes after addition of Kovac´s reagent proved the presence of indole in the medium and capacity of bacterial isolates to produce the enzyme tryptophanase. The ability of bacteria to produce siderophores was tested according to Schwyn and Neilands (1987), on chrome-azurol S (CAS) medium. The change of colour from blue to orange indicated ability of bacteria to produce siderophores. The ability to mineralize organic phosphorus compounds was tested on a modified Menkina substrate (Liu et al., 2011). Pikovskaya (1948) medium was used to examine the ability of bacteria to solubilize insoluble $Ca_3(PO_4)_2$. Phosphate mineralization and solubilization was verified by the appearance of a transparent zone around bacterial colony, respectively. Effectiveness of phosphate solubilization and mineralization of phosphorus organic compounds was evaluated according to zone diameter.
Ability to produce cellulase was tested on CMC agar (carboxymethyl cellulose agar). Solution of Congo-red (1 mg/cm^3 H_2O) was poured over bacterial colonies after incubation period. The

solution was decanted after 15 min and the colonies were overflowed with 1M NaCl. A transparent zone around the colonies was the proof of the cellulase activity.
Lipase activity was determined by growing the isolates on the nutrient medium (peptone 10 g/L, NaCl 5 g/L, $CaCl_2xH_2O$ 0.1 g/L and agar 15 g/L) with Tween 80. Discoloured zone around the isolates colony was the proof of lipolytic activity. Christensen’s urea agar (urea 20 g/L, NaCl 5 g/L, glucose 1 g/L, peptone 1 g/L, KH_2PO_4 2 g/L, phenol red indicator 0.012 g/L and agar 15 g/L) was used to examine the urease activity. Since urea is unstable, it was filtered through syringe filter (0.2 μm) and added separately, after autoclaving. The appearance of the red color was proof of the urea decomposition. Amylase activity was examined by flooding iodine on colonies grown on starch agar (starch 10 g/L, KH_2PO_4 0.5 g/L, K_2HPO_4 0.5 g/L, $MgSO_4 \times 7\ H_2O$ 0.2 g/L, agar 15 g/L). Absence of a halo zone around the colony confirmed hydrolysis of starch. Nutrient medium with pectin was used to test pectinase production by bacteria (Soriano et al., 2000). After 24h, colonies were overflowed with lugol. A discolored zone around the colony was proof of the pectinase activity.

Results and Discussion

From the rhizosphere of ribwort plantain, different bacteria were isolated. Out of 50 isolates, 12 were chosen for detailed characterization. The bacteria isolates were denoted as follows: genus *Streptomyces* (S4/1 MPA, S4, S5), *Pseudomonas* (K1/1, K1/2, K1/3), *Bacillus* (MPA 1/1, MPA(UB)1/1, MPA(UB)1/2, MPA(UB)1/3) and *Azotobacter* (F1/1, F1/2). These strains were further studied for different biochemical, physiological and PGP properties.
Influence of temperature, salt and pH levels on bacterial colony growth are presented in Table 1.

Table 1. Effect of different temperature, salinity and pH levels on growth

Isolates	Temperature (°C)			Salt (%)			pH value		
	5	28	45	3	5	7	5	7	9
S4/1 MPA	-	+++	-	+++	++	+	+++	+++	++
S4	-	-	++	+++	-	-	+++	-	++
S5	-	-	+	+	-	-	++	-	-
K1/1	-	+	-	-	+	-	++	-	++
K1/2	+	++	+++	++	+	-	+++	++	+++
K1/3	-	++	-	-	-	-	+	+++	+
MPA 1/1	-	+	+	++	++	++	++	++	++
MPA(UB)1/1	-	+	-	++	-	-	+++	++	+++
MPA(UB)1/2	-	+	++	++	-	-	++	++	++
MPA(UB)1/3	-	+	+	+	+	-	++	++	++
F1/1	+	++	+	++	++	+	+++	++	+++
F1/2	+	++	+	++	++	+	+++	++	+++

Legend: intense growth (+++), optimal growth (++), minimal growth (+), absence of growth (-);

For the most isolates, optimum temperature for the growth was at 28°C. Similarly, bacteria isolates showed good growth at 45°C, except S4/1 MPA, MPA(UB)1/1 and bacteria of the genus *Pseudomonas* (K1/1 and K1/3). The results showed good tolerance of *Azotobacter* isolates to all salt concentrations. Isolates S4/1 MPA (*Streptomyces sp.*) and MPA 1/1 (*Bacillus sp.*) showed optimal colony growth, too. The majority of bacteria isolates grew better and formed larger colonies at lower salt concentration contrary to the highest NaCl concentration where only four isolates grew. All isolates had intense or optimal growth at pH 5. Similar results were observed at pH 7 (except for S4, S5 and K1/1) and pH 9 (except for S5). Strain S5, belonging to the genus *Streptomyces*, showed higher sensitivity compared to the other isolates (Table 1). The ability of bacteria to grow in extreme conditions such as low or high pH, salinity or temperature allows them to survive and to adapt to diverse surroundings (Stamenov et al., 2016). Based on this, strain K1/2, MPA 1/1, F1/1 and F1/2 showed good resilience to adverse environments. Results of Krishna Samal et al. (2020) indicated similar tolerance properties of *Azotobacter* isolates to different salts (2, 5 and 7%) and pH levels (6, 7, 8 and 9). According to Stamenov et al. (2021), *Bacillus* isolate B85 formed colonies at, both 10°C and 45°C as well as at salt levels ranging from 5% and 7%. The ability of *Bacillus* and *Pseudomonas* isolates to grow at extreme temperatures and at high concentrations of NaCl is reported by Stamenov et al. (2020).

Utilization of various carbon sources by rhizospheric bacteria are presented in Table 2. None of 12 isolates utilize all six examinated carbon sources. However, three out of 12 bacteria isolates (S4/1 MPA, F1/1, F1/2) utilize five carbon sources. According to the Parveen et al. (2018) bacteria isolate WRPA26 showed best potential of various carbon sources utilization. This strain successfully utilized glucose, citrate, adonitol, arabinose, lactose, sorbitol, mannitol, rhamnose and sucrose. On the other hand, study of Krishna Samal et al. (2020) showed good utilization of glucose, maltose, inositol, mannose and rhamnose by *Azotobacter* isolates (A2 and A3). Results of this research indicate that *Pseudomonas* isolate (K1/3) poorly utilized carbohydrates. On the contrary, Stamenov et al. (2020) observed good utilization of different carbon sources (glucose, galactose, fructose, saccharose and xylose) by *Pseudomonas* isolates.

Table 2. Utilization of different carbon source

Isolates	Glucose	Galactose	Xylose	Sacharose	Lactose	Fructose
S4/1 MPA	+	+	+	+	-	+
S4	-	+	+	+	-	+
S5	-	-	-	-	-	-
K1/1	+	+	+	-	-	+
K1/2	+	-	-	-	-	+
K1/3	-	-	-	-	-	+
MPA 1/1	+	-	-	+	-	+
MPA(UB)1/1	+	-	-	+	-	+
MPA(UB)1/2	+	-	+	+	-	-
MPA(UB)1/3	+	-	+	+	+	-
F1/1	-	+	+	+	+	+
F1/2	-	+	+	+	+	+

Legend: colony growth (+), absence of growth (-)

Both *Azotobacter* isolates (F1/1, F1/2), *Bacillus* (MPA(UB)1/1, MPA(UB)1/2, MPA(UB)1/3), *Streptomyces* S4/1 MPA and *Pseudomonas* K1/1 produced HCN (Table 3). According to Stamenov et al. (2021), 74.2% of total bacteria isolated from common thyme rhizosphere were able to produce HCN. On the contrary, in the study of Parveen et al. (2018), all examined bacterial isolates from wheat rhizosphere were found negative for HCN production. Hydrogen cyanide production by rhizospheric bacteria could induce suppression of many pathogenic bacteria and fungi.

Indole-3-acetic acid (IAA) is the main auxin phytohormone. Auxins participate in the regulation of basic plant physiological processes such as cell division, tissue differentiation and response to stress conditions (Parmar et al., 2023). All isolates of the genus *Streptomyces* (S4/1 MPA, S4 and S5) showed intense production of IAA contrasted to one isolate of genus *Azotobacter* (F1/2) which showed minimal production. Interestingly, pseudomonads and bacilli did not produce IAA. Many results indicated IAA production by more than 54%

(Stamenov et al., 2021) and 70% (Parveen et al., 2018) of the total number of isolated rhizobacteria.
All isolates were screened for production of siderophores but none were found (Table 3). In the study of Stamenov et al. (2016), only one isolate of the *Azotobacter* sp. was found to be positive for siderophores production. On the contrary, results of Parveen et al. (2018), showed potential of all investigated bacterial isolates for siderophore production where solubilization efficiency varied from 72.7% to 250%.
Phosphorus is one of the most important macronutrient for plant growth and development. All isolates of the genus *Azotobacter* (F1/1, F1/2) showed ability to mineralize phosphorus organic compounds (Table 3). Also, two isolates *Streptomyces* (S4/1 MPA, S4) and two isolates of *Bacillus* (MPA(UB)1/2, MPA(UB)1/3) showed similar activity. This is in accordance with the results of Stamenov et al. (2016). The authors showed that two *Azotobacter* isolates (A1 and A2) utilized organic phosphorous.

Table 3. PGP traits and enzyme production ability

Isolates	PGP traits*					Enzyme production**				
	HCN	IAA	S	P_{min}	P_{mob}	C	L	U	A	P
S4/1 MPA	+	+++	-	+++	+++	-	+	-	-	-
S4	-	+++	-	+++	+++	-	+	-	-	-
S5	-	+++	-	-	++	-	-	-	-	-
K1/1	+++	-	-	-	-	-	-	-	-	-
K1/2	-	-	-	-	+	+	-	-	-	+
K1/3	-	-	-	-	-	+	-	-	-	-
MPA 1/1	-	-	-	-	-	+	-	-	-	-
MPA(UB)1/1	++	-	-	-	-	+	-	-	-	-
MPA(UB)1/2	++	-	-	+	-	+	-	-	-	+
MPA(UB)1/3	++	-	-	+	-	+	-	-	-	+
F1/1	++	-	-	++	-	+	-	+	-	+
F1/2	+++	+	-	++	+	-	-	+	-	+

*Legend for HCN, IAA and S: (+++) intense production, (++) optimal production, (+) minimal production, (-) not detected; legend for Pmin and Pmob: (+) 4 mm day^{-1}, (++) 4-5 mm day^{-1}, (+++) >5 mm day^{-1}, (-) not detected; hydrogen cyanide production (HCN), siderophore production (S), mineralization of phosphorus organic compounds (Pmin.), phosphate solubilization (Pmob.), **cellulases (C), lipases (L), ureases (U), amylases (A), pectinases (P)

The results of our study showed that only 5 out of 12 isolates could solubilise inorganic phosphates. These were isolates of *Streptomyces* (S4/1 MPA, S4 and S5), one isolate of *Pseudomonas* (K1/2) and one isolate of *Azotobacter* (F1/2). Microbial solubilization in soil is alternative, eco-friendly process for enhancing bioavailability of plant nutrients. According to Parveen et al. (2018), more than 50% of investigated bacterial isolates were able to solubilize phosphates. The PGP features could affect plant growth indirectly by increasing soil fertility via solubilization of inorganic phosphorus, or directly by secretion of HCN, IAA etc.
The isolate F1/1 had the ability to produce three (cellulases, ureases and pectinases) out of five examined enzymes (Table 3). Some *Pseudomonas* and *Bacillus* isolates denoted as K1/2, MPA(UB)1/2 and MPA(UB)1/3 showed cellulases and pectinases production capacity. Similar result was found by Niyonzima (2019). That study indicated the ability of *Bacillus* sp. MSL2, *Bacillus megaterium* BMS4 and *Pseudomonas fluorescens* to produce cellulose degrading enzymes while *Bacillus subtilis* proved as an excellent producer of pectinases. All isolates were screened for amylases production but it was found that none were able to produce this enzyme (Table 3). Meanwhile, according to the Al-Maqtari et al. (2019), most of amylases are of microbial origin (*Bacillus subtilis*).

Conclusion

Plantain rhizosphere soil harbors many, potentially beneficial bacteria genus/species that can survive in conditions of elevated salt concentration. They also showed excellent ability to grow in wide range of pH level (varying from acidic to alkaline condition). Out of total 12 fully characterized bacterial isolates, four demonstrated production of indol acetic acid (IAA), and seven were good producer of hydrogen cyanide (HCN). Six isolates showed the ability to mineralize organic phosphorus (P) compounds as well as to mobilize water insoluble tertiary phosphates (five isolates). *Streptomyces* sp. isolates showed the best PGP potential, especially the isolate S4/1 with four out of five investigated PGP traits. Also, important isolates with significant PGP traits were *Pseudomonas* sp. K3/2 and K5/1, *Bacillus* sp. M3/1 and *Azotobacter* sp. F1/2. Further investigation of these isolates is necessary before they could be used as a potential base in creation of a bacteria based formulation(s).

Abstract

The effect of four concentrations of auxin of bacterial origin (0 - control without auxin, 0.1, 5, and 50 μg ml^{-1}) on germination and early seedling growth in five field crops was investigated. The genetic materials for this study included the maize hybrid 'ZP 684', the wheat variety ‘Evropa 90’, the soybean variety 'Galina', the field pea variety 'Kosmaj', and the sunflower hybrid 'NS Oskar'. Energy germination and germination were recorded according to ISTA rules. After 10 days, root length, shoot length, and seed vigor were determined. Energy germination did not depend on auxin, but germination did, except for maize. Wheat, soybean, and field pea had significantly higher germination at 5 and 50 μg ml^{-1} auxin and sunflower at 50 μg ml^{-1} auxin compared to the control. The results showed that the auxin of bacterial origin promoted early seedling growth in all crops compared to the control. Compared to the control, 0.1 and 5 μg ml^{-1} auxin increased root length in maize, 0.1, 5, and 50 μg ml^{-1} in wheat and sunflower, 5 and 50 μg ml^{-1} in soybean, and 50 μg ml^{-1} in field pea. Compared to the control, the auxin treatments increased shoot length in the crops studied, except for field pea, where the 50 μg ml^{-1} auxin did not contribute to the increase in this trait. Compared to the control, all treatments with auxin increased seed vigor in maize, soybean, field pea and sunflower, while this was observed in wheat when treated with 5 μg ml^{-1} auxin. Auxin-treated seeds are therefore expected to have the advantage of surviving under unfavorable environmental conditions caused by abiotic and biotic stress. Auxin-treated seedlings were more vigorous and better developed.

Keywords: *Early seedling growth, Germination, Auxin of bacterial origin.*

Introduction

Microbiological natural biostimulants have great potential for plant production worldwide. Numerous countries such as the members of the EU, the USA, China, India, and Japan are trying to increase the use of microbiological inoculants and thus biostimulants through legal regulations and incentives in agriculture. The development of ecological awareness and the good results of the application of PGPBs in agriculture led to their use in other areas of human activities, i.e. forestry, horticulture, bioremediation, and recultivation. The use of PCR techniques enables the detection and control of species and strains of PGPR bacteria involved in the synthesis of phytohormones.

High-quality seed processing is crucial for profitable crop production. The number of plants per unit area under natural field conditions and thus the crop yield per unit area in agriculture depends on how successful and high quality the seed will develop. According to Bajguz and Piotrowska-Niczyporuk (2023), 12 groups of plant hormones (phytohormones, plant growth regulators) have been identified in plant species: auxins, gibberellins, cytokinins, ethylene, abscisic acid, salicylic acid, brassinosteroids, jasmonates, polyamines, melatonin, peptide, and terpenoid lactones hormones. These hormones are necessary for the growth and development of plants. Numerous chemical and bacterial biostimulants containing hormones are available on the world market under various trade names for the preparation of seed and planting material. Chemical biostimulants contain synthetic auxins and can be harmful to the plant if used inadequately. Compared to natural auxins, they are degraded slowly in excessive amounts, remain longer in the plants, and are often lethal (Pazmiño *et al*., 2012). Their higher concentration leads to deformation and twisting of the leaf tissue due to uncontrolled and distorted cell division and collapse of the tissue structure, which eventually leads to the death of the plant (Grossmann, 2010). Unfortunately, the overuse of synthetic auxins during the flowering stage of crops, especially herbicides containing synthetic auxins, has reduced pollinator visitation and caused pollinator mortality (Bohnenblust *et al*., 2016). It is precisely for these reasons that research into the use of natural microbiological biostimulants for pre-sowing seed treatment has begun worldwide. The research to invent new bacterial biostimulants is based on testing different species and strains of bacteria and their combinations to find the most effective preparation to improve the quality of seed germination. Unlike chemical biostimulants, natural biostimulants contain microorganisms that produce phytohormones, and their quantity is balanced so that there is no fear of undesirable side effects (Saharan and Nehra, 2011). The basis of natural biostimulants is primarily plant growth-promoting bacteria (PGPB), which synthesise hormones that have a positive effect on seeds, seedlings and plants (Backer *et al*., 2018). According to Singh and Purohit (2008) PGPB hormones are natural analogues of plant hormones. About 80% of pathogenic and beneficial soil bacteria produce auxin and belong to different genera such as *Pseudomonas*, *Bradyrhizobium*, *Rhizobium*, *Mesorhizobium*, *Azospirillum*, *Serratia*, *Bacillus* and *Azotobacter* (Ahemad and Kibret, 2014; Gupta *et al*., 2015). Indole-3-acetic acid (IAA) is the most studied auxin produced by PGPB (Woodward and Bartel, 2005). Auxins produced by PGPR have a positive effect on seed germination (Miransari and Smith, 2014), root growth by improving water and nutrient availability (Arora *et al*., 2013), vegetative organ growth, photosynthesis, pigment formation, metabolite biosynthesis, biomass production and yield (Spaepen and Vanderleyden, 2011) and increases resistance to stress conditions (Gamalero and Glick, 2011).

The main objective of this paper is to study the effects of four concentrations of auxin of bacterial origin (0 - control without auxin, 0.1, 5, and 50 $\mu g\ ml^{-1}$) on seed germination and seedling growth of five crops (maize, wheat, soybean, field pea, and sunflower).

Materials and methods

Bacillus spp. were isolated from the rhizosphere of maize using the classical microbiological method. Subsequently, species identification was performed by cytological-morphological and biochemical analyses based on Bergey's Manual of Systematic Bacteriology, i.e. cell morphology, analysis of fermentation products, enzymatic activity, cell wall structure, and other phenotypic tests as a starting point for the preliminary classification of the genus *Bacillus*. Final genetic identification was performed by DNA amplification using the polymerase chain reaction (PCR) method by amplification of the 16S rRNA gene. Prior to DNA extraction, each isolate was subcultured in LB broth for 24 hours at room temperature. DNA extraction was performed using the Quick-DNA™ Fungal/Bacterial kits (Zymo Research, Irvine, USA). For PCR analysis, universal primers for 16s, 27F (5'- AGA GTT TGA TCM TGG CTC AG-3'), and 1492R (5'- TAC GGY TAC CTT GTT ACG ACT T-3') were used to determine the identity of 2 isolates. Reactions were performed in a final volume of 30 μL and contained the EconoTak® Plus 2 × Master Mix, 0.5 mM of each primer and 10 ng of genomic DNA. The following PCR amplification conditions were set in a thermal cycler: 5 minutes at 94°C, then 35 cycles at 94°C/30 seconds, 30 seconds at 55°C and 60 seconds at 72°C with a final extension of 7 minutes at 72°C. PCR products were mixed with Safe-Orange G dye and run on a 1.5% agarose gel in 1 × Tris-boric acid-EDTA (TBE) buffer at 80 V/1.2h. The gels were visualized with a UV transilluminator (UV-26, MRC LAB). Amplicons were purified using the PCR product purification kit QIAquick PCR Kit/250 (Qiagen GmbH, Hilden, Germany) and then sent to MACROGEN for sequencing. The resulting sequences were screened for homology with previously sequenced genes in the GenBank database using the National Center for Biotechnology Information Blast Nucleotide Search Program (BLASTN). A 100% sequence match was found for *Bacillus subtilis* and *Bacillus megaterium*.

Colorimetric determination of auxin concentration was performed according to the Salkowski method (De-Bashan *et al*., 2008). The Avena test was used to confirm the biological activity of the isolated auxins (Nitsch and Nitsch, 1956; Sirois, 1966). The analysis of auxin (indole-3-acetic acid) was confirmed and quantified by tandem mass spectrometry - MRM experiment (Đorđević *et al*., 2017).

The four concentrations of auxin of bacterial origin (0, 0.1, 5, and 50 μg ml^{-1}) were analyzed. Certified seeds of five crops (maize hybrid 'ZP 684', the wheat variety 'Evropa 90', the soybean variety 'Galina', the field pea variety 'Kosmaj' and the sunflower hybrid 'NS Oskar') were used.

The seeds were disinfected with 2% NaClO and washed 3 times in sterile distilled water. Germination tests were performed by placing 100 seeds in sterilized Petri dishes in a phytotron at a temperature of 20°C on filter paper soaked with 10 ml of a suitable medium in four replicates. According to ISTA (2024), the seed is germinated when the root length is 2 mm. Stem and root length were determined after 10 days on 20 randomly selected seedlings in each treatment and replication. Seed vigor was calculated using the following formula:

Seed vigor = (shoot + root length) × germination.

Statistica version 13 (StatSoft, Tulsa, Oklahoma, USA) was used to analyze the data. The mean values were compared with Tukey's test at a 5% level.

Results and discussion

It is generally known that the *Bacillus* genus produces indole-3-acetic acid, siderophores, and hydrogen cyanide. Different isolates produced different amounts of auxin (indole-3-acetic acid). The colorimetric and Avena tests showed that *B. subtilis* had a higher auxin concentration than *B. megaterium* (Table 1).

Table 1. The concentration of auxin produced (colorimetric test and Avena test).

Species of Bacteria	Auksin, μg ml^{-1}	
	Colorimetric test	Avena test
B. subtilis	14.50	14. 36
B. megaterium	12.78	12.21

During germination, the seed goes through a phase of imbibition (the seed absorbs water and swells, enzymes are activated and the seed begins to respire) and seedling emergence (begins with the emergence of the primary root). During germination of maize, wheat and field pea, the epicotyl elongates and the cotyledon(s) remain in the soil (hypogeal germination), while in soybean and sunflower, the hypocotyl grows above the soil (epigeal germination).

Our results showed that auxin had no significant effect on the germination energy of the tested crops compared to the control treatment (Table 2). In general, germination energy values were high in wheat (ranging from 90.2 at 0 μg ml^{-1} to 92.0 at 50 μg ml^{-1}), soybean (ranging from

88.0 at 0 μg ml^{-1} to 93.5 at 50 μg ml^{-1}), field pea (ranging from 90.0 at 5 μg ml^{-1} to 91.5 at 0.1 μg ml^{-1}) and sunflower (ranging from 88.8 at 0.1 μg ml^{-1} to 92.2 at 50 μg ml^{-1}).

Table 2. Effect of auxin of bacterial origin on seed germination and seedling growth of maize, wheat, soybean, field pea, and sunflower.

Parameters	Auxin concentration effects (A)	Crop

Auxin of bacterial origin significantly increased germination, except in maize. The lowest germination was observed in the control treatment without auxin (wheat 92.9%, soybean 91.8%, field pea 96.8%, and sunflower 91.5%). In terms of germination, the crop seed meets the requirements established by the Rulebook on the quality of seeds of agricultural plants (Official Gazette of SFRY 47/1987) according to which the minimum germination for maize is 85%, wheat 82%, soybean 70%, field pea 75% and sunflower 80%. The hormone auxin regulates seed dormancy and germination (Li *et al*., 2016) primarily by mediating the ABA signaling pathway (Ye *et al*., 2016). Also, auxin had a significant effect on the root length of the tested crops compared to the control treatment, except for soybeans. Maize, wheat, field pea, and sunflower had the least root length in the control (18.29 mm, 11.65 mm, 19.57 mm, and 14.80 mm, respectively). However, soybean had the lowest root length (18.94 mm) in the 0.1 μg ml^{-1} treatment with auxin. The highest root length was obtained in maize (22.79 mm) in the treatment with 0.1 μg ml^{-1} auxin, in wheat (20.54 mm) in the treatment with 5 μg ml^{-1} auxin, in soybean in the treatment with 5 (20.46 mm) and 50 μg ml^{-1} auxin (20.47 mm), in field pea (24.71 mm) and sunflower (20.88 mm) in the treatment with 50 μg ml^{-1} auxin. Auxin increased shoot length in the crops, except for field pea, where treatment with 50 μg ml^{-1} did not increase the trait. In contrast, maximum shoot length was achieved in maize (10.16 mm), wheat (18.36 mm), soybean (10.61 mm), and sunflower (10.17 mm) when treated with 50 μg ml^{-1} auxin. Field pea had significantly higher shoot lengths in the treatments with 0.1 (8.42 mm) and 5 μg ml^{-1} (8.38 mm) auxin than in other treatments. Auxin influenced seed vigor. The highest seed vigor was obtained in maize (3126.3) in the treatment with 0.1 μg ml^{-1} auxin, in wheat and field pea in the treatment with 5 μg ml^{-1} auxin (3663.4 and 2987.0, respectively), and in soybean and sunflower in the treatment with 50 μg ml^{-1} auxin (3014.8 and 2939.0, respectively). Similar to our research, auxin of bacterial origin increases germination and the length of roots and shoots of maize seedlings (Lwin *et al*., 2012; Noumavo *et al*., 2013), wheat seedlings (Akbari *et al*., 2007; Fatima *et al*., 2009), soybean seedlings (Cvijanović *et al*., 2020) and sunflower seedlings (Miladinov *et al*., 2015; Miklič *et al*., 2016). The hormone auxin promotes root growth and thus tolerance to drought stress by improving nutrient uptake (Kurepa and Smalle, 2022). When plant seeds are inoculated with auxin (IAA-synthesising PGPB), they have a more developed root system and a greater height of the aerial part, a larger leaf area, and biomass, and ultimately a higher yield due to the elongation of primary roots and the formation of lateral and adventitious roots (Malhotra and Srivastava, 2009; Puente *et al*, 2010; Glick, 2012). Accordingly, young plants with a better developed root system are more stable because they are more connected to the substrate and their ability to absorb water and nutrients from the substrate increases. Auxin stimulates plant cell division, plant tissue expansion and differentiation, thereby stimulating seed germination and seedling rooting, the rate of xylem and root system development, and the control of vegetative growth processes (Hussain, 2010; Spaepen and Vanderleyden, 2011). Stanojević *et al*. (2014) and Đorđević *et al*. (2017) also indicated that bacterial auxin has a stimulatory effect on wheat and maize seedlings as it affects the elongation of roots and stems. In addition, inoculation of maize seeds with PGPB bacteria in the field increased the abundance, activity, and biodiversity of soil microorganisms, the resistance of stems to lodging and grain yield, and reduced the number of infertile plants (Mandic *et al*., 2016; Mandić *et al*., 2018).

Conclusion

Auxin of bacterial origin showed an effect on seed germination (except for maize) and seedling growth. Compared to the control, the significantly higher germination of wheat, soybean, and field pea was observed at 5 and 50 μg ml^{-1} auxin, and sunflower at 50 μg ml^{-1} auxin. Compared to the control, the significantly higher root length of maize was observed at 0.1 and 5 μg ml^{-1} auxin, wheat and sunflower at 0.1, 5, and 50 μg ml^{-1} auxin, soybean at 5 and 50 μg ml^{-1} auxin, and field pea at 50 μg ml^{-1} auxin. Auxin treatments significantly increased shoot length in the crops compared to the control, with the exception of 50 μg ml^{-1} auxin in field pea. In addition, auxin treatment significantly increased seed vigor in maize, soybean, field pea, and sunflower, and 5 μg ml^{-1} auxin in wheat. Accordingly, auxin of bacterial origin can be used to improve germination and seedling growth and can be a cost-effective commercial agricultural input.

Abstract

Heavy metals are significant environmental pollutants because they represent potential metabolic inhibitors. The aim of the research was to determine the content and influence of heavy metals on tree development in the varieties *Pobeda* and *Ljiljana*. The tolerance of certain wheat genotypes to high concentrations of heavy metals was determined through comparative tests in vessels. The experiment was set up in vessels where two different concentrations of heavy metal mixture, 50 ppm and 250 ppm, were added under controlled conditions. Higher concentrations of heavy metalmixture had a negative effect on wheat stem height. Higher concentrations of heavy metals significantly reduced plant growth in both cultivars.

Key words: *Atomic absorption Spectrophotometry, Heavy metals, Wheat steam, Triticum sp.*

Introduction

Current agricultural practices involve widespread use of chemical pesticides and mineral fertilizers known for their ability to cause negative impacts on human health and degrade the natural environment (Rastija, 2022). Contamination alongside roads was evident through significant negative correlations between metal concentrations in soil and plants samples and distance from the road edge. Only cadmium concentrations in soil and plant samples were not associated with roadside pollution. Pollution of plants and soil alongside roads did not extend muchbeyond 20 meters from the road (Kanmani and Gandhimathi, 2013).

Differences in stress-induced effects of elevated concentrations of toxic metals indicate differenttolerance of plants to metals. Based on the results of depth variation of heavy metal concentration,it is concluded that heavy metal concentrations present in solid waste samples depend on the site conditions, as well as on the conditions prevailing at the sampling sites. Based on the average concentration, the concentration of heavy metals in the collected solid waste sample was determined in the following order: Mn > Cu > Pb > Cd (Zhao et al., 2017).

Research initiated in the 1960s has shown that soils in urban and industrial areas contain extremelyhigh concentrations of heavy metals. Plants are most sensitive to industrial pollution, which is whythey are successfully used as indicators to assess environmental pollution and establish adequate biomonitoring. The aim of this study is to determine the content of heavy metals in the leaves of Plantain (Plantago major L.) in the Tuzla area, as well as to assess the influence of thermal power
plants and industrial facilities on surrounding areas. It was found that the content of heavy metals in Plantain leaves often did not decrease with increasing distance from the dominant anthropogenicsources of heavy metal emissions (Bektić et al., 2020).

At the cellular level, the consequences of prolonged exposure to high metal concentrations can include membrane disintegration, ion loss, lipid peroxidation, DNA/RNA degradation, and ultimately cell death. For plants to develop and grow normally, they must maintain

concentrationsof essential elements within optimal values - a state of homeostasis (Stojanović, 2017).
Studies have shown that it is not the total concentration but the reactive fraction of heavy metals in the soil that dictates their toxicity to plants, microbes, and human beings. Exchangeable forms of heavy metals that are soluble in water are much more reactive and biologically available than precipitated species (Kim et al., 2015). However, the distribution of heavy metal species is influenced by numerous environmental factors, especially pH, redox potential, clay content, Fe/Mnoxide content, organic matter content, and the presence of other cations and anions in the solid phase (Pietrzykowski et al., 2014). To accurately assess the bioavailability of heavy metals in the soil, factors of influence must be taken into account.
In soil and sediment, heavy metals exist in various forms, such as: dissolved ions (e.g., $Cu^{2+,}$ Cd^{2+}, $CrO4^{2-}$, $Cr_2O_7^{2-}$ and MnO_4^{2-}), organic complexes (e.g., Cu^{2+}, Pb^{2+}, and Hg^{2+} bindingto dissolved organic matter), exchangeable ions (e.g., Cu^{2+}, Zn^{2+}, Cd^{2+}, Ni^{2+}, and Pb^{2+}) adsorbed onto soil solid particles, and those (co-) precipitated as part of soil particles (e.g., $Cd_3(PO_4)^2$, ZnS, $PbCO_3$, and $HgSO_4$). These three forms maintain thermodynamic equilibrium in activities and mutual concentration with insoluble precipitate as the dominant species (Liu et al.,2019).

Materials and Methods

The study on the influence of heavy metal mixture concentration on the dynamics of heavy metal accumulation in wheat plants and plant growth was conducted through experiments in pots in the greenhouse of the Faculty of Agriculture in Zemun, where controlled conditions of temperature and humidity were maintained. The vegetative trial was arranged in three repetitions, with a total of 36 pots in which two varieties of wheat, *Pobeda* and *Ljiljana*, were sown. Before sowing, the pots were filled with 2 kg of dry extract of Novobalt, which was subsequently contaminated with a mixture of heavy metal chemical compounds in the form of solutions of the following compounds: zinc in the form of zinc acetate-$Zn(CH_3COO)_2$ x $2H_2O$, lead in the form of lead acetate $C_4H_6O_4Pb$ x $3H_2O$, chromium in the form of chromium trioxide-CrO_3, copper in the form of copper sulfate-$CuSO_4$, and cadmium in the form of cadmium nitrate-$Cd(NO_3)_2$ x $4H_2O$.
The following concentrations of solutions were applied: 0 ppm (control), 50 ppm, 250 ppm
In addition to the heavy metal content in wheat plants, the height of the plants from the soil level was first measured. Afterward, the heavy metal content in wheat plants was determined. The *Pobeda* and *Ljiljana* wheat varieties were chosen because they are predominantly grown in the southern Banat region. Twelve seeds were sown in each pot at a depth of 5 cm. Samples from the trial in pots were analyzed during the tillering and heading phases, where four plants were taken from each pot. After sampling, the roots were manually separated from the wheat stem. Subsequently, the plant mass-stems were washed with distilled water and kept for several hours in 0.1 M HCl to remove soil and mineral oxides from the surface. Then, the plant mass was ground and dried in a dryer at 80˚C. A 1 g sample was taken and poured with 20 ml of 60% HNO_3. Mild boiling was performed for 2 hours. After cooling, 3 ml of H_2O_2 was added, followed by boiling for 15 minutes. The peroxide procedure was repeated. After cooling, 2 ml of $HClO_4$ was added, and mild evaporation was performed until dense white fumes of perchloric acid appeared (Jones and Case, 1990). After cooling, 5 ml of 5M HCl was added, and then the samples were quantitatively transferred into normal 50 ml vessels. The vessels were filled up to the final volume with distilled water. The solution was filtered through quantitative filter paper. Readings were performed using atomic absorption spectrophotometry (Varian Spectr AA 220FS instrument) in acetylene/air flame. The analysis of the obtained data was conducted using the statistical softwarepackages STATISTICA 8 for Windows and SPSS Statistics 17.0.

Results and Discussion

Plant height

The variety *Pobeda* had a slightly lower average height (39.40 cm), while the variety *Ljiljana* had a higher average height (44.50 cm). The average height of the tree per sample for the variety *Pobeda* varied from 34.00 to 42.60, and for the variety *Ljiljana* from 35.50 to 50.00 (tables 1 and 2).

Table 1. Plant Height, *Pobeda* Variety, cm

Treatment	Zn, Pb, Cr, Cu, Cd	LSD 5%	LSD 1%
Control	42.60	7.9889	14.6647
50 ppm	41.60	8.1768	15.0097
250 ppm	34.00	1.8371	3.3723
Mean	39.40		

Table 2. Plant Height, *Ljiljana* Variety, cm

Treatment	Zn, Pb, Cr, Cu, Cd	LSD 5%	LSD 1%
Control	50.00	1.8371	3.3723
50 ppm	46.00	14.5818	26.7668
250 ppm	35.50	5.1143	9.3881
Mean	44.50		

During metal mixture contamination at a concentration of 50 ppm, the *Ljiljana* variety had a plant height of 46.00cm, while the *Pobeda* variety had a slightly lower height of 41.60 cm. At aconcentration of 250 ppm, the plant height for the *Ljiljana* variety was 35,50 cm, while for the *Pobeda* variety, it was lower at 34.00 cm.

The process of photosynthesis is most sensitive to the toxic effect of lead. Long-term exposure causes inhibition of chlorophyll biosynthesis (Ernst et al., 2000; He et al. 2014). Studies have shown that lead negatively affects photosynthesis, transpiration, and stomatal conductivity when its concentration in the soil exceeds 300 ppm (Fu and Wang, 2015). Differences in the effects caused by stress due to elevated concentrations of toxic metals indicate varying plant tolerance tometals (Zhao et al., 2017).

Under the influence of higher concentrations of lead in plants are main processes inhibited, suchas germination, growth and development, photosynthesis process, water intake, mineral diet andenzymatic activity (Agami and Mohamed, 2013; He at al., 2016; Sharma and Dubey, 2005).

The content of heavy metals in the stem of wheat

The content of heavy metals in the *Pobeda* and *Ljiljana* varieties varies significantly (Tables 3 and 4). According to their average content in wheat plants, the heavy metals investigated in thePobeda variety can be ranked in the following order:

zinc > cadmium > copper > lead > chromium

The lead content of the *Pobeda* variety in the wheat stem is on average 3.77 mg kg $^{-1}$ and varies from 2.46 mg kg $^{-1}$ (control) to 5.45 mg kg $^{-1}$ (variant with 250 ppm). The cadmium content of the *Pobeda* variety in the wheat stem is on average 4.99 mg kg $^{-1}$ and varies from 0.65 mg kg $^{-1}$ (control) to 9.12 mg kg $^{-1}$ (variant with 250 ppm).

According to their average content in the wheat stem of the *Ljiljana* variety, the investigated heavymetals can be arranged in the following order:

zinc > cadmium > copper > lead > chromium

The lead content of the *Ljiljana* variety in the wheat stalk is on average 3.08 mg kg $^{-1}$ and varies from 2.14 mg kg $^{-1}$ (control) to 4.33 mg kg $^{-1}$ (variant with 250 ppm).

The cadmium content of the *Ljiljana* variety in the wheat stem is on average 9.05 mg kg $^{-1}$ and varies from 0.39 mg kg $^{-1}$ (control) to 17.31 mg kg $^{-1}$ (variant with 250 ppm).

Table 3. Content of Heavy Metals in Wheat Plants, *Pobeda* Variety mg kg^{-1}

Treatment	Zn	Pb	Cr	Cu	Cd	Ftest	LSD5%	LSD1%
Control	19.39	2.46	1.23	4.49	0.65	38832.27**	0.1197	0.1655
50 ppm	22.80	2.78	1.63	4.13	5.20	14839.17**	0.2168	0.2998
250 ppm	49.10	5.45	1.75	5.54	9.12	49105.52**	0.2678	0.3703
Mean	30.43	3.77	1.54	4.72	4.99	-	-	-

Table 4. Content of Heavy Metals in Wheat Plants, *Ljiljana* Variety mg kg^{-1}

Treatment	Zn	Pb	Cr	Cu	Cd	F test	LSD5%	LSD1%
Control	29.99	2.14	0.58	4.65	0.39	38832.27**	0.1197	0.1655
50 ppm	69.93	3.13	0.64	5.05	9.45	37006.43**	0.4607	0.6372
250 ppm	79.13	4.33	1.23	5.41	17.31	58501.43**	0.4087	0.5652
Mean	59.68	3.2	0.82	5.04	9.05	-	-	-

Conclusion

The vegetative trial in pots was conducted with different concentrations of heavy metal mixtures. Increasing the concentration of metal mixtures had a negative impact on plant height. Higher concentrations of heavy metals significantly reduced plant growth in both varieties. The results of the statistical analysis (analysis of variance) show that the experimental factor - the concentration of heavy metal mixtures for soil contamination - had a very significant impact on the content of heavy metals in wheat plant parts, as evidenced by the calculated F-values.

Abstract

Intercropping of annual legumes and cereals reduces the weediness of the plot and increases the forage yield. Legumes have a beneficial effect on the soil, leaving respectable amounts of nitrogen and maintaining soil fertility. On the other hand, cereals reduce the laying of legumes, representing their support. The aim of the research is to determine the influence of combined sowing of common vetch and oats in different ratios on forage yield and weediness. The experiment was set up in 2022, in the village Radoinja, municipality of Nova Varoš. The trial variants were spring vetch in pure sowing, oats in pure sowing, vetch 75% : oats 25% and vetch 50% : oats 50%. Average forage and hay yields of pure crops and mixtures did not differ significantly. The share of weeds in the pure vetch crop was high, on average 80%. In the mixtures of vetch and oats, the share of weeds was significantly reduced compared to the pure vetch crop. The lowest number of weed plants was in the pure oat crop and in the mixture with 50% vetch and 50% oats.

Keywords: *vetch, weeds, oats, yield, intercropping*.

Introduction

Annual legumes are one of the most important plant groups in conventional agricultural production systems and are an indispensable component of sustainable agricultural systems, i.e. organic production. A greater proportion of annual legumes in forage production systems can be ensured by growing them in a mixture with small grains. As a result of the complementarity between the components in the use of agroecological resources, the advantages of such mixtures are mainly reflected in higher forage yields compared to the yields of pure crops of the components (Bedoussac and Justes, 2010; Chapagain and Riseman, 2014). Better control of weed flora as well as biotic and abiotic stress are further potential advantages of such mixtures compared to pure plant components (Anil *et al.*, 1998; Semahegn, 2022). In forage production systems, mixtures of annual legumes and cereals have a number of advantages over their pure counterparts. One of the most important is the supply of nitrogen to the soil, which comes from nitrogen fixation, and thus the preservation of its chemical properties. Annual legumes generally have a relatively low forage yield potential, especially in regions with low rainfall. They are also difficult to harvest as they tend to lie down. The complementarity of legumes and cereals in terms of utilization of agroecosystem resources (nutrients, light, water) is often manifested in higher yields and better forage quality when grown in intercropped compared to pure legume and cereal crops (Balabanli *et al.*, 2010).

In all production systems, annual legumes as components of intercrops provide a far more sustainable source of nitrogen through symbiotic nitrogen fixation (Crews and Peoples, 2004). Cultivation of legumes and cereals as intercrops can also minimize nitrogen losses, which are more pronounced with pure legumes, mainly through the uptake of inorganic nitrogen by the cereals and the reduced rate of mineralization during the decomposition of organic matter, due

to the higher C/N ratio in cereals (Hauggaard-Nielsen *et al.*, 2003). The intercropping of legumes and cereals can provide numerous advantages, such as: increased biomass yield and utilization of soil resources, increased yield stability, improved utilization of nutrients, water and light, as well as control of weeds, diseases and pests (Ton, 2021; Semahegn, 2022).
The aim of the work was to determine the degree of forage yield and weediness of a intercropped of spring vetch and oats at different combinations.

Materials and methods

The experiment was carried out in 2022 in the village Radoinja, near Nova Varoš (43^0 30'41" N, 19^0 42'59" E, 790 m above sea level) in Serbia. The soil on which the experiment was carried out is mountain black soil on limestone (calcomelanosol), up to 70 cm deep, the arable layer is up to 30 cm. The parent substrate is limestone, loose and present in the subsoil horizon. The soil has a neutral reaction (pH KCl = 6.90), rich in humus (5.15%), very carbonated (18.25%), rich in nitrogen (0.25%), well supplied with potassium (30.90 mg/100 g) and very poor in phosphorus (5.00 mg/100 g).
The climate in the area of the municipality of Nova Varoš is determined by the altitude and relief. The lowest temperatures are in January, and the hottest months are July and August. The daily air temperatures during July and August are very high, but the nights are cool, so the average values are not high (16.6 and 18.2 ℃). The average air temperature in 2022 was 8.8 ℃. The sum of precipitation during 2022 was 724.9 mm. The most precipitation in 2022 was during May and September. The least amount of precipitation was in October, March and July.
The basic tillage of the soil was done in autumn by plowing to a depth of 25 cm. With the basic treatment, 300 kg ha^{-1} of NPK fertilizer formulation 16:16:16 was introduced. The experiment was set up according to a completely randomized block system in 3 repetitions, with the size of an elementary plot of 5 m^2 (5 x 1 m). The trial variants were: vetch - pure crop, 120 kg ha^{-1} (A1); oats - pure crop, 120 kg ha^{-1} (A2); vetch + oats - 75%+25%, 90 kg + 30 kg ha^{-1} (A3) and vetch + oats - 50%+50%, 60 kg + 60 kg ha^{-1} (A4).
Sowing was done on March 27, 2022, with an inter-row distance of 20 cm, and the row distance was 4 cm, at a depth of 4-6 cm. The spring vetch cultivar Ovčepoljska and the oat cultivar Lovćen were used for testing.
The weed flora and the number of weeds were determined twice. The first weed count per 1 m^2 was done when the vetch was 20 cm high, and the second before mowing the crop. Mowing of the green mass of the crop was carried out in the phase of full flowering of vetch on July 8, 2022.
After mowing, the forage yield was measured. The forage yield was recalculated based on the mass of fresh forage from the elementary plot and expressed in t ha^{-1}. Then, a sample of 1 kg of green mass was taken using the method of random selection, and the weight share of vetch, oats and weeds was determined from it. Then the sample was left to dry naturally at room temperature. After drying, the share of vetch, oats and weeds in dry matter was calculated. The dry matter content was determined as the proportion of the dry sample in relation to the fresh green sample. Hay yield (t ha^{-1}) was determined by multiplying the total amount of green biomass with the content of dry matter.
The results were processed by the one-factor analysis method (ANOVA), using the SPSS 4.5 program. The significance of the differences in treatment means was tested by the LSD test.

Results and discussion

Based on the results of the first weed count, 11 weed species were recorded (Table 1). Redroot pigweed (*Amaranthus retroflexus* L.) was the most abundant in the crops, followed by white goosefoot (*Chenopodium album* L.), potato weed (*Galinsoga parviflora* L.), Persian speedwell (*Veronica persica* L.) and field sowthistle (*Sonchus arvensis* L.).
The higest number of weed plants was detected in the pure vetch crop (173 plants m^{-2}), while in the pure oat crop there were 129 plants per 1 m^2. The number of weed plants in the mixtures decreased compared to the pure vetch crop (144 and 110 plants per m^2). The fewest weeds were in the mixture with 50%+50% of vetch and oats. With the increase in the share of oats in sowing, the number of weed plants also decreased.

Table 1. Floristic composition of weeds and number of plants per m^2

Weed name	First count				Second count			
	A1	A2	A3	A4	A1	A2	A3	A4
Redroot pigweed (*Amaranthus retroflexus* L.)	127	60	79	64	77	33	44	29
White goosefoot (*Chenopodium album* L.)	10	39	16	12	8	11	7	8
Potato weed (*Galinsoga parviflora* L.)	17	6	11	9	0	0	0	7
Persian speedwell (*Veronica persica* L.)	12	3	12	11	0	0	0	0
Field bindweed (*Convolvulus arvensis* L.)	4	3	1	4	0	11	0	0
Field buttercup (*Ranunculus arvensis* L.)	1	9	0	4	0	4	0	0
Field sowthistle (*Sonchus arvensis* L.)	1	0	17	0	13	4	16	4
Chickweed (*Stellaria media* L.)	1	1	7	3	4	0	0	0
Charlock mustard (*Sinapis arvensis* L.)	0	3	0	0	0	0	0	0
Birthwort (*Aristolochia clematitis* L.)	0	1	1	3	0	0	4	4
Pale smartweed (*Polygonum lapatifolium* L.)	0	4	0	0	0	4	0	0
In total	173	129	144	110	105	67	71	52

A1-vetch, A2-oats, A3- vetch 75% + oats 25%, A4- vetch 50% + oats 50%

Based on the results of the second count, the highest number of weed plants was also counted in the pure vetch crop (105 plants) (Table 1). There were 67 plants in the pure oat crop, and 71 and 52 plants in the mixtures. The least amount of weed plants was in the 50% vetch + 50% oat treatment, due to strong oat competition.
During the second count, 9 weed species were identified. Among them, the most numerous were redroot pigweed (*Amaranthus retroflexus* L), white goosefoot (*Chenopodium album* L.), field bindweed (*Convolvulus arvensis* L.) and field sowthistle (*Sonchus arvensis* L.).
Based on the results of the first and second weed counts, the highest weediness was in the pure vetch crop. In the mixture with 75% vetch and 25% oats, there were fewer weeds than in the vetch pure crop, more compared to the pure oats crop. The mixture with 50% vetch and 50% oats had the fewest weeds.

Average forage and hay yield of pure crops of vetch and oats, as well as their mixtures, did not differ significantly. The lowest forage and hay yield was recorded with pure vetch (23.38 t ha^{-1} and 7.40 t ha^{-1}), and the highest with a pure oat crop (30.61 t ha^{-1} and 9.69 t ha^{-1}) (Table 3). The results are in agreement with the results of other authors (Lithourgidis *et al.*, 2006; Tuna *et al.*, 2007; Ansar *et al.*, 2013). On the basis of previous research, related to the methods of combining intercropping of cereals and grain legumes and the impact on yield and yield stability, it was determined that cultivation in a mixture is a significantly more reliable method of production than individual cultivation of this forage crops (Raseduzzaman and Jensen, 2017).

Table 2. The forage yield, hay yield and the share of dry matter in the total yield of spring vetch and oat crops

	Forage yield (t ha^{-1})	Hay yield (t ha^{-1})
A1- vetch	23.38	7.40
A2- oats	30.61	9.69
A3- vetch + oats 75%:25%	27.33	8.65
A4- vetch + oats 50%:50%	30.15	9.54

Based on the obtained results, the share of vetch in the pure crop and mixtures did not differ significantly. The share of vetch had values from 8.75 to 20.61%. The proportion of oats in the A3 treatment was significantly lower compared to the pure oat crop (A2) and to the A4 treatment (Table 3).

Table 3. Share of vetch, oats and weeds in hay

	Vetch	Oats	Weeds
A1- vetch	20.61a	-	79.39a
A2- oats	-	95.44a	4.56c
A3- vetch + oats 75%:25%	22.44a	57.29b	20.27b
A4- vetch + oats 50%:50%	8.75a	83.73a	7.57bc

Values marked with different lowercase letters per column are significantly different at the P≤0.05 level according to the LSD-test

The share of weeds was the highest in the pure vetch crop (79.39%). A large share of weeds in a pure crop of vetch is a consequence of later sprouting and dead vetch stem in 2022. Weeds have taken over the surface of the soil and overgrown the vetch. The lowest share of weeds was recorded on the variant with oats in pure sowing. On the variants with combined sowing of vetch and oats, a significantly lower share of weeds was recorded compared to the pure vetch stand. In treatments A3 and A4, the share of weeds was significantly lower compared to the pure vetch crop. Treatment A4 had 7.52% weeds and treatment A3 20.27% weeds, and they did not differ significantly for this trait. Simić *et al.* (2018) also came to similar research. Intercropping, i.e. growing crops in a mixture, is a good measure to reduce weediness (Dolijanović and Simić, 2015).

Oats had favorable conditions for growth and development in 2022 and sprouted before the weeds and suppressed the weeds with their further intensive growth. For this reason, there are the fewest weeds in the pure oat crop. As the share of oats in the mixture increased, the share of weeds decreased.

Conclusion

Based on one year results (2022), forage and hay yield on varieties with pure crops and mixtures did not differ significantly. The share of weeds in hay was the highest in the pure crop of vetch, the lowest in the pure crop of oats, and in the mixtures it was significantly lower compared to the pure crop of vetch. The number of weed plants was the highest in the pure crop of vetch, and lowest in the pure crop of oats and in varieties with 50%+50 vetch and oats in both counts. The lowest share of weeds was recorded on the treatment with 50% of vetch and oats. Cultivation of intercropping leguminous and grain crops can provide numerous advantages, such as: increased biomass yield and adequate utilization of land resources, increased yield stability as well as more effective control of crop weediness.
Because, both crop production and weed infestation depend in a high level of the meteorological conditions of the year, the investigations will continue in next years.

Abstract

The maize cultivation trial was conducted at the Research and Experimental Field "Radmilovac" of the Faculty of Agriculture in Belgrade in 2022 on the soil type luvic chernozem in completely randomized blocks. The cropping system included tillage with a disk harrow at 25-30 cm with complete incorporation of winter wheat crop residues and tillage with a harrow before sowing. Basic fertilizer was applied in the fall at 500 kg ha^{-1} NPK (15:15:15). The following microbiological fertilizers were used for top dressing in spring: Biofertilizer ("Slavol", manufacturer "Agrounik" Serbia) with 5 l ha^{-1} in two treatments and Eko lame with 10 l ha^{-1} in 3 treatments. The top dressing in the control variant was done with nitrogen fertilizer AN at the rate of 60 kg ha^{-1} N. Maize varieties (ZPSC 666) were used. The maize was grown in a six crop rotation. Statistical analysis confirmed that top dressing had a greater effect on morphological, productive characteristics and grain yield of maize. The highest grain yield was achieved in the variant with the “Eko Lame” fertilizer (5900 kg ha^{-1}) and the lowest in the control treatment (3500 kg ha^{-1}). The differences achieved were statistically very significant. In addition to the analysis of the grain yields obtained, a similar trend was found by comparing the morphological and productive characteristics of the maize plants obtained. The correlation-regression analysis of the obtained data showed a statistically positive dependence of the grain yield on the height of the plant, the length and width of the maize cob, and on the mass of grains per plant and the kernel weight.

Keywords: fertilizer, yield, maize, top dressing.

Introduction

Maize (*Zea mays* L.) is the most important cereal in Serbia in terms of agriculture. In Serbia, maize was cultivated on an area of 923 thousand hectares with a production of 6.6 million tons and an average productivity of 7200 kg ha^{-1} in recent years. Compared to the ten-year average (2013-2022), maize production is 5.0% higher. In Serbia, maize productivity is low compared to global productivity, which is due to several limiting factors. Among other things, weed infestation and poor weed control methods lead to yield losses. In addition, the timing of sowing and the selection of maize hybrids should be better coordinated, especially taking into account climatic changes. Adhering to the principles of crop rotation and increasing the frequency of cultivation have an invaluable positive impact (Dolijanović et al., 2017). The reduction in soybean acreage and the lack of another, alternative crop for the simplest three-field rotation has an impact on the decline in yields of maize and also winter wheat.

One of the most important issues in modern maize cultivation is the question of fertilizer selection and application. This agrotechnical measure must first and foremost be adapted to the type and quality of the soil, the selected hybrid and the intensity of production. The role of

mineral fertilizers and manure is invaluable. As there is less and less liquid manure in recent times, the use of microbiological fertilizers is a rational solution. They play a key role in the mineralization of organic compounds, the mobilization of poorly soluble inorganic compounds as well as in the supply of nutrients to plants and in yield formation. To feed the growing population, the increase in grain production depends critically on the supply of chemical fertilizers that can compensate for nutrient deficiencies (Zhang et al., 2019). However, the excessive use of chemical fertilizers can reduce nutrient use efficiency and potentially lead to soil acidification (Guo et al., 2010), eutrophication (Zhang et al., 2011), greenhouse gas emissions and N leaching (Li et al., 2016). Previous research has shown that the use of microorganisms in crop production increases the accessibility and efficiency of nutrients, which can reduce the need for mineral fertilizers by 50% without reducing crop yield (da Costa et al., 2013). Microbial fertilizers help plants to grow healthy and stay strong as they contain fertilizers and beneficial microorganisms. Microbial fertilizers (MF), also known as organic fertilizers, are environmentally friendly as they are mainly composed of food and agricultural wastes (animal manure, straw, etc.) and beneficial microorganisms (Sahin and Yilmaz, 2023).
The aim of this work is to investigate the effect of microbial fertilizers (by seed and foliar treatments) on grain yield and yield components of maize, in addition to the basic fertilizer applied in autumn.

Material and methods

The trial on maize cultivation with low-input technology was conducted in 2022 at the research and experimental field "Radmilovac" of the Faculty of Agriculture of the College of Belgrade (Serbia) on the soil type luvic chernozem in completely randomized blocks. The cropping system included tillage with a disk harrow at 25-30 cm with complete incorporation of the previous crop residues and tillage with a harrow before sowing. The basic fertilization was carried out in autumn with 500 kg ha^{-1} NPK (15:15:15). The following microbial fertilizers were used for top dressing in spring: Biofertilizer ("Slavol", manufacturer "Agrounik" Serbia) with 5.0 l ha^{-1} in two treatments and Eko lame 10 l ha^{-1} in three treatments. Top dressing in the control variant was carried out with the nitrogen fertilizer AN at a rate of 60 kg ha^{-1} N. The maize varieties (ZPSC666) were used. Cultivation was carried out in a six-crop rotation (winter wheat-maize-summer barley+red clover-red clover-soybean-sunflower). Maize was sown on April, 15. The size of a one-year crop rotation field (field) was about 10 ares.
The application of microbial fertilizers and herbicides in maize cultivation was carried out according to the schedule shown in Table 1. The seeds were treated 24 hours before sowing and the other treatments were applied over the leaves using a hand sprayer designed for this type of experiment.

Table 1. Schedule of application of microbiological preparations and application of herbicides

Preparation/ Date	Seed treatment	First treatment-foliar	Weediness evaulation	Herbicide	Second treatment -foliar	Third treatment-foliar
Eko lame	14.04.	17.05.	30.05.	31.05.	03.06	17.06
Slavol	14.04.	17.05.	30.05.	31.05.	03.06	-

For study of the morphological and productive characteristics of maize, on each treatment the samples of 10 maize plants were taken on September 13. These plants were used for

analysis the stalk height, cob diameter, number of rows of grains in the cob, number of grains, cob length, weight of 1000 seeds, grain yield per plant and per unit area (per ha).
The data obtained were statistically evaluated using analysis of variance and correlation analysis with the Pearson coefficient, taking into account the microbial fertilizers as factors, while the LSD test was used for the individual comparisons.
The meteorological conditions during the growing season of maize, especially the optimum average air temperatures, had a significant effect on the formation of high yields. The data in Table 2 show that low rainfall in May and June had an impact on yield reduction this year. The higher rainfall in September had an effect on later ripening and higher moisture content of maize grains in varieties without microbiological fertilization.

Table 2. Average air temperatures and amount of precipitation from April to September at Radmilovac

Months	Temperature (°C)	Precipitation (mm)
April	12.3	80.1
May	20.3	32.2
June	24.8	43.3
July	25.8	63.9
August	25.0	89.7
September	18.0	98
Average/Sum	21.03	407.2

Results and discussion

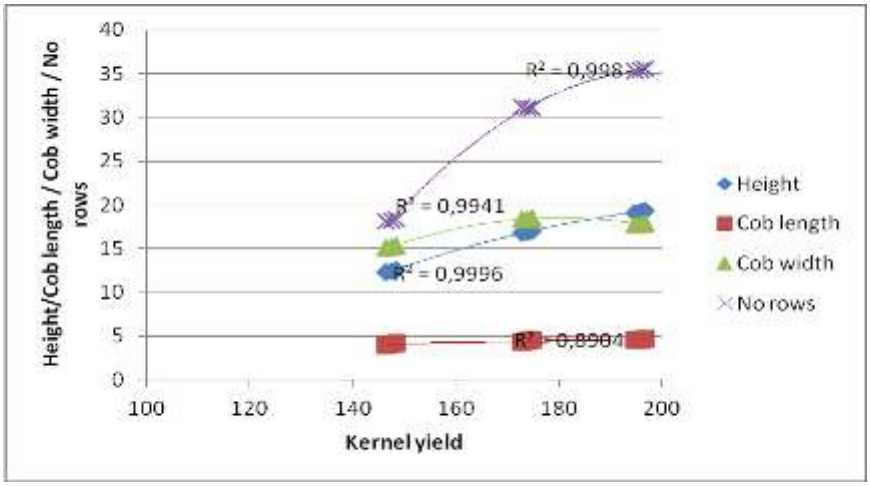
Based on the data on the influence of the studied preparations on the morphological and productive characteristics of maize plants , we can see that the application of the preparations influences the increase in the value of all the studied characteristics (Table 3). It can be seen that all investigated traits were statistically significantly or very significantly different in the fertilizer application variants compared to the control variant. The growth and development of maize plants is partly determined by the activity and abundance of microorganisms introduced into the rhizosphere by fertilizers (Wang et al., 2024), as well as by the application of microbiological foliar fertilizers. The results showed the lower moisture content of the grain when using the Eko-Lame preparation, what is important advantage for easier storage, a lower risk of storages diseases and pests, as well as for reduction in the cost of drying the grain.

Table 3. The influence of investigated microbiological fertilizers on the morphological and productive properties of maize

Parameters/Treatments	Control	"Eko Lame"	Slavol	Average
Plant height (cm)	147.4[a]	195.7[c]	173.8[b]	172.3
Cob length (cm)	12.4[a]	19.2[c]	16.9[b]	16.2
Cob width (cm)	4.1[a]	4.6[c]	4.4[b]	4,4
No of rows of grain in the cob	15.2[a]	17.8[b]	18.4[c]	17.1
No of grains in the row	18.2[a]	35.4[c]	31.1[b]	28.2
Grain weight per plant (g)	53.6[a]	151.7[c]	121.3[b]	108.9
Mass applause (g)	11.5[a]	29.3[c]	24.8[b]	21.9
Weight 1000 seeds (g)	227.1[a]	254.8[b]	250.7[b]	244.2
Seed moisture (%)	16.9[a]	16.3[a]	18.5[b]	17.2
Grain yield (kg/ha)	3500[a]	5900[c]	4900[b]	4767

Values of means followed by the same letter are not significant.

All morphological and productive characteristics of the maize plants showed higher values when using the Eko Lame preparation compared to Slavol, although the number of treatments, which is higher with the first preparation, must also be taken into account. Grain yield, the most important parameter in this study, was statistically significantly increased by the application of microbiological fertilizers (Table 3). In a study on the inoculation of maize with nine Azospirillum strains, a yield increase of 24–30 % was observed (Hungria et al., 2010), with an increase in maize grain yield of 17 (Cavallet et al., 2000) and 20-21 % (Zambrano Gavilanes et al., 2023). In the research Pacheco et al. (2021), was found that microbial inoculants under field conditions, clearly showed that microbial inoculants increased maize productivity while improving P (Phosphorus) use efficiency and reducing P concentration in the grain. Furthermore, the use of these microbial inoculants proved to be compatible with conventional agricultural management practices. This is very important as rock phosphate (a high quality P source used in conventional agriculture) is a non-renewable, finite resource whose reserves are rapidly being depleted, so prices are expected to increase dramatically in the near future (Dias et al., 2015).
The correlation analysis revealed a statistically very high dependence of maize grain yield on the height of the maize plants and the length and width of the maize cob (Figure 1). Only developed maize plants with a growth habitus that can carry a large ear or even two ears can guarantee grain yields in the field that come close to the genetic fertility potential of these hybrids. In the experiments, Srećkov et al. (2023) found the strongest interdependence between grain yield and the number of grains in a row and, for the other traits studied, between ear length and the number of grains in a row.



Graph 1. Correlation-regression analysis of certain characteristics of maize

Conclusion

The results of this work show that microbial fertilizers have a positive effect on the tested characteristics of maize in a dry climate without irrigation. Microbial fertilizers which were used contain microbes that promote plant growth at the beginning of the growing season and increase grain yield. The applied microbiological fertilizers in in one-year research showed a positive effect on increasing grain yield on treatment with Eco-lime (5.900 kg ha^{-1}) on treatment with Slavol (4.900 kg ha^{-1}) in comparison to control (3.900 kg ha^{-1}), In this study established that grain yield of maize the mostly varied in dependance to the height of the maize plant and the length and width of the cob.

Acknowlegdement

The work was created within the framework of the "Agreement on the transfer of funds to finance scientific research work by teaching staff at accredited Universities in 2024, file number of the agreement: 451-03-65/2024-03/200116".

Abstract

The yield of medicinal plants and the quality of their active compounds are influenced by various factors, including soil composition and nutrient content. The extent of yield increase depends on soil fertility, which can be enhanced with fertilizers. The aim of this study was to evaluate the effect of applying a nitrogen fertilizer based on ammonium thiosulfate on qualitative properties of selected plants. The content of chlorophyll *a*, chlorophyll *b*, chlorophyll *a/b*, and essential oils was investigated in selected spice and aromatic plants, including *Mentha* × *piperita* 'Danica', *Ocimum basilicum* 'Dark Green', and *Melissa officinalis*. All selected species were grown in two variants: the Control variant was grown without the use of fertilizer, and the ATS variant, where a nitrogen fertilizer based on ammonium thiosulfate was applied. The fertilizer was applied to the soil in two repetitions at a dose of 2x 6 ml/m². Two harvests were conducted, and the content of chlorophyll *a* and *b* in the fresh biomass was determined spectrophotometrically, while the content of essential oils in the dry biomass was determined by steam distillation. Results suggest that the application of nitrogen fertilizer did not significantly affect the levels of chlorophyll *a*, chlorophyll *b*, or essential oils. The experiment was a part of a larger research project that primarily examined indicators of crop yields when nitrogen fertilizer was applied. The findings serve as the foundation for prospective future scientific research, from the perspective of quality parameters.

Keywords: *mint, basil, lemon balm, ammonium thiosulfate, chlorophyll a, chlorophyll b, essential oil.*

Introduction

Aromatic plants and their bioactive compounds have been utilized for thousands of years in traditional medicine, and contemporary efforts persist to study and apply them in pharmacology (Rasool et al., 2020). For centuries, humans have depended on aromatic plants for sustenance, flavouring, and healing. Various parts of these plants—seeds, leaves, flowers, fruits, stems, and roots - are rich in bioactive compounds, offering significant therapeutic properties (Sun and Shahrajabian, 2023). Aromatic plants not only enhance the flavour and aroma of food and aid in preservation but also possess medicinal properties (Gonçalves et al., 2020). They contain essential oils, phenolic compounds, fibre, vitamins, and minerals (Fierascu et al., 2021). The family *Lamiaceae* comprises more than 7,000 plant species. Many of these plants contain valuable essential oils and include medicinal, aromatic, honey-producing, and ornamental species (Khoury et al., 2016). *Mentha* × *piperita* 'Danica', *Ocimum basilicum* 'Dark Green', and *Melissa officinalis* all belong to this plant family. There are many factors which can influence the yield of herbs and a quality of content substances, such as soil structure and a content of nutrients. The extent of yield increase depends on soil fertility which can be increased by the usage of fertilizers (Kováčik, 2013). Fertilization and nutrition of spice, aromatic, and medicinal plants require a specific approach due to differences in cultivation methods, duration, and nutrient requirements throughout their growth period. Important principles include considering agroecological conditions and individual plant nutrient needs, calculating fertilizer doses based on soil chemical analysis, and protecting soil quality and the environment. Factors such as soil type, rainfall, and soil pH must also be considered. Fertilizers should be applied no later than six weeks before harvest for medicinal plants (Habán et al., 2013). Industrial fertilizers, made chemically or physically from mineral raw materials, provide essential nutrients that improve soil fertility, yield, and product quality. These nutrients are present in various inorganic or organic compounds in different forms, concentrations, and ratios, contributing to better quality, longer shelf life, disease resistance, and resilience to adverse weather conditions (Varga and Ducsay, 2015). Fertilizing medicinal herbs with nitrogen (N) and sulphur (S) is essential for their optimal growth and development. Nitrogen is crucial for the formation of leaves and biomass, as it is a key component of chlorophyll (Habán et al., 2013). Symptoms of nitrogen deficiency include stunted growth, thin stems, yellowing leaves, and reduced chlorophyll and protein synthesis (Kalina, 2005; Varga and Ducsay, 2015). Sulphur is essential for amino acids and protein synthesis (Kováčik, 2013). Fertilizers combining both nutrients are often used to meet the plants' simultaneous needs for nitrogen and sulphur, ensuring better flavour, health value, and overall quality of the herbs (Kalina, 2005). This study aims to determine the effect of ammonium thiosulfate-based nitrogen fertilizer application on the content of chlorophyll *a*, chlorophyll *b*, chlorophyll *a/b*, and essential oils in selected spice and aromatic plants, including *Mentha* × *piperita* 'Danica', *Ocimum basilicum* 'Dark Green', and *Melissa officinalis*.

Material and Methods

Plant material

In this study, three species of aromatic plants were cultivated: *Ocimum basilicum* 'Dark Green', *Mentha* × *piperita* 'Danica' and *Melissa officinalis*. The seeds were purchased from the company Semo, the mint seedlings were taken from cultivar collection of Botanical Garden, SUA in Nitra.

Fertilizer characterization

The ammonium thiosulfate-based nitrogen fertilizer used in this study is a liquid containing sulphur, characterized by a clear to yellow-brown colour. According to Stercorat company, this fertilizer comprises of ammonium thiosulfate, bisulphite, sulphate, and water, with at least 11% of total nitrogen content, 11% of ammoniacal nitrogen, and 25% sulphur by weight. With a pH of 6.5-7.8, it provides rapidly absorbable ammoniacal nitrogen and dual oxidation state sulphur, ensuring optimal plant availability. The fertilizer decomposes to provide both immediate and sustained sulphur supply. Recommended application rates are 15-230 litres per hectare annually, and it can be applied via foliar spray, band placement, pre-plant soil preparation, furrow irrigation, drip irrigation, or hydroponics. For medicinal, aromatic, and ornamental plants, the suggested dosage is 30-60 litres per hectare. The goal is to enhance yield, durability, and plant vitality (Stercorat, 2016).

Characterization of an experimental site soil and climatic conditions

The Nitra region is located in the southwestern part of Slovakia in the Danubian Lowland. It is known for its high-quality soil types and subtypes, including brown soils, chernozems, black soils, and fluvisoils, making it one of the most productive agricultural areas in Slovakia. It has a warm climate with long, hot, dry summers and short, mild, dry winters, making it one of the warmest and driest areas in Slovakia. Average annual precipitation ranges from 500-600 mm, and the average annual temperature is around 9-10°C (Hreško, 2006). Soil samples were taken in spring 2019, showing in Table 1 a medium nitrogen content, and given the nitrogen fertilizer testing, no additional fertilization was applied.

Table 1: Soil analysis of the experimental area

	pH	Nan	Nutrient content ($mg.kg^{-1}$) (Mehl.III)					Cox (hummus)
		$mg.kg^{-1}$	P	K	S	Ca	Mg	%
2019	6.89	13.0	77.5	495.0	5.0	5200	964.0	3.85

The data of climatic conditions (Table 2) monitored at the experimental site for 2019 were provided by the Institute of Landscape Engineering of Slovak University of Agriculture in Nitra using meteorological station.

Table 2: Evaluation of temperature and precipitation during experiment according to air temperature and climatic normal 1961 - 1990

Month	Temperature 1961 - 1990 [ºC]	t [ºC] 2019	Characteristic – 2019	Precipitation 1961 – 1990 [mm]	Precipitation 2019 [mm]	Characteristic - 2019

VIII.	19.7	22.3	very warm	54.2	83.7	very wet

Plant cultivation and fertilization

Sowing and cultivation of seedlings took place in the greenhouses of University Botanical Garden. The cultivation was carried out on small experimental plot located in demonstration garden of Institute of Horticulture, Slovak University of Agriculture in Nitra in 2019. Basil was sown on March 21st. Seedlings were transplanted into pots on April 3rd, and later planted outdoors on May 27th. Plants were spaced 35 x 40 cm apart. Mint was planted on May 27th, from separated cuttings rooted plant spaced 30 x 30 cm apart. The plot with lemon balm plants spaced 30 x 30 cm apart was fixed up on April 16th. Dried parts of the plants were removed, and the soil was loosened to remove weeds. During the growing season, the plot was managed as needed to remove weeds and soil crust. The crop was irrigated as necessary in the early morning hours. The first application of nitrogen fertilizer to the selected plants was carried out on June 3rd, at a dose of 6 ml/m². After the first harvest, the second application of nitrogen fertilizer was conducted on July 4th, at a dose of 6 ml/m².

Plant harvest and postharvest processing

The two-phase harvest of aboveground parts was carried out manually. The first harvest was conducted on July 3rd at the beginning of flowering, with plants being trimmed approximately 10 cm above the soil surface. The second harvest was performed on August 12th. After harvesting, individual plant species were weighed, and the chlorophyll content was determined from average samples. The remaining samples were then spread out on screens and air dried at room temperature. Well-dried foliage was used for essential oil content analysis.

Determination of chlorophyl *a* and *b* content

These analyses took place in the premises of the Institute of Horticulture and at the AgroBioTech Research Centre in Nitra. An average 1 g sample of fresh plant material was prepared and homogenized in small amount of acetone (80 %) (Heidolph Silent Crusher M, Heidolph Instruments, Schwabach, Germany). After homogenization, the acetone extract was carefully filtered using the fritted glass filters S4. The prepared extract was quantitatively transferred into the volumetric flask (50 mL) and filled with acetone to the final volume. The intensity of extract colour was measured at 649 nm for chlorophyll *a* and at 665 nm for chlorophyll *b* (spectrophotometer, PHARO 200, Spectoquant, Darmstadt, Germany). The zero position was controlled by pure acetone at 750 nm wavelength. The possible dispersion value was deducted from individual absorbance values. The calculation of chlorophyll content was performed according to Hegedűsová et al. (2018).

Determination of essential oils content

This analysis was carried out by distillation with water vapour. Before the distillation, the dry drug of the plants is grinded into smaller fractions and 20 g sample is weighed and then transferred into distillation flask with distilled water and brought up to a boil when the distillation begun. 10 minutes after the volume of distillate was consistent the heating was turned off and the essential oils content in splitting funnel is counted. The essential oil content is calculated according to Hegedűsová et al. (2018).

Statistical analysis

A statistical analysis was performed by using of the Statgraphics Centurion XVII (StatPoint Inc., The Plains, VA, USA). Obtained results were evaluated by analysis of variance (ANOVA), and average values were tested by the least significant difference (LSD) test performed at the significance level of 95 % (at $p < 0.05$).

Results and Discussion

Chlorophyll *a* and *b* content

The average values of chlorophyll *a* and *b* content in tested plant species, are shown in Table 3. The highest chlorophyll a content (102.13 mg/100g) was found in *Mentha* × *piperita* 'Danica' in the first harvest with ATS fertilizer, while the lowest (34.60 mg/100g) was in *Ocimum basilicum* 'Dark Green' with ATS in the first harvest. The highest chlorophyll *b* content (65.32 mg/100g) was measured in *Mentha* × *piperita* 'Danica' in the second harvest with ATS, while the lowest (14.79 mg/100g) was in *Ocimum basilicum* 'Dark Green' in the first harvest with ATS. The only significant difference in chlorophyll *b* content was measured in *Mentha* × *piperita* 'Danica' in second harvest with ATS treatment. Gažíová (2019) found no significant effect of ATS on leaf chlorophyll *a* or *b* content, a finding confirmed by our results for soil-applied nitrogen fertilizer. Polyticka and Goldz (2002) reported nitrogen fertilizers affecting chlorophyll content, but our data did not support these findings. Csámpai (2018) noted higher chlorophyll *a* in the first harvest of *Ocimum basilicum* 'Dark Green', with our results showing slightly higher levels in the second harvest.

Table 3. Chlorophyll *a* and *b* content [mg/100g fresh weight]

Species	Chlorophyll *a*				Chlorophyll *b*			
	1st harvest		2nd harvest		1st harvest		2nd harvest	
	Control	ATS	Control	ATS	Control	ATS	Control	ATS
Ocimum basilicum	39.63 ± 1.83a	34.60 ± 3.17a	40.63 ± 0.08a	44.39 ± 1.11a	17.15 ± 0.56b	14.79 ± 1.30b	18.54 ± 0.97b	20.17 ± 1.02b
Mentha × *piperita*	97.98 ± 16.98a	102.13 ± 9.24a	73.16 ± 3.20a	76.52 ± 0.07a	55.09 ± 9.85c	57.27 ± 6.10c	51.87 ± 6.68c	65.32 ± 2.52**b**
Melissa officinalis	59.58 ± 1.31a	59.84 ± 11.34a	60.77 ± 0.99a	59.71 ± 3.46a	30.21 ± 0.57b	34.32 ± 6.00b	31.40 ± 0.07b	31.28 ± 2.23b

*a, b - Different letters in a **row** indicate a statistically significant difference*

The chlorophyll *a/b* ratio is a critical indicator of plant stress and damage, with a lower chlorophyll *a* content suggesting greater plant damage (Paučová, 2019). Our measurements (Table 4) showed the highest chlorophyll *a/b* ratio in the Control variant of *Ocimum basilicum* 'Dark Green' during the first harvest (2.31 mg/100g). The lowest ratio was in the ATS variant of *Mentha* × *piperita* 'Danica' during the second harvest. Polyticka and Goldz (2002) found that chlorophyll *b* content in *Ocimum* species is half that of chlorophyll *a*, which was confirmed by our data. The ATS variant's chlorophyll *a/b* ratio was lower or equal to the Control. Statistical analysis showed these differences were not significant, suggesting minimal plant damage from nitrogen fertilizer. The only significant difference, confirmed statistically, was in *Ocimum basilicum* 'Dark Green,' with a 16% decrease in the ATS variant.

Table 4. Ratio of chlorophyll *a* and *b* content in fresh weight

Species	**1st harvest**		**2nd harvest**	
	Control	**ATS**	**Control**	**ATS**
Ocimum basilicum	2.31**a**	1.94b	2.19a	2.2a

Content of essential oils

The average essential oil content for both variants in both harvests is shown in Table 5. *Mentha* × *piperita* 'Danica' had the highest essential oil content at 2.85% in the first harvest with nitrogen fertilizer, while the lowest content was 0.18% in *Melissa officinalis* in the first harvest with ATS application. The only statistically significant difference (0.91%) was in *Mentha* × *piperita* 'Danica,' with the Control variant containing 1.94% and ATS 2.85% essential oils in the first harvest. Other species showed minimal differences.

Table 5. Content of essential oils in dry weight [%]

Species	**1st harvest**		**2nd harvest**	
	Control	**ATS**	**Control**	**ATS**
Ocimum basilicum	0.54 ± 0.05a	0.68 ± 0.18a	0.59 ± 0.06a	0.54 ± 0.00a
Mentha × piperita	1.94 ± 0.09**b**	2.85 ± 0.02a	2.72 ± 0.03a	2.70 ± 0.00a
Melissa officinalis	0.20 ± 0.02a	0.18 ± 0.00a	0.29 ± 0.10a	0.29 0.03a

a, b - Different letters in a ***row*** *indicate a statistically significant difference*

Gažíová (2019) found no significant changes in essential oil content with ATS, confirmed by our soil application results. Hussain et al. (2008) noted that harvest timing influenced essential oil content in mint, with higher content in the first harvest (May, 23°C) compared to the second harvest (November, 18.5°C), decreasing from 12.2 g/kg to 10.5 g/kg in *Mentha* × *piperita*. In a study by Ostadi et al., it was found that the highest essential oil content (2.7 %) was present in the first harvest of plants treated by 50% chemical fertilizer in combination with nano chelated fertilizer. The lowest essential oil content (1.4 %) was determined in plants with no fertilizer treatment in the second harvest (Ostadi et al., 2020).

Conclusions

This study was a part of an extensive body of work that was mainly concerned with qualitative factors and found that, in the case of the studied species, nitrogen fertilizer was beneficial. Producers of fertilizer were also curious about any impact it might have on qualitative criteria that are economically significant. The study in two harvests show that the effect is variable and does not reach statistical significance.

Abstract

The research aim was the evaluation of biostimulants (Agriful, Tecamin Max and Tecamin Brix) effect on selected qualitative and quantitative properties of six varieties of highbush blueberry (Duke, Huron, Draper, Bluecrop, Calypso a Liberty). The study was carried out during the growing season of 2023 in the planting of the Botanical Garden in SAU Nitra, Slovakia. It can be concluded that the application of biostimulants caused a statistically evident increase in total yields on average by 87.2%. The increase occurred due to the increase in the number of fruits, while the length and weight of the fruits did not change. Furthermore, we can state that the application of biostimulants under given conditions did not have a demonstrable effect on the change of most of the measured quality indicators, except the content of malic acid, the content of total acids and the pH value. These three indicators are significantly correlated with each other. Since malic acid makes up approximately 90% of the content of total acids, we can conclude that the decrease in its content, as well as the decrease in the content of total acids, was caused precisely by the application of biostimulants, which resulted in a lower production of secondary metabolites (in this case malic acid), which are formed during cellular stress. Biostimulants created a situation in the plant where the level of stress hormones was apparently lower and did not force the cells to defend themselves by producing secondary metabolites and therefore also malic acid.

Key words: *blueberry, biostimulant, total yield, malic acid.*

Introduction

Blueberries are deciduous shrubs of the genus *Vaccinium* (family Ericaceae; subfamily Vacciniaceae). The genus *Vaccinium* comprises about 450 species, including cranberry (*V. macrocarpon* Ait.), bilberry (*V. myrtillus* L.), lingonberry (*V. vitis-idaea* L.), and huckleberry (*V. parvifoium*), which are valued for their sweet flavoured and nutrient-rich fruits (Song 2012). Berries with the highest nutritional density is the blueberry, which is rich in antioxidants, fiber, and vitamins. Flavonoids and phenolic acids are an extensive group of compounds with functional effects that decrease the risk of heart disease, diabetes, and cognitive impairment. (Silva 2020, Tobar-Bolanos 2021, Kalt 2020).
It is commonly acknowledged that blueberry production and sales will continue to rise gradually for the foreseeable future due to the health advantages of blueberries and their increased demand worldwide. (Yue 2017, Gallardo 2018).
Enhancing the nutritional quality of fruit by adding more bioactive chemicals is another major goal (Mezzetti 2016). Environmental elements like light, temperature, and water availability have a big impact on this (Xu 2019, Pinto-Morales 2022). Knowledge of the environmental factors and growing conditions that positively influence bioactive accumulation will provide an opportunity to develop agronomic practices that can enhance the nutritional quality of blueberry fruits (Krishna 2023). Prior research has demonstrated that growing blueberries

without fertilizer results in essentially nonexistent yields; as such, fertilization is required to guarantee sufficient output. (Ciucu Paraschiv 2023).
Substances or microorganisms that support and defend the physiological functions of plants are known as biostimulants (du Jardin 2015); while elicitors induce physiological defence responses in plants (Ali 2021). Upon detecting the signals, plants initiate cellular pathways to expedite the synthesis of chemicals and enzymes associated with antioxidant capability, consequently elevating the concentration of health-promoting bioactive substances (Mannino et al. 2021; Teklić et al. 2021).
The positive impact of organic fertilizers on the physical, chemical, and biological characteristics of soil and crops has been demonstrated by several studies (Manea et al., 2019, Khan et al., 2020, Wajid et al., 2020). In addition to enhancing soil quality, biostimulating substances have an indirect impact on plant physiology and metabolism. Seaweed extract-treated plants have stronger growth and a better-developed root system that allows for more widespread nutrient uptake. They also absorb and assimilate nutrients more quickly than untreated plants. (Lenart 2023). According to Van Oosten et al. (2017) biostimulants aid in the proper utilization of water and minerals by plants, promote their growth, and mitigate the effects of abiotic stressors.
The specialty crop business is very interested in using biostimulants such as natural seaweed extracts and humic compounds (fulvic and humic acids) to increase plant development and yield. This is especially true in the cultivation of blueberries (*Vaccinium* sp.) (Vargas, 2015).
Due to their role as signaling mediators, elicitors and/or biostimulants can produce stimuli that increase the concentration of bioactive substances without compromising quality and production. (du Jardin 2015; Ahmad et al. 2019; Ali 2021).

The aim of the study was to evaluate the effectiveness of the selected biostimulants (Agriful, Tecamin Max and Tecamin Brix) on the selected qualitative and quantitative properties of blueberry (*Vaccinium cormybosum*) in growing season 2023.

Material and Methods

The implementation of the study was carried out during the growing season of 2023 in the semi-productive blueberry-planting of the Institute of Horticulture, FHLE SAU in Nitra, Slovakia. The planting was carried out in the spring of 2022. The plants are planted in containers with a diameter of 0.5 m and embedded in the ground in their entire volume. The spacing is 4.0x1.0m. The space in the row is mulched with chips from conifers, any weeds were removed mechanically. The interrows are sown with a special mixture of grasses designed for intensive fruit orchards and, as needed, were mowed several times per vegetation after reaching a height of 0.2-0.3m. The plants were irrigated by drip irrigation from its own well. Irrigation hoses are placed on the surface of the soil and are doubled. The intensity of irrigation is 2.3 l/hour, the spacing of the drippers is 0.5 m. Irrigation was started automatically (Irritrol Total Controll-R TC15EX-R, Riverside, California, United States) according to a predetermined schedule.
There are a total of 6 varieties in planting, Duke, Huron, Draper, Bluecrop, Calypso and Liberty. The number of plants in a row from one variety is 20, except for the Calypso variety, which has 10. The application of biostimulants was on 10 plants and the remaining 10 plants served as a control. Varieties are planted and arranged in the planting according to the date of ripening, from the beginning of July (Duke) to the beginning of September (Liberty). Within the objectives, the following parameters was measured after harvest: fruit size, fruit weight, total sugars, total acids, total soluble solids, glucose, fructose, malic acid, pH level.

Three commercial biostimulants were used. Agriful (Agri Tecno Brand, Spain) - containing 25% fulvoacids, 45% other organic substances, 4.5% nitrogen, 1% phosphorus and 1% pottasium. Tecamin Max (Agri Tecno Brand, Spain) - 14.4% aminoacids, 12% free L-aminoacids, 7% nitrogen, 60% organic compounds. Tecamin Brix (Agri Tecno Brand, Spain) – 10% sea algae extract, 18% potassium, 0.2 boron, aminoacids.
According to the plan, Agriful was applied by watering in the number of 6 times and a dose of 50ml/10l of water, Tecamin Max was applied by spraying in the number of 3x in a dose of 30ml/10l of water and Tecamin Brix was applied also by spraying in the number of 3x in a dose of 30ml per 10l water. The spray was applied using a Stihl SR 200 back-mounted motorized sprayer. The application date was determined according to the weather from the end of April to the beginning of July. The dosage was determined based on an agreement with the sponsor of the study. Harvesting of the fruits was done gradually, according to the ripening of the fruits. We picked all the fruits from each bush, the harvest was done once.

Results and Discussion

All applications were applied according to the plan, there was no major disruption to application plans. All applications were implemented from 26.4.2023 to 6.7. 2023. The sprays were applied when there was no wind, or with only a very light wind. The temperature during application was from 11 to 18°C. The time of application was in the morning, the weather was clear to partly clear.
The harvest dates were as follows: Duke, 10.7., Huron 17.7., Draper 1.8., Bluecrop 21.8., Calypso 28.8. and Liberty 4.9.2023.
Table 1 shows the average harvests from 10 bushes . We would like to remind, that this is a planting in the first year after planting, so, of course, the yields are lower than with in full-bearing period. In addition, no fertilizers were applied, either by watering, spraying, or fertigation, in order to eliminate as many influences as possible outside of biostimulants. We can state that the yield increase depending on the varieties was from 31.8 to 178.5%, on average 87.2%. The yield increase was statistically significant for all varieties ($p < 0.05$).
In agriculture, these biostimulants are widely used as soil supplements, and they usually work best when combined with fertilizers. Unfortunately, the majority of research on biostimulants has been conducted on annual crops, which has left a gap in our knowledge of their full potential when it comes to perennial crops like blueberries. Previous research found that applying humic materials to blueberries increased plant growth in the first two years after planting (Vargas, 2015).

Table1. Results of quantitative indicators after the application of biostimulants.

Variety	**Total yields**			**1 berry diameter**		**1 beery weight**	
	control	**biostimulants**	**increase**	**control**	**biostimulants**	**control**	**biostimulants**
	(g)	***(g)***	***(%)***	***(mm)***	***(mm)***	***(g)***	***(g)***
Duke	1184	2338	97.5	13.5	12.9	1.32	1.13
Huron	480	1337	178.5	12.6	14.2	1.06	1.54
Draper	936	2015	115.3	14.5	14.2	1.63	1.52
Bluecrop	1197	1940	62.1	13.5	11.2	1.33	1.2
Calypso*	546	753	37.9	12.5	14.6	1.54	1.44
Liberty	1861	2453	31.8	13	11.8	1.23	1.11
priemerné zvýšenie			**87.2**	**Ø 13.3**	**Ø 13.1**	**Ø 1.35**	**Ø 1.32**

By variety Calypso the data were from 5 bushes.

When evaluating the average diameter and weight of the berries, we can state that the application of biostimulants did not result in a statistically significant increase in the length and weight of the berries. The reported differences are not statistically significant ($p < 0.05$).
Humic acids did not improve blueberry root growth, fruit yield, or fruit quality (Nunez 2023). Growers are increasingly interested in using humic acid (HA) for blueberry production. However, previous research describing blueberry responses to HA applications is scarce. In 'Legacy' northern highbush blueberry (NHB, Vaccinium corymbosum), HA application did not affect root growth, shoot growth, fruit yield, or fruit quality (Shoebitz et al., 2016; Shoebitz et al. 2019). In contrast, HA application promoted root growth in 'Draper' NHB (Bryla and Strik, 2015). Prior research has demonstrated that growing blueberries without fertilizer results in essentially nonexistent yields; as such, fertilization is required to guarantee sufficient output. (Ciucu Paraschiv 2023).

We present the measured analytical parameters in table 2. Overall, it can be concluded that the application of biostimulants in the given characteristics did not had a demonstrable effect on the change of most of the measured indicators, except for the content of malic acid, the content of total acids and the pH value, when there was a demonstrable decrease in these indicators.

Table 2. Results of qualitative indicators after the application of biostimulants

variety/variant		**fructose**	**glucose**	**TSS**	**malic acid**	**pH**	**total acids**	**total sugars**
		(g/l)	***(g/l)***	***(°Brix)***	***(g/l)***		***(g/l)***	***(g/l)***
Duke	control	65.1	56.82	12.98	8.20	3.12	9.26	128.83
	biostimulants	65.54	56.08	12.96	6.79	3.21	7.53	129.25
Huron	control	55.91	47.53	10.82	9.45	2.99	10.89	111.08
	biostimulants	63.01	55.57	12.30	7.13	3.12	8.06	126.34
Draper	control	69.94	63.49	13.84	8.42	3.05	9.84	138.52
	biostimulants	64.22	54.17	12.25	8.46	3.07	9.55	123.62
Bluecrop	control	64.19	51.59	12.06	7.64	3.14	8.35	121.31
	biostimulants	66.74	53.21	12.53	7.01	3.22	7.43	125.54
Calypso	control	59.82	52.14	11.76	10.20	2.93	12.02	118.04
	biostimulants	64.24	55.32	12.46	7.11	3.14	7.98	126.76

The fructose content in the control variant was from 55.91g/l to 69.94g/l, while in the treated variant it was from 63.01g/l to 66.74g/l. The average fructose content in the control variant was 62.99g/l, while it was 64.75g/l in the treated variant. The measured differences within the evaluation at the species (not variety) level are not statistically significant ($p < 0.05$), therefore we can conclude that the application of the mentioned biostimulants in the mentioned concentrations and the mentioned varieties did not cause a demonstrable increase in fructose in blueberry fruits.
The results observed in the study by the author Vrhovsek et al. (2012) show that the variety Draper achieved the most significant concentrations of fructose, among other varieties, reaching a value of 82.8 g/l. This finding agrees with our own measurements
The glucose content in the control variant was from 47.53g/l to 63.49g/l, while in the treated variant it was from 53.21g/l to 56.08g/l. The average glucose content in the control variant was 54.32g/l, while it was 54.87g/l in the treated variant. The measured differences within the evaluation at the level of the species (not the variety) are not statistically significant (p <

0.05), we can therefore conclude that the application of the mentioned biostimulants in the mentioned concentrations and the mentioned varieties did not cause a demonstrable increase in glucose in the blueberry fruits.

From the studies of the authors Vrhovsek et al. (2012), the range of glucose in fruits ranges from 22.4 g/l to 48 g/l, but our research shows different values, from 47.53 g/l to 63.49 g/l. In their research, Madrera et al. (2021) identified and reported glucose content values for the variety Duke. Specifically, their study showed that the glucose content in the cranberry fruits of this variety reached a value of 35.51 g/l. These low values reported by both authors, compared to our measured higher values, we attribute to the fact that the fruits we studied were collected at a later stage of maturity. At this advanced stage of ripening, more fructose and glucose accumulate in the fruit, which also leads to a higher content of total sugars in the cranberry fruit. Zhang et al. (2020) identified in their study a range of glucose content in cranberry fruits that ranged from 33.8 g/l to 61.3 g/l. At the same time, it is important to note that these results are consistent with our own measured values.

The content of TSS in the control variant was from 10.82°Brix to 13.84°Brix, while in the treated variant it was from 12.25°Brixl to 12.96°Brix. The average content was 12.29°Brix for the control variant, while it was 12.50°Brix for the treated variant. The measured differences within the evaluation at the level of the species (not the variety) are not statistically significant ($p < 0.05$), therefore we can conclude that the application of the mentioned biostimulants in the mentioned concentrations and the mentioned varieties did not result in a demonstrable increase in the content of refractometric dry matter in blueberry fruits.

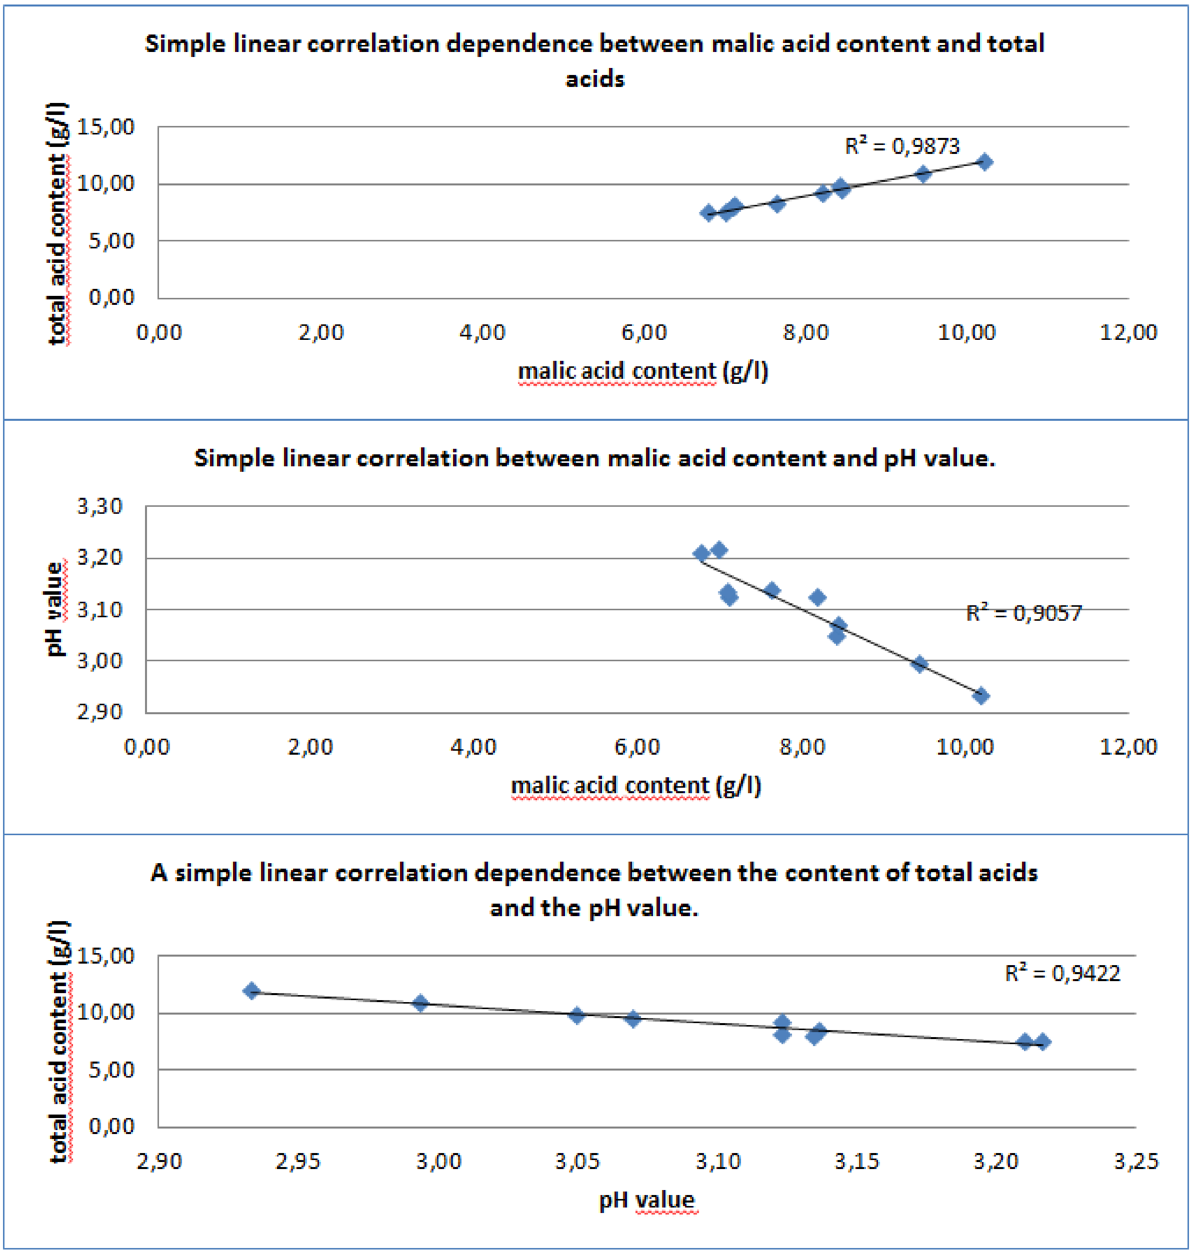
Based on our findings, it can be observed that the refractometric dry matter values obtained by us differ slightly from those reported by Zdunić et al. (2016) in their work. In this study, the range of refractometric index of dry matter of cranberries is presented in the range from 9.7 to 11.6 °BRIX. Our own measurements report data that show little deviation compared to these benchmarks. This variability can result from a variety of factors, including the genetic characteristics of the variety, environmental conditions, and measurement methods. Our study showed values that are somewhat different compared to the values of Sinelli et al. (2008), who reports an average content in cranberry fruits of 8.42 °Brix. He noted that the content of refractonic dry matter in cranberries can be higher and depends on the stage of maturity and varietal characteristics of the fruit.

The content of malic acid in the control variant was from 7.64g/l to 10.2g/l, while in the treated variant it was from 6.79g/l to 8.46g/l. The average content was 8.78g/l in the control variant, while it was 7.3g/l in the treated variant. The measured differences in the assessment at the species level are statistically significant ($p < 0.05$), we can therefore state that the application of the mentioned biostimulants in the mentioned concentrations and the mentioned varieties resulted in a demonstrable decrease in the content of malic acid in the blueberry fruits.

The decrease in malic acid content in cranberry fruits may be the result of a complex set of factors that include the genetic characteristics of a specific variety, the variability of environmental conditions and the methods used in the measurement (Vrhovsek et al., 2012). Michalska (2015) states in her study that during the ripening process of cranberries, their acidity gradually decreases, which reduces the titratable acidity. Further in his study, he claims that the dominant organic acid responsible for the acidity of cranberry fruits is malic acid.

Regarding the pH value, we can state that it was from 2.93 to 3.14 in the control variant, while it was from 3.07 to 3.22 in the treated variant. The average value was 3.05 for the control variant, while it was 3.15 for the treated variant. The measured differences in the assessment at the level of species (not varieties) are statistically significant ($p < 0.05$), therefore we can conclude that the application of the mentioned biostimulants in the

mentioned concentrations and the mentioned varieties resulted in a demonstrable change in the pH value of the blueberry fruits.
We found the highest pH in the treated variant of the Bluecrop variety with a value of 3.22 and the Duke variety with a value of 3.21. The lowest measured pH values for the control variant of the Calypso variety were 2.93. According to research by Madrera et al. (2021) found the Duke variety to have a pH value of 2.72 pH, a difference of 0.21 from our own findings.
The content of total acids in the control variant was from 8.35g/l to 12.02g/l, while in the treated variant it was from 7.43g/l to 9.55g/l. The average content was 10.07g/l in the control variant, while it was 8.11g/l in the treated variant. The measured differences in the assessment at the species level are statistically significant ($p < 0.05$), we can therefore state that the application of the mentioned biostimulants in the mentioned concentrations and the mentioned varieties resulted in a demonstrable reduction in the content of total acids in the blueberry fruits.
According to research by Nookaraju (2010) and Li et al. (2019) it is clear that the balance between sweetness and acidity plays a fundamental role in the process of determining the taste and quality of fruits. This fact emphasizes the importance of acidity as an important factor influencing the sensory properties of fruits, together with their sweetness. Zhang et al. (2020) state in their study that the range of total acid content ranges from 2.5 g/l to 14.2 g/l with an average occurrence at the level of 8.63 g/l. These values are consistent with our own observations, which showed a range from 7.43 g/L to 12.02 g/L.
The content of total sugars in the control variant was from 111.08g/l to 138.52g/l, while in the treated variant it was from 123.62g/l to 129.25g/l. The average content of total sugars in the control variant was 123.56g/l, while it was 126.30g/l in the treated variant. The measured differences within the evaluation at the species (not variety) level are not statistically significant ($p < 0.05$), therefore we can conclude that the application of the mentioned biostimulants in the mentioned concentrations and the mentioned varieties did not result in a demonstrable increase in total sugars in the blueberry fruits.
Authors Crespo et al. (2010) state in their study that the most dominant sugars in cranberry are glucose and fructose, while their accumulation in berries is significantly influenced by genetic factors and variability of climatic conditions, especially light intensity. According to Zdunić et al. (2016), the observed range of total sugar content in cranberries ranges from 68 g/l to 78 g/l. These data are inconsistent with our own findings in the control variant. A scientific study published by Leeuwen et al. (2012), states that the average sugar content in cranberries usually ranges from 80 g/l to 100 g/l. We explain this difference by the fact that the fruits that were subjected to our study were collected at an advanced stage of maturity. At this stage of ripening, higher amounts of fructose and glucose accumulate in the fruit, which can lead to an increase in the total sugar content of the cranberry fruit.
The synergistic effect of technology with biostimulation, based on seaweed extracts, on the percentage of large fruit and on qualitative yield was shown by Kaplan et al (2013). An experiment conducted by Lenart et al (2022) showed that algal fertilizers increase the antioxidant activity of highbush blueberry fruit, the content of anthocyanins and total polyphenols, which is related not only into better fruit health promoting properties but also into better storage. Graph 1 demonstrates a simple linear correlation between the content of malic acid, total acids and pH value. This knowledge is important from the point of view of the provenance of the measured values, or their reduction after the application of biostimulants. In this case, malic acid appeared as a secondary metabolite formed at a certain level of stress. Since we observe a decrease in the content of malic acid, total acids and pH after the application of biostimulants, we conclude that the biostimulants reduced the production of stress hormones, which we consider a positive reaction.



Graph 1. Linear correlation between selected analyzed parameters.

Conclusion

Overall, it can be concluded that the application of biostimulants in the given characteristics caused an increase in total yields, depending on the varieties, from 31.8 to 178.5%, on average by 87.2%. The yield increase was statistically evident for all varieties. When evaluating the average length and weight of the berries, we can state that the application of biostimulants did not result in a statistically significant increase in the length and weight of the berries. The stated differences are statistically unprovable. The increase in yields after the application of biostimulants occurred due to an increase in the number of fruits, while the length and weight of the fruits did not change.

Furthermore, we can state that the application of biostimulants did not have a demonstrable effect on the change of most of the measured quality indicators, except for the content of malic acid, the content of total acids and the pH value, when there was a demonstrable decrease in these indicators, respectively at the pH value, its increase. These three indicators in this study are significantly correlated with each other (graph 1). Since malic acid makes up approximately 90% of the content of total acids, we can conclude that the decrease in its content, as well as the decrease in the content of total acids, was caused precisely by the application of biostimulants, which resulted in a lower production of secondary metabolites (in this case, malic acid), which arise during cellular stress. Biostimulants created a situation in the plant where the level of stress hormones is apparently lower and does not force the cells to defend themselves by producing secondary metabolites and therefore also malic acid.

Abstract

Turnip, rutabaga and radish are less-known, or less-grown, vegetable species in Slovak Republic. All these species belong to Brassicaceae family which is known by important health-promoting properties. However, all root vegetables have not a long-term storage ability, mainly turnip or radish. Plant material for analyses came from field experiment realized at SUA in Nitra in 2022. Within study, following cultivars were used: turnip - Amelie F1, Oasis F1, Purple Top White Globe, Tonda a Coletto Viola; radish - black skin - Kulatá Černá, Nero Tondo d'Iverno, white skin/purple pulp - Red Meat; rutabaga - Dalibor, Magres. Lyophilization (freeze drying at -58°C; 72 hours) and conventional drying (60°C; 10 hours) of roots were tested in connection to antioxidant activity (DPPH; FRAP; ABTS) and polyphenol content of processed chips. Statistical evaluation of gained results revealed significant differences among cultivars and processing method in AOA and TPC of processed chips. The highest TPC was confirmed in radish cultivar 'Red Meat' (lyophilization 10312.40 mg GAE.kg^{-1} d. w.; drying 9044.02 mg GAE.kg^{-1}) with purple pulp of roots. The highest AOA, because of polyphenol abundance, were confirmed by all three methods in mentioned radish cultivar 'Red Meat'. TPC and AOA in lyophilized samples were significantly higher than in conventionally dried samples of tested crops. On the other hand, lyophilization is method more demanding to energy costs for processing, as well as costs for lyophilizer buying compared to common drying. If qualitative increase of chips is evaluated in connection to mentioned costs, conventional drying can be marked as suitable method for root processing.

Keywords: *Root vegetables, Cultivar, Processing, Antioxidant activity, Polyphenols.*

Introduction

Turnip, rutabaga and radish belongs to less known, or less-grown, root vegetables in Slovak Republic. These species are just grown in local/home gardens (Meravá, 2021). According to Grubben (2004), turnip (*Brassica rapa* ssp. *rapa*) is reportedly the oldest vegetable species from *Brasssicaceae* family. Turnip was described in 356-323 years BC in area of the Near East and Persia. Sun (2015) describes Europe, Near East and Middle Asia as probable origin area. Nowadays, it is currently introduced world-widely. Rutabaga (*Brassica napus* var. *napobrasssica*) comes probably from Scandinavia, Czech Repulic or Russia. Rutabaga was originally grown as feeding crop for animals and it was consumed by people just in famine period (Morgan, 2012). Welbaum (2015) indicates that first reference about its domestication is approximately from the end of 16th and beginning of 17th century from England. In recent period, it is more intensively grown northern European countries especially (Pokluda et al., 2022). First reference about radish (*Raphanus sativus* var. *longipinnatus*), mainly black radish, comes from Egypt approximately 2780 years BC when it was offered to workers on pyramides. Lately, it was spread to the world (Singh *et al.*, 2017).

Turnip, rutabaga and radish belong to the *Brassicaceae* family. All *Brassica* species are known for their health-promoting properties due to the abundance of glucosinolates and polyphenols (Swastika *et al.*, 2018; Sanlier and Guler Saban, 2018; Kapusta-Duch *et al.*, 2012). These metabolites are responsible for providing a unic and distinctive taste (Wieczorek *et al.*, 2019). Moreover, consumption of *Brassica* vegetables rich on glucosinolates and polyphenols are known by interesting potential for prevention and treatment of various, chronic diseases, e.g. obesity, type 2 diabetes, cardiovascular diseases (including hypertension or stroke), cancer or osteoporosis (Chen *et al.*, 2018; López-Chillón *et al.*, 2019; Raiola *et al.*, 2018; Silva Dias, 2019; Favela-González *et al.*, 2020).
Quality of raw or processed vegetables is key factor from aspect of final consumers (Rahman *et al.*, 2021). According to Pokluda *et al.* (2022), turnip, rutabaga and radish can be stored 2-5 months in cooling room with low temperature (0-1 °C) and high air humidity (90-95%). On the other hand, mentioned storage conditions is not able to apply for local grower due to absence of cooling room with exact atmosphere. Thus, production of chips (or other products) is possible solution for processing of higher yield which is not able to sell directly. Methods for chips processing are various in dependent to quality keeping or energy costs, e.g. heat (conventional) drying, infrared radiation drying, freeze-drying (lyophilisation) or deep frying (Frîncu *et al.*, 2022). Conventional drying and lyophilisation are probably two most-used methods for production of vegetable chips.
The aim of this study was to compare the effect of mentioned drying methods to quality of chips (antioxidant activity, polyphenols) made from turnip, rutabaga and radish.

Material and Methods

Plant material for analyses came from field experiment realized at Slovak University of Agriculture in Nitra (Slovakia) in 2022. The climate of experimental area is characterized by warm and dry summer and slightly warm, dry or very dry winter.
In realized study, tested cultivars were following: turnip - Amelie F1, Oasis F1, Purple Top White Globe, Tonda a Coletto Viola; radish - black skin - Kulatá Černá, Nero Tondo d'Iverno, white skin/purple pulp - Red Meat; rutabaga - Dalibor, Magres.
Within sample preparation, ten roots of each tested cultivar were taken for chips processing. Roots were precisely washed and cleaned from all impurities. Sequentially, roots were quartered and opposite parts of root were taken for chips processing and its analyses. Root samples were cut to the slices with diameter of 1 mm. Two treatments of chips processing were tested. In conventional (heat) drying method, slices were dried at 60^{0} C during 10 hours. In lyophilization, slices were dried at -58^{0} C during 72 hours. The antioxidant activity of produced chips was measured spectrophotometrically by using of DPPH (Brand-Williams *et al.*, 1995), FRAP and ABTS (both Paulová *et al.*, 2004) methods. Its values were expressed in ųmol TE per gram (TE - Trollox equivalent). The polyphenol content was determined by spectrophotometric method of Lachman *et al.* (2003) and expressed in mg GAE per kilogram (GAE - gallic acid equivalent).
The statistical analysis of obtained results was performed by using of the Statgraphic Centurion XVII (StatPoint, USA). Results were evaluated by analysis of variance (ANOVA) and average values were tested by LSD test performed at the significance level of 95% ($p <0.05$).

Results and Discussion

Phenolic compounds represent a large group of phytochemicals wide-spread in the plant kingdom. Depending on their structure, they can be classified in various groups. The most

wide-spread polyphenol group in turnip, rutabaga and radish, as well as in other Brassicaceae species, are flavonoids and derivates of hydroxycinnamic acid (Cartea *et al.*, 2011).
Statistical analysis of obtained results showed significant differences of total polyphenol content (TPC) among cultivars of tested crops and methods of chips processing. In case of conventional drying, TPC values were ranged from 2267.78 (rutabaga 'Magres') to 9044.02 mg GAE.kg^{-1} (radish 'Red Meat'). In lyophilization treatment, TPC values were ranged from 2650.45 (rutabaga 'Magres') to 10312.40 mg GAE.kg^{-1} (radish 'Red Meat').

Table 1 Polyphenol content in turnip, rutabaga and radish chips (mg GAE.kg^{-1} ±SD)

Species	Cultivar	Conventional drying	Lyophilisation
Turnip	Amelie F1	3384.72 ±33.75^{j}	4154.83 ±25.76^{m}
	Oasis F1	2748.63 ±27.61^{e}	3336.07 ±28.09^{i}
	Purple Top White Globe	2732.54 ±9.01^{e}	3388.50 ±36.51^{j}
	Tonda a Coletto Viola	3231.74 ±13.32^{h}	4024.06 ±33.16^{l}
Rutabaga	Dalibor	3529.40 ±26.85^{k}	4349.27 ±44.04^{n}
	Magres	2267.78 ±8.98^{a}	2650.45 ±22.51^{d}
Radish	Kulatá černá	2532.33 ±8.94^{c}	3044.33 ±9.52^{g}
	Nero Tondo d´Inverno	2435.92 ±13.15^{b}	2895.40 ±36.52^{f}
	Red Meat	9044.02 ±22.74^{o}	10312.40 ±41.93^{p}

Note: SD - standard deviation; Values with different letters among rows and columns are significantly different at p <0.05 by LSD in ANOVA.

Table 2. Antioxidant activity of turnip, rutabaga and radish chips measured by DPPH method (µmolTE.g^{-1} ±SD)

Species	Cultivar	Conventional drying	Lyophilisation
Turnip	Amelie F1	24.69 ±0.32^{c}	28.56 ±0.13^{f}
	Oasis F1	28.16 ±0.36^{f}	31.27 ±0.27^{i}
	Purple Top White Globe	30.09 ±0.33^{gh}	33.36 ±0.35^{j}
	Tonda a Coletto Viola	28.39 ±0.26^{f}	31.67 ±0.09^{i}

	Magres	26.41 ±0.09^{d}	29.73 ±0.28^{g}
Radish	Kulatá černá	19.06 ±0.09^{a}	21.67 ±0.25^{b}
	Nero Tondo d´Inverno	21.69 ±0.06^{b}	24.95 ±0.07^{c}
	Red Meat	51.67 ±0.12^{k}	54.41 ±0.21^{l}

Note: SD - standard deviation; Note: Values with different letters among rows and columns are significantly different at p <0.05 by LSD in ANOVA.

The antioxidant activity (AOA) is often used for expression of nutritional benefit of individual vegetables, fruits and other plant products (Prenzler *et al.*, 2022). This important parameter of product quality can be determined by various methods based on different principle (Shahidi and Zhong, 2015). Statistical analysis of obtained results showed significant differences of AOA among cultivars of tested crops and chips processing in all used AOA determination methods (table 2-4).
DPPH radical scavenging assay is probably the most frequently used methods of AOA determination and it offers the first approach for evaluating of AOA. It is a method based on single electron transfer with mechanism of hydrogen atom transfer being only a marginal

reaction pathway in the assay (Prior et al., 2005). DPPH method is based on electron donation of antioxidants to neutralize DPPH (2,2-Diphenyl-1-picrylhydrazyl) radical (Hegedűsová *et al.*, 2018). In conventional drying (table 2), AOA was varied from 19.06 (radish 'Kulatá černá') to 51.67 ųmolTE.g^{-1} (radish 'Red Meat'). In lyophilization treatment, AOA were ranged from 21.67 (radish 'Kulatá černá') to 54.41 ųmolTE.g^{-1} (radish 'Red Meat').

Table 3. Antioxidant activity of turnip, rutabaga and radish chips measured by ABTS method (ųmolTE.g^{-1} ±SD)

Species	Cultivar	Conventional drying	Lyophilisation
Turnip	Amelie F1	12.30 ±0.14^{ij}	14.54 ±0.20^{i}
	Oasis F1	9.61 ±0.16^{d}	12.45 ±0.12^{j}
	Purple Top White Globe	10.88 ±0.16^{g}	12.91 ±0.07^{k}
	Tonda a Coletto Viola	9.37 ±0.14^{c}	11.59 ±0.16^{h}
Rutabaga	Dalibor	10.51 ±0.20^{f}	12.20 ±0.17^{i}
	Magres	9.76 ±0.10^{d}	11.75 ±0.05^{h}
Radish	Kulatá černá	7.42 ±0.07^{a}	8.85 ±0.08^{b}
	Nero Tondo d´Inverno	10.23 ±0.09^{e}	11.54 ±0.11^{h}
	Red Meat	58.74 ±0.08^{m}	61.06 ±0.08^{n}

Note: SD - standard deviation; Note: Values with different letters among rows and columns are significantly different at p <0.05 by LSD in ANOVA.

Table 4. Antioxidant activity of turnip, rutabaga and radish chips measured by FRAP method (ųmolTE.g^{-1} ±SD)

Species	Cultivar	Conventional drying	Lyophilisation
Turnip	Amelie F1	14.53 ±0.04^{j}	17.43 ±0.39^{l}
	Oasis F1	11.32 ±0.06^{e}	13.10 ±0.73^{gh}
	Purple Top White Globe	12.66 ±0.27^{fg}	15.79 ±0.24^{k}
	Tonda a Coletto Viola	14.00 ±0.16^{i}	15.53 ±0.10^{k}
Rutabaga	Dalibor	12.57 ±0.19^{f}	14.28 ±0.33^{ij}
	Magres	9.64 ±0.10^{d}	13.25 ±0.29^{h}
Radish	Kulatá černá	6.70 ±0.19^{a}	7.46 ±0.27^{b}
	Nero Tondo d´Inverno	6.39 ±0.15^{a}	8.52 ±0.17^{c}
	Red Meat	34.87 ±0.19^{m}	38.42 ±0.24^{n}

Note: SD - standard deviation; Note: Values with different letters among rows and columns are significantly different at p <0.05 by LSD in ANOVA.

According to Prior *et al.* (2005), ABTS method is based on measurement of antioxidant ability to scavenge the stable radical cation ABTS^{+} (2,2′-azinobis(3-ethylbenzothiazoline-6-sulphonic acid)). In this method (table 3), AOA values were ranged from 7.42 (radish 'Kulatá černá') to 58.74 ųmolTE.g^{-1} (radish 'Red Meat') in conventional drying treatment, respectively from 8.85 (radish 'Kulatá černá') to 61.06 ųmolTE.g^{-1} (radish 'Red Meat')
Prior *et al.* (2005) indicate that FRAP method is based on measurement of ferric ion (Fe_3^{+}) to ferrous ion (Fe_2^{+}). In conventional drying (table 4), AOA was ranged from 6.39 (radish 'Nero Tondo d´Inverno') to 34.87 ųmolTE.g^{-1} (radish 'Red Meat'). In lyophilization treatment, AOA were ranged from 7.46 (radish 'Kulatá černá') to 38.42 ųmolTE.g^{-1} (radish 'Red Meat').

TPC values were varied among tested cultivars and crops; thus, it is not possible to evaluate the richest source of polyphenols from tested crops. Radish cultivar 'Red Meat' was significantly different from other tested cultivars. In this cultivar, the expressively higher TPC was determined. It should be caused by purple color of root pulp because of abundance of anthocyans as it was described by Bozdogan and Yasar (2011). Our results confirmed fact that cultivar belongs to the most important factors influencing on the quality of root vegetables (Önder *et al.*, 2020; Bystrická *et al.*, 2015; Sengul *et al.*, 2011), or horticultural products generally. According to obtained results, AOA has connection to TPC in roots of tested crops. The highest AOA value was found by all three analysis methods in radish cultivar 'Red Meat' with purple pulp color. A similar finding about AOA and TPC correlation was also shown in the experiments with other crops, e. g. red beet (Šlosár *et al.*, 2020), potato (Gupta *et al.*, 2015), sweet potato (Ji *et al.*, 2015) or carrot (Scarano *et al.*, 2018).

Our results indicated that processing method of vegetables or fruits has a significant impact on final product properties. Using of lyophilization resulted in significantly higher TPC compared to the conventional drying in all tested cultivars. Alean *et al.* (2016) describe that polyphenol degradation during crop processing in very depending on temperature and drying period. These factors effect to the irreversible oxidation processes of polyphenols and they can be also affected by cell destruction. Higher TPC in lyophilised chips compared to heat-drying method was presented also in the study of Jia *et al.* (2019) with Asian persimmon. On the contrary, authors found approximately the same results of chips sensorial evaluation in both tested drying methods.

According to obtained results and discussion with other studies, lyophilization can be marked as more preserve method for keeping of bioactive substances in product processing. On the other hand, important factor is also energy demanding of used processing method; definitely, financial costs have impact to price of marketed products which belongs to key factors of final consumer. It is known that process of lyophilization is significantly longer that coventional heat drying. Because of not so significant differences between tested methods, heat drying appeared as more suitable for smaller grower which would like to process excessive (non-longer storable) yield of root crops.

Selection of cultivars used for chips production is depending on various factors. Mostly, it is taste, favour, structure and nutritional value of final product. Nowadays, interest in vegetable chips, as healthier alternative to potato chips, is increasing. They are suitable for direct consumption, as well as additive for food decoration with aim to increase of nutritional value in food cooking. From rutabaga and turnip tested cultivars, it can be recommended to use 'Dalibor' and 'Amelie F1'. From radish tested assortment, cultivar 'Red Meat' can be definitely recommended because its nutritional value. Additive advantage of this cultivar is purple color of pulp, visually interesting for using in modern, creative gastronomy.

Conclusions

Turnip, rutabaga and radish belongs to less known, or less-grown, root vegetables in Slovak Republic. All these species be to the *Brassicaceae* family. Crops from this family are known for their health-promoting properties due to high antioxidant activity and abundance of polyphenols or glucosinolates. Quality of processed vegetables is key factor from aspect of final consumers. Methods for chips processing are various in dependent to quality keeping or energy costs. Conventional drying and lyophilisation are probably two most-used methods for production of vegetable chips. Production of chips (or other products) is possible solution for processing of higher yield which is not able to sell directly. Obtained results confirmed significant impact of cultivar and processing method to quality of prepared chips. From all tested cultivars, radish cultivar 'Red Meat' can be recommended for chips processing because of its nutritional value and unique, visually interesting pulp color. It is known that process of lyophilization is significantly longer and more financially demanding that conventional heat drying. Differences among tested processing methods were not so significant; thus, heat drying appeared as more suitable for smaller grower which would like to process excessive (non-longer storable) yield of root crops.

Abstract

Saffron (*Crocus sativus* L.), an autumn-blooming plant that produces a highly valuable spice, is primarily cultivated in Mediterranean climates. In Lebanon, it is mainly grown in the North Bekaa Valley. Recently, it has been introduced to the central part of the Bekaa Valley. To evaluate the response of saffron to organic matter and potassium-nitrogen chemical fertilizer in the semi-arid climate of Lebanon, an experiment was conducted at a private farm in Deir el Ghazel. The study, carried out from 2019 to 2022, utilized a split-plot design based on randomized complete blocks with three replications over three consecutive crop growth seasons. The correlation coefficient analysis revealed a strong and significant relationship between initial corm density and various treatments (R=0.975). These two factors significantly influence second-year parameters such as flower number (R_{treat}=0.928; R_d=0.922) and saffron weight (R_{treat}=0.914; R_d=0.916). They also moderately affect factor of flower number (R_{treat}=0.631; R_d=0.6). Their influence slightly weakens in the third year, with flower number showing a moderate significant correlation (R_{treat}=0.613; R_d=0.582), saffron weight showing a weak but significant correlation (R_{treat}=0.377; R_d=0.346), and factor of flower number maintaining a moderate significant correlation (R_{treat}=0.576; R_d=0.553). Notably, the individual corm weight at the end of the experiment was moderately but negatively impacted by both factors (R_{treat}=-0.514; R_d=-0.469), while the final corm number was strongly positively affected by both factors (R_{treat}=0.757; R_d=0.715).

Keywords: *Crocus sativus, Lebanon, organic matter, potassium-nitrogen fertilization.*

Introduction

Saffron (*Crocus sativus* L., Iridaceae) is widely recognized as one of the most valuable and expensive medicinal plants globally (Nazarian *et al*., 2024). Initially confined to specific geographic areas, its significance has led to its cultivation worldwide (Mathew, 1999). Typically grown in arid and semi-arid regions, saffron is planted in early fall and completes its growth cycle by mid-spring (Pirasteh-Anosheh and Kamgar-Haghighi, 2019). Successful production depends on key soil characteristics, such as good nutrient content, suitable bulk density, a well-developed flexible structure, proper drainage, and adequate water-holding capacity (Shahandeh, 2020).
The economic yield of saffron varies significantly across different regions, with no clear pattern or explanation for these variations (Pirasteh-Anosheh *et al*., 2023). This variation is hypothetically attributed to soil properties, which significantly influence saffron flower yield and highlight the importance of soil conservation for high-quality production (Aghhavani Shajari *et al*., 2018; Cardone *et al*., 2020).

In areas where saffron is cultivated, the absence of specific fertilizer recommendations is notable due to variations in soil organic matter, climate, and agricultural practices (WBSE, 2006). Some researchers argue that fertilization might not be crucial in fertile soils, as saffron corms can store ample nutrients to support plant growth. This perspective is reinforced by the relatively low nutrient absorption observed in saffron (Shahandeh, 2020). Thus, the economic yield, particularly the stigmas, relies more on corm nutrient reserves than direct soil conditions. When evaluating saffron's nutrient requirements, it is essential to consider both stigma and corm yield (Douglas *et al*., 2014).
Optimizing saffron growth and yield requires emphasizing fertilization and proper nutrition to balance vegetative and reproductive growth (Koocheki, 2004). Studies highlight that soil physicochemical and biological properties are critical indicators for designing crop yield plans and guiding the selection of manure to improve soil properties and crop yield (Ma *et al*., 2021).
Various studies have investigated the effects of different nitrogen fertilizers on saffron growth and production. Kirmani *et al*. (2014) reported a substantial increase in saffron yield and corm output with the application of nitrogen at 90 $kg.ha^{-1}$. Similarly, Omidi *et al*. (2009) demonstrated the positive effects of nitrogen chemical and bio-fertilizers on saffron yield and quality components. Potassium, the second most vital nutritional element for spice crops, enhances nitrogen utilization, protein production, size and weight, oil content, and coloration (Fatematuzzohora and Karim, 2020). In saffron, potassium acts as a flowering stimulator and plays a crucial role in providing nutritional support during the reproductive growth stage (Jabbari *et al*., 2017; Khayyat *et al*., 2018).
The objective of this paper is to provide an overview of how various fertilization regimens and saffron planting densities correlate with saffron growth and yield characteristics.

Material and Methods

Experimental site:
The experiment took place over three years in Deir el Ghazel, Lebanon, using 6000 healthy saffron bulbs (2.8 cm diameter) selected from 9000 bulbs at Qaa Farm in northern Lebanon.
The pedo-climatic conditions of the experimental site:
According to ICARDA, Deir el Ghazel has a hot, dry season from May to September and very cold weather for the rest of the year. Average rainfall is 450 mm, with 80% occurring between November and March, and no rain from June to September.
Experimental set up:
The experiment assessed the effects of "Bulb Density," "Vegetal Organic Matter" (VOM), and "Potassium Nitrogen Fertilization" (KNO_3) on saffron. At two density levels, 30 and 56 bulbs per unit area, KNO_3 was applied at 0, 5, 10, and 15 units, with VOM included at 1% in selected treatments. Using a Randomized Complete Block Design (RCBD), the study included 16 treatments across two bulb density categories with 3 replicates each. Controls had no KNO_3 and no VOM. Fertilizers were manually applied in February 2020, January 2021, and February 2022.
Statistical analysis:
IBM SPSS Statistics 20 software was used for Pearson's correlation analysis to examine how the fertilization regime and saffron density affect the growth and yield indicators.

Results and Discussion

Table 1 shows a strong positive correlation (R = 0.975) between fertilization regimes and initial corm density which imply their mutual codependence in potential yield improvement.

However, their influence was altered notably over two years. In the second year, both fertilization regimes and corm density were highly positively correlated with flower number (R_{treat} = 0.928; R_d = 0.922) and saffron weight (R_{treat} = 0.914; R_d = 0.916), and moderately correlated with flower number (R_{treat} = 0.631; R_d = 0.6) and leaf length (R_{treat} = 0.554; R_d = 0.633). In the third year, the correlations decreased, showing moderate positive correlations with flower number (R_{treat} = 0.613; R_d = 0.582) and weaker correlations with saffron weight (R_{treat} = 0.377; R_d = 0.346) and flower number (R_{treat} = 0.576; R_d = 0.553).
According to the literature, saffron production can be influenced by different factors, including planting method, irrigation method and applying fertilizers (Fallahi *et al*., 2021), climatic factors (like air temperature and precipitation), and cultivation site conditions (Cardone *et al*., 2019). Focusing specifically on the impact of fertilization—both chemical and organic—on saffron growth and yield, our results demonstrate that fertilization type and dosage significantly affect saffron growth and yield, varying by year. This finding contrasts with Pirasteh-Anosheh *et al*. (2023), who found no significant correlation between chemical fertilizer amounts and saffron yield, though they noted that higher bulk density was linked to higher yields. In contrast, Maktabdaran *et al*. (2018) identified a significant linear relationship between nitrogen percentage and yield.
Planting density generally boosts yield, with more corms per area leading to more flowers and stigmas, as seen in the second year. This effect, however, diminishes by the third year. Douglas *et al*. (2014) also noted that planting density can influence crop productivity and yield components, particularly the number of flowers per square meter. When evaluating factors that impact saffron growth and yield, it is crucial to consider the strong correlation between saffron’s behavior and climatic factors, such as temperature, precipitation and extreme weather events (Kouzegaran *et al*., 2020). This correlation is evident in the results of both years. The temperature remained relatively consistent between the two years; however, in the third year, additional rain just before and during the production season restrained growth compared to the second year, when there was no rain just before and during the production period.

Table 2 shows that in the final third year, corm parameters were variably affected by fertilization regimes and densities. Total corm weight had a weak but highly significant positive correlation with both factors (R_{treat} = 0.398; R_d = 0.386). In contrast, the final number of corms was strongly positively correlated with high significance (R_{treat} = 0.757; R_d = 0.715) with the factors. Notably, individual corm weight was moderately negatively correlated with both fertilization and density factors, with high significance (R_{treat} = -0.514; R_d = -0.469), suggesting that different fertilization types, dosages, and densities lead to variations in individual corm weight. Additionally, the corm multiplication factor was weakly negatively correlated with fertilization (R_{treat} = -0.354) and more significantly negatively correlated with density (R_d = -0.435).

Effective fertilizer management is essential for maintaining balanced nutrient availability, which is critical for saffron production, especially in arid and semi-arid regions (Amiri, 2008). Our study indicates that the choice of fertilization regime, dosage, type and planting density should be aligned with the specific objectives of saffron cultivation to achieve optimal results. Research shows that applying macronutrient fertilizers increases corm size (Dewir *et al*., 2022) and corm fresh weight (Salas *et al*., 2020). However, regardless of fertilizer treatments, increasing planting density leads to a significant reduction in the number and weight of medium and large daughter corms per plant (Seyyedi *et al*., 2018). This reduction may be due to heightened competition among corms for nutrients. Koocheki and Seyyedi (2016) observed a negative correlation between the number of corms and corm dry weight, suggesting that higher planting densities make mother corms more susceptible to nutrient limitations (Seyyedi *et al*., 2018). Other studies have highlighted the importance of mother corm nutrition for promoting growth and nutrient uptake in daughter corms (Amiri, 2008; Koocheki and Seyyedi, 2015b).
The previous observations are consistent with our findings. Our results regarding the corm multiplication factor and individual weight indicate that higher initial planting densities lead to fewer and smaller final corms compared to lower densities. Although the final number of corms is influenced by planting density and fertilization, this pattern is primarily due to competition for space and nutrients, as well as the characteristics of the initial corm. Additionally, Cardone *et al*. (2019), observed that corm behavior is also affected by its initial size and geographical origin.

Table 2. Pearson Correlation Analysis of corm parameter, chlorophyll content and flower weight

	0.056	0.007	<.001	0.002	<.001	0.602

FW: Flower weight; CW: Corm weight; F nb C: Final number of corm; C_{mult} F: corm multiplication factor; $_{Ind}$CW: Individual corm weight; Ch C: Chlorophyll content. ** Correlation is significant at the 0.01 level (2-tailed); * Correlation is significant at the 0.05 level (2-tailed).

Conclusion

Based on the obtained results, we can conclude that achieving optimal saffron yield, both in terms of stigma and corms, requires specific agricultural practices, including customized fertilization regimes and appropriate corm densities. Additionally, the initial corm parameters and weather conditions are as crucial as the fertilization regime and planting density in influencing production outcomes.

Abstract

Current population growth trends suggest that global food production is unlikely to meet future demand. However, according to projected climate change scenarios, this trend could be mitigated through the use of new drought-tolerant hybrids and sustainable management of crops and natural resources. Climate change is currently one of the main factors affecting agricultural production. These negative impacts are already evident, and projections indicate that this will only intensify in the coming years. This growing concern has sparked interest among domestic and international scientists in conducting detailed analyses of global warming and its effects on agricultural production. Agricultural producers will increasingly face the challenge of finding alternatives to reduce the negative effects of climate change. Agricultural production, particularly crop production, is essentially an 'open-air factory,' carried out in fields and thus highly susceptible to external environmental factors. The aim of this research was to examine the impact of climate parameters on sunflower yields from 2015 to 2023 in the Republic of Serbia. The study also assessed the effects of climate conditions on the economic outcomes of sunflower production, both under optimal growing conditions and in conditions where the effects of climate change were evident.

Keywords: *sunflower, climate change, yield, crops, economic results.*

Introduction

Agriculture represents a very important activity in the Republic of Serbia. Sunflower (Helianthus annuus) is a significant crop in both the Republic of Serbia and the world, with a tendency toward increasing cultivation areas and market importance. Sunflowers are cultivated in Serbia on just over 250,000 hectares (FAO, 2022). The success of stable production largely depends on the sowing time, applied agricultural techniques, hybrid selection, and weather conditions (Stojković et al., 2023). Given that agricultural production is mostly conducted in open fields, environmental conditions significantly affect its success. For the Serbian region, analyses of observed climate changes indicate a clear trend of rising air temperatures across the entire country, while precipitation changes show seasonal and spatial variability (Luković et al., 2014; Milovanović et al., 2017). It is expected that rising air temperatures, changes in the amount and distribution of precipitation, and increased frequency and intensity of drought will lead to higher crop water needs, both in Europe (Rio et al., 2018) and in Serbia (Gregorić et al., 2020). In recent years, we have witnessed frequent occurrences of severe droughts, as well as frequent weather hazards such as strong winds, storms, hail, and similar events. All these occurrences indicate that Serbia is among the countries highly susceptible to the negative effects of climate change (European Environment Agency, EEA, 2017). The increase in air temperature and changes in the distribution and amount of precipitation negatively impact the agricultural production of European countries, water resources, and consequently socio-economic changes due to the frequent changes in the supply of agricultural raw materials, which affect the uncertainty of operations in the food industry, trade, and other associated sectors of the economy and society as a whole (Fronzek et al., 2019). All of this raises concerns that, in the future, agricultural production may not be possible without the use of irrigation. Irrigation is considered the most reliable measure for adapting to climate change (Agovino et al., 2019). However, it has its limitations, primarily due to the scarcity of water resources, which will become increasingly limited and/or highly variable in terms of available water quantities (Idrizović et al., 2020). Research on the impact of climate change in Serbia indicates that the climate will remain favorable for agricultural production (Mihailović et al., 2015). Agriculture in southeastern Europe will be affected by climate change, as confirmed by numerous studies (Webber et al., 2018).

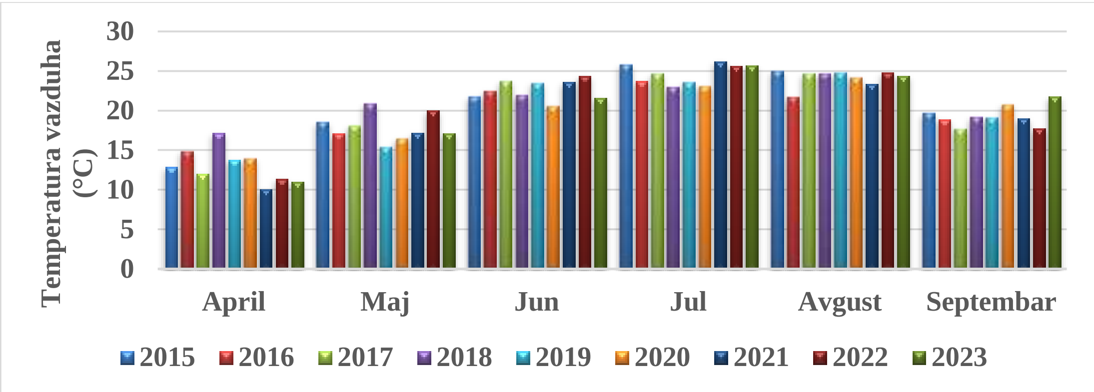
Material and methods

In order to assess the overall sunflower production in the Republic of Serbia from 2015 to 2023, data from the Republic Hydrometeorological Institute portal was used to gather information on average monthly air temperatures and total monthly air temperatures over the past 9 years (RHMZ, 2023). The average yield of the studied crops for the mentioned period was obtained from the portal of the Republic Statistical Office (RZS, 2023). Based on the data collected from these portals, an assessment was made of the impact of air temperature and total precipitation during the growing season on sunflower yield. Additionally, based on the data from variable cost calculations, the gross margin amounts for sunflower production were determined, and an analysis of the sensitivity of yield and price changes on the gross margin of sunflower production was conducted.

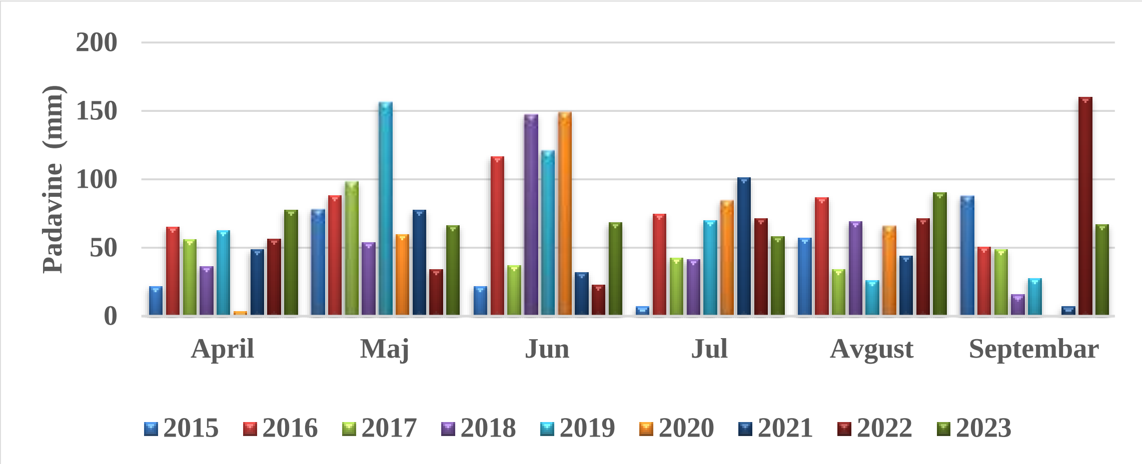
Results and discussion

Crop production is often referred to as a "factory under the open sky," which is why environmental conditions have a significant impact on production success. Climate change, based on observed climate parameters, indicates negative consequences, but it is also possible to expect some positive effects on agriculture (Stričević et al., 2019). In Serbia, an increase in the average daily temperature of 1.2°C, exceeding global averages, has been recorded. This increase is particularly notable during the summer period, along with a lack of precipitation, which is one of the limiting factors for the growth of the most important crops (Lalić et al., 2013). Studies have shown that the water requirements for certain crops in Serbia (orchards, grasses, sugar beets, soybeans) will increase by the end of the century (Stričević et al., 2019). The average long-term air temperatures in Serbia during the period from 1921-1940 were 10.2°C, while in the period from 1961-1990, they were 10.1°C. Precipitation amounts were approximately similar, ranging from 721 to 734 mm. Each crop type has a critical period for water and heat, with some having longer, and others shorter durations. For sunflowers, these critical phases are during the phenological stages of intensive growth, flowering, and grain filling. Sunflower is a significant oilseed crop grown worldwide due to its diverse uses in the food, industrial, and pharmaceutical sectors. It is known for its high oil content, nutritional value, adaptability to various climate conditions, and environmental benefits. Sunflower is an annual plant with a growing period of 90-130 days, during which it undergoes both vegetative and generative phases of growth and development: germination and emergence, leaf development, appearance of flower buds (buttoning), the stage where the flower bud elongates above the top leaf, bud opening, flowering phase, and maturation phase. Sunflower is a heavy consumer of water. In addition to 250 mm of winter reserves (in our region), it requires about 300 mm of rainfall during the growing season. Its greatest water needs are during the periods of intense growth and flowering (about 65% of the total water absorbed). In many years, insufficient rainfall leads to poorer flowering and reduced grain yield. The sum of active temperatures (above 10°C) required for sunflower growth and development ranges between 1,600 and 2,800°C. Newly emerged plants can withstand frosts down to -6°C. The optimal temperatures for flowering, seed formation, and filling are between 20-25°C. Very high temperatures (> 35°C), especially combined with a lack of rainfall from flowering to maturation, negatively affect seed and oil yield.



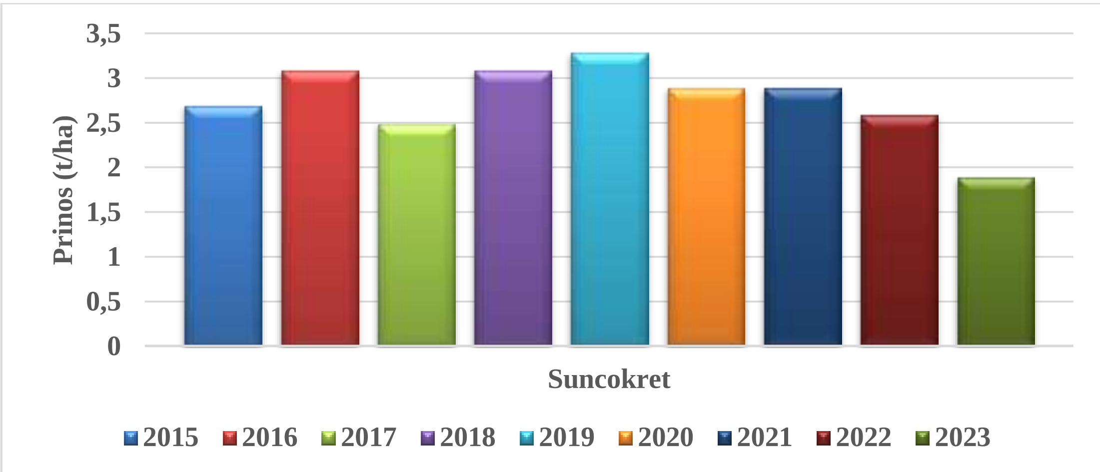
Graph 1. Average monthly air temperatures during the growing season of spring crops (RHMZ, 2023).

Based on the data from Graph 1, we can conclude that average air temperatures during the growing season of spring crops did not vary significantly over the years. The greatest variation was observed in April, and a similar trend was seen in May, but with smaller temperature fluctuations. The summer months of June, July, and August exhibited fairly consistent average monthly air temperatures over the past 9 years, with a slight increase in the last 3 years, except for June 2023, when temperatures were slightly lower than in 2021 and 2022. The highest average monthly air temperature during the observed period was recorded in July 2021, at 26.3ºC, while the lowest temperature was recorded in April of the same year, at 10.2ºC. The highest air temperature during the sunflower growing season occurred in 2018, averaging 21.27°C, while the lowest was in 2016, at 19.90°C. In the vegetative growth stages of sunflower, from 12-16 BBCH to 18-32 BBCH, average temperatures in April and May did not deviate much from the optimal range, which was favorable for proper germination and plant growth. The greatest temperature variations occurred in April, where a decrease in average daily temperatures has been observed in the last three years. The optimal temperature for the stages of seed formation, filling, and maturation is between 22-23°C. Average temperatures from June to August were higher than the optimal range: June by 2.73°C, July by 1.70°C, and August by 1.29°C.



Graph 2. Total monthly precipitation during the growing season of spring crops (RHMZ, 2023)

Based on the data from Graph 2, we can say that the total monthly precipitation amounts do not exhibit a clear pattern and vary significantly from year to year. The highest average precipitation was recorded in September 2022, measuring 160.8 mm, while the lowest amount during the studied period was measured in September 2020, with only 1.2 mm of rain on average for the month. The year 2020 was particularly unfavorable for crop production because insufficient rainfall in April slowed and unevenly affected the germination and emergence of spring crops.



Graph 3. Sunflower yield in the period 2015-2023 (RZS, 2023).

The sunflower yield during the observed period was significantly more uniform (with the exception of 2023), ranging from 1.9 to 3.3 t/ha. Although 2023 was not an extremely dry year, high air temperatures during June, July, and August led to a decrease in sunflower yields. In 2017, a satisfactory amount of rainfall occurred in May, June, and July, which coincided with the critical water period for sunflowers, resulting in a high yield that year. Research is being conducted to identify alternative preventive measures, including changes in sowing dates, variety selection, and the application of breeding methods (Popović et al., 2014), as well as various plant cultivation systems aimed at preserving soil moisture.

Table 1. Analysis of the sensitivity of the gross margin of sunflower production to changes in yield and price (average in the period 2015-2023)

		Price (din/kg)				
		-20%	-10%	Average	10%	20%
Yield (kg/ha)		**34.58**	**38.91**	**43.23**	**47.55**	**51.88**
-20%	**2,136.00**	16,398.07	25,632.00	34,865.93	44,099.86	53,333.79
-10%	**2,403.00**	25,632.00	36,020.17	46,408.34	56,796.51	67,184.68
Average	**2,670.00**	34,865.93	46,408.34	**57,950.75**	69,493.16	81,035.57
10%	**2,937.00**	44,099.86	56,796.51	69,493.16	82,189.81	94,886.46
20%	**3,204.00**	53,333.79	67,184.68	81,035.57	94,886.46	108,737.35

Source: Editing by the author

In Table 1, the results of the sensitivity analysis of the gross margin from sunflower production to changes in yield and price for both 10% and 20% variations (for both increases and decreases) are presented. The average price of sunflower during the period from 2015 to 2023 was 43.23 din/kg, while the average yield was 2,670.00 kg/ha. The average gross margin from sunflower production during the analyzed period was 57,950.75 din/ha. The sensitivity analysis of the gross margin from sunflower production established that even with a decrease in price and yield by 20%, the gross margin remains positive, amounting to 16,398.07 din/ha. Even in 2023, when the price of sunflower was 37.5 din/kg and the yield was 1,900.00 kg/ha, the gross margin would still remain positive at 13,776.65 din/ha. Based on this, it can be concluded that although affected by climate change, specifically drought, sunflower yields in certain years with pronounced drought can be significantly lower (by up to 30%), and with prices approximately 15% lower than the averages during the analyzed period of 2015-2023, the gross margin from sunflower production remained positive.

Conclusion

Based on the analysis of climate parameters and sunflower yields, a constant increase in average monthly temperatures in June, July, and August has been observed, which adversely affects the development of sunflowers and other spring crops. The total monthly amounts of precipitation show significant irregularity; insufficient rainfall in June, July, and August—when most crops are in their generative growth stages, representing a critical period for water—can lead to stunted growth, lack of fertilization, and reduced yields. It can be concluded that it is essential to work on developing new genotypes that would be adapted to the emerging conditions, to conduct research aimed at expanding the irrigation network, and to implement alternative agronomic methods to mitigate stress conditions with fewer consequences. Although the impact of climate change, specifically drought, is significantly expressed through reduced sunflower yields, the gross margin during the analyzed period from 2015 to 2023 remained positive. Specifically, agricultural producers who cultivated sunflowers did not incur losses and achieved positive economic results.

Abstract

Climate change poses a significant challenge to Greek agriculture, impacting crop productivity and sustainability. Wheat is a crucial crop, primarily grown in regions with favorable climatic conditions and fertile soils. Climate change negatively affects wheat production through increased temperatures, extreme weather events, and changes in precipitation, leading to reduced yield and seed quality. The impact varies by region, with high-altitude areas experiencing temperature fluctuations and reduced snow cover, while coastal areas face sea-level rise and coastal erosion. Practices such as cultivating resilient wheat varieties, adjusting sowing dates, and improving water management are essential. Climate change impacts increasingly rely on ensembles, which combine multiple climate models to balance individual model errors. Careful selection and evaluation of ensemble members is essential for accurate predictions. In this study, a region in central Greece was selected for its diverse elevation and climate conditions. Data from eight meteorological stations for the period 2006 to 2023 and 11 EURO-CORDEX regional climate model simulations for three emission scenarios (RCP2.6, RCP4.5, RCP8.5) were used. The selection methodology ranked models based on the sRPI index, which evaluates temperature deviation performance. Preliminary results from the calibrated CERES-Wheat model in Greek conditions showed that selecting only the best simulation scenarios provided more reliable predictions for flowering, maturity, and potential yield compared to using the full ensemble. Careful selection of ensemble members based on climate is expected to ensure more reliable agronomic model predictions, helping farmers better adapt to climate change and maintain crop sustainability and productivity.

Keywords: *ensemble model evaluation, climate change, wheat production, CERES-Wheat, simulation scenarios, Greece.*

Introduction

Climate change significantly impacts crop productivity and sustainability, posing a challenge for Greek agriculture (IPCC, 2023). Among the various crops cultivated in Greece, wheat holds particular importance. It is mainly grown in Thessaly, Macedonia, Thrace, and central Greece, areas known for their good climate and fertile soil (Koutsika et al., 2010). However, the effects of climate change (rising temperatures, extreme weather events, and alterations in precipitation patterns, etc.) are increasingly threatening wheat production, leading to reduced yields and compromised seed quality (Farooq et al., 2023; Jägermeyr et al., 2021).
The impact of climate change on wheat production differs among various regions in Greece. High-altitude areas experience significant variations in temperature and reduced snow cover,

while coastal areas face the difficulties posed by rising sea levels and coastal erosion. To mitigate these adverse effects, modern agricultural practices, such as cultivating resilient wheat varieties, adjusting sowing dates, and enhancing water management strategies, are crucial (Collins & Chenu, 2021).

Climate data analysis indicated a general trend of increasing temperatures and changing precipitation patterns across Central Greece. Average temperatures are projected to rise by 1.5°C to 2.5°C by mid-century, with more pronounced increases during the summer months (Georgoulias et al., 2022). Precipitation patterns are also expected to vary, with some models predicting drier conditions and others indicating increased winter rainfall. These changes are expected to impact the wheat growing season, affecting crop development stages and yields.

To mitigate the adverse effects of climate change, several adaptation strategies are recommended. These include cultivating resilient wheat varieties with enhanced tolerance to heat and drought, adjusting sowing dates to avoid peak temperature periods and align with favorable climatic windows, and improving water management through efficient irrigation practices and water conservation techniques (Collins & Chenu, 2021). The adaptation strategies proposed here are essential for sustaining wheat production in central Greece amid climate change, supporting farmers in making informed decisions to enhance crop resilience and ensure food security.

Accurate climate analysis is fundamental for developing effective adaptation measures. Such analysis often relies on ensembles, which combine multiple climate models to mitigate individual model errors and provide a comprehensive picture of future climate scenarios. Reliable predictions necessitate thorough selection and evaluation of ensemble members. The targeted selection of ensemble members, based on climate variables and geomorphological characteristics, is anticipated to ensure more accurate agronomic model predictions (Minaei et al., 2022; Ruane & McDermid, 2017; Wada et al., 2023). These advances help farmers adapt to climate change, thereby ensuring the sustainability of Greece's agricultural sector and maintaining crop productivity (Brunner et al., 2020; Knutti et al., 2017; Merrifield et al., 2020). In this study, a region in central Greece was chosen due to its varying elevation and climatic conditions. The research utilized data from eight meteorological stations for the period 2006 to 2023 and 11 EURO-CORDEX regional climate model (RCM) simulations across three emission scenarios (RCP2.6, RCP4.5, RCP8.5). Models were ranked using the sRPI index, which assesses temperature deviation performance of RCMs.

Materials and methods

The study focuses on a region in central Greece, due to its diverse elevation and climatic conditions, providing a comprehensive landscape for studying the impacts of climate change on wheat production. Data were collected from eight meteorological stations within this region (Fig. 1). These stations provided daily observations of precipitation (mm), maximum and minimum temperatures (^{o}C), while solar radiation data were provided from the Copernicus Atmosphere Monitoring Service (CAMS) (Guevara et al., 2021) for the period from December to June (i.e., the growing season) over 17 years (2006-2023). These stations are located at altitudes ranging from 98 to 760 meters above sea level.

Additionally, simulated climate data were obtained from 11 Regional Climate Models (RCMs) of the EURO-CORDEX project, with a spatial resolution of approximately 12.5 km. The RCMs simulated climate conditions under three emission scenarios: RCP2.6, RCP4.5, and RCP8.5 (Georgoulias et al., 2022). The consistency between the simulated and observed data was guaranteed by utilizing data from the grid cells that contained the meteorological stations (Figure 1).

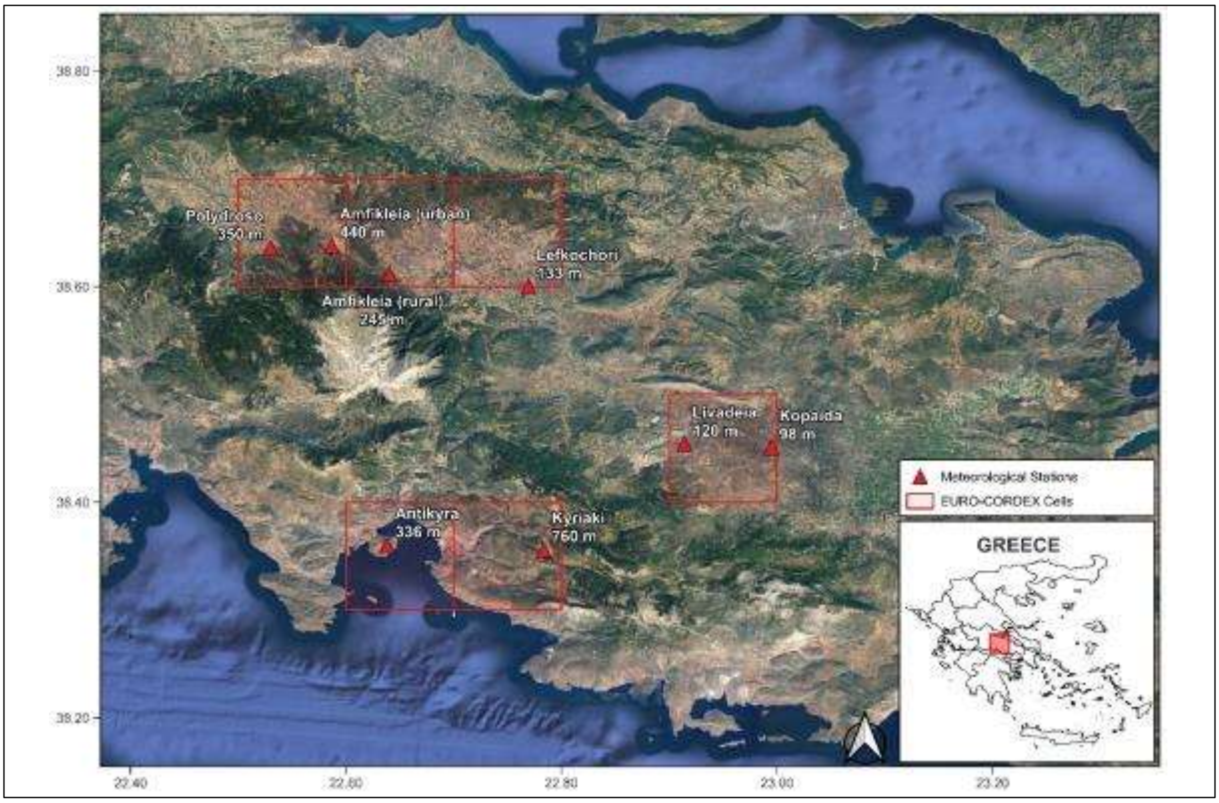

Figure 1. Study area with meteorological stations (red triangles). Their elevations and the respective EURO-CORDEX cells (red rectangles) are also shown

To ensure the selection of suitable climate model ensemble members, the methodology proposed by Aschonitis et al. (2019) was adopted. This method involves evaluating each of the 11 climate models using the standardized Root Mean Square Error index (sRPI) for each emission scenario. The sRPI index assesses model performance based on 12 statistical criteria that measure the deviation of temperature simulations from observations (Table 1). Models were ranked accordingly, with the models being categorized into top-performing models (sRPI > 50%) and low-performing models (sRPI < 50%) (Table 2).

Table 1. Statistical Criteria Used to Evaluate Climate Models

Abbreviation	Statistical Criterion
d	Index of Agreement
NSE	Coefficient of Efficiency (Nash-Sutcliffe efficiency)
KGE	Kling-Gupta efficiency
VE	Volumetric Efficiency
AME	Absolute Maximum Error
MAE	Mean Absolute Error
MBE	Mean Bias Error
RMSE	Root Mean Squared Error
R4MS4E	Fourth Root of the Mean Quadrupled Error
RAE	Relative Absolute Error
RVE	Relative Volume Error
SSE	Sum square error

Regional agronomic data from greek conditions were used to calibrate the CERES-Wheat model (Nikou and Mavromatis 2023), a crop model of the Decision Support System for Agrotechnology Transfer (DSSAT) (Hoogenboom et al. 2019). Crop simulated flowering dates, maturity dates, and potential yield were compared between the top-performing models, low-performing models, and the full ensemble to determine if there are any advantages of selective model inclusion. The performance of climate models and the CERES-Wheat model was assessed using common statistical metrics.
Based on crop model predictions, three sowing dates (November 15, December 1, and December 16) were tested to evaluate climate models and to determine if changing the sowing date could effectively mitigate the adverse impacts of climate change on wheat production. Accurate climate predictions combined with agronomic models are intended to provide practical insights that could assist Greek farmers adjust to changing climate conditions and maintain sustainable wheat production and food security in the region.

Results and discussion

The evaluation of the 11 climate models using the standardized Root Mean Square Error index (sRPI) revealed significant variability in their performance. Models, which had the highest sRPI scores, consistently showed lower deviations from observed temperature data, indicating their suitability for simulating local climate conditions. Conversely, models with lower sRPI scores exhibited higher errors and were deemed less reliable (not shown).

Table 2. Performance of Regional Climate Model Simulations

Category	Model Simulation
Top-Performing	CCLM4-8-17_ICHEC-EC-EARTH

The CERES-Wheat model simulations provided insights into how different climate scenarios would impact wheat phenology and yield. The results for the three sowing dates revealed several key findings. For anthesis dates, the best-performing models predicted dates within a range of 4-6 days (based on means and medians of Fig 2) earlier than observations, while the low-performing models 8-11days later and the full ensemble within a range of 1-4 days later. There is agreement between the three emission scenarios.
For maturity dates, the best simulation runs provided more accurate predictions (within 3-4 days earlier than observations), whereas low-performing models and the full ensemble predictions resulted in later (11 to 12 days and 3 to 5 days accordingly) predictions. An agreement was also found between the three emission scenarios.

Yield predictions from the top-performing models showed a variability in deviation ranging from -8% to +6% depending on the emission scenario compared to the low-performing models that showed an increase in the range of 23% to 28% and the full ensemble indicating also an increase by 16% to 20%. These results demonstrate the value of evaluating the climate model simulations before its use in impact assessment studies.

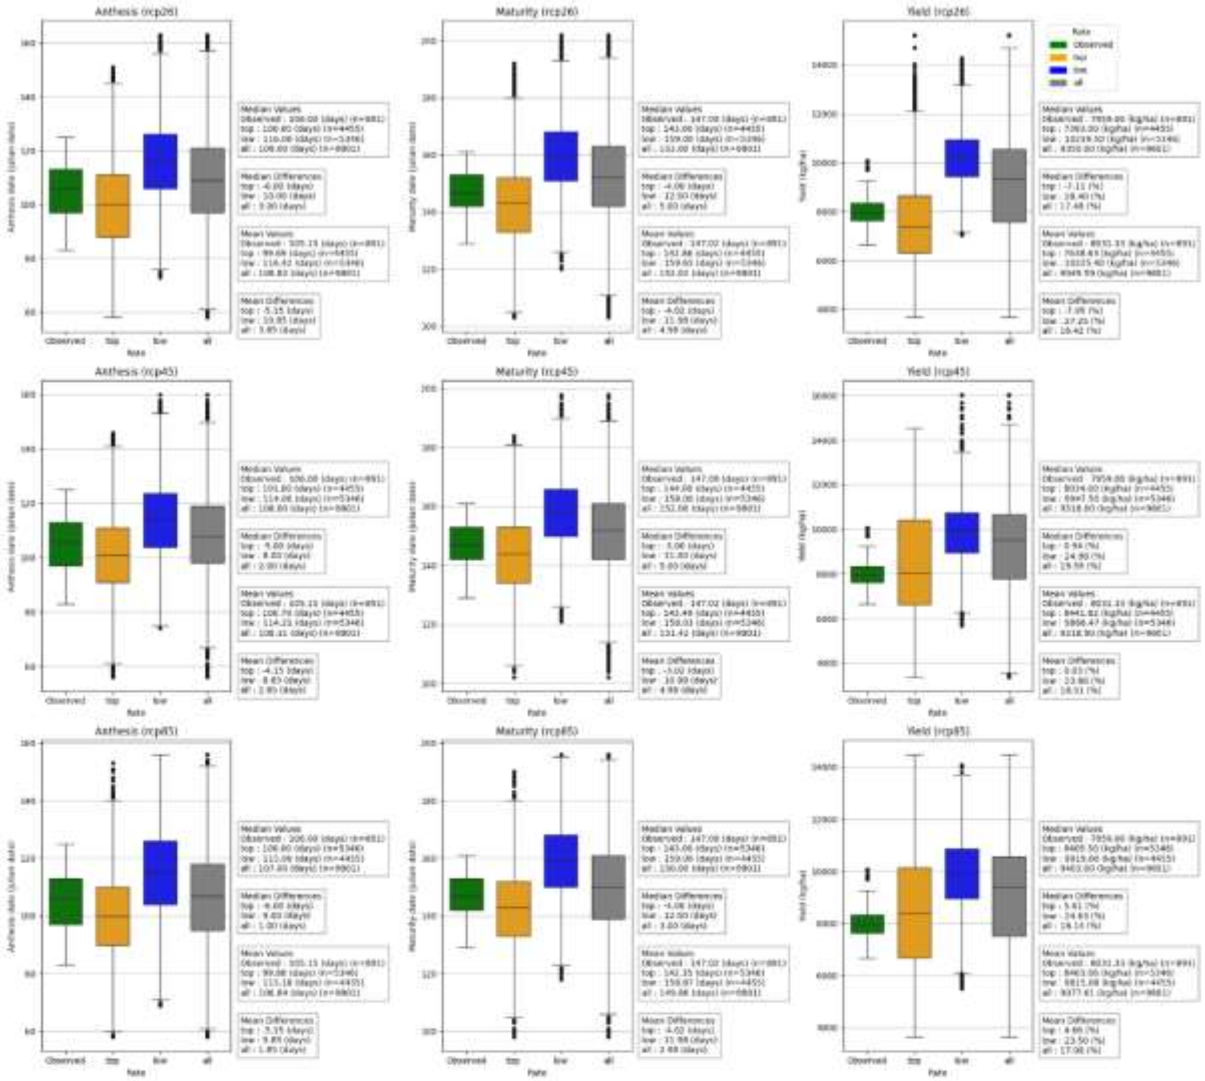

Figure 2. Comparison of anthesis days, maturity days (Julian dates), and yield (kg/ha), as derived from CERES-Wheat, for three different planting dates (15 November, 1 and 16 December), for the rcp26, rcp45 and rcp85 scenarios, for the observations (Observed), the total (all), the best (top: sRPI>50%) and worst (low: sRPI<50%) simulation scenarios. The sample size (total n of growing seasons) for each category is also presented.

Conclusion

This study highlights the critical role of climate model selection in enhancing the accuracy of crop model predictions. The study’s findings underscore the importance of selecting appropriate climate models for reliable agronomic predictions. The calibrated CERES-Wheat model, when driven by the best-performing climate models, provided more accurate predictions of wheat anthesis, maturity and potential yield, enabling better adaptation planning. Further research should continue to refine model calibration and explore additional adaptation measures to address the evolving challenges posed by climate change.

Abstract

Pepper (*Capsicum annuum* L.) is an economically important vegetable species in the Balkan region. Production of pepper, in recent years, has become very challenging, where abiotic stresses (extreme temperatures, drought) can reduce crop yield by more than 50%. In our region, bell pepper is one of the most popular types of pepper on the market. This experiment was conducted on 14 genotypes of bell peppers (different geographical origin) during two vegetative seasons (2020, 2021) in an open field and in the greenhouse (semi-controlled conditions) in Smederevska Palanka. Nine characteristics related to plant development and yield were observed. The aim of this study was to estimate the impact of abiotic stress conditions on pepper plant development, fruit quality and yield. The maximum recorded temperature during the observed growing seasons was 40.7 (flowering and fruiting period). The total amount of precipitation was below the optimum in both observed years: 540.7 mm (2020) and 380.1 mm (2021). The average yield recorded in greenhouse trials was higher by 56% (2020) and 78% (2021) in comparison to the trials in the open field. The results from the open field trial showed that genotype CA11 (USA origin) had the highest yield (2020 and 2021). A lower amount of precipitation in the open field had a negative effect on all observed traits (plant height, flowering time, fruit setting time, fruit size). Obtained results are essential in overcoming the problems caused by environmental changes and for improving the response of pepper plant resistance to abiotic stress.

Keywords: *Capsicum annuum L., drought, abiotic stress, high temperature, climate change.*

Introduction

Pepper (*Capsicum annuum* L.; n = 12) is an annual crop, belonging to family *Solanaceae*. It is a widely produced crop, whose area of cultivation is in the mid-latitudes (Erickson and Markhart, 2002). Based on FAO data (FAOStat. 2022), pepper is grown on a total of 2.02 million hectares, and the largest producers are China (0.757 mha), Indonesia (0.334 mha) and Mexico (0.156 mha). In the last 50 years, the area with pepper production has increased by 170% in the world (657% in China).
The origin of the genus *Capsicum* (perennial wild form) is from the tropical South American region - central and southern Bolivia (Gonzales-Perez et al., 2014). The species *Capsicum annuum* originated in the more humid areas of the Amazon river, and the further evolution of this species continued in Mexico and the northern part of Central America (Zou and Zhu, 2022). *Capsicum annuum* L. is characterized by great fruit diversity in size (1-25 cm), shape, color, pungency, pericarp thickness (Palma et al., 2020). The shape of the fruit is a very important trait, and basic characteristic for classification genotypes in groups (Zhigila et al., 2014). Genotypes of bell pepper can be very different according to the shape of the fruit: elongated, blocky, almost round, square (Sood et al., 2023). In the last few years, the

production of bell pepper has increased significantly (Anaya-Esparza et al., 2021). Besides the nutritional value of pepper fruits, it is an important source of various vitamins, phenols, carotenoids, antioxidants (Nadeem et al., 2011). The success of bell pepper production depends on various conditions, including environmental conditions (primarily temperature and precipitation), genetic diversity, as well as the resistance to diseases and pests. Changes in environmental factors (extreme temperatures and humidity) can lead to changes in the length of the vegetative season in pepper cultivation due to changes in physiological processes in plants (Bisbis et al., 2018). The optimum temperature for bell pepper cultivation is 21-33°C (Thuy and Kenji, 2015). Bell pepper is sensitive to high temperature (Erickson and Markhart, 2002), and temperature below 18°C and above 27°C for extended period slow down the development and ripening of fruits (Berke et al., 2003) and lead to a decrease in yield and fruit quality (Bisbis et al., 2018).
Climate change and its impact on agriculture is one of the most important topics today. Changes in climate parameters (extreme temperatures, rising atmospheric CO2 levels, drought) have significant impacts on agricultural production (Skendžić et al., 2021). There is evidence that the growing seasons of certain plant species have prolonged, and that the beginnings of the vegetative seasons of certain plant species have shifted due to milder winters (Lavalle et al., 2009). The consequences of climate change are also evident in the increase of insect populations (change of location, increased survival rate, number of generations, reduced number of natural enemies).
The aim of this study was to determine the effect of abiotic stress conditions on plant growth, fruit quality, and yield of 14 bell pepper genotypes.

Materials and methods

This experiment was conducted during two growing seasons (2020-2021) on the experimental fields of the Institute for vegetable crops in Smederevska Palanka, Serbia (latitude 44.354933”N, longitude 20.947183”E, elevation 101 m). A parallel trial was set up in an open field and in a greenhouse (semi-controlled conditions). Fourteen bell pepper genotypes of various geographical origins were chosen from the Institute of Vegetable Crops' gene bank collection and were used as material in this experiment. In the first decade of April, the seeds of each genotype were sown in styrofoam containers (ϕ 35 mm) and stored in a greenhouse with appropriate nourishment, irrigation and fertilization until planting. Half of the produced plants were planted in an open field (spacing between plants in row 25 cm, row spacing 70 cm). The experiment was organized in three repetitions using a complete randomized block design with 14 plots in one block and 10 plants in one plot. The experiment in the open field was conducted on the vertisol. Crop care consisted of inter-row cultivation, fertilization, protection against plant diseases and pests. Irrigation was conducted as needed, with a typhoon, several times during the growing season. In the greenhouse, the plants were planted in plastic pots (ϕ 28 cm). The temperature in the greenhouse was regulated by shading, regular nursing of the plants was carried out, and watering was carried out daily.
Nine traits related to plant development and yield were observed (1. Length of stem to first flowering brunch (cm) – 100 days from sowing; 2. Plant height (cm) – 100 days from sowing; 3. Fruit pericarp thickness (cm); 4. Fruit weight (g); 5. Sugar content (°Bx); 6. Fruit width (cm); 7. Fruit length (cm); 8. Time of fruit maturity – days from planting; 9. Flowering time - days from planting). The obtained results were analyzed using AMMI analysis (Gauch, 2006). Statistical analysis was performed using R software, version 4.4.0 (R Core Team, 2024). Based on the results of the AMMI analysis, ASV coefficient was calculated (Purchase et al., 2000) and genotypes and environments were ranked by stability.

In Figure 1 (a and b) are shown meteorological data in Smederevska Palanka for the periods 1949-2009 and 2010-2022. These data were collected from meteorological yearbooks of Republic hydrometeorological service of Serbia (RHMZ, 1946-2022). In addition, the image also shows meteorological data for the two observed years - 2020 and 2021.

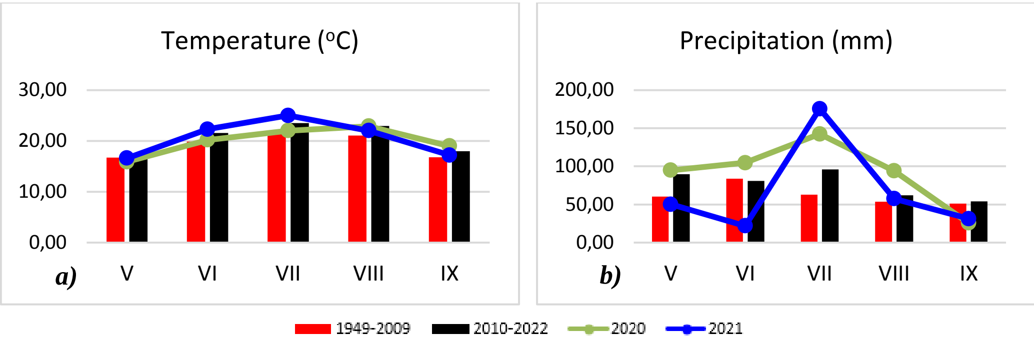

Figure 1. Meteorological data for Smederevska Palanka - a) average monthly temperatures (°C), b) total monthly precipitation (mm)

Based on the results shown in Figure 1, we can conclude that there is certain evidence of climate change in Smederevska Palanka. When compared to meteorological data recorded in a period of 50 years (1949-2009), the average monthly temperature in Smederevska Palanka in the last decade is higher by 1.49% (May) to 9.10% (July). The number of days where the maximum daily temperature is above 25°C has increased by 2-5 days (15.88% (August) to 35.89% (September)) in the last decade compared to the period 1949-2009. In 2020, the average monthly temperature was higher than the fifty-year average from June to September (by 0.36°C, 0.44°C, 1.82°C, 2.23°C, respectively). In May, the average temperature was 0.82°C lower than in the observed fifty-year period. In 2021, the number of days with a maximum daily temperature > 30°C was higher in all months of cultivation, compared to the multi-year average. The maximum recorded temperature during the observed growing seasons was 40.7°C (June 2021 - flowering and fruiting period).
The total amount of precipitation was below the optimum in both observed years: 540.7 mm (2020) and 380.1 mm (2021).The number of days with more than 10 mm of precipitation in the period of intensive plant development, flowering and fruit setting (June) decreased in the last decade compared to the fifty-year average by 11.7%, while the difference compared to the experimental years is even greater (2020 - 24 %, 2021 – 220%).

Results and discussion

Based on the AMMI analysis results (Table 1), it was determined that the genotype and the environment have a statistically significant effect on the variability of the nine observed pepper characteristics. The total sum of squares of the characteristics: length of stem and plant height were explained with the main effects of environment (66.33% and 59.04%, respectively). This means that these two observed traits were significantly influenced by the environment and that the obtained results differed depending on the environment in which the plants were grown. The variability of the trait fruit pericarp thickness was affected predominantly by the environment, although it was also affected by the GxE interaction. The variability of the remaining 6 observed traits was significantly affected by the divergence of genotypes. The total sum of squares for the characteristics fruit weight and fruit width were explained with the sum of squares of the environment with 38.27% and 40.39%, respectively. Based on this, we can conclude that the variability of these two traits was also significantly influenced by the environment in which the genotypes were grown.

Table 1. Percentage of SS in total SS of 9 observed traits (ANOVA for the AMMI model)

Source of variation	*T1	T2	T3	T4	T5	T6	T7	T8	T9

Error	0.99	1.40	11.56	0.65	4.02	3.97	0.38	2.92	8.74

**T1 - Length of stem; T2 - Plant height; T3 - Fruit pericarp thickness; T4 - Fruit weight; T5 - Sugar content; T6 - Fruit width; T7 - Fruit length; T8 - Time of fruit maturity; T9 - Flowering time; G – Genotype; REP – repetition; E – environment; SS – Sum of square*

Based on the obtained results, it was established that cultivation in semi-controlled environments provided more stable results compared to open-field pepper cultivation. However, the results also showed that the trait fruit weight had the most stable results recorded in open field production in 2020. The trait length of stem to the first fruit branch had a greater stability in 2021. During the year 2020, higher amounts of precipitation were recorded compared to the year 2021, while extreme temperatures during flowering and fruit setting were only observed for 5 days in 2020 (June). Except for the CA10 genotype, for the genotypes with the lowest variability of the trait length of stem to the first fruit branch (CA1, CA5, CA8, CA13) were also recorded below-average values for this trait, which means a lower number of fruits per plant and therefore a lower yield for the producers. The characteristic the flowering time is specific. The share of the sum of squares of the environment in the total sum of squares for this trait is only 1.68%, while the share of the sum of squares of the GxE interaction is 11 times higher.

It has been confirmed that over 80% of the potential yield of agricultural crops is lost annually due to abiotic stresses: extreme temperatures, drought, salinity, etc. (Hirt and Shinozaki, 2004). Crop sowing is often delayed due to extreme conditions during the period of optimal sowing dates (April and May). Plants enter the generative phase faster due to high temperatures, physiological processes are disrupted, pollen is sterile, flowers and fruits fall (Lee and Choi, 2013). The lack of moisture during production leads to the formation of fruits of poorer quality. For this reason, one of the most important steps in planning pepper production is to determine a good sowing date (Saqib and Anjum, 2021). It is recommended that production, especially during the period of initial development (up to the 10-leaf stage), be transferred to controlled conditions. It is predicted that by 2050 the number of inhabitants in the world will reach 9 billion. As a result of climate change and extreme abiotic conditions, many cultivated areas have been destroyed, we are facing drought and a lack of water for irrigation. To ensure safe food, it is necessary to work on plant genetic potential, resistance to abiotic stress and the introduction of new agrotechnical measures in the production of peppers.

The origin of all observed genotypes is from the northern hemisphere, from 19.39° to 52.69° latitude (CA12 and CA9, respectively). The genotypes that stood out with the highest stability, when considering all traits, are CA4, CA6, CA9, CA10 and CA13 (Hungary, Japan, France, Canada and Serbia). We can conclude that under the conditions of our country, the best adaptability still have genotypes originating from approximately the same latitude (around 45°). The highest fruit weight was recorded in genotype CA12 (originating from the United States); however, except for earliness and plant height, this genotype presented significant variability in all other parameters. The average yield recorded in greenhouse trials was higher by 56% (2020) and 78% (2021) in comparison to the trials in the open field.

Conclusion

The genotypes (14 bell peppers of different origin) and the environments (open field and greenhouse, observed for two years) have a statistically significant effect on the variability of the nine observed pepper characteristics. Based on the obtained results, there is evidence of certain climate changes in Smederevska Palanka. An increase in average monthly temperatures was recorded in the last decade (2010-2022) compared to the fifty-year average (1949-2009). Total precipitation decreased in both observed years: 540.7 mm (2020) and 380.1 mm (2021). Despite the above, appropriate measures such as on time sowing, shading, proper irrigation, seedling production under controlled conditions, and the good genetic potential of seed material, can significantly reduce side effects of climate change. Finally, it was determined that genotypes originating between latitudes 40° and 50° are stable enough to achieve satisfactory results in the climate conditions of our region.

Abstract

In Kosovo, grapevine production has been extended in recent years. Its main production region is in Rahovec and neighboring municipalities. Due to the favorable weather conditions of the country, important grapevine pests and diseases have been developed. Therefore, the aim of this study was to investigate the genus *Xiphinema* species in symptomatic and damaged vineyards. Total number of seventy-one soil samples were collected in early autumn of the year 2022 and early spring of the year 2023. Soil samples were taken and transferred to the laboratory for nematode extraction and further analysis. The extraction of nematodes was carried out using Flegg modified Cobb technique. Each sample was subjected to morphological and microscopic identification. Of seventy-one soil samples, thirty-two samples were morphologically identified as *Xiphinema* spp. Furthermore, single nematodes from the positive samples were subjected to DNA extraction with commercial kits. In order to confirm morphological diagnosis, molecular analysis using the D2-D3 expansion segments of the 28S rDNA and the ITS containing region were undertaken using universal primer sets D2A-D3B and ITS1-ITS2, respectively. D2-D3 expansion domains of the ITS region and 28S rDNA gene region produced single fragments of 730 bp and 980 bp, respectively. Two years of monitoring survey conducted in two different seasons confirmed the occurrence the genus *Xiphinema* species in Kosovo vineyards.

Keywords: *Xiphinema* species, vineyards, ecto parasitic nematodes.

Introduction

In terms of production, grapevine is one of the largest cultivated crops worldwide, both for wine and table grapes production (Li *et al*. 2021; Pertot *et al.* 2017). In terms of cultivation, Europe incorporates around 40% of the vineyards worldwide (Fraga, 2019). Even though it has largest production area, grapevine faces many challenges like pests and diseases. In particular, plant parasitic nematodes pose a major threat to grapevine production. These nematodes usually damage below ground of its parts. Moreover, the injuries caused by plant parasitic nematodes on roots become prone to infections of other pathogens like bacteria, fungi or viruses leading to secondary infections (Malik *et al.* 2022). It is well known that the genus *Xiphinema* commonly called dagger nematode is characterized by the presence of a stylet used for root tissue penetration. Recent studies revealed that annual crop losses caused by this genus are estimated between 8 to 15% of total crop production worldwide (Archidona-Yuste *et al.* 2020). Particular species of this genus are vectors of several important plant viruses that cause significant damage to grapevine production (Decraemer *et al*. 2007). Among dagger nematodes, *Xiphinema index* and *Xiphinema americanum* are pathogenic in vineyards and cause economic damage by feeding on the roots (Xu *et al*. 2018; Taylor and Brown, 1997).

In Kosovo, the grapevine production area has been extended in recent years. Its main production area is in the Municipality of Rahovec and its neighboring municipalities. According to the *Green Report 2023*, total vineyard area in Kosovo has reached 3472 ha (MAFRD, 2023), however, many problems due to pests and diseases have also raised. It is well known that Kosovo has favorable weather conditions for the development of many important pests and diseases affecting grapevine production. Despite common fungal diseases, interesting studies were conducted in previous years. The presence of many important virus diseases, phytoplasma and insects affecting grapevine production have been previously recorded in Kosovo (Gjinovci *et al*. 2022; Bunjaku *et al*. 2022; Dida *et al*. 2017; 2018). Meanwhile, no data have been found concerning the presence of nematodes in affected vineyards. Apparently, no information is available in Kosovo regarding the occurrence and distribution of the genus *Xiphinema* species.

Therefore, to know the current situation of grapevine about the presence and distribution of parasitic nematodes in Kosovo, an intensive survey was conducted in symptomatic and damaged vineyards. Our study has investigated the genus *Xiphinema* species only in affected vineyards particularly, aimed to investigate the importance of *X. index* as a vector of Grapevine fan-leaf virus (GFLV).

Materials and Methods

This study was carried out in the Municipality of Rahovec which is considered the most important vineyard region in Kosovo (Fig. 1).

Fig. 1: Map of Kosovo focusing the main vineyards area of Rahovec

A total number of seventy-one soil samples were collected in early autumn of the year 2022 and early spring of the year 2023. Each sample consisted of 2 kg of soil collected from the rhizosphere with 30-60 cm depth and transferred to the laboratory with a portable cooler for nematode extraction. Each soil sample was extracted according to the EPPO protocol PM7/119 (EPPO, 2013) using Flegg modified Cobb technique. Extracted samples were then subjected to morphological and microscopic identification using Olympus CX 43 Microscope (Tokyo, Japan) with 40-fold magnification. Furthermore, a single nematode from each morphologically positive sample was subjected to DNA extraction using NucleoSpin® Tissue

XS Kit (Macherey-Nagel, Duren, Germany) strictly following manufactures protocol. The DNA isolated from each individual nematode was directly amplified by using two sets of universal primers. The ITS containing region was amplified using the forward primer ITS1 (5-TTGATTACGTCCCTGCCCTTT-3) and the reverse primer ITS2 (5-TTTCACTCGCCGTTA CTAAGG-3) (Vrain et al. 1992), while the D2A (5-ACAAGTACCGTGAGGGAAAGTTG-3) and D3B (5-TCGGAAGGAAC CAGCTACTA-3) were used to amplify the D2–D3 fragments of the 28S rDNA gene (Nunn et al. 1992). PCR amplification reactions were performed in a final volume of 25 μl containing 13.7 μl of MGW, 2.5 μl of PCR buffer 10X (Qiagen), 2.5 μl of $MgCl_2$ 25mM (Qiagen), 2 μl of dNTPs 10mM (Qiagen) 2 μl of extracted DNA and 0.3 μl of TapTaq 5U (Qiagen). In each PCR cycle 1 μl of each primer set (ITS1-ITS2) and 1 μl of each primer set (D2–D3) were added. The thermal cycling program employed an initial denaturation at 95°C for 3 min, followed by 39 cycles with a denaturation at 94°C for 1 min, annealing at 55°C for 1 min and extension at 72°C for 1 min. A final extension was performed at 72°C for 5 min (Wang *et al*. 2003). Amplification success was evaluated electrophoretically on 1.5 % agarose gel. The remaining PCR product was prepared for sequencing.

Results and discussion

In the present study, the determination of *Xiphinema* species was performed using an integrated approach based on morphological analysis combined with molecular-based techniques. Out of seventy-one soil samples included in our study, thirty-two of them were distinguished as assumed *Xiphinema* species. Morphological identification of these findings about the genus *Xiphinema* were carried out using the key described by Coomans *et al.* 2001. *Xiphinema* (Cobb, 1913) is among the largest genera in the family Longidoridae and has a body length of 1.2–7.3 mm, habitus straight to spiral with a stylet composed of needle-like (Fig. 2).

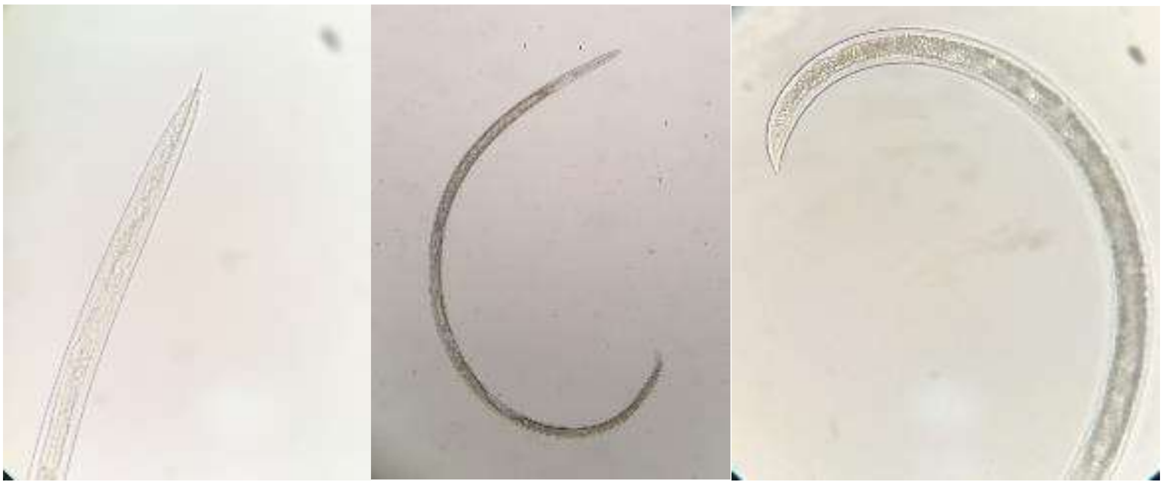

Fig. 2: Anterior part with stylet (left), habitus of *Xiphinema* spp. (middle), and posterior part (right)

In order to confirm morphological findings, single nematodes from each positive sample were subjected to molecular analysis. Two sets of universal primers were used to amplify the ITS containing region using ITS1–ITS2 primer set according to Vrain *et al*. (1992) and the D2A and D3B primer set were used to amplify the D2–D3 fragments of the 28S rDNA gene as described by Orlando *et al*. (2016). In each analyzed sample, the amplified product of the ITS1-ITS2 and D2-D3 expansion domains of the ITS region and 28S rDNA gene region produced single fragments of 730 bp and 980 bp, respectively (Fig. 3). Furthermore, ten selected samples were chosen based on different locations and delivered for multi-locus sequence analysis.

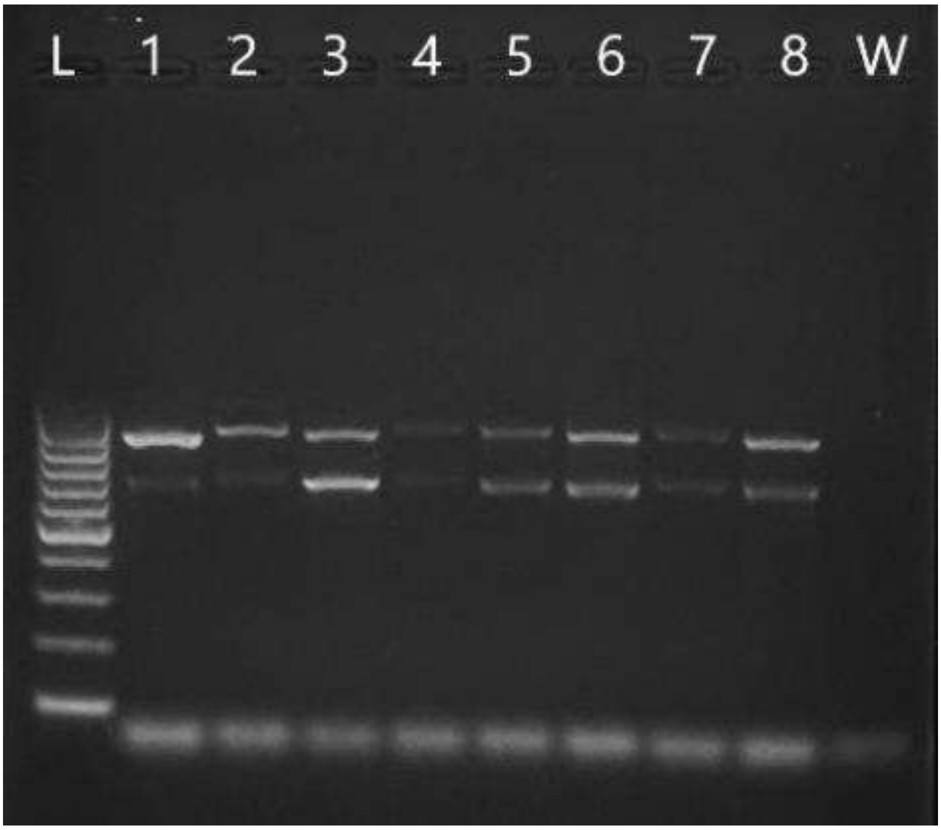

Fig. 3: Electrophoresis gel showing results of the ITS1-ITS2 and D2-D3 expansion domains producing single fragments of 730 bp and 980 bp, respectively.

Conclusion

To our best knowledge, this is the first evidence about the investigation and preliminary data about the genus *Xiphinema* species in Kosovo vineyards. These results highlighted the occurrence and distribution of *Xiphinema* species in the surveyed area. The collected data indicated that regulated dagger nematode of the genus *Xiphinema* species were distributed mainly in confined GFLV infected area. Indeed, our findings were significant in correlation with the recent study described by Singh *et al*. (2020). However, precautions and appropriate sanitation practices should be adopted by nurseries and farmers to avoid the spread of this species in proven healthy and protected vineyards of the country. The presence of ectoparasitic nematodes could encourage farmers to monitor their grapevine fields and prevent expanding their vineyards in infested areas. This study will help farmers to avoid planting close to GFLV symptomatic vineyards and possibly to use any cultural practice to maintain healthy infested vineyards. The first evidence of *Xiphinema* species in Kosovo vineyards shall be an alert for deeply investigating and evaluation of the impact of these ectoparasitic nematodes and their damage to the grapevine yield production.

Abstract

In this study, we evaluated the allelopathic effects of essential oils of *Thymus vulgaris* and *Citrus sinensis* on the seeds (seed germination and length of roots) of 7 varieties of cereals (durum wheat : VITRON, SIMETO, CHEN'S, OUED BARED; soft wheat : MAWNA, ARZ ; and barley: SAIDA). The chemical composition of the essential oils was determined using gas chromatography/mass spectrometry (GC/MS). The main constituents of essential oil were carvacrol (48.56%) for *Thymus vulgaris* and β - pinene (30%) for *Citrus sinensis*. The results of seed bioassay showed that essential oils of *Thymus vulgaris* and *Citrus sinensis* exhibited an phytotoxic effect at high concentrations (1 and 0.1 mg/ml), The essential oils suppressed the seed germination and length of roots. Germination of seeds was inhibited 100 % with concentration 1 and 0.1 mg/ml for both essential oils. A similar inhibitory effect was observed regarding the length of roots, *Thymus vulgaris* essential reduced length of roots at 1 ;0.1 and 0.01 mg/ml. The data suggest a greater effect of *Thymus vulgaris* essential oils compared to *Citrus sinensis* essential oils. Our study confirmed the phytotoxic effect of *Thymus vulgaris* and *Citrus sinensis* essential oils. further studies are necessary for essential oils of *Thymus vulgaris* and *Citrus sinensis* to be used as bioherbicides. The research needs to focus on determining the herbicidal effect on cereal weeds and the minimum inhibitory dose that cannot cause damage to host plants under field conditions.
.

Key words: *Citrus siensis, Thymus vulgaris, Essential oil, Germination, cereals.*

Introduction

The losses caused by weeds are one of the main limiting factors for staple crops worldwide. Interest in pesticides of natural origin (particularly plant-based) as an alternative to chemical pesticides has grown, as they are environmentally friendly, biodegradable, non-toxic and have a specific action, thus attracting considerable attention (Tripathi and Dubey, 2004 ; Isman ,2000; Ishii,2006; Ito and al.,2023). The yield of major crops, as well as the quality of harvested products, are severely compromised by weed infestation (Đorđević and al.,2022). In recent years, research has focused on exploring new ecological compounds with herbicidal activity for crop protection and weed management (Araniti and al., 2014). Particularly on cereals, Đurđić et al.(2016) considers, The wheat is the most important grainy plant used in human nutrition and it is the second on the ladder of overall grain production, after the corn Essential oils represent alternatives to chemical herbicides and have been widely studied as valuable ecological compounds with herbicidal activity for weed management (Araniti and al, 2018, Sarić-Krsmanović and al, 2023). The phytotoxicity of certain essential oils against weed seed germination has been proven (Tworkoski, 2002 ; Ibanez and Blazquez , 2020). However, the phytotoxic activity of essential oils must be selective, so that they do not harm crops. Therefore, besides the study of the herbicidal activity of essential oils, it is also necessary to know their potential effect on crops. Among essential oils, many have been identified as allelochemicals and tested for phytotoxicity(Kostina-Bednarz and al., 2023). The herbicidal effect of *Citrus sinensis* and *Thymus vulgaris* essential oils has been reported by Nepomuceno and Salgueiro, (2012) and Alexa and al, (2018). Zheljazko and al, (2021), *Thymus vulgaris* essential oils showed promise as a potential suppressor of seed germination and radicle growth of the weed species Raphanus sativus, Lactuca sativa, and Lepidium sativum. Our objective was to evaluate the phytotoxic effect of *Citrus sinensis* and *Thymus vulgaris* essential oils on cereal seeds considered as strategic crops in Algeria.

Materials and methods

Cereal seeds

Mature, healthy seeds of 7 cereal varieties donated by the Chlef cereals and pulses cooperative (CCLS) were used: 4 durum wheat varieties (VITRON, SIMETO, CHEN'S, OUED BARED), 2 soft wheat varieties (MAWNA, ARZ) and one barley variety (SAIDA).

Plant essential oils

Fresh *Citrus sinensis* and *Thymus vulgaris* fresh leaves were used for isolation of the essential oil, air-dried plant material was submitted to water distillation for 3 h using a Clevenger-type apparatus according to the European Pharmacopoeia method. The essential oils are stored in opaque bottles in the refrigerator at a temperature of 4°C and protected from light.

Gas chromatography (GC) analysis

The chemical composition of the essential oils was determined using gas chromatography/mass spectrometry (GC/MS). The operating conditions were as follows: the carrier gas was helium at a flow rate of 1 ml/min, the injector temperature was 250°C and 0.1 µl was injected in splitless mode for 0.1 min onto an HP5MS capillary column (30 m x 0.25 mm, film thickness 0.25 µm); the column temperature was programmed from 60°C to 260°C at a rate of 5°C/min with a final hold time of 10 min. For the Agilent 5973 model mass spectrometer, the temperature is: interface (280°C), source (230°C), quadrupole (150°C); ionization energy is 70 eV. Kovats indices of the compounds were calculated using the retention time of a series of n-alkanes.

Biological test

Using bioassays (% seed germination and root growth) we investigated the phytotoxic effect of the essential oils of *Thymus vulgaris* and *Citrus sinensis* on the seeds of 7 varieties of cereals. A total of 20 seeds were placed in 90mm diameter Petri dishes, containing a layer of filter paper (Whatman N01). The essential oil was emulsified with Tween20 (v/v 0.05%) and dissolved in distilled water. to obtained the final concentration: 0.0001, 0.001, 0.01, and 1 mg/ml of *Citrus sinensis* and *Thymus vulgaris* essential oils . 4 ml of the solution obtained was used to impregnate the germinating seeds. Distilled water mixed with Tween 20 (v/v 0.05 %) served as a control. The petri dishes were placed in a growth chamber at 25°C ± 2°C in dark for 10 days. The seed germination and elongation of radicel was observed in Petri dishes every 24 hours.

Statistical analyses

The results were subjected to an analysis of variance (ANOVA). Mean comparison tests were performed using the Fisher method at the 5% level and the software used to process the data was XLSTAT software

Results and discussion

Chemical composition of *Citrus sinensis* and *Thymus vulgaris* essential oils.
Essential oils were isolated from the leaves of *Citrus sinensis* and *Thymus vulgaris* by hydro distillation. Qualitative and quantitative analysis of essential oil chemical profiles is reported in Table 1. GC/MS analysis identified and characterized 26 compounds representing 95.72% of the *Citrus sinensis* essential oil and 22 compounds representing 91.75 % of the total *Thymus vulgaris* essential oil. The essential oil of *Citrus sinensis* was characterized by high levels of β - pinene (30%) while content of other components ranged from 9.37% to 0.07%. 15 components were present at less than 1%. Chi et al, (2020) and Mohammed et al, (2024) reported a similar number of constituents in *Citrus sinensis* essential oil, but with a different percentage of main compounds; in particular, a higher content of limonene. The essential oil of *Thymus vulgaris* was characterized by high levels of carvacrol (48.56%) and thymol (17.54%) and other components ranging from 8.70 to 0.09%. Five components were present at less than 1%. These results are in accordance with those previously reported. by Alexa and al., (2018) who reported that the major component of thyme essential oil was thymol.Vinciguerra et al. (2019) reported that p-cymene (36.36%) and thymol (24.35%) were the main components of *Thymus vulgaris* essential oil.

Phytotoxicity of *Citrus sinensis* and *Thymus vulgaris* essential oils
The results of seed bioassay showed that seed germination and length of roots of durum wheat, common wheat and barley varieties was inhibited at high concentrations (1 and 0.1 mg/ml) of *Thymus vulgaris* and *Citrus sinensis* essential oils. *Thymus vulgaris* essential oil show a strong inhibitory power (100%) at concentrations of 1, 0.1 and 0.01 mg/ml with VITRON, SIMETO and MAWNA varieties and 1 and 0.1 mg/ml for CHEN'S, OUED BARED, ARZ and SAIDA varieties (Figure 1). Sarić-Krsmanović and al, (2023) report the inhibiting effect that essential oils can have on seed germination. A comparable effect was observed on length of roots at levels of 1; 0.1 and 0.01 mg/ml, resulting in a 50% reduction in length of roots compared to the control (Table 2). The inhibitory effect was confirmed by statistically significant differences between all test concentrations (for seed germination and length of roots) and the control across the seven cereal varieties. However, no statistically significant difference was found for the low concentrations (0.001, 0.0001, and 0.00001 mg/ml). The effect of the high concentration used on the inhibition of seed germination was reported by Dorđević and al., (2022) for *S. glauca*, the allelopathic effect expressed through the inhibition of seed germination was more pronounced only after treatments with the highest used concentrations of extracts. Similar effect was observed with *Citrus sinensis* essential oils at the concentration 1 mg/ml (seed germination and length of roots) (Figure 2) (Table 3). The data suggest a greater effect of *Thymus vulgaris* essential oils compared to *Citrus sinensis* essential oils. The literature highlights a good phytotoxic capacity for *Thymus vulgaris* essential oil (Rolli et al. ,2014). The high phytotoxicity recorded for the essential oil of *Thymus vulgaris* compared with that of *Citrus sinensis* may be related to its high thymol and carvacrol content. Effectively Synowiec et al., (2017) report that the most phytotoxic group consisted of four essential oils, namely *Carum carvi*, *Thymus vulgaris*, *Mentha piperita* and *Salvia.officinalis* principally composed of oxygenated monoterpenes, while the second least phytotoxic group consisted of *S. canadensis* essential oil, rich in mono- and sesquiterpene hydrocarbons. Abd-ElGawad and al ,(2020) have mentioned that α- and β-pinene, 1,8 cineole, linalool, and carvacrol were the most effective allelopathic monoterpene compound.It has been suggested that the effect of essential oils can disrupt the permeability of the cell membrane structure. Such a phenomenon is due to the penetration of monoterpenes through the cell wall and cell membrane, or causes a leakage of cellular potassium that inhibits glucose-dependent respiration (Mutlu et al., 2011). Varietal sensitivity to essential

oils was different, with the VITRON variety being the most sensitive to *Thymus vulgaris* and *Citrus sinensis* and essential oils, followed by CHEN'S, OUED BARED, MAWNA, ARZ and SAIDA, in contrast to SIMETO, which recorded the highest percentage of seed germination. Abrahim et al. (2000) and Batish et al. (2004), reported that reduction of a plant's respiratory activities by monoterpenes reduces the amount of photosynthesis and disrupts germination as well as radicle growth.

Conclusion

Our study confirmed the phytotoxic effect of Thymus vulgaris and Citrus sinensis essential oils used in higher doses on seed germination and length of roots in vitro. further studies are necessary for essential oils of Thymus vulgaris and Citrus sinensis to be used as bioherbicides. The research needs to focus on determining the herbicidal effect on cereal weeds and the minimum inhibitory dose that cannot cause damage to host plants under field conditions.

Abstract

Microbiologically acceptable water is one of the basic preconditions for animal health and food safety. The experiment used drinking water originating from primary food production, including water from animal farms and meat, milk and fish production, sampled in 2021-2022 from Republic of Srpska (Bosnia and Herzegovina). A total of 757 samples were examined, of which 55.48% originated from the water supply system and 44.52% from wells. The aim of the study is to determine the microbiological status of drinking water from primary food production, using standard methods BAS EN ISO 6222, BAS EN ISO 7899-2 and BAS EN ISO 9308-1. The research determined 70.54% satisfactory samples and 29.46% unsatisfactory samples. Analyzing the results of unsatisfactory samples in relation to the origin, 31.39% of the samples were from the water supply system, and 68.61% were from wells. In relation to the tested parameters, 17.83% of samples were unsatisfactory due to an increased total count of bacteria cultivated at 22°C, and 20.21% of samples were unsatisfactory due to an increased total count of bacteria cultivated at 37°C. When it comes to pathogens, 13.47% unsatisfactory samples were due to the presence of intestinal enterococci, 15.59% due to the presence of *Escherichia coli* and 15.98% due to the presence of coliform. The microbiological status of water from primary food production is of concern, as almost a third of the samples are unsatisfactory especially considering the presence of intestinal enterococci, coliforms and *Escherichia coli*.

Keywords: *water, food, animal, production, microbiology.*

Introduction

Water is used in various ways in milk production and dairy industry, thereby becoming part of the food intentionally, inevitably or accidentally. No source of water that is intended for human consumption can be assumed to be free from pollution. All sources have different microbiological qualities and may be subject to natural or manufactured sources of pollution that may result in the deterioration of water quality to the point where treatment is no longer effective in removing all of the contamination. Zero-probability level of microbiological contamination of drinking water does not exist (Directive, 2020).

The presence of bacteria in drinking water *per se* is not an issue, as long as no pathogenic organisms are present: there are bacteria in drinking water, even in relatively high numbers (10^3 to 10^6 cells/mL), without consequences on human health (Hoefel *et al*., 2005; Hammes *et al*., 2008).

Water temperature is an essential factor influencing bacterial growth kinetics and competition processes. Drinking water temperatures typically range between 3 and 25°C in European countries (Niquette *et al*., 2001), and fluctuate seasonally within this temperature range even within a single drinking water distribution system. Elevated water temperatures have often been associated with increased bacterial abundance in drinking water distribution systems (Francisque *et al*., 2009; Liu *et al*., 2013), and with higher numbers in indicator organisms.

The microbiological quality of water is commonly defined as a maximum acceptable number or concentration of bacteria that do not constitute a health hazard (Directive, 2020).
Minimum requirements for parametric values used to assess the quality of water intended for human consumption is 0/100 ml for *Escherichia coli* and intestinal enterococci. In Republic of Srpska (Bosnia and Herzegovina) the limit value for total count on 22°C is 100 CFU/ml and for total count on 37°C the limit is 20 CFU/ml. Also, coliform bacteria, *Escherichia coli* and intestinal enterococci must not be detectable in 100 ml sample of water (Official Gazette, 2017).
The production and distribution of biological stable drinking water should be a non-negotiable goal for water utilities with the perspective of providing the same water quality to consumers than produced at the treatment facility. This can only be achieved by adequate monitoring and control of microbial processes during water treatment and distribution (Prest *et al*., 2016).
The presence of *Escherichia coli* in a sample of drinking water may indicate the presence of intestinal pathogens. However, the absence of *Escherichia coli* cannot be taken as an absolute indication that intestinal pathogens are also absent. *Escherichia coli* is a coliform bacteria and has historically been regarded as the primary indicator of faecal contamination of both treated and untreated water (Edberg, 2000; WHO, 2008).
The water used during handling and processing of milk products can be potential sources of microbial contamination with possible negative consequences on food safety. Especially, the water used in keeping the hygiene of milking and milk storage utensils is crucial to keep the quality and safety of the products. *Escherichia coli* was isolated in 39.20% of samples of water (Amenu *et al*., 2016).
Use of contaminated water in the handling and processing of milk products can cause a higher potential health risk than the risk through direct drinking. This is due to the fact that multiplication of pathogenic micro-organisms can occur in milk and milk products with amplification of the load of the pathogens (Amenu, 2013).
Some studies revealed that wash water can be source of bacterial contamination for milk and further compromise the quality and safety of milk or milk products (Kivaria *et al*., 2006; Perkins *et al*., 2009).
In a study by Habes *et al.* (2015) it has been founded that all water samples used in the production of milk and milk products were microbiologically safe.
Kalaba *et al*. (2020) found that in 2015-2017 of the 584 water samples, 26.20% were unsatisfactory.
In the study of testing water at milk collection points, 20.40% of unsatisfactory samples were found, of which 10.20% was detected *Escherichia coli* and coliforms, and faecal streptococci in 12.24% (Denžić *et al*., 2013).
Analysis of water from milk collection points, originating from wells, it was found 63.90% of unsatisfactory samples (Jaki *et al*., 2010).
The aim of the study is to determine the microbiological status of drinking water from primary food production.

Material and methods

The experiment used drinking water originating from primary food production, including water from animal farms and meat, milk and fish production, sampled in 2021-2022 from Republic of Srpska (Bosnia and Herzegovina). A total of 757 samples were examined (311 in 2021, and 446 in 2022).
Laboratory testing of samples was performed at the Public Veterinary Institute of the Republic of Srpska "Dr Vaso Butozan" Banja Luka.

Microbiological examination was carried out according to the Official Gazette (2017). This included enumeration of colony forming units (CFU) expressed as total count of bacteria cultivated at 22°C, and 37°C according to BAS EN ISO 6222 (ISBIH, 2003a), coliform bacteria and *Escherichia coli* according to BAS EN ISO 9308-1/A1 (ISBIH, 2018) and intestinal enterococci according to BAS EN ISO 7899-2 (ISBIH, 2003b).

In our research and in the statistical analysis of the obtained results, we used, as basic statistical methods, descriptive statistical parameters. The research results are presented in tables and figures.

Results and discussion

Water supplies within food production premises should be subject to risk and hazard assessment to ensure that appropriate water quality is maintained throughout the production process (Dawson, 2000).

The presence of pathogenic bacteria from water supply system is a particularly worrying fact given that water must be microbiologically correct, which means that it must not contain pathogens (Official Gazette, 2017). A possible explanation for this is dilapidation and damage to water supply installations leading to water contamination.

Many infectious diseases of animals and humans are transmitted by water contaminated with human and animal excrement, which becomes a source of pathogenic bacteria, viruses and parasites (protozoa, parasite eggs) capable of surviving for different periods, and raise the health risk for many people throughout the world. In order to eliminate the risk related to disease transfer, water intended for mass consumption is treated and disinfected before use (Sasakova *et al*., 2013; Fridrich *et al*., 2014). On the basis of the results, adequate measures can be taken that include prevention of contamination and systemic disinfection.

The research determined 70.54% satisfactory samples and 29.46% unsatisfactory samples. The obtained results are similar to the results of Kalaba *et al.* (2020) and Golić *et al.* (2023).

When it comes to the representation of samples in relation to the category, 55.48% of samples was from water supply system and 44.52% was from wells. Analyzing the results of unsatisfactory samples in relation to the origin, 31.39% of the samples were from the water supply system, and 68.61% were from wells. Comparing the results of water testing in relation to the category, it can be noticed that there is a significantly higher number of unsatisfactory samples of well water in relation to water supply sistem, which is expected considering that the public water supply system is under daily control with regular chlorination. In contrast, well waters do not flow, stagnate and are not under constant control or very rarely, usually once a year as an official control.

Indicator organisms are used to assess the microbiological quality of water. Many pathogens are present only under specific conditions and, when present, occur in low numbers compared with other micro-organisms (Edberg, 2000).

The use of indicator bacteria, in particular *Escherichia coli* and the coliform bacteria, as a means of assessing the potential presence of water-borne pathogens has been paramount to protecting public health (Hijnen *et al*., 2000).

Enterococci include a number of species that occur in the faeces of humans and warmblooded animals. The main reason for their enumeration is to assess the significance of the presence of coliform bacteria in the absence of *Escherichia coli*, or to provide additional information when assessing the extent of possible faecal contamination. As such, they are regarded as secondary indicators of faecal pollution (WHO, 2008).

According to the WHO (2008), colony counts are enumerations of the general population of heterotrophic bacteria present in water supplies. The enumerations may represent bacteria whose natural habitat is the water environment or those that have originated from soil or

vegetation. Two incubation temperatures and times are used for total count, 37°C for 48 h to encourage the growth of bacteria of mammalian origin, and 22°C for 72 h to enumerate bacteria that are derived principally from environmental sources.
In relation to the tested parameters, 17.83% of samples were unsatisfactory due to an increased total count of bacteria cultivated at 22°C and 20.21% of samples were unsatisfactory due to an increased total count of bacteria cultivated at 37°C. When it comes to pathogens, 13.47% unsatisfactory samples were due to the presence of intestinal enterococci, 15.59% due to the presence of *Escherichia coli* and 15.98% due to the presence of coliform. The results obtained differ significantly from the results Golić *et al.* (2023).

Conclusion

The microbiological status of water from primary food production is of concern, as almost a third of the samples are unsatisfactory, especially considering the presence of intestinal enterococci, coliforms and *Escherichia coli*. This is of particular concern given the significant participation of well water in the primary food industry, given that it is not under constant monitoring. For these reasons, it is recommended to take additional measures in order to improve the microbiological quality of water in primary food production, as well as regular and more frequent monitoring.

HARMFUL ENTOMOFAUNA ON STRAWBERRY IN BIJELJINA AREA (BOSNIA AND HERZEGOVINA)

Dejana STANIĆ*, Milanka MAŠANOVIĆ

Faculty of Agriculture, University of East Sarajevo, Bosnia and Herzegovina
*Corresponding author: dejana.stanić@pof.ues.rs.ba

Abstract

During the cultivation, strawberry is attacked by numerous harmful insect species that cause direct and indirect damage, thus significantly reducing quality and yield. Harmful entomofauna on strawberry in Bijeljina area (entity of Republic of Srpska, Bosnia and Herzegovina) was examined in 2024, in the location Mala Obarska). Using entomological methods such as visual examination of plants, using an entomological catcher and collecting insects using an exhauster, their presence, abundance and symptoms of damage were determined. Small insects (shield moths, cicadas, etc.) were collected directly from the plants using an exhauster. All collected larvae and pupa of collected insects, were reared in the lab to adult stadium. Total number of determined insect species was 18, from five orders and 16 families. The largest number of species from the order of Hemiptera have been determined, nine species from seven families (*Aphis forbesi* Weed, *Chaetosiphon fragaefolii* (Cockerell), *Graphosoma lineatum* (L.), *Dolycoris baccarum* (L.), *Lygus pratensis* (L.), *Coreus marginatus* (L.), *Pyrrhocoris apterus* (L.), *Cercopis vulnerata* (Rossi) and *Trialeurodes vaporariorum* Westwood. From the order of Coleoptera, five species from five families have been determined (*Phyllotreta undulata* Kutschera, *Anthonomus rubi* (Herbst), *Agriotes obscurus* (L.), *Stelidota geminata* Say and *Cetonia aurata* (L.). The species *Tettigonia viridissima* L. and *Omocestus* spp. from the order of Orthoptera were determined. From the order of Thysanoptera, *Frankliniella occidentalis* (Pergande) was determined and from the order of Lepidoptera, it was the species *Acleris comariana* (Lienig & Zeller).

Keywords: *harmful insects, strawberry, Bijeljina.*

Introduction

Strawberry production in the world is constantly increasing. According to FAO (Food and Agriculture Organization of the United Nations, 2024), the largest strawberry producer in the world is China with 3,336,690 million tons per hectare, followed by the USA with 1,055,963 million tons per hectare, and then Egypt, Mexico, Turkey, Spain, Brazil and Russia. In recent years, strawberry production in Bosnia and Herzegovina has also tended to grow, driven by significant investments, primarily in the fruit processing process (Kurtović et al., 2012). Strawberries are grown in BiH on an area of 1332 ha, with an average yield of 7.7 t/ha (Maličević et al., 2015). One of the most important strawberry production areas in Bosnia and Herzegovina is the area of the city of Bijeljina.

Strawberry is a fruit species that is inhabited by a large number of harmful insect species that can cause economically significant damage. Most of them are polyphagous and they attack the other plant species, especially from the Rosaceae family (Sarajlić et al., 2018). According to Alford (1984), about 90 species of strawberry pests have been recorded, ten of which cause economically significant damage. The most important harmful insects of strawberries worldwide are *Lygus rugulipennis* Poppius, *Anthonomus rubi* (Herbst), *Otiorhynchus sulcatus* (Fabricius), *Frankliniella occidentalis* (Pergande) and the other species (Cross et al., 2001; Gotlin Čuljak, 2015.a.). As more important pests of strawberries, Radman et al. (1981)

mention the next species: *Otiorhynchus rugosostriatus* Goeze, *Aphis forbesi* Weed., *Pentatrichopus fragaefolii* Cockerell, *Philaenus spumarius* L., *Melolontha melolontha* L., *Anthonomus rubi* Herbst., *Coenorrhynchus germanicus* Hb., *Priophorus padi* L., *Argyroploce lacunana* Denis & Schiff, *Cnephasia incertana* Tr., *Cnephasia communana* Tr., and species from families Noctuidae, Cicadellidae and Halticinae. According to Ciglar (1989) the most important harmful insects species on strawberry are *Anthonomus rubi* Herbst, *Acleris comariana* (Lienig&Zeller) and *Rhynchites germanicus* Herbst. In our region, in the early 70s of the last century, the appearance of insects species from the genus *Lepyrus* was mentioned as a pest of strawberries, while in Western Europe and Russia, species from the genus *Polydrosus* were mentioned (Petrova et al., 2013). In the territory of Bosnia and Herzegovina, the harmful entomofauna of strawberries has been studied very little. Thus, in this area as a harmful insects, Festić (1996) mentioned the next species: *Philaenus spumarius* L., *Aphis forbesi* Weed, *Anthonomus rubi* Herbst, *Eudia pavonia* L., *Glyptina fallax* Weise and *Haltica pusilla* Duft. Most of them are polyphagous, while a significantly smaller number of species are associated only with strawberries. During a three-year study (2009-2011) in the territory of Bosnia and Herzegovina, Zovko (2021) identified 70 species of harmful insects from seven orders. The most numerous order was Hemiptera with a total of 29 species, followed by the Coleoptera order with 15 species. The lowest number of species belonged to the orders Hymenoptera and Thysanoptera. Certain species of insects damage the root system, while many inhabit the above-ground part of the plant, causing various damage symptoms. Thus, the larvae of the following species cause damage to the root system: *Agriotes* spp., *Tipula* spp., *Scutigerella* spp., *Agrotis* spp., *Melolontha melolontha, Phyllopertha horticola* L., *Hoplia philanthus* Füessly and *Serica brunnea* L. (Cross et al., 2001). In Croatia, Maceljski (2002) mentioned three species from the genus *Otiorhynchus* (*O. ovatus* (L.), *O. mastix* (Olivier) and *O. rugosostriatus* (Goeze)) whose larvae gnaw the roots of strawberries, and in case of large numbers, they cause wilting and decay of plants (Cross et al., 2001; Gotlin Čuljak, 2015.a.). According Radman et al., (1981), *Otiorhynchus rugosostriatus* is a very important species in the area of Prijedor and Sarajevo. Occasional damage to the root system is caused by polyphagous species *Melolontha melolontha* L., *Phyllopertha horticola* (L.), *Amphimallon solstitiale* (L)., *Hoplia philanthus* (Füessly) and *Serica brunnea* (L.), especially if the strawberry plants were there was a pasture (Cross et al., 2001). A large number of aphids species occur on strawberry, but few species cause significant damage worldwide, such as *Aphis forbesi* Weed, *Chaetosiphon fragaefolii* (Cockerell), *Aphis gossypii* Glover, *Macrosiphum euphorbiae* (Thomas), *Myzus persicae* (Sulzer) and *Myzus ascalonicus* Doncaster (Cross et al., 2001; Maceljski, 2002). Blackman and Eastop (2000) were mentioned 30 aphids species of strawberry in the USA. Among them the most common species are *Aphis forbesi*, *Aphis gossypii* and *Chaetosiphon fragaefolii*, while they occur occasionally *Aphis ruborum* (Börner), *Aulacorthum solani* (Kaltenbach), *Chaetosiphon jacobi* (Hille Ris Lambers), *Ericaphis fimbriata* (Richards), *Macrosiphum euphorbiae* (Thomas), *Macrosiphum rosae* (L.), *Myzus ornatus* Laing and *Sitobion fragariae* (Walker). One of the most important harmful aphid species of strawberry in the world is *Chaetosiphon fragaefolii* (Cross et al., 2001; Rondon et al., 2004). In the Bosnia and Herzegovina, the fauna aphids species on strawberry has been studied very little. Radman et al. (1981) were mentioned two species, *Aphis forbesi* and *Chaetosiphon fragaefolii*. Both species the sap sucks from leaves and buds and, thus, causing direct damages such as chlorosis, curling and deformation (Rondon and Cantliffe, 2004; Gotlin Čuljak, 2015.b.). Also, these species cause indirect damage because they make large amounts of honeydew which covers the plant and represents a favourable base for developing the fungus black mould. All this causes a decrease in yield and reduced quality of fruits (Cédola and Greco, 2010). In addition, *Chaetosiphon fragaefolii* transmits several very important strawberry viruses such as strawberry mild yellow edge virus (SYEV), strawberry crinkle virus (SCV), strawberry mottle virus (SMV) (Blackman and Eastop, 2000; Cross et al., 2001; Rondon and Cantcliffe, 2005). A serious problem, especially in greenhouses can be the polyphagous species *Aphis gossypii* Glover (Lecant and Deguine, 1994), which causes great damage, especially in warmer production areas.

In addition to the mentioned species, thrips are also important pests of strawberries. Thus, during two years of research in Turkey, Atakan (2008) found 14 different species of thrips. Among them, *Frankliniella occidentalis* Pergande was the dominant species. In many countries this species causes significant damage to strawberries grown in greenhouses and the open fields (Atakan, 2008; Pinent et al., 2011). By sucking the sap from leaves and floral organs, this species prevents fruit set. Also feeding on strawberry fruits it causes deformation, which significantly reduces their quality (Atakan, 2011).

Bedbugs also cause significant damage to strawberries by feeding on parts of the flower, seeds or young fruits. In the area of Central and Northern Europe, the following species cause damage to strawberries: *Lygus rugulipennis* (Poppius), *Plagiognathus arbustorum* (Fabr.), *Plagiognathus chrysanthemi* (Wolff), *Closterotomus norwegicus* (Gmelin), *Closterotomus fulvomaculatus* (De Geer) and *Lygocoris pabulinus* L. (Cross et al., 2001; Alford, 2014). A very widespread species throughout Europe and an important pest of strawberry in the southern and western parts of the USA is *Lygus hesperus* Knight (Swezey et al., 2007; Zalom et al., 2014). The polyphagous species *Lygus rugulipennis* often occurs in large numbers and is highly adaptable to different weather conditions (Accinelli et al., 2002). The damage is caused by larvae that feed on flower buds, flowers and fruits. As a result of their feeding, the fruits remain small, deformed and lose marketability (Easterbrook, 2000; Cross et al., 2001; Cross, 2004; Łabanowska, 2007b). Significant damages from *Lygus hesperus* and *Lygus rugulipennis* were recorded on strawberries grown in greenhouses (Mešić et al., 2016). One of the most important pests that, in addition to strawberry, attacks raspberry, blackberry and wild rose is *Anthonomus rubi* (Herbst) (Alford, 2014). Thus, in Poland this species causes 10-30% damage every year (Łabanowska and Chlebowska, 1999; Łabanowska, 2002), and in some cases over 80% (Popov, 1996). Damage is caused by adults that feed on strawberry leaves during the supplementary feeding period. After oviposition in the flower buds, the female bites the stalk of the bud that doesn’t open, withers and bends downwards. It’s a characteristic symptom of the presence of this species. This significantly increases the intensity of damages (Aasen et al., 2004). Greater damage from this species in one location can be expected in the second and third year of strawberry cultivation (Aasen et al., 2004; Krauß et al., 2014). The intensity of the damage depends on the cultivars characteristics, the weather conditions during the oviposition and the length of the flowering period (Popov, 1996). Thus, significantly less damage was present on strawberry cultivars that have a shorter flowering period (Cross and Easterbrook, 1998; Cross et al., 2006). In the Northern and Central Europe, damage to strawberries is also caused by several species tortrix moths (Tortricidae, Lepidoptera). Among them, the most common are *Acleris comariana* (Lienig & Zeller), *Clepsis spectrana* (Treitschke), *Olethreutes lacunana* (Denis & Schiff.), *Cacoecimorpha pronubana* (Hübner) and *Cnephasia asseclana* (Denis & Schiff.) (Gratwick, 1992; Cross et al., 2001).

According to survey by Radman et al. (1981) the most widespread tortrix moths species of strawberry in Bosnia and Herzegovina are *Argyroploce lacunana* (Denis & Schiff.), *Cnephasia incertana* (Treitschke) and *Cnephasia communana* (Herrich-Schäffer). The larvae of these species gnaw the leaves, and often feed on parts of the flower. Such damaged flowers don’t to fructify or develop deformed fruits. The larvae of *Cnephasia asseclana* and *Cnephasia incertana*, in addition to damaging the leaves, often bore into the fruits, usually in the region of the sepals (Alford, 2014). Although tortrix moths larvae are often present in commercial strawberry plantations, economically significant damage are very rare (Cross et al., 2001). In our region, the most abundant species is *Acleris comariana*, which is widely distributed in Europe, North America, China and Japan (Gratwick, 1992; Alford, 2014). Damage is caused by larvae that gnaw and feed on young leaves, but sometimes also feed on flowers (Barić, 2015). An increase of tortrix moths population can also be caused by the excessive application of pesticides, since the population of natural enemies is significantly reduced in such plantations (Gratwick, 1992).

Materials and Methods

The survey was completed in 2024, in the field, in Bijeljina area (location Mala Obarska) and in the laboratory of the Faculty of Agriculture in East Sarajevo. The area under strawberries was 2000 m^2, there were 8,000 seedlings. The time of planting was August 10th, 2023. The distance between the rows is 140 cm, while the distance between plants in a row is 20 cm.

Entomological methods were used to determine insect presence, abundance, and damage symptoms. These methods included visual plant examination, 'mowing' with an entomological catcher, and insect collection using an exhauster. The visual method consists in examining plant organs (buds, leaves, flowers, whole plants). By randomly selection, ten plants at ten places were examined. The visual examination was carried out from April to the beginning of June. The number of aphids was evaluated according to the Banks scale (Maceljski and Igrc-Barčić, 1999). The scale is from 0-4 (0-without the presence of aphids, 1-very weak attack (individual aphids or very small colonies); 2-weak attack (small number of colonies on plants); 3-medium attack (mass appearance of aphids, large number colonies that aren’t yet connected); 4-strong attack (plants are covered by aphids, colonies are very numerous, large and connected and cover plant organs). The walking diagonally across the field, 100-200 plants were examined. The intensity of damage caused by *A. rubi* was determined by randomly selecting ten strawberry bushes at each visual examination and determining the number of damaged flower buds in relation to the total number of flower buds on the selected strawberry plants (Kikas and Libek, 2002).

Using the entomological catcher and the "mowing" method were used to pass over the plants, so that all the insects that were on the surface of the plant organs fell into the catcher. This method is used to collect and determine the presence of winged insects (cicadas, flea beetles, bed bugs) (Dimić et al., 2013). Small insects (shield moths, cicadas) were collected directly from the plants using an exhauster. All sampled infested plant matherial was observed in laboratory. All collected larvae and pupa of collected insects, were reared in the lab to adult stadium. In this purpose was used plastic containers and Petri dishes. In the bottom placed a layer of cellulose wadding occasionally misted in order to maintain the freshness of the leaf. The collected insects were fixed in 70% alcohol; some of them were prepared, making microscopic preparations or the entomological collection. The determination of collected insects was done in the laboratory using appropriate keys (Blackman and Eastop, 1994; Blackman and Eastop, 2000; Dietrich and Eastop, 2006; Jelinek and Audisio, 2010).

Results and Discussions

A one-year survey of the entomofauna affecting strawberries in the Bijeljina area identified 18 species from five orders and 16 families. From the Orthoptera order, *Tettigonia viridissima* (Tettigoniidae) and *Omocestus* spp. (Acrididae) were found. The Hemiptera order was the most diverse, with nine species from seven families. These included *Graphosoma lineatum* and *Dolycoris baccarum* (Pentatomidae), *Aphis forbesi* and *Chaetosiphon fragaefolii* (Aphididae), *Lygus pratensis* (Miridae), *Coreus marginatus* (Coreidae), *Pyrrhocoris apterus* (Pyrrhocoridae), *Cercopis vulnerata* (Cercopidae), and *Trialeurodes vaporariorum* (Aleurodidae). Five species from five families were identified in the Coleoptera order:

Anthonomus rubi (Curculionidae), *Phyllotreta undulata* (Bruchidae), *Agriotes obscurus* (Elateridae), *Stelidota geminata* (Nitidulidae), and *Cetonia aurata* (Scarabaeidae).
From the order Thysanoptera, *Frankliniella occidentalis* (Pergande) (Thripidae) was determined, and from the order Lepidoptera *Acleris comariana* (Lienig & Zeller) (Tortricidae) was determined (Tab. 1).

Table 1. The presence of insects on strawberry in the Bijeljina area in 2024 year

	Ordo	**Family**	**Species /date of collection**	April 20	May 9	May 15	May 26	June 5	June 17

*Presence and abundance of aphids according to the Banks scale (Maceljski and Igrc-Barčić, 1999).

The species from the order Orthoptera (*T. viridissima* and *Omocestus* spp.) during May and June by visual examination and using an entomological catcher were determined. These species fed on strawberry leaves in the form of larger or smaller irregular bites on young leaves. However, their number was not high, so they didn't cause significant damage. According to Rotim (2019), damage from the species from the families Tettigoniidae and Acrididae is greater in years with a dry spring. Literature data about damage on strawberry caused by species from the order Orthoptera are very scarce. Petrova et al. (2013) mention the

species *Omocestus rufipes* (Zetterstedt) as a common species in strawberry plantations in Latvia.
During the survey, five species of bedbugs by visual examination and using an entomological catcher during May and June were identified (*L. pratensis, G. lineatum, D. baccarum, P. apterus* and *C. marginatus*). The mentioned species didn’t cause significant damage to strawberries. In the world, several species of these insects are reported as important pests of strawberries. In Europe, damage to strawberries is caused by species *Lygus rugulipennis* Poppius, *Lygus hesperus* Knight, *Plagiognathus arbustorum* (Fabricius), *Plagiognathus chrysanthemi* Wolff, *Calocoris norwegicus* (Gmelin), *Calocoris fulvomaculatus* (De Geer) and *Lygocoris pabulinus* (L.) (Easterbrook, 2000; Cross et al., 2001; Özgen, 2012; Alford, 2014; Mešić et al., 2016). Damage from these species varies depending from environmental conditions, cultivar sensitivity, length of flowering period and fruit development (Łabanowska, 2007b). According to Cross (2004), due to the feeding of bedbugs, losses can be up to 80%. By sucking on flower parts, seeds or young fruits, these species cause fruit deformation. Damage in the form of necrotic changes is visible on the leaf, flower and leaf petioles. The species often feed on the seeds of the strawberry fruit, so the fruits remain deformed and lose their market value (Cross et al., 2001). Among of them, the highest number of individuals was in *C. marginatus* (Tab. 1). Younger larvae of this species suck juices from leaves, and older larvae and adults feed on generative parts of plants. It prefers to feed on plants from the families Polygonaceae, Asteraceae and Rosaceae. It’s very often found on various berry fruit trees, especially in blackberry and raspberry plantations (Fitzgerald and Jay, 2011). During the survey, *P. apterus* was the least numerous. It is an omnivorous species that mostly feeds on fruits and seeds of plants from the Malvaceae and Tilaceae families. Similar damage is caused by the species *Dolycoris baccarum*, which by feeding on larvae and adults can cause deformation of strawberry fruits. It’s considered a minor pest of strawberries (Alford, 2007), although it can be considered potentially harmful (Petrova et al., 2013). The total number of individuals the species *G. lineatum* during May and June was seven (Tab. 1). This species is extremely polyphagous and is widespread in southern Europe. It prefers plants from the Apiaceae family, and is often present on *Rumex* plant species. It’s not listed as a strawberry damage insects pest.
The studying the strawberry entomofauna in Bosnia and Herzegovina, Radman et al. (1981) stated that cicadas were sometimes present in greater abundance in strawberry plantations. During the survey, in May and June, the species *C. vulnerata* (total of seven individuals) by visual examination and using an entomological catcher was also determined. In addition, strawberries are regularly inhabited by aphids. According to literature data, several species of aphids occur on strawberries. That are *A. forbesi, C. fragaefolii, M. persicae, A. gossypii, M. euphorbiae, M. ascalonicus* and the other species. However, the most important and common species are *A. forbesi* and *C. fragaefolii,* which is in accordance with results of our research. These species most often inhabited young strawberry shoots and the reverse side of young leaves mostly along the main leaf nerve (Fig. 1), which is in accordance with literature data (Cross et al., 2001; Maceljski, 2002). During the survey, the abundance of these species was assessed as a very weak attack at the end of April because as single individuals or very small colonies were found in this period. However, during May, their number increased, and the attack was assessed as medium strong. In this period a large number of colonies were found that were not yet connected. Furthermore, at the beginning of June, their number gradually decreased.

Figure 1. C. fragaefolii (https://influentialpoints.com)

Figure 2. T. vaporariorum (orig.)

At the end of May and beginning of June, visual examination individuals of *T. vaporariorum* were determined (Fig. 2). This species has a cosmopolitan distribution. It’s a polyphagous species that feeds on many cultivated plants, primarily vegetable plants and flowers, but also weeds (Sekulić et al., 2008). The presence of this species on strawberry is most likely accidental, because there were plants in the immediate vicinity that serve as food for them, so they were present there at the time of coolection.
According to numerous literature data, *Anthonomus rubi* is one of the most important pests of strawberries. Adult is black colour, body length 2-4 mm (Fig. 3). During our survey, at the end of April and beginning of May adults on strawberry leaves were found. The damage to flower stems was recorded during May, according to literature data about the harmfulness of this species (Berglund, 2007; Lindsey, 2009). According to the results of our survey, the intensity of damage to flower buds determined during visual examination was 1,7% (May 9), then 2,3% (May 15) and 2,9% (May 26). Newly hatched adults were determines in the first decade of June and mid-June, which is in agreement with literature data about the bionomy of this species (Sarajlić et al., 2018; Graora, 2022). According to Łabanowska and Chlebowska (1999), the percentage of damaged strawberry flower buds varies significantly depending on the earliness of the cultivar, weather conditions during the flowering period and the oviposition period. Thus, significantly greater damage from this species was recorded on cultivars that bloom earlier (Kikas and Libek, 2002; Alford, 2014; Krauß et al., 2014).

Fig. 3. Anthonomus rubi (orig.)

Fig. 4. Fruit damage from S. geminata (orig.)

In addition, *C. aurata* is also a very common species on strawberries. The adult appears from April to September, especially during May and June, which is in agreement with the results of our research. The damage from adults of this species hasn’t been determined. According to Maceljski (2002), this species causes the greatest damage to soft fruits such as pears, peaches and figs. At the end of May and the beginning of June, the *S. geminata* was determined. In the last few years, the presence of the species has been confirmed in many European countries (Köhler, 2009; Merkl et al., 2009; Spasić et al., 2011; Stan, 2019). The main damage were caused by adults feeding on ripe strawberry fruits (Fig. 4). After copulation, the female lays her eggs on the fruits, most often on already bitten places. The larvae feed on the surface and inside the fruit. Fruits damaged by adults and larvae, as well as pathogens that inhabit damaged fruits, deteriorate very quickly and aren’t suitable for harvesting. According to Spasić et al. (2011), this species caused significant damage in several locations in Serbia, while Nikolić and Nježić (2019) report significant damages of this species in the west part of the Republic of Srpska. The presence of *A. comariana* larvae on strawberry at the beginning of May and until mid-June were determined. In that period, the larvae fed on leaves and parts of the flower, which is in accordance with literature data about the bionomy and harmfulness of this species (Sigsgaard et al., 2014; Barić, 2015).

Conclusion

The harmful insects of strawberry causes significant damage, reducing the yield and quality of the fruit. It’s necessary to determine the composition of the entomofauna, the development cycle of insect species in order to take appropriate protection measures. During our survey, the total number of determined species was 18, from five orders and 16 families. The largest number of species from the order Hemiptera was determined which indicates the importance of monitoring them in the following growing seasons, in order to take plant protection measures in time.

Abstract

Intercropping increases biodiversity and helps farming systems cope with changes in cultivation conditions. Growing different crops together reduces pest damage and the need for chemical crop protection. The aim of the present work was to determine the quantitative changes in soil plant parasitic nematodes during mixed cultivation of cereal and leguminous crops with marigold in the context of sustainable agricultural production and biodiversity. The research was carried out in 2021-2023, under field conditions in training trial field Vrazhdebna of the Forestry University, Sofia (42°70'76.1"N, 23°43'73.1"E). The intercropping system included winter barley, malting barley and common winter wheat, sown in rows of strips, between which the legumes chickpea and vetch were successively sown in the spring and marigold was added. The results showed that intercropping of cereal and leguminous crops led to a significant reduction of nematodes, the lowest value of Pf/Pi was 0.41, compared to growing them alone. The inclusion of marigolds was also found to further reduce nematode populations, the Pf/Pi value was 0.35. The performance of the intercropping systems was also evaluated on the basis of the intercropping index land equivalent ratio (LER). The LER values for economic yield were highest in the variants winter barley + legumes /vetch and chickpea/ + marigold (2.31) and malting barley + legumes /vetch and chickpea/ + marigold (2.94), which showed that these systems had an advantage in using the resources of the environment. Intercropping of these crops can be used by farmers to control plant parasitic nematodes to reduce the use of synthetic pesticides.

Keywords: *intercropping, soil plant parasitic nematodes*.

Introduction

The plant-parasitic nematodes cause delays in the development of crops by damaging the plants mechanically and disrupting the water and nutrient balance. Furthermore, the damage caused by these pathogens also serves as an entrance for numerous other soilborne phytopathogens. It is frequently observed that nematodes, in conjunction with pathogenic microorganisms such as bacteria and fungi, can give rise to complex diseases (Powell, 2012; Ravichandra, 2014). This can result in what is termed 'synergistic damage' to cultivated plants, including possibly overcoming existing plant resistance against certain pathogens. In conventional agriculture, plant-parasitic nematodes are primarily controlled by chemical nematicides (Haydock *et al*., 2006). However, chemical products are typically only capable of achieving a partial and transient reduction in the populations of harmful nematodes (Kapagianni *et al.*, 2010; Timper, 2014). In recent years, a number of alternative strategies have been developed to suppress plant-parasitic nematodes in different crop groups. These include the use of biological control, breeding of resistant/tolerant varieties, cultural practices and others (Raina *et al.*, 2020; Reddy and Reddy, 2021). Nevertheless, there has been only limited progress in implementing them. Concurrently, the emergence of nematode resistance to commonly used nematicides (Oka, 2020) is increasing the necessity for the development of alternative control options.

The practice of growing two or more crops simultaneously in the same place for a period of time can be regarded as a cultural phenomenon that enhances biodiversity within the agroecosystem, maintains ecological equilibrium, and facilitates more efficient utilisation of natural resources (Reddy and Reddy, 2017). The cereal-legume intercropping is an approach that employs the mechanisms of competition and natural regulation, thereby enhancing soil fertility, reducing the necessity for fertilisers and the application of herbicides (Hauggaard-Nielsen et al., 2008). Intercropping may be regarded as an alternative control measure within the framework of Integrated Pest Management (IPM), with the potential to reduce damage from pest populations while reducing the use of synthetic pesticides and limiting their negative impacts on the environment and human health (Mir *et al.*, 2022). Furthermore, intercropping offers enhanced lodging resistance for lodging-susceptible cereals, reduces the risk of yield loss, improves the quality and quantity of production, and provides greater financial stability for farmers (Reddy and Reddy, 2017). The emergence of novel and expanding trends in agriculture necessitates the conduct of research to facilitate the development of cost-effective and readily implementable alternatives to conventional synthetic pesticides or to identify measures compatible with integrated programmes to safeguard and minimise the utilisation of chemical agents. The existing literature on the impact of intercropping cereals, legumes and Tagetes on plant parasitic nematodes control is insufficient and inconsistent.

The objective of the present study was to quantify the changes in soil nematodes that parasitize plants during the cultivation of cereal and leguminous crops in conjunction with marigold in the context of sustainable agricultural production and biodiversity.

Materials and methods

The experiment was carried out under field conditions at the Vrazhdebna training field of the University of forestry in Sofia (42°70'76.1"N, 23°43'73.1"E) in Bulgaria, during the 2021-2023 growing season. The area exhibits a temperate continental climate characterised by an average annual precipitation of 620.8 mm, an average annual duration of sunshine of 500 h to 1,750 h, and an average annual temperature of 12.02 °C. The soil of the area is classified as slightly stony Fluvisols according to the classification system of the Food and Agriculture Organization (FAO).

Experimental design

The trial intercropping system included barley (*Hordeum vulgare* L.), cv. Obzor winter barley and cv. Veslets malting barley. It also included common winter wheat (*Triticum aestivum* L.), cv. Enola. The cereal crops were sown in autumn. The sowing depth was 5 cm, with an inter-row distance of 13 cm and an intra-row distance of 6 cm. In the spring, vetch (*Vicia sativa* L., cv. Obrasets 666) and chickpea (*Cicer arietinum* L., cv. Plovdiv 8) were sown successively between the strips, with a sowing depth of 5 cm, a row spacing of 20 cm, and an inter-row distance of 20 cm. Simultaneously with the sowing of leguminous crops, marigold (*Tagetes patula* nana Brocade Spanish) was sown between the rows of wheat, vetch and chickpea. The sowing depth was 1 cm, with 30 plants in a row. Plant protection measures were not applied, except application of herbicide after sowing the crops. The total area of the experimental block was 600 m², with each experimental plot comprising 6 rows of crops each with a length of 5 m.

The experiment was laid out in complete randomized block design (RCBD) with 10 variants and 3 replicates. The following variants were tested: WB: winter barley: 6 rows; MB: malting barley: 6 rows; CWW: common winter wheat: 6 rows LVC: legumes: 6 rows /3 rows vetch и 3 rows chickpea/; WB + LVC: 6 rows /2 rows winter barley + 1 row vetch и 1 row chickpea +2 rows winter barley/; MB + LVC: 6 rows /2 rows malting barley + 1 row vetch и 1 row chickpea + 2 rows malting barley/; CWW + LVC: 6 rows /2 rows common winter wheat + 1 row vetch и 1 row chickpea + 2 rows common winter wheat/; WB + LVC + M: 6 rows /2 реда winter barley + 1 row vetch и 1 row chickpea +2 rows winter barley/+ marigold; MB + LVC + M: 6 rows /2 rows malting barley + 1 row vetch и 1 row chickpea + 2 rows malting barley/; CWW + LVC + M: 6 rows /2 rows common winter wheat + 1ред vetch и 1 ред chickpea + 2 rows common winter wheat/

The impact of intercropping was determined using the quantitative parameter land equivalent ratio (LER), which compared the economic yields obtained by intercropping the specified crops with the yields obtained by growing the same crops as monocultures (Chapagain and Riseman, 2014).

Nematological analysis

All plots in the 10 variants were sampled after sowing of cereals for initial nematode population densities (Pi) and once before harvest for final nematode densities (Pf).

In order to ascertain the presence of free-living soil nematodes, soil samples were collected from 10 distinct target points for each variant. These samples were placed in plastic bags and stored in a refrigerator at 4°C. They were then processed within 10 days. Following the mixing of the soil samples, a representative sample of 100 cm^3 was extracted using a measuring cylinder. The data obtained pertains to this volume. The nematodes were extracted from the soil by the centrifugation method, killed and fixed in accordance with the methodology outlined by Van Bezooijen (2006). To ascertain the total number of individuals isolated, the liquid containing the nematodes was refilled to a volume of 100ml with water. The suspension was then stirred with a magnetic stirrer and 5 times the volume of 1 ml was transferred to the Bogorov Modified Counting Chamber. A stereomicroscope with a magnification of 40× was used to enumerate all nematodes initially. On re-enumeration, plant-parasitic nematodes were separated out if present. The number of dead and living nematodes was quantified following the sowing of the tested crops and prior to the harvesting of the crops. The mean number of nematodes extracted was determined by Peters (2013).

Due to the laboriousness of the process of determining the nematode species affiliation and the multivariate experiment, the individuals of the nematode communities were analysed only quantitatively.

Statistical analysis

The data were subjected to one-way analysis of variance (ANOVA) and differences of means (3 replicates × 2 years, $n = 6$) were determined by Duncan's multiple range test ($P \leq 0.05$) using the statistical software package SYSTAT 13.

Results and discussion

The initial population density (Pi) of the plant-parasitic nematodes within each variant exhibited a high degree of similarity, with no statistically proven differences (Table 1).

At the conclusion of the growing season, an increase in the population of plant-parasitic nematodes was observed in the monocultures of winter barley, malting barley, and common winter wheat in comparison to the period following sowing. The density of plant-parasitic nematodes was found to decrease when cereals were grown in conjunction with leguminous crops. The final population density (Pf) in the variant malting barley and legumes (chickpea and vetch) had the lowest value of 118 per100 cm^3 soil, followed by the density in winter barley and legumes (chickpea and vetch) of 199 per 100 cm^3 soil, and the highest value was found in common winter wheat legumes (chickpea and vetch) of 209 per 100 cm^3 soil. The reduction in nematode numbers was statistically validated in the malting barley and legumes and winter barley and legumes combinations. The final nematode density (Pf) data indicates that the addition of marigold had a significant impact on the population. Prior to harvest of malting barley from the legume and marigold co-cropping variant, the nematode population density showed a significant reduction in soil free-living plant-parasitic nematodes, with a Pf value of 75 per 100 cm3 soil.

Table 1. Effect of intercropping systems on soil plant-parasitic nematodes

Intercropping crops	Plant parasitic nematodes per 100 cm^3 of soil (PPNs/100cm^3 soil)		Proportion of final and initial population of nematodes (Pf/Pi)
	Initial population (Pi) after sowing of cereals	Final population (Pf) before final harvest	
WB	281a	343a	1.22a

Mean ± SE; different letters in column = stat. difference; Duncan's multiple range test ($P \leq 0.05$);
WB-wheat barley, MB-malting barley, CWW-common winter wheat, LVC- legumes vetch and chickpea, M-marigold

The incorporation of marigold into the variant winter barley with legumes (Pf = 98) demonstrated a proven quantifiable impact on soil free-living nematodes. Although the addition of marigold had a smaller effect on nematode density in the variant with wheat (Pf = 123), the nematode densities in combinations with marigold were statistically lower compared to monoculture and intercropping with legumes only.

The design of the experiment precluded a direct comparison of nematode densities across crops. However, using Pf/Pi ratios, it was possible to gain insight into the impact of crops in the intercropping system on plant-parasitic nematode densities. (Table 1).

The intercropping of malting barley and legumes (chickpea and vetch) resulted in a significant reduction of nematodes, with a Pf/Pi value of 0.41, which was statistically significantly lower than that observed in single cropping and the variants winter barley with legumes and wheat with legumes. The effect of mixed crops of winter barley with legumes and wheat with legumes was almost similar. The Pf/Pi ratio values were 0.76 and 0.78, respectively. The inclusion of marigold in the variants resulted in a further reduction in nematode population density, with the lowest Pf/Pi value of 0.35 being observed in the variant malting barley, legumes and marigold, and the highest Pf/Pi value of 0.49 being observed in common winter wheat, legumes and marigold. The intermediate position was occupied by the variant winter barley, legumes and marigold, with a value of Pf/Pi =0.38.

The ratio Pf/Pi is a quantity that depends on the density of Pi (McSorley and Gallaher 1995), and changes in the abundance of nematode populations depend on environmental factors that can cause rapid and short-term changes in nematode populations in soil (Thoden *et al.*, 2011). Therefore, further research is needed to establish the relationships between Pf and Pi within the intercropping of these crops. A substantial body of research has been conducted on the efficacy of *Tagetes* in the control of plant parasitic nematodes (Koleva and Mitova, 2021; Munif *et al.*, 2021; Fourie, 2024). It is known that the Tagetes species are highly toxic to plant parasitic nematodes, suppressing them through a biochemical interaction known as allelopathy. Tagetes plants secrete root exudates containing toxic bioactive substances (such as α-terthienyl and others) that have nematicidal, insecticidal, fungicidal, antiviral and cytotoxic activities (Bhattacharyya, 2017). In addition to the previously discussed mechanisms, Tagetes also suppresses plant-parasitic nematodes through the following means: it is an unsuitable host for nematodes, activates microorganisms that are antagonistic to nematodes, and acts as traps for nematodes (Grubišić *et al.*, 2018). The control of plant-parasitic nematodes by antagonistic plants provides several benefits, including biodegradability, selective toxicity to target organisms, safety to non-target organisms and the environment, and renewability in nature (Bhattacharyya, 2017). It is established that marigold can be employed as an alternative to synthetic nematicides. In certain instances, *Tagetes* sp. has been demonstrated to reduce nematode populations at greater depths within the soil than soil fumigation (Karakas and Bolukbasi, 2019). The successful incorporation of *Tagetes* sp. into an integrated nematode management programme necessitates the undertaking of research to ascertain its effectiveness against locally occurring nematode populations and in different farming systems.

To ascertain the impact of competition between the species utilised in the intercropping system, the Land Equivalent Ratio (LER) was calculated. The highest total LER was observed in the variant comprising malting barley, legumes and marigold (2.78), while the lowest LER was observed in the variant comprising winter wheat and legumes without marigold (2.07). The mean LER values of the other intercropping variants were greater than 1.0 (Figure 1), indicating superior crop development (Dhima *et al.*, 2007).

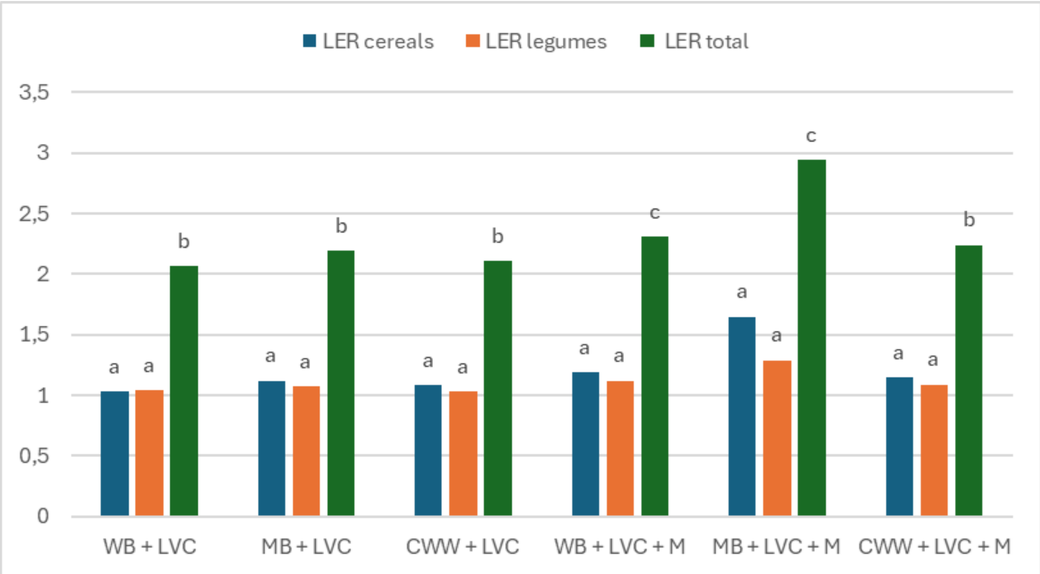

Figure 1. Means of LER of cereal-legume intercropping and marigold

Different letters within the same LER (bars with the same color) indicate statistically significant differences, Duncan's multiple range test ($P \leq 0.05$); WB-wheat barley, MB-malting barley, CWW-common winter wheat, LVC- legumes vetch and chickpea, M- marigold

The higher yield obtained serves to demonstrate the advantage of intercropping over monoculture cultivation. The temporal and spatial differences of crops in the intercropping system facilitate the more efficient utilisation of nutrients in agroecosystems (Duchene *et al*, 2017; Yang *et al.*, 2021). An advantage of intercropping systems of cereals and leguminous crops has been previously reported for crops such as barley and lentil (Dahmardeh, 2013), field beans and wheat (Kamalongo and Cannon, 2020), barley and faba bean (Tang *et al.*, 2023). In general, the quantitative parameters nematode density and the Land Equivalent Ratio (LER) index were significantly affected by marigold intercropping, indicating that intercropping is an effective method of utilising environmental resources compared to monocultures.

The data obtained here may be pertinent to the selection of certain crops for co-cropping in agro-ecosystems where inter-crop competition can assist in overcoming biotic stress factors.

Conclusions

The addition of *Tagetes patula* into the cereal-legume intercropping system was found to have a proven effect on soil free-living plant-parasitic nematodes.

The final nematode density (Pf) was lowest in the *Tagetes* variants, followed by the legume variants, and the highest values were observed in the cereal monoculture.

The LER values demonstrate that yields were significantly higher in the cereals-legume intercrop and *T. patula* than in the monoculture crops.

Abstract

In vitro study of the vapor antifungal activity of 10 essential oils (EO’s): *Ilicum verum* (anise), *Pinus mugo* (pine), *Cinnamomum zeylanicum* (cinnamon), C*upressus sempervirens* (cypress), *Eucalyptus globulus* (eucalyptus), *Lavandula angustifolia* (lavender), *Laurus nobilis* (laurel), *Mentha piperita* (mint), *Rosmarinus officinalis* (rosemary) and *Thymus vulgaris* (thyme) on the mycelial growth and sporulation of plant pathogen *Botrytis cinerea* was performed. The EO’s were applied in five concentrations of 0.02, 0.04, 0.1, 0.15 and 0.2% of air phaser. At all concentrations, the EO’s of thyme and cinnamon showed complete inhibition of the mycelial growth of *B. cinerea* after 168 hours. Mint oil completely inhibited mycelial growth in all treatments except in treatment with the lowest concentration of oil (0.02% of air phase) while lavender oil completely inhibited mycelial growth in treatments with the three highest concentrations of oil. For treatments in which mycelial growth was determined, sporulation was also measured. The effect of EO’s on sporulation was expressed as a percentage in relation to the number of conidia in the control, which was marked as 100%. There was no sporulation in treatments with pine oil (0.15 and 0.2% of air phase), while sporulation less than 50% compared to the control was found in treatments with lavender oil (0.02% of air phase), eucalyptus oil (0.02 and 0.04%), anise oil (0.02 and 0.04%), laurel oil (0.02, 0.04 and 0.1%), rosemary oil (0.02, 0.1, 0.15 and 0.2%) and pine oil (0.04%).

Key words: *essential oils, antifungal activity, Botrytis cinerea.*

Introduction

The causal agent of gray mold, *Botrytis cinerea* Pers., is aggressive polyphagous non-specific plant pathogenic fungus. This pathogen causes devastating diseases on more than 1400 cultivated and wild plant species including fiber, protein, oil and horticultural crops (Elad *et al*., 2016; Cheung *et al*., 2020). It is estimated that this pathogen causes annual losses of up to USD 100 billion all over the world.
The use of synthetic fungicides is still the most effective protection against many plant pathogens including *B. cinerea*. In spite of their efficiency, the widespread use of synthetic pesticides has significant drawbacks including handling hazards, pesticide residues in food, feed and soil, fungal resistance against synthetic compounds, ecosystem equilibrium disruption and threats to human health (Palfi, 2017). All these negative effects of pesticides have indicated the need for alternative non-chemical methods in plant protection. In order to find new and ecologically acceptable biofungicides, many studies related to antifungal effects of alternative products are being conducted (Combrinck *et al*., 2011; Duduk *et a*l., 2015; Sharma *et al*., 2017, Nguyen *et al*., 2017). Biological compounds extracted from plants could be one of the most important alternatives which do not have any hazardous effects on human

health and environment. Essential oils reduce the growth of fungal hyphae and promote the degradation of the fungal cell membrane. Also, they cause changes in the composition of the cell wall, plasma membrane disorders, disorganization of the mitochondrial structure and disruption of the enzymatic reaction in mitochondrial membrane such as electron transport, proton transport and affects phosphorylation (Knobloch, 1989).

Materials and methods

The in vitro antifungal properties of 10 EO’s: Ilicum verum (anise), Pinus mugo (pine), Cinnamomum zeylanicum (cinnamon), Cupressus sempervirens (cypress), Eucalyptus globulus (eucalyptus), Lavandula angustifolia (lavender), Laurus nobilis (laurel), Mentha piperita (mint), Rosmarinus officinalis (rosemary) and Thymus vulgaris (thyme) on the mycelial growth and sporulation of plant pathogen Botrytis cinerea were tested. The EO’s used in this study were commercial samples produced in Kemig Ltd., Sesvete – Soblinec, Croatia. The selected fungal strain was obtained from the culture collection of the Faculty of Agrobiotechnical Sciences in Osijek, Croatia. The pathogen was isolated 2020 from grapes and identified based on morphological characteristics, taking into account the cultural characteristics of the fungi as well.

For determination of vapor effect of EO’s, the modified method of Edris and Farrag (2003) was used. A piece of mycelium (diameter 4 mm) is placed in the middle of Petri dishes with 15 mL of PDA, and essential oil is applied to the dishes cover on sterile filter paper (diameter 7 mm). The EO’s were applied in five amounts (10 µL, 20 µL, 50 µL,75 µL and 100 µL) which corresponded to 0.1, 0.2, 0.5, 0.75 and 1% EO’s concentrations of air phase. Petri dishes are stored in a thermostat chamber at a temperature of 25°C and a light regime of 12 hours light / 12 hours darkness. In the control, filter paper soaked in an appropriate amount of sterile distilled water was used. The inhibition zone was measured after 168 hours. The effect of essential oils on the growth of B. cinerea mycelium was calculated according to the formula of Wu et al. (2013):

$$I (\%) = [(C-T)/(C-0.4)] \times 100$$

where is:

I (%) - percent inhibition of mycelial growth
C – mycelial growth in control
T - mycelial growth in the presence of essential oil

After measuring the mycelial growth, sporulation was determined by preparing a suspension of conidia in 100 ml of sterile distilled water, and the concentration of conidia of suspension was measured using a hemocytometer. The effect of essential oils on sporulation was expressed as a percentage in relation to the number of conidia in the control, which was marked as 100%.

In order to determine the germination of conidia, from the prepared suspension for each variant of the experiment, 20 µl was taken and spread on the PDA medium. Petri dishes are placed

at a temperature of 25 °C and a light regime of 12 hours light / 12 hours darkness. After 24 hours, the number of germinated conidia is determined on a sample of 3 x 20 conidia. Conidia were considered germinated if the germ tube is equal to or greater than the length of the conidia.

The reduction/inhibition of germination of conidia was calculated according to the formula of Youssef *et al.* (2019) and expressed as a percentage:

$$\text{Reduction/inhibition (\%) of germinating conidia} = \frac{\text{gc} - \text{gt}}{\text{gc}} * 100$$

where is:
gc - average germination of conidia of isolate in the control
gt - average germination of conidia isolate at a certain concentration of essential oil

Statistical analysis of experimental results was performed with the SAS 9.2 statistical package (SAS Institute Inc, Cary, NC, USA) using analysis of variance ANOVA and the Fisher LSD test (P= 0.01).

Results and discussion

The vapor effect of essential oils on mycelial growth, sporulation and conidia germination of *B. cinerea* were tested. The results of the influence of essential oils on mycelial growth are shown in Table 1.

At all concentrations, the EO’s of thyme and cinnamon completely inhibit the mycelial growth of *B. cinerea*. It is worth mentioning the excellent inhibitory effect of mint oil, where a slight inhibition (39.01%) of mycelial growth was observed only at a concentration of 0.1% of air phase, but with no statistically significant difference compared to the control. Anise oil also had a very good inhibitory effect on the growth of the fungal mycelium, but only at higher concentrations of the EO. At concentrations of 0.5, 0.75 and 1% of air phase, anise oil showed statistically significant differences compared to the control with an inhibitory effect of 64.81 and 100%. The results confirmed other findings on fungistatic activity of thyme, cinnamon, anise and mint essential oils (Arras and Usai, 2001; Behnam *et al.*, 2006; Allagui *et al.*, 2023). Laurel, cypress, and eucalyptus oils had the weakest inhibitory effect. Allagui *et al.* (2023) states that cypress oil completely inhibited growth of *B. cinerea* mycelia, while Grgić *et al.* (2016) states that cypress oil weakly inhibited the growth of the same pathogen. Pine oil had a slightly better inhibitory effect than the previously mentioned oils. There were statistically significant differences compared to the control only at a concentration of 0.1% of air phase with an inhibitory effect of 35.26% and 32.51% at a concentration of 1% of air phase.

The effect of EO’s on sporulation was expressed as a percentage in relation to the number of conidia in the control, which was marked as 100% (Graph 1). There was no sporulation in treatments with pine oil (0.75 and 1% of air phase), while sporulation less than 50% compared to the control was found in treatments with lavender oil (0.1% of air phase), eucalyptus oil (0.1 and 0.2%), anise oil (0.1 and 0.2%), laurel oil (0.1, 0.2 and 0.5%), rosemary oil (0.1, 0.5, 0.75 and 1%) and pine oil (0.2%).

The inhibitory effect of essential oils on conidium germination has been reported by several authors (Wilson et al., 1997; Andrade and Vieira, 2016; Hou *et al.*, 2020). In our research, after 24 hours incubation the germination rate was decreased by 6.67 (0.1% of air phase for rosemary oil) to 71.67% (0.1 and 0.2% of air phase for anise oil) compared to control (Table 2).

Control	0,00 ± 0,00	0,00 ± 0,00	0,00 ± 0,00	0,00 ± 0,00	0,00 ± 0,00
LSD 0,01	11.33	9.40	9.18	7.50	5.30

Data are presented as the mean ± standard error of four repetitions. The individual columns show the differences between different essential oils at the same concentration. The rows show the difference between different concentrations within the same oil. Fisher's LSD test (P≤ 0.01).

Conclusion

The research examined the effect of ten essential oils on the suppression of the mycelium growth, sporulation and conidia germination of the plant pathogenic fungus *B. cinerea*. Thyme and cinnamon essential oils completely inhibit mycelial growth and sporulation of *B. cinerea* at all applied concentrations. Although mint oil did not completely inhibit mycelial growth at the lowest concentartion (0.1 % of air phase), sporulation was also not determined. Compared to control, sporulation decreased at least 50% in treatments with lavender oil (0.1% of air phase), eucalyptus oil (0.1 and 0.2%), anise oil (0.1 and 0.2%), laurel oil (0.1, 0.2 and 0.5%), rosemary oil (0.1, 0.5, 0.75 and 1%) and pine oil (0.2%), while germination rate was decreased by 6.67 (0.1 % of air phase for rosemary oil) to 71.67% (0.1 and 0.2% of air phase for anise oil).

Abstract

Botrytis cinerea is the most important and most frequently isolated pathogen within the genus *Botryotinia*. This necrotroph is considered to be one of the most destructive pathogens in agriculture in greenhouses and in the field. In tomatoes, *B. cinerea* causes grey mould, with symptoms appearing on ripe fruit, but can also be spread to leaves and stems. Pyridine derivatives are extremely important chemical compounds due to their physico-chemical properties and their diverse biological applications. Scientific studies indicate the antifungal effect of quaternary pyridinium compounds, especially nicotinamide derivatives. Most studies to date have focused on *in vitro* tests. Therefore, further investigation of the effects of these compounds on phytopathogenic fungi through *in vivo* experiments is crucial for the improvement and development of environmentally friendly fungicides. This study aimed to investigate the antifungal activity of four selected compounds, chosen based on previous *in vitro* antifungal results, on the growth of *B. cinerea* mycelia and their inhibitory effect on conidia germination. The *in vivo* experiments were carried out on ripe tomato fruits at concentrations of 100 µg/ml. Mycelial growth was measured 96, 120, and 144 hours after inoculation to determine possible differences in the antifungal activity of the nicotinamide compounds compared to the controls. All tested compounds showed a significantly weaker inhibitory effect regardless of the incubation time and positive controle (fenhexamide). Compound (12) Na-DBP showed significantly stronger antifungal activity compared to the other compounds tested, with the highest efficacy observed 120 and 144 hours after inoculation. All applied compounds used showed significantly higher inhibition of conidia germination compared to the control (pure PDA).

Keywords: *antifungal activity, nicotinamide compounds, B. cinerea, tomato.*

Introduction

Botryotinia fuckeliana (de Bary) Whetzel, also known as *B. cinerea* in the anamorphic stage, is the main and most frequently isolated pathogen within the genus *Botryotinia*. The adaptation of *B. cinerea* to different climatic conditions is reflected in its wide distribution in different geographical areas, ranging from tropical and subtropical areas to cold temperate and northern and southern areas. *B. cinerea* causes major losses to horticultural crops in the field and the greenhouse at all stages of plant development (Williamson et al., 2007). In his recent study, Singh (2024) lists 616 genera that serve as hosts for this pathogen. This necrotroph is considered one of the most destructive pathogens in agriculture, especially when it comes to fruit, vegetables, and flowers before and after harvest during storage and transport (Jarvis, 1977; Williamson et al., 2007). *B. cinerea* attacks various parts of the host plant at different stages of development, from germination to fruit ripening. It can attack the stem, flowers, leaves, and fruits and can also occur in the seeds (Yahaya et al., 2015). However, it causes the most damage to mature, older, weakened, or injured host tissue. Symptoms caused by this pathogen include fruit rot, soft fruit rot, yellow-brown lesions on leaves and stems that can spread in concentric rings, and wilting. A characteristic symptom of this pathogen is an accumulation of conidia in the form of a grey coating. The appearance of this symptom usually occurs under favourable conditions, such as cold to moderate temperatures (10 - 25°C) with high humidity (Williamson et al., 2007; Quesada-Ocampo, 2015). Different modes of infection, the ability to infect a wide range of plant hosts, a high reproductive potential, and the ability to survive for a long time under unfavourable conditions in the form of sclerotia form the basis for the success of *B. cinerea* as a pathogen (Williamson et al., 2007). Despite constant warnings about the negative consequences for human health and the environment (Zemmouri et al., 2022), using fungicides is still the predominant method of controlling this pathogen. Given the pronounced tendency to develop resistance to fungicides, this pathogen is becoming increasingly important in agriculture and scientific research (Amselem et al., 2011; Adnan et al., 2018; Adnan et al., 2019). Research is increasingly focusing on the search for new chemical compounds with antifungal activity, which should be less toxic and harmful to the environment than commercial fungicides. One of these is quaternary pyridinium compounds, which are derivatives of vitamin B3. They are considered important chemical compounds due to their properties and diverse biological applications (Altaf et al., 2015). Numerous scientific studies confirm their antifungal activity against important phytopathogenic fungi, including the pathogen *B. cinerea* (Wu et al., 2012; Wu et al., 2013, Siber et al., 2019; Bušić et al., 2022). Based on the preliminary results of the *in vitro* investigation of 12 newly synthesized nicotinamide pyridinium compounds, those exhibiting very effective antifungal activity against the growth of *B. cinerea* pathogen mycelia were selected. This study aims to investigate the selected nicotinamide compounds and their potential as more environmentally friendly fungicidal agents for protection against *B. cinerea* pathogens under *in vivo* conditions.

Material and Methods

The *in vivo* test of the effect of the synthesized compounds on the growth of mycelia of the pathogen *B. cinerea* was carried out with selected compounds that showed an antifungal effect in the *in vitro* test. The *in vivo* test was carried out using the modified method of Hao et al. (2020) on undamaged medium-sized tomato fruits. A *B. cinerea* isolate from the culture collection of the Department of Phytopathology of the Faculty of Agrobiotechnical Sciences Osijek was used for the experiment. The isolate was grown on a PDA (potato dextrose agar) medium enriched with antibiotics. An isolate that had been incubated for seven days was used for the artificial infection. Before artificial infection, tomatoes were sterilized with 1% NaClO solution (sodium hypochlorite) for 2 minutes, then washed with distilled water and dried at room temperature. A needle was used to puncture a wound in the dried and disinfected tomato fruit. A concentration of 100 µg/mL of the synthetic compound was injected into each wound using a micropipette. The injection of 1% DMSO into the tomato fruit served as a negative control, while the positive control was a tomato injected with a commercial fungicide at the recommended dose. Two to three hours after treatment, a piece of *B. cinerea* mycelium was removed from the PDA growing culture using a circular cutter with a diameter of 4 mm and placed on the wounds of the fruit with a sterile needle. Each treatment was carried out in 4 replicates with 4 tomatoes each. The tomato fruits were placed on moist, absorbent paper in plastic containers. Each container was placed in a plastic bag for 48 hours to maintain moisture for initial infection. The containers were incubated at room temperature. The diameter of mycelial growth was measured 48, 72, 96, 120, and 144 hours after inoculation.

The inhibitory effect of the tested synthesized compounds on the germination of the conidia was performed in 2 replicates for each compound at a concentration of 100 µg/ml. DMSO (1%) was used as a negative control, while a commercial fungicide at the recommended dosage was used as a positive control. A control variant with distilled water was also set up. Conidia older than 10 days were used for the *in vitro* germination test according to the modified method described by Cao et al. (2016). After harvesting the conidia from the PDA medium, they were filtered and suspended to a concentration of 1×10^8 spores per milliliter of sterile water. The spore concentration was determined using a Neubauer hemocytometer. The resulting conidial suspension and the treatments concentration of 100 μg/mL were pipetted onto 60 mm diameter Petri dishes containing clean PDA medium. The dishes were then incubated for 4 hours in a climate chamber at 25°C and 90% relative humidity. The same procedure was repeated for the positive and negative controls and control variant with distilled water. From 80 conidia per treatment (4 replicates of 20 conidia each), the number of germinated conidia was recorded and the length of the germ tubes was measured using an Olympus BX41 microscope. The conidia were considered germinated if the germ tube was equal to or larger than the diameter of the conidium (Qin et al., 2010). According to the formula given by Youssef et al. (2019), the percentage of inhibition of germinated conidia was calculated: Inhibition (%) of germinated conidia = (gc - gt) / (gc) * 100

Where:

gc - average germination of conidia of the isolate in the control

gt - average germination of conidia of the isolate in the synthesized compound

Results and Discussion

The *in vivo* study on the effect of selected nicotinamide pyridinium compounds (concentration 100 μg/ml) on the growth of *B. cinerea* mycelia is shown in Table 1 for different incubation times. ANOVA showed a statistically significant difference between the compounds for 96, 120 and 144 hours. At 48 hours after inoculation there was no increase, and at 72 hours after inoculation there was a slight increase in some treatments (data not showed).Tukey's multiple comparison tests were used to test which compounds showed statistically significant differences ($p \leq 0.05$).

Table 1. Effect of nicotinamide pyridinium compounds (concentration 100 μg/mL) on the growth of *B. cinerea* mycelia

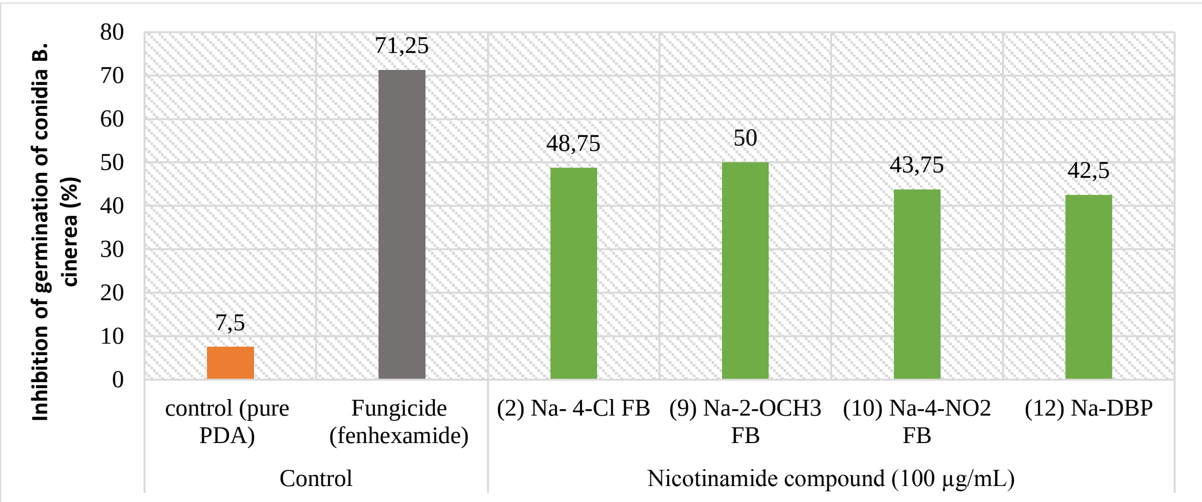
Nicotinamide compound / h from inoculation	96 h M ± SEM	120h M ± SEM	144h M ± SEM
(2) Na- 4-Cl FB	29.00 ± 1.47 A	37.25 ± 2.04 A	45.33 ± 1.70 Aa
(9) Na-2-OCH3 FB	26.67 ± 1.08 A	37.00 ± 1.83 A	43.86 ± 2.14 Aa
(10) Na-4-NO2 FB	27.21 ± 1.16 A	39.77 ± 2.04 A	46.62 ± 2.32 Aa
(12) Na-DBP	27.00 ± 0.94 A	34.71 ± 1.89 A	37.86 ± 2.39 A
control (pure PDA) a	25.58 ± 0.62	32.83 ± 1.25	35.08 ± 1.62
positive control (fenhexamide) A	0.00 ± 0.00	0.00 ± 0.00	0.00 ± 0.00
Comparison of nicotinamide compounds (Tukey's test)	—	—	10 > 12

The columns show the mean of four replicates (M) and the standard error of the arithmetic mean (SEM).

Significant differences between the compounds and the positive control are labelled with the letter A ($p \leq 0.05$), significant differences between the compounds and the control (pure PDA) with the letter a ($p \leq 0.05$).

Significant differences between the compounds, i.e. Tukey's test ($p \leq 0.05$), are labelled with numbers next to the corresponding compound

The results of the study show that no nicotinamide compound with an applied concentration of 100 µg/ml completely inhibited (100%) the growth of the pathogenic mycelium of B. cinerea. 96 and 120 hours after inoculation, the compounds did not differ statistically significantly in their antifungal activity compared to the control (pure PDA). In the incubation period, i.e. 144 hours after inoculation, the three compounds (2) Na-4-Cl FB, (9) Na-2-OCH3 FB and (10) Na-4-NO2 FB showed a significantly weaker effect on the growth of mycelia compared to the control ($p \leq 0.05$). A significant difference was also observed for compounds (10) Na-4-NO2 FB and (12) Na-DBP, with compound (12) Na-DBP having a significantly stronger antifungal effect. Similar results were obtained by Yan et al. (2022) in their study in which they synthesized 15 new pyridine derivatives. In vitro tests showed that all compounds exhibited moderate to good antifungal activity against B. cinerea, while in vivo tests showed that only one compound exhibited good antifungal activity. Overall, these results suggest that the inhibitory effect of nicotinamide pyridinium compounds decreases with the applied concentration of 100 µg/ml when the incubation period is delayed, except in the case of compound (12) Na-DBP. Finally, all pyridinium nicotinamide compounds showed a significantly weaker inhibitory effect than commercial fungicides regardless of the incubation time. On the other hand, Xu et al. (2023) investigated 19 newly synthesized pyridinium compounds on seven different pathogenic species, including B. cinerea. In this study, ten compounds showed an inhibitory effect of more than 90% on B. cinerea, with one compound exhibiting the highest antifungal activity, even better than commercial fungicides.
Bušić et al. (2022) also investigated the antifungal activity of 11 synthesized pyridine derivatives in vitro using a mycelial growth assay on four different pathogenic fungi, including B. cinerea. The results showed that 8 of the 11 compounds tested exhibited less than 50% antifungal activity against B. cinerea, suggesting that the activity of each compound depends on the type of pathogen. The inhibitory effect of selected compounds on the germination of the conidia of the B. cinerea pathogen is shown in Graph 1.



Graph 1. Inhibitory effect of nicotinamide pyridinium compounds on the germination of *B. cinerea* conidia (%)

All applied compounds showed a significantly higher inhibition of conidia germination compared to the control (pure PDA). Comparing the compounds with the control (pure PDA), the strongest inhibition of conidia germination was observed with compound (9) Na-4-Ph FB and compound (2) Na-4-Cl FB. However, none of the compounds showed stronger inhibition of conidia germination than the positive control. Among the compounds, the least inhibition of conidial germination was observed with compound (12) Na-DBP. In addition, Xuet al.

(2023) reported a significant inhibition of the germination of *B. cinerea* conidia. According to their studies, two pyridinium compounds showed the strongest inhibition of conidia germination with 64% and 76%, respectively.

Conclusion

Based on preliminary *in vitro* results of newly synthesized nicotinamide pyridinium compounds, four compounds were selected that showed good to very good antifungal effects on the growth of the mycelium of the pathogen *B. cinerea*. The antifungal activity of the selected compounds was tested in an *in vivo* test on tomato fruits. The results obtained show that the compounds exhibit good antifungal activity compared to the control only after a delay in the incubation period, i.e. 120 hours after inoculation, but without statistical significance. Numerous studies show that pyridinium compounds, thanks to their good antifungal effect, indicate a possible application as new, more environmentally friendly fungicides in plant protection. From these results we can conclude that some of the compounds tested *in vivo* can even stimulate the growth of the pathogen *B. cinerea*, which does not mean that these compounds could not have antifungal activity against other pathogens. On the other hand, the results show that compounds (2) Na-4-Cl FB and (9) Na-4-Ph FB, although they had lower antifungal activity on the growth of *B. cinerea* mycelium, had the most significant inhibitory effect on spore germination. Despite the insufficient antifungal effect of the synthesized compounds on the mycelial growth of the causal *B. cinerea*, further research with these compounds is needed, not only on the pathogen *B. cinerea* but also on other important species of phytopathogenic fungi.

THE LIPOLYSIS LEVEL OF SOME GREEK ARTISANAL CHEESES: A REVIEW OF LAST YEAR’S DATA

Aikaterini GEORGALA*

Laboratory of Dairy Research, Agricultural University of Athens, 75 Iera Odos Str., 11855, Athens, Greece
*Corresponding author: georgala@aua.gr

Abstract

In this review the lipolysis level of some Greek artisanal cheeses was studied. Researchers studied the lipolysis profile of the artisanal mountainous hard Kefalotyri cheese made traditionally in Pindos mountains from raw ewe’s milk without starter cultures, during summer. Free fatty acids (FFAs) were the most abundant volatile group of this cheese with butyric acid and 3-methyl butanoic acid to be the main. Cheese showed a rather satisfactory hygienic sanitary condition. Researchers studied the lipolysis level of Kashkaval Pindos cheese a semi-hard pasta-filata cheese made from raw ewe’s milk without starter addition or made by pasteurized milk with addition of a commercial cheese starter. Raw milk Kashkaval cheeses showed higher levels of lipolysis than pasteurized ones. Butyric, myristic, palmitic, stearic and oleic acids were the main FFAs. All cheeses were found to be safe. Artisanal Tsalafouti cheese resembles to fresh acid an acid rennet curd cheeses with spreadable texture and no gas openings. It is traditionally made from ‘boiled’ (90^0C) ewe’s milk in the mountains at the end of the lactation period. Researchers found a high level of hexanoic acid in a semi-industrial way made cheese. Xinotyri of Naxos Island is an artisanal fully ripened hard raw goat’s cheese. Researchers found that FFAs profile was similar to other goat cheeses with oleic, palmitic, myristic, stearic and capric acid to be the main. Soft Xinotyri Naxos cheese is an acid-curd goat’s milk cheese typically made from raw milk. Researchers found a low lipolysis level that was not affected by using raw or pasteurized milk.

Key words: *lipolysis, artisanal cheeses.*

Introduction

Lipolysis (lipid hydrolysis) is essential for the development of cheese flavour. Lipolysis results in the formation of FFA, which may directly contribute to cheese flavor, especially short and intermediate chain FFA or act as precursors for other flavour compounds such as esters, methyl ketones and secondary alcohols which are also of importance (Fox etal., 1993; Molimard & Spinnler, 1996; Collins et al., 2003).

Lipolysis level varies considerably among cheese varieties from slight in many internal, bacterially ripened varieties such as cheddar, gouda and Swiss cheeses to extensive in hard Italian varieties, surface bacterially ripened (smear) cheeses and blue mould cheeses (Woo et al., 1984 a, b; Fox et al., 1993; Fox & Wallace, 1997; McSweeney & Fox, 1993; Collins et al., 2003). For some cheese varieties, a specific group of volatile compounds is recognized as being the major contributor to its flavor. In hard Italian cheese varieties FFAs are important contributors to cheese flavor. However, in blue-mould ripened cheeses the impact of FFA to cheese flavour is less than that of Italian varieties. This was due to the dominant influence of methyl ketones to the flavour of these cheeses (Woo et al., 1984 a,b; Mollimard & Spinnler, 1996).

Artisanal cheeses are known to take recognition by consumers during the last years. These cheeses are frequently linked to certain local regions. They are made by traditional methods in dairy farms using a simple equipment by family members as a staff and without certification or label (Koutsoukis et al., 2017). Due to their recognition in the last years, efforts should be made to standardize their production process with a view to make safe cheeses of high and constant quality. In this way the local economy will be supported and export of these cheeses outside the region of their production should be done. With a view to meet consumers demands, artisanal cheeses should be produced in an industrial scale. The transition from the local small scale cheesemaking to the large industrial includes milk pasteurization, addition of starters, control of ripening conditions, packaging etc. to improve cheese quality and safety. The combination of traditional and industrial practices in cheese manufacture results in a standard cheese product that is greatly accepted by the consumers. This work is a review of last year's data on lipolysis profile of some Greek artisanal cheeses.

Materials and Methods

Data of this review were collected from research papers on the field of artisanal Greek cheeses. All methods used for lipolysis determination are reliable and known ones in literature.

Results and Discussion

Kashkaval cheese is a pasta filata cheese variety that is produced in many countries. In Greece, the traditional way of making Kashkaval cheese has been referred many years ago from the previous century. Kashkaval cheese is a local, hard crafted pasta filata cheese which is produced in specific Greece places such as the mountains of Pindos by using a traditional method. Its production has been transferred from generation to generation. Pappa et al (2019) studied the biochemical characteristics of the traditional type of Kashkaval cheese that was made by using raw or pasteurized ewe's milk, during ripening and storage. Generally, lipolysis was not intense in Kashkaval cheese. Pasteurization of milk significantly affected the total free fatty acids (TFFAs) content of Kashkaval cheese (Table 1). Pasteurized milk cheeses had lower amount of TFFAs than raw ones (Table 1), except for the 30 days cheeses where no differences were found (Table 1). Pappa et al. (2020) made a semi-industrial Kashkaval of Pindos cheese by using 100% sheep milk (KS) or with the addition of 10% goat milk (KG). The free fatty acid content of KS and KG Kashkaval of Pindos cheeses is shown in Table 1.

Table 1. Free fatty acids (peak area x 10^3) of semi-industrial produced Kashkaval of Pindos cheese made from 100% sheep milk (KS) or a mixture of 90% sheep milk-10% goat milk (KG) during ripening and storage.

Kashkaval cheese	60 Day		90 Day		180 Day	
Free fatty acids	KS	KG	KS	KG	KS	KG
Propanoic acid, 2 methyl	3636.63	2314.9	3558.8	1486.6	5052.8	2061.3
Butanoic acid, 2 methyl	7317.6	1667.7	9961.35	1880.55	24,456.6	2256.15
Butanoic acid, 3 methyl	6817.7	4928.25	7821.7	4091.3	26,031.7	3465.6
Hexanoic acid	3494.3	2094.93	3479.07	4079.5	5315.05	4191.97
Hexanoic acid, 2 ethyl	137.9		1114.6	1198.65		802.3
Butyric acid	7814.2				13,580.2	
Octanoic acid					1061.7	
Total free fatty acids	29,218.3	11,005.8	25,935.5	12736.6	75,498.05	12,777.3

*Source: Pappa et al. (2020)

Total free fatty acids increased from day 60 to day 180 in KS cheese, while in KG cheese they remained stable (Table 3). 3 methyl butanoic acid, 2 methyl butanoic acid and butanoic acid were among the most abundant volatiles found in KS cheese.

Soft Xinotyri cheese is an acid-curd goat’s milk cheese variety that is produced traditionally in Naxos Island of the Cycladic complex. Soft Xinotyri cheese is not shaped and is consumed as fresh or ripened and it is cold stored. Pappa *et al.* (2017) studied the lipolysis level of soft Xinotyri cheese that was made from raw or pasteurized milk without the addition of starter cultures, during storage at 4^0C for 60 days. The results showed no significant differences in individual as well as in total FFA content were found between raw and pasteurized milk soft Xinotyri cheese. This probably happens as the time of 60 days is short enough to arise important differences in lipolysis level between raw and pasteurized milk cheeses. Regardless the use of raw or pasteurized milk in soft Xinotyri cheese production, the most abundant free fatty acids determined were oleic (C18:1), palmitic (C16:0), myristic (C14:0), capric (C10:0) and caprylic (C8:0) acids (Table 1). Also, a low lipolysis level was found in both raw and pasteurized milk as well as in pasteurized milk cheeses (Table 2).
Xinotyri cheese is a hard short ripened and acid-curd farmhouse cheese that is made in the mountains of Naxos Island in the Cyclades complex from raw goat’s milk from indigenous breeds. Often goat’s milk is mixed with a small amount (5%) of cow’s milk. No starter cultures are added. However, sometimes a small amount of cheese whey from the previous day is used to avoid a long coagulation time (24 h). Free fatty acids content was found to increase significantly during Xinotyri cheese ripening (Table 2). Oleic, palmitic, myristic, stearic and capric acid were the most abundant free fatty acids determined in Xinotyri cheese (Table 1). Total free fatty acid content of 6-day Xinotyri cheese differ significantly of that of 45 days cheese and of cheeses of the following days (Table 2). Xinotyri cheese showed an intense lipolysis with total FFA content at the end of ripening to be 20,024 $mgkg^{-1}$ (Bontinis et al., 2012). A 15% percent of the total free fatty acids were short and medium chain acids (C4:0 to C12:0).

Table 2. Free fatty acids (mg kg^{-1}) of hard Xinotyri cheese, fresh soft Xinotyri cheese and Kashkaval cheese during ripening and storage.

Cheese type	Ripening time	Treatment	C2:0	C4:0	C4ISO	C5ISO	C6:0	C8:0	C10:0	C12:0	C14:0	C16:0	C16:1	C18:0	C18:1	C18:2	C18:3	Total	Reference

1: Cheese made from raw milk, 2: Cheese made from pasteurized milk

Kefalotyri is a traditional hard Greek cheese that is made from ewe’s or goat’s milk or mixtures of them. Sometimes cow’s milk can be used. Kefalotyri cheese is produced in various parts of Greece with technologies that vary from place to place. A very popular Kefalotyri cheese is the artisanal mountainous Kefalotyri cheese that is still traditionally manufactured in the mountains of Pindos, Greece. This artisanal cheese is made by using raw ewe’s milk without the addition of starter cultures, during summer. Pappa et al. (2021) studied the biochemical characteristics of mountainous Kefalotyri cheese during ripening and storage. Free fatty acids were the most abundant group of volatiles found. However, butyric acid and 3 methyl butanoic acid were the most abundant free fatty acids determined (Table 3).

Table 3. Free fatty acids (peak area x 10^3) in mountainous Kefalotyri cheese and Tsalafouti cheese during ripening.

Tsalafouti is a traditional Greek cheese that resembles to fresh acid and acid/rennet curd cheeses. It has a spreadable texture with no gas openings. Due to its high moisture level, Tsalafouti cheese has a relative low-fat content that makes it a healthy alternative for consumers that are on diet. Due to its pleasant organoleptic characteristics which are much appreciated by the consumers there is an increasing trend for making Tsalafouti cheese during the last years. Artisanal Tsalafouti cheese is traditionally made in the mountains from ewe’s milk at the end of the lactation period. The milk is ‘boiled’ (90^0C) and then is left to acidify. Milk ripens naturally by the action of diverse indigenous lactic acid bacteria (LAB), mainly mesophilic LAB which grow slowly at approximately 10^0C for 15-20 days. However, Pappa et al. (2023) made a Tsalafouti cheese with a semi-industrial way in to standardize its making technology by using mesophilic commercial starters that contain a mixture of *Lactococcus lactis* subsp. *lactis* and *Lactococcus lactis* subsp. *cremoris* strains. Free fatty acids were not found in high amounts. However, hexonoic acid (C6:0) was the most abundant free fatty acid determined (Table 3).

Conclusions

This review describes the lipolysis level of some Greek artisanal cheeses. Raw milk Kashkaval of Pindos cheeses showed higher lipolysis levels than the pasteurized ones. In general no differences in lipolysis were observed between sheep milk and goats'(10%) Kashkaval cheeses. Lipolysis of soft Xinotyri cheese was not affected by using raw or pasteurized goat's milk. An intense lipolysis was observed in hard Xinotyri cheese. FFAs were the main volatiles of mountainous Kefalotyri cheese. FFAs of Tsalafouti cheese were not found in high amounts.

Abstract

Insect farming is an opportunity for production of protein meals, pet food, novel food and oils (for feed and bioenergy). Industrial farms are now present in many countries and highlight the need for greater sustainability, safety for operators and feed efficiency. Like livestock sector, the pellet form of feed could also contribute to these needs in the breeding of Yellow Mealworm (*Tenebrio molitor* L.). In fact, the pellet has greater density, allowing for savings in transport costs; helps provide balanced and more efficient diets; reduces the dustiness, improving the healthiness of the working environment. Commonly, the production of *T. molitor* begins with the oviposition of adults directly in boxes with feed for the new larvae. This work evaluated the effect of the form of the feed on the productivity of adults. Egg-laying adults were used to compare bran of size <0.5 mm (A), size 0.5-2 mm (B), bran assembled into pellets (C) and into “cookie” (D). After one month of oviposition, results showed adult survival between 91% and 96%, without significant differences between forms. The number of larvae produced/female was significantly greater on A (65.7 larvae) and B (65.3 larvae) compared to the assembled forms C (33.9 larvae) and D (44.8 larvae). Among the latter, the number of larvae was significantly greater on bran assembled into cookie (D) compared to the pelleted form (C). In conclusion, the first results show lower productivity of adults on assembled feed (pellets and cookies), the causes of which (greater cannibalism or mortality of newborn larvae) should be investigated to obtain improvements. Furthermore, observations on growing larvae would complete the knowledge for the entire breeding cycle.

Keywords:*Rearing insect, Tenebrio molitor, Diet, Bran, Pellet.*

Introduction

Insect farming is a circular economy opportunity (Cadinu*et al*., 2020) for the production of feed (Gasco *et al*., 2023), novel food (Baek *et al*., 2017), and also oils for energy purposes (Manzano-Agugliaro *et al*., 2012). In this context, Yellow Mealworm larvae function as decomposers, exhibiting an impressive ability to transform organic inputs, such as by-products and former foods, into high-value proteins, fats, and chitin (Luciano *et al*., 2022; Lienhard *et al*., 2023). Furthermore, their rearing by-product (frass) is a recognized nutrient-rich fertilizer (Poveda *et al*., 2019). The breeding of Yellow Mealworm (*Tenebrio molitor* L.) on a large scale highlights the need for improved healthiness of the working environment and greater efficiency in the production cycle. However, mealworms are generally reared on bran or ground cereals, leading to workplace dustiness. Nebbia *et al*., (2019) have demonstrated a significant association between exposure to flour dust and the development of asthma-related respiratory allergies among workers involved in the breeding of *Tenebrio molito*r. As a potential solution to these health risks, using pelleted feed could reduce the dustiness and transport costs of bran. The pelleted form has been studied in other animal husbandry

(Abdollahi *et al*., 2013; Bonfante *et al*., 2016) but its use in *T. molitor* breeding is poorly documented. Good results have been obtained on growing mealworms fed on pelleted rabbit feed, with larvae’s growth, and nutritional profile remaining unaffected due to the change of feed form (Brai*et al*., 2023). Moreover, diets assembled in pellets or cookies have already been used in studies of the efficacy of insecticides and mycoinsecticides against Tenebrionidae (Ahmad *et al*., 2016, Rice *et al*., 2019). Mixtures of by-products in assembled form are often used in the evaluation of new diets for mealworms. This experimental methodology allows to reduce the self-selection of the food by the larvae (Morales-Ramos *et al*., 2020; Baldacchino *et al*., 2023). However, studies on the use of pelleted feed administered to egg-laying adults are lacking. This is particularly important since the production of mealworms begins with the oviposition of adults directly into boxes with feed for the new larvae. The aim of the work is to test the influence of the feed form given to adults in the phase of oviposition.

Materials and Methods

Feed in four different forms was tested on egg-laying adults of *Tenebrio molitor* L., at *insectarium* of CIHEAM-Bari (Apulia region – Italy) in 2023. Wheat bran pellets (CESAC s.c.a., Conselice, RA, Italy) were ground and sieved on 2 mm and 0.5 mm mesh sieves. Bran sizes <0.5 mm and 0.5-2 mm were used for feed forms A and B, respectively; unground pellets were used for feed form C. Finally, feed form D was obtained from the mixture of A and B (ratio 50:50 w/w), assembled into “cookies” according to the method described in a previous study (Baldacchino *et al*., 2023).
The insects were provided by the colony reared on bran and yeast (ratio 95:5 w/w), supplemented with pumpkin as a wet source. Pupae were sexed (Bhattacharya *et al*., 1970) under a stereoscope (mod. SMZ745T, Nikon Europe B.V.) and stored separately for sex until the beetles’ eclosion. Groups of five males and five females (per replicate) were placed in plastic cups measuring 13 x 7 cm (h x Ø) and containing the specific feed form to be tested. The trial included ten replications/feed form in a completely randomized design. Every ten days for a month, the living adults were counted and transferred to cup with new feed. Adult productivity was verified on the 30th day, by counting the number of live larvae/replicate. The data were subjected to homogeneity and normality test. The Kruskal-Wallis test and pairwise multiple comparisons with Bonferroni correction were applied to number of live females. The repeated measures ANOVA and Tukey-Kramer HDS test post-hoc were applied to number larvae/female.

Results and discussion

Adult mortality was negligible in all feed forms tested. In fact, after one month of oviposition, the percentage of live adults was between 91% and 96%, and not significantly different between feed forms (H=2.479; df=3; p=0.479). These values are in accordance with what has been recorded in previous studies of bran (Baldacchino *et al*., 2024) and ensure the stock of egg-laying females in the period of maximum fertility (Morales-Ramos *et al*., 2012).
The productivity of the adults (calculated as larvae produced/female) was similar between feed forms in the first 10 days of oviposition. Subsequently, the number of larvae was constant in the sieved feed (A and B) while it decreased in both feeds assembled in pellets and cookies (C and D) (Figure 1). However, the results derive from observations limited to the first month of oviposition; the trend of subsequent oviposition could provide more complete data. Nevertheless, these preliminary results are already transferable, as some breeders use egg-laying adults for a month or slightly more.

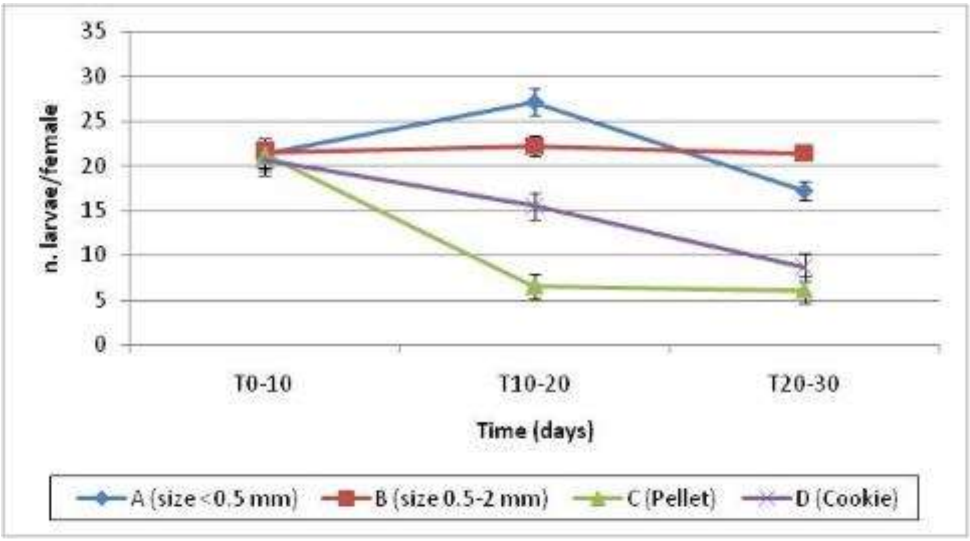

Figure 1. Production of larvae/female on different feed forms. Bran sizes <0.5 mm (A); bran sizes 0.5-2 mm (B); bran assembled in pellets (C); bran assembled in “cookies” (D). The mean values ± SE (n= 10) represent the number of larvae produced by female every 10 days.

The total productivity at the end of the month confirmed the differences between feed forms recorded during the oviposition period (F=15.51; df=3,36; p<0.001). Indeed, feed form A and B provided significantly more larvae (65.7 and 65.3 larvae, respectively) than assembled feed forms C and D (33.9 and 44.8 larvae, respectively) (Figure 2).

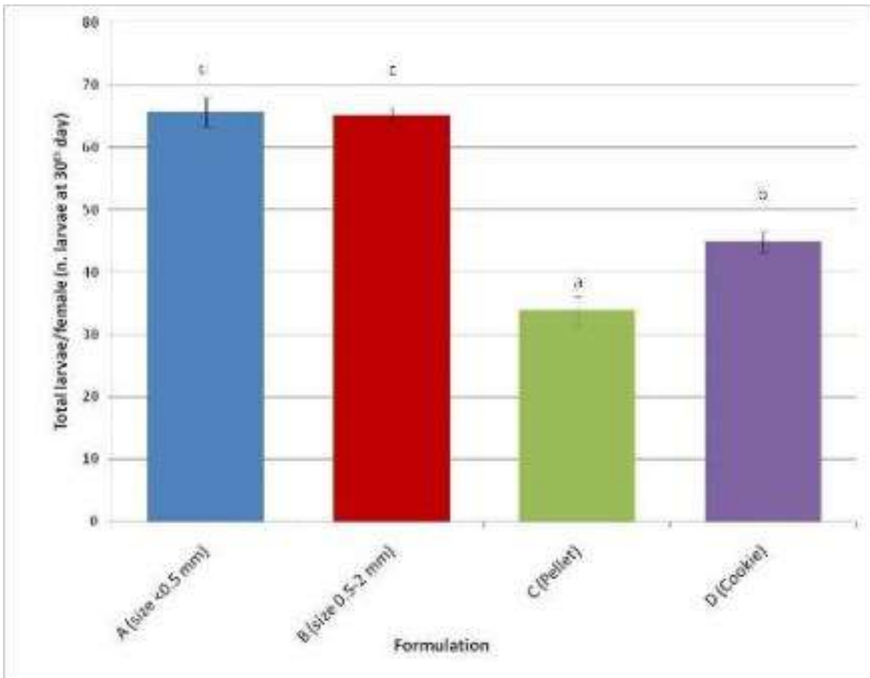

Figure 2. Total production of larvae/female on different feed forms. Bran sizes <0.5 mm (A); bran sizes 0.5-2 mm (B); bran assembled in pellets (C); bran assembled in “cookies” (D). The mean values ± SE (n= 10) represent the total number of larvae produced by female at 30th day.

However, the number of larvae produced was significantly greater on the cookie-assembled bran (D) compared to the pelletized form (C). Thus, in our study, the assembled diets negatively influenced the productivity of the adults, with 51.8% (C) and 68.4% (D) of larvae

produced compared to ground bran. Furthermore, the significant difference between pellet bran and cookie bran highlights the possible influence of other factors (hardness, shape, hygroscopicity, etc.).
Adult productivity estimated through the number of larvae in the diet (according to Berggreen *et al*., 2018) provides more realistic results for breeders of *Tenebrio molito*r. However, adults may cannibalise eggs (Deruytter*et al*., 2019; Frooninckx*et al*., 2022) and the feed form may also have affected egg survival. Newborn larvae may have had difficulty feeding, considering that the particle size of some feeds negatively affects larval growth (Naser El Deen *et al*., 2022). Recently, pelleted feed has been used to feed growing larvae with good results (Brai*et al*., 2023; Hwang *et al*, 2023), nevertheless, experiences on newborn larvae are lacking. All these aspects should be investigated for the best use of pelleted diets from the oviposition stage of *T. molitor*.

Conclusion

In this study, preliminary results showed that pelleted bran is less suitable than powdered bran (size <0.5 mm and 0.5-2 mm) and cookie-assembled bran for the oviposition of *Tenebrio molitor*. This limits the advantages of using pelleted feed (lower dustiness and lower transport costs) in a complete rearing cycle of yellow mealworm. However, further studies are needed to understand the effects on the development of newborn larvae to make the use of pelleted feed more efficient.

Abstract

The fall army worm (FAW) has recently invaded many countries in Africa and Asia causing serious damage to many crops, especially in corn fields. The search for natural enemies of this pest was conducted in infested corn fields in the Jordan Valley and eastern desert of Jordan, Gaza, and the West Bank. The egg-larval parasitoid, *Chelonus inanitus* (L., 1767) (Brachonidae: Hymenoptera) was found in three areas in Jordan. The general predator, *Chrysoperla carnea* (Neuroptera: Chrysopidae) was collected from the different corn fields in Jordan and Palestine. The species *Lapidura riparia* (Pallas, 1773) (Dermaptera: Labiduridae) was found in Jordan. The FAW egg parasitoid, *Telenomus remus* Nixon, 1937 (Hymenoptera: Scelionidae), the coccinellid predator, *Hippodamia tredecimpunctata* (Linnaeus, 1758), and a predatory bug, *Anthocoris* sp., were found in Palestine. Other undetermined insect species associated with the fall army worm belonging to several families of Hymenoptera and Diptera were also collected. All specimens were deposited in the University of Jordan Insect Museum.

Key words: *Spodoptera frugiperda, Natural enemies, Jordan, Palestine.*

Introduction

The fall army worm (FAW) *Spodoptera frugiperda* has achieved the status of a cosmopolitan pest, also in many countries it is a quarantine pest. Therefore, the search for efficient biological-control agents for this pest would have a global impact, particularly because of its resistance to insecticides and Bt plants (Wengrat et al. (2021). A total of 353 FAW larval host plants belonging to 76 plant families, mainly Poaceae (106), Asteraceae (31) and Fabaceae (31) are known so far (Montezano, 2018). Many studies on its hosts and natural enemies in different parts of the world were conducted. Molina-Ochoa et al. (2003) conducted an inventory for the parasitoids and parasites of fall armyworm (FAW), *Spodoptera frugiperda* (J. E. Smith) in the native distributional areas (North, Central and South America and the Caribbean Basin). Tepa-Yotto, et al. (2021) reported that in the Americas, about 150 parasitoids were found to be associated with FAW. Computer modeling to predict the habitat suitability of fall armyworm FAW and its major parasitoids (*Chelonus insularis*, *Cotesia marginiventris*, *Eiphosoma laphygmae*, *Telenomus remus* and *Trichogramma pretiosum*) under current and future climate scenarios were utilized. This provided important data needed for decision making in worldwide biological control programs and long-term management of FAW (Tepa-Yotto et al., 2021).
Tendeng et al. (2019) recorded *Chelonus* sp. and *Campoletis* sp. (Hymenoptera) and Nematode *Hexamermis* sp. from Senegal. Abang et. al. 2021 conducted field surveys and laboratory studies on parasitoids associated with FAW and Southern army worm (SAW) (*Spodoptera eridania*) in Cameroon. Sisay *et al.*, (2019) surveyed the distribution of FAW and its natural enemies in Ethiopia, Kenya, and Tanzania in 2017 and 2018. Edmardash et al. (2011) listed 16 species of Cheloninae (Braconidae) from Egypt and provided a key for

species identification. *Orius albidipennis* and *Orius laevigatus* were collected from maize fields in Egypt (Karaman 2009). From India, Shylesha et al. (2018) recorded two egg parasitoids, three larval parasitoids, one predator and one entomopathogenic fungus.

Lists of parasitoids from Palestine were presented by Bodenheimer (1930 and 1937). Kugler (1966) listed 81 parasites from 56 Lepidoptera hosts. *Chelonus inanitus* (L.) was a common parasitoid of *Spodoptera littoralis* (Boisduval) in the Middle East, mostly in alfalfa fields (Gerling 1969). Hamdan and Abu-Awad (2007) studied the effect of host plants on the predatory bug, *O. laevigatus* in Palestine. Rechav and Orion (1975) studied the development of *Chelonus inanitus* immature stages. This species was released in a cotton field to study its ability to control *Spodoptera littoralis* (Boisduval) (Rechav, 1976) but it was found to be not effective. Rechav (1978) studied its oviposition, host preferences and sex ratio. In their study on the Egyptian Cheloninae Edmardash et al. (2011) listed *Chelonus inanitus* (L), 1767. *Chelonus (Microchelonus) basalis* Curtis, 1837 *Chelonus (Microchelonus) sulcatus* Jurine, 1807 *Phanerotoma (Phanerotoma) dentata* (Panzer, 1805) *Phanerotoma (Phanerotoma) leucobasis* Kriechbaumer, 1894 from Palestine. Najajrah, et al. (2019) listed 35 species of lady beetle family (Coleoptera: Coccinellidae) with data on their geographic distribution and ecological significance.

The FAW was first observed in August 2020 in Jordan (Katbeh-Bader et al., 2020) and because its introduction was recent no studies on its the natural enemies were conducted. However, studies on natural enemies on Lepidopteran pests or other pests can be found in earlier literature. Katbeh-Bader et al. (2000) listed the Heteroptera of Jordan based on the specimens preserved in the University of Jordan Insects Museum. Some potential natural enemies of the FAW may be found in this list such as *Orius niger* Wolff, 1811 (Anthocoridae), four species of the genus *Geocoris* (Lygaeidae) and 17 species of Reduviidae. Three hemipterans were collected from *Tuta absoluta* (Meyrick) (Lepidoptera: Gelechiidae) heavily infested tomato plants in the Jordan Valley (*Orius albidipennis*, *Orius* sp. (Anthocoridae) and *Nesidiocoris tenuis* (Miridae). In addition, the parasitic wasp *Bracon* (*Habrobracon*) *concolorans*, (Hymenoptera: Brachonidae) was recorded for the first time from Jordan (Al-Jboory et al., 2012). A total of 66 parasitoid species in 11 families from the superfamily Chalcidoidea were recorded previously from Jordan (Noyes, J.S. 2003: Universal Chalcidoidea Database). Some potential natural enemies of the FAW may be found in these species.

The objectives of this paper are to record the natural enemies of the FAW found in our study in Jordan and Palestine (West Bank and Gaza).

Materials and Methods

Several field trips were conducted to corn fields in the Jordan Valley, Eastern Desert of Jordan, Gaza and Jericho (West Bank) during September to December 2021 to inspect for the infestation with FAW and the presence of natural enemies of the pest. Egg masses, larvae, and pupae of the FAW were collected from infested corn plants and adults were collected from pheromone traps. Plant host, location (coordinates), date, collector name, and notes regarding any relevant ecological data were recorded. Male-genitalia were mounted on slides with glycerin for positive identification of the FAW, since the wing scales were usually removed from adult moths collected by pheromone traps. Collected larvae were reared on corn leaves to detect emergence of natural enemies. Edmardash et al. (2011) identification key was used to identify *Chelonus inanitus*. Collected insect samples were sorted into putative species and preserved in 75% ethanol. All specimens were kept in the University of Jordan Insects Museum.

Results and Discussion

A promising species, *Chelonus inanitus* (L., 1767) (Brachonidae: Hymenoptera) was found in three areas, one corn field in Dayr Alla in Jordan Valley and two corn fields in Al Hallabat in Eastern Desert (Figure 1A). *Chelonus inanitus* is a well-known natural enemy of the FAW. It was seen in large numbers in heavily infested, unsprayed corn field in the Jordan Valley. *Chrysoperla carnea* (Figure 1B) was found in the different corn fields. Its larvae are natural enemies of many insect pests like whiteflies, aphids, mealybugs, scale insects, psyllids, leafhopper eggs, thrips, beetle larvae, leaf miners and other caterpillars. *Lapidura riparia* (Pallas, 1773) (Dermaptera: Labiduridae) (Figure 1D) is another common natural enemy of many pests. It is a cosmopolitan species found mainly in tropical to subtropical regions.

D E

Figure 1. A. Chelonus inanitus. B. Chrysoperla carnea C. Telenomus remus D. Lapidura riparia E. Hippodamia tredecimpunctata.

Important general predators were recorded previously in Jordan (Katbeh-Bader et al. 2000) should be taken in consideration in conservation control since all of them are expected to be found in corn field in both Jordan and Palestine. *Geocoris* (s. str.) *megacephalus* (Rossi, 1790) (Hemiptera: Lygaeidae) has already been observed in Lebanon feeding on early instars of the FAW (Zinatt, personal communication). *Orius niger* Wolff, 1811 (Hemiptera: Anthocoridae), was also observed in corn fields in Jordan. *Geocoris* (S. str.) *ater* (Fabricius, 1780), *Geocoris* (s. str.) *phaeopterus* (Germar, 1837), *Geocoris* (*Eilatus*) *chloroticus* Puton, 1888 (Hemiptera: Lygaeidae) may eventually be collected in Jordan. The diverse parasitoid species from the superfamily Chalcidoidea (Noyes, J.S. 2003: Universal Chalcidoidea Database) should also be taken into consideration in conservation control programs.

The FAW egg parasitoid, *Telenomus remus* Nixon, 1937 (Hymenoptera: Scelionidae), was found (Figure 1C). And 3 species of general predators, *Chrysoperla carnea*, *Hippodamia tredecimpunctata* (Linnaeus, 1758) (Figure 1E), and *Anthocoris* sp. were found. The relatively small number of parasitoids found in this study in Palestine is mainly due to the use of insecticides in the surveyed fields Such fields were treated with insecticides such as Lufenuron, Emamectin benzoate, Chlorfluazuron, and Diesel.

The selection of a candidate parasitoid species for a biological control program should be based on pest risk clearance, its reproductive performance, its functional and numerical response profile, high behavioral host selection, resilience at low host population densities and its dispersal ability (Tepa-Yotto, et al., 2021).

Magaña et al. (2022) stated that *C. inanitus* may be an interesting parasitoid of *Spodoptera* species. They mass reared this parasitoid on *E. kuehniella* mature eggs which resulted in increased the female percentage in the offspring and shortened the parasitoid life cycle. In addition, a high number of females parasitizing simultaneously reduced the emergence of non-parasitized hosts. However, information on the performance of *C. inanitus* under field conditions is rare indicating that it could be highly sensitive to broad-spectrum pesticides (Rechav, 1976). Its release in a cotton field to control *S. littoralis* was not very successful because it was affected by the application of organophosphates used to control *S. littoralis.*

Chelonus inanitus has 3 larval instars. The parasitoid female lays its eggs in the host egg under the outer shell of the egg but outside the host egg cell. Later the 1st instar parasitoid penetrates to the yolk and enters the haemolymph of the embryo before the host hatches. The 3 instars of *C. inanitus* float on the host haemolymph between the Malpighian tubules.

Wengrat (2021) recorded *Telenomus remus* on *Spodoptera* spp. in Brazil for the first time and studied its phylogeography. They suggested that the *T. remus* strain distributed by anthropogenic action into the Americas, Africa, and Asia is able to adapt to different agricultural landscapes. Therefore, reintroductions of natural populations of *T. remus* from different geographical origins may be an efficient tactic for classical and augmentative biological control of *S. frugiperda* in different parts of the world. Accurate identification of *T. remus* and its genetic strains is essential for the success of biological control programs using this parasitoid. Liao et. al. (2019) reported *Telenomus remus* for the first time parasitizing *Spodoptera frugiperda* in southern China. Kenis et al., 2019 considered *Telenomus remus* as a candidate parasitoid for the biological control of FAW in Africa.

Conclusion

Two important natural enemies of the FAW are recorded in this study. The egg-larval parasitoid, *Chelonus inanitus*, is recorded from Jordan for the first time, and the egg parasitoid, *Telenomus remus* which was previously introduced into Palestine was also found in our study in Palestine. Other nonspecific natural enemies such as aphid lions, earwigs, lady beetles and predatory bugs were also found. This qualitative study should be considered as a preliminary one taking in consideration the time and season limitations. Therefore, additional natural enemy species are expected to be found if more extensive collecting is conducted during most seasons of the year in a wider geographical range in both Jordan and Palestine.

Acknowledgments

This research was sponsored by the FAO, project no. TCP/RAB/3803. We appreciated the help in collecting specimens by Heba Obeidat from in Jordan, Rana Samara and Emad Eid from West Bank, Mohammad Khader and Husam Ammar from Gaza.

Abstract

The biopesticides sector is currently experiencing significant growth, with numerous discoveries being made in the development of new products based on microorganisms and plant extracts, which are fuelling a growing global market. Currently, around 75% of all biopesticides in use are *Bacillus*-based products and their toxins. The objective of this study was to elucidate the effects of a *Pseudomonas* isolate as a biopesticide against tomato crop diseases and pests, and the modes of action involved in antagonism. *Pseudomonas* isolates were isolated from rhizospheric tomato soils at Melk zhar (Agadir, Morocco). These isolates were tested against the fungus *Botrytis cinerea*, the mite *Tetranychus urticae* and the insect *Bemisia tabaci*. The results demonstrated that the isolates exhibited strong inhibitory effects against *B. cinerea*, with inhibition levels reaching up to 60%. The pest test results indicated that three isolates, Q110B, Q036B, and Q172B, exhibited significant mortality against *T. urticae*, and *B. tabaci*. Isolate Q036B exhibited a higher mortality rate than Q172B and Q110B. The results of this study indicate that selected Pseudomonas strains have good efficacy against tomato diseases and pests. They could potentially serve as an alternative biopesticide to chemicals for use in integrated pest management programs in agro-ecosystems.

Keywords: Tomato, *Pseudomoans, Botrytis cinerea, Tetranychus urticae, Bemisia tabaci*.

Introduction

Tomatoes are one of the most cultivated crops in Mediterranean greenhouses (Abou Hadid, 2013). In Morocco, greenhouse tomatoes cover approximately 16,000 hectares, producing around 1.5 million tons per year. They are considered an essential crop grown in the Souss Valley (Ait Hou et al., 2015). However, tomato productivity faces significant constraints and risks from increased pathogenic agents and pests, making it imperative for farmers to reduce the damage caused by these threats. Chemical pesticides have long been used to combat pests and diseases affecting tomato crops. However, these products can have negative impacts on the environment and human health. Additionally, the emergence of pathogen resistance is exacerbated by the use of chemical fungicides (Chung et al., 2009). For instance, Elad et al. (1992) reported that B. cinerea developed rapid resistance to specific fungicides, including benzimidazoles, dicarboximides, and sterol biosynthesis inhibitors. Similarly, Halime et al. (2019) reported a high level of resistance of B. cinerea to Fenhexamid in Moroccan tomato greenhouses. Moreover, the use of chemical products causes soil pollution and poses health risks to humans (Martínez-Romero et al., 2008). To find a safer fungicidal control, alternative strategies have been considered. Among these, biopesticides have emerged as a promising alternative. Biopesticides are biological control agents derived from natural organisms such as bacteria, fungi, or plants. Non-phytopathogenic bacteria from rhizospheric, endophytic, or halophilic environments have frequently been reported to protect plants against phytopathogens (Van Loon et al., 1998; Magnin-Robert et al., 2007; Compant et al., 2010; Verhagen et al., 2011). Bacterial genera such as Bacillus, Pseudomonas, and Enterobacter, along with fungi belonging to the Pythium and Trichoderma genera, and actinomycetes, have shown significant biocontrol potential (Lange et al., 1993; Chernin et al., 1995; Amkraz et al., 2010; Gao et al., 2018). Certain strains of Pseudomonas have demonstrated the ability to inhibit the growth of numerous plant pathogens while being relatively harmless to the environment (Qessaoui et al., 2020; 2021). Their modes of action vary, ranging from competition for nutrients to the production of insecticidal, antifungal, or antibacterial metabolites. Therefore, the objective of this study is to test the effect of Pseudomonas strains against diseases and pests of greenhouse tomatoes.

Materials and method

Pseudomonas isolates

The three Pseudomonas isolates (Q172B, Q110B, and Q036B) were obtained from an experimental farm of the INRA in Agadir, southwestern Morocco. These bacteria were characterized in a previous study as *Pseudomonas* sp. (Qessaoui et al., 2019).

In vitro selection of antagonistic Pseudomonas against B. cinerea

In vitro evaluation of *Pseudomonas* isolates was carried out using dual culture technique on PDA (Kaur, 2003). A heavy inoculum was applied as a band of 1.5 cm length equidistantly on three opposite edges of the agar medium in Petri plates using an inoculation loop. A mycelial disc of 5 mm diameter from a 7 day-old culture of B. cinerea was placed at the center of the Petri plate. Three replications were made for rhizobacteria. Plates containing the pathogen alone served as control. Plates were incubated for five days at 25°C (Kaur et al., 2007). After incubation, the mycelial growth inhibition percentage (IP) was calculated using the following expression.

$$IP= R1-R2/R1*100$$

Where R1 is radial growth of the fungus in the control and R2 is radial growth of the fungus in the treated plates . The bacterial isolates showing maximum zones of inhibition were selected for further studies.

Effects of *Pseudomonas* isolates on *B. tabaci adult*

Tomato leaves were collected, thoroughly washed with tap water, rewashed with sterile distilled water and then dipped for 1 min in each bacterial suspension (10^8 cfu/mL) for each isolate. Control tomato leaves were dipped in only distilled water for 1 min. The inoculated leaves were dried and introduced individually in sterile tubes. Fifteen adult whiteflies were then introduced in tubes containing the treated tomato leaves. The tubes were sealed by muslin tissue to allow ventilation. Three replicates were evaluated for each treatment, and the bioassay was replicated thrice. The tubes were incubated at T° = 25±2°C, RH = 70±5% and adult mortality was calculated 72h after treatment application.

Acaricidal activity

Three Pseudmonas bacterial strains Q110B, Q036B and Q172B were assessed for their ability to cause mortality to homogeneous age adults of *T. urticae* on tomato (Solanum lycopersicon) leaves. Fresh leaves of tomato were collected from unsprayed plants growing in a greenhouse (INRA experimental farm, Agadir, Morocco). The leaves were first washed with tap water and rewashed with sterile distilled water, and then dried under a laminar flow hood. The effect of bacterial isolates on *T. urticae* adults was studied under laboratory conditions using a leaf dip bioassay (Bouharroud et al. 2007). A leaf cage was prepared from Petri dishes (9 cm) containing Whatman paper soaked in sterile distilled water. A 1.5 cm diam. hole was made in the lid of Petri dishes and covered with muslin. Tomato leaflets were dipped in strain concentration (108CFU/ml) for 20 s. The treated leaflets were dried under a laminar hood then transferred to leaf cages. The control leaflets were dipped only in sterile distilled water. Fifteen T. urticae adults (male to female sex ratio: 1–1.1) were then transferred to treated leaflets. Four replicates for each leaf cage were used. The cages were incubated at 24±2°C with a photoperiod of 16 : 8 h (L : D), and T. urticae mortality rate was assessed 72 h after treatment. The bioassay was replicated three times. Two-spotted mite mortality rates were corrected using Abbott’s formula (Abbott 1925):

$$CrrM = \frac{DMN - DMNC}{MTN - DMNC} * 100$$

where: CrrM – corrected mortality, DMN – dead mite number, DMNC – number of dead mites in control, MTN – total mite number.

Statistical analysis

The mycelial growth inhibition percentage (IP) was calculated for each Pseudomonas isolate. To determine the efficacy of *Pseudomonas* strains on T. urticae, and *B tabaci* mortality data were analyzed using Abbott’s formula for acaricide activity (Abbott 1925). The data were subjected to Analysis of Variance test (ANOVA) using Statistical software, STATISTICA (Ver. 6). Any difference mentioned is significant at P< 0.01 using the Newman–Keuls multiple range test.

Results and discussion

In vitro selection of *B. cinerea* antagonistic *Pseudomonas*

The results demonstrated that the three Pseudomonas strains tested exhibited significant antagonistic potential (IP > 65%) against B. cinerea (Table 1) compared to the control. This inhibition was evidenced by a reduction in the colony diameter of the mycelium compared to the control (Figure 1).

Acaricidal activity

All three Pseudomonas strains caused significant mortality in T. urticae adults 72 hours after treatment (Table 1). The symptoms induced by the Pseudomonas isolates in T. urticae included reduced movement and the appearance of brown-black coloration (Aksoy et al., 2008). The highest mortality rate was achieved by strain Q036B, which resulted in approximately 97% mortality (Table 1).

The efficacy of *Pseudomonas* isolates against *B. tabaci* adults

All three Pseudomonas isolates (Q110, Q036B, and Q172B) had an effect on the mortality of B. tabaci adults (Table 1). The most significant effect of Pseudomonas was observed with Q036B.

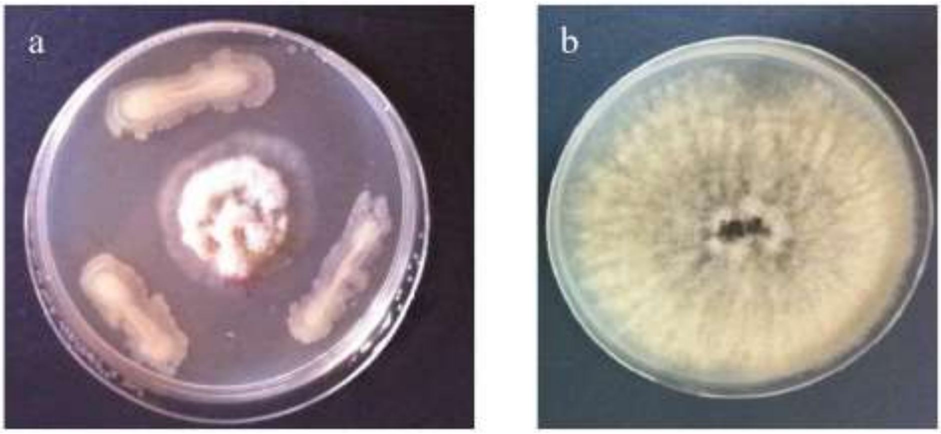

Figure 1. Inhibition of B. cinerea by Pseudomonas isolates in PDA medium. a: treated with Pseudomonas, b: control

Table 1. In vitro screening of bacterial isolates based on mycelial growth inhibition of B.cinerea.

Strain	IP % (Botrytis)	$CrrM$ % (T. urticea)	Mortality % (B. Tabaci)
Q036B	65,28±2,41[a]	97.6 ± 5.4 [a]	74% [a]
Q172B	66,86±5,64[a]	88.0 ± 14.4 [a]	63% [a]
Q110B	65,48±5,15[a]	84.4 ± 9.7 [a]	63%[a]

The principal findings of this research indicate that bio-inoculation with Pseudomonas isolated from rhizospheric soil effectively inhibits Botrytis cinerea development. These Pseudomonas strains show potential for plant protection against pests, causing significant mortality in B. tabaci under laboratory conditions and displaying acaricidal and repellent activities against Tetranychus urticae adults. Mechanistically, the isolates produce bioactive metabolites such as proteases, cellulases, chitinases, and siderophores (Qessaoui et al., 2021), which inhibit conidia germination, germ tube elongation, and mycelial growth of B. cinerea. Studies have demonstrated their secretion of antibiotics like lipopeptides, 2,4-diacetylphloroglucinol, and phenazine-1-carboxylic acid (PCA), reducing pathogenic infections directly (Lugtenberg and Kamilova, 2009; Mitter et al., 2013; Jaaffar et al., 2017; Paulin et al., 2017). Furthermore, siderophore production and volatile compounds (e.g., HCN) contribute to their biocontrol effectiveness against fungi (Ramette et al., 2003; Kumari and Khanna, 2014). These findings support the role of enzyme-producing bacteria in inhibiting phytopathogenic fungi (El-Tarabily, 2006), highlighting their potential as effective biofungicides and bioinsecticides. Additionally, Pseudomonas strains have been observed to induce mortality in Drosophila melanogaster due to their strong hemolytic activities, including lipases, chitinases, and hydrolases (Vodovar et al., 2006). This study represents a preliminary step towards future research supporting agroecological practices that balance industrial needs with ecological sustainability.

Conclusion

The findings of this study indicate the potential of Pseudomonas isolates as effective biopesticides for the management of tomato diseases and pests. The demonstrated inhibitory effects against B. cinerea and the significant mortality rates observed in T. urticae and B. tabaci underscore the promising role of these isolates in integrated pest management (IPM) programs. In particular, the higher efficacy of isolate Q036B suggests that it could be a valuable addition to the reduction of reliance on chemical pesticides. The results support further research and development of Pseudomonas-based biopesticides as sustainable alternatives for enhancing crop protection in agro-ecosystems.

Abstract

One of the most common strategies to increase agricultural production is to improve soil fertility. Phosphorus is the second macronutrient essential for the growth and development of plants. However, the solubility of this macronutrient is very low, and 75 to 90% of phosphate fertilizers are precipitated by iron. The use of rhizospheric microorganisms appears to be the most effective biological method for enhancing the solubilization of phosphate, as some bacteria are capable of degrading Ca3(PO4)2 to available phosphate (P_2O_5). Four isolates (R25, R36, R4, and R10) of fluorescents *Pseudomonas* were isolated from the rhizosphere soil of tomato plants in the Souss-Massa of Morocco. The strains were tested for their ability to solubilize phosphates on solid and liquid media of NBRIP. The phosphate solubilization was estimated by measuring the diameter of the clear halo on the solid media and by measuring the evolution of absorbance at 820 nm and pH during five days in the liquid media according to the Olsen method. The most significant clear halo was obtained by R25 (15.00 ± 5.94 mm). On liquid NBRIP media, R36 produced the greatest quantity of available phosphate (P_2O_5) 96 hours after inoculation (32.65 ± 0.01 µg/ml). This strain demonstrated the ability to acidify the media, resulting in a pH of 3.73 ± 0.16, in comparison to the control, which exhibited a pH of 6.18 ± 0.10. This phenomenon can be attributed to the production of organic acids by fluorescent Pseudomonas in the media. This finding has the potential to enhance the yield of tomato crops grown in soil with limited phosphate or available phosphate.

Keywords: *Pseudomonas, phosphate solubilization.*

Introduction

One of the most common strategies for increasing agricultural production is the improvement of soil fertility. Phosphorus is an essential macronutrient for the growth and development of plants, following nitrogen. However, it is considered to be one of the elements that limits plant growth. Chemical fertilizers represent the primary strategy for ensuring the availability of phosphorus in agricultural soils. However, it has been estimated that between 75 and 90% of phosphate fertilizers added are precipitated by iron, aluminum, and calcium complexes present in soils (Gyaneshwar et al., 2002; Turan et al., 2006). This accumulation of this form is a significant challenge in agriculture. The use of rhizospheric microorganisms represents the most effective biological approach to enhance the solubilization of phosphate in the soil and to provide sufficient quantities for plant nutrition (Pradhan and Sukla, 2005; Singh et al., 2011). The ability of certain microorganisms to convert the insoluble phosphate to an accessible form is an essential trait for plant growth-promoting rhizobacteria (PGPR) to enhance plant performance. Phosphate-solubilizing rhizospheric bacteria have been identified as a promising source for use as a biofertilizer in agriculture (Kucey et al., 1989). The population of microorganisms capable of solubilizing phosphates varies depending on the type of soil. These bacteria can be found in both fertile and deficient soils (Oehl et al., 2001). A significant proportion of them is located in the rhizosphere, which contains between five and twenty times more phosphate-solubilizing bacteria than non-rhizospheric soil (Bowen and Rovira, 1999). A multitude of microbial species are capable of solubilizing phosphates, with *Pseudomonas* and *Bacillus* exhibiting a notable proclivity for this element. These bacteria are predominantly found in soil and are adept at resisting adverse environmental conditions. The phosphate-solubilizing capacity of these bacteria is frequently evaluated on media containing calcium phosphate as the sole source of phosphates. A variety of media are recommended for this type of study, including Pikovskaya medium (Pikovskaya, 1948), the PVK bromophenol blue (BBP) and National Botanical Research Institute Phosphate (NBRIP) medium (Nautiyal, 1999). The mechanism of phosphate solubilization is initiated by the release of H+ ions, the production of organic acids and chelating substances. The production of organic acids represents the primary mechanism. Several studies have indicated a correlation between phosphate solubilization and a decrease in medium pH (Hinsinger, 2001). The purpose of this study was to assess the ability of four Pseudomonas isolates from tomato rhizospheric soil to solubilize phosphate.

Material and methods

Isolation of bacteria from tomato roots Isolation was performed as described by Qessaoui et al., (2019). Samples of rhizospheric soil were collected from tomato greenhouses of the experimental farm at the Regional Agricultural Research Center of Agadir in Morocco. Extract samples were diluted and dilutions were spread on King B medium and incubated at 26°C for 48h. Results were expressed as colony forming units per gram (CFU g-1) of rhizospheric soil Fluorescent colonies were purified by streaking and were stored at -80°C in 40% glycerol.

Phosphate solubilization

Phosphate solubilization by the isolated fluorescent *Pseudomonas* isolates was tested in solid media by the method described by Nautiyal1999. Ten microliters of the culture of each strain was spotted on the surface of the solid media in Petri dishes. The solubilization capacity was assessed by the transparent area formed around the colony. Ten days after incubation at 30 °C, the diameter of the solubilization halo (DSH) was determined by the following formula

DSH=THD−CD

where THD is the total halo diameter, and CD is the colony diameter.

Quantitative estimation of phosphate solubilization in broth was carried out in Erlenmeyer flasks (250 ml) containing 100 ml of NBRIP medium. The flasks were incubated at 28 °C for 5 days at 120 rpm. Then, 5 ml of each isolate culture was centrifuged at 3000 rpm for 20 min. Phosphate concentration in culture supernatant was estimated as described by Olsen and Sommers[71]. Three replicates were used, and a standard calibration curve was made with KH_2PO_4 solution (Sigma-Aldrich).

Results and discussion

Phosphate Solubilization on Solid Medium

The results showed that these four isolates formed a clear halo of solubilization on NBRIP medium. The most significant clear halo was observed for isolate R25 (15.00±5.94 mm), while the smallest halo was obtained with isolate R10 (7.75 mm) (Table 1). These results were compared with a bacterial control that showed no solubilization on solid medium. This halo of solubilization indicates the production of substances that solubilize phosphate; a larger halo suggests a greater production of these substances in the medium.

Table 1. Solubilisation halo diameter by P*seudomonas* isolate

	R10	R4	R36	RF25
DSH (mm)	7,75±2,06	10,50±0,58	12,00±3,16	15,00±5,94

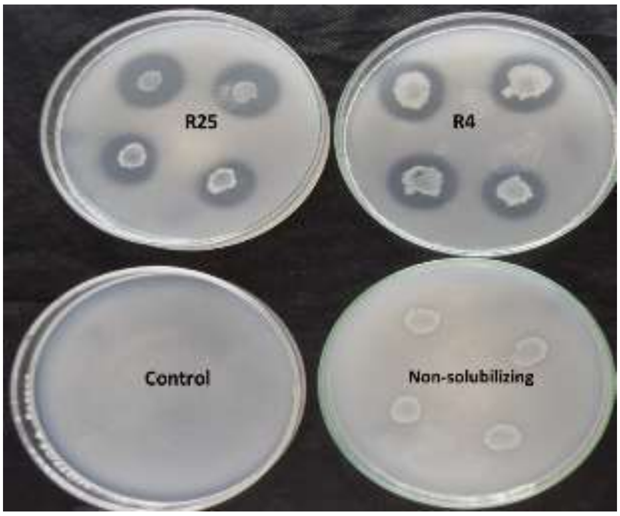

Figure1. Effect of *isolates* on the solubilization of phosphate (solid medium) after 8 days of incubation

Phosphate solubilization on liquid medium

To confirm the phosphate solubilization observed on solid medium, these isolates were tested for their ability to solubilize phosphate in liquid medium. The results showed that all four isolates effectively solubilized phosphate in liquid medium. The results showed that phosphate solubilization in liquid medium began 24 hours after inoculation, with the highest rate of solubilization observed 96 hours after treatment (Figure 2). This solubilization was indicated by a clarification of the medium's appearance compared to the control medium, which did not contain any bacteria (Figure 3). The analysis of variance showed significant efficacy for all four isolates in solubilizing phosphate. Isolate R36 produced the highest quantity of available phosphate (P_2O_5) 96 hours after inoculation (32.65±0.01 µg/ml). After 96 hours, a decrease in the concentration of soluble phosphate was observed for all isolates (Figure).

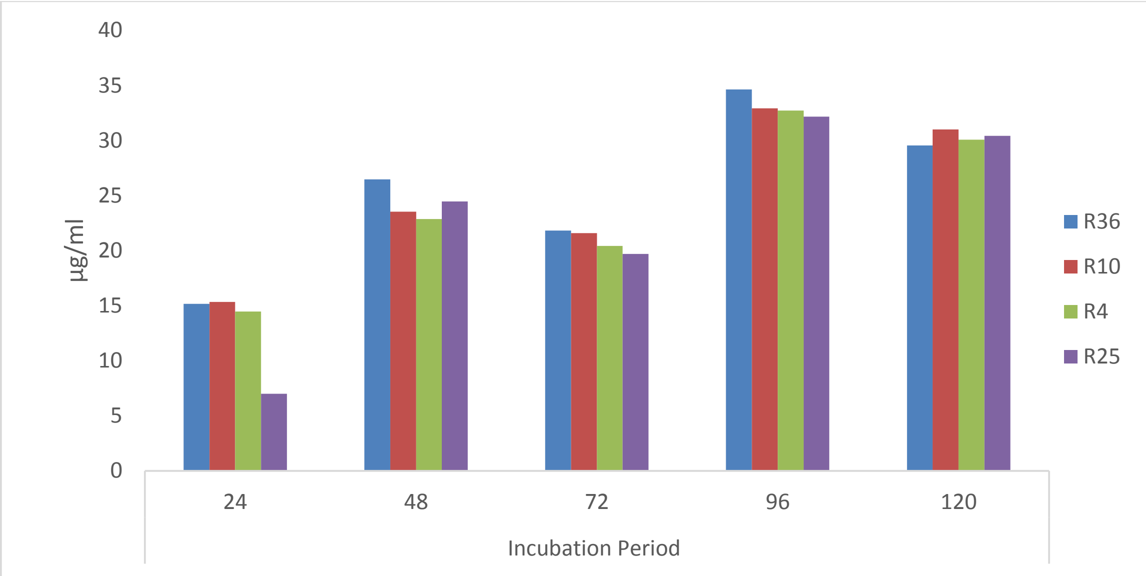

Figure 2. Evolution of Phosphate solubilization on liquid medium

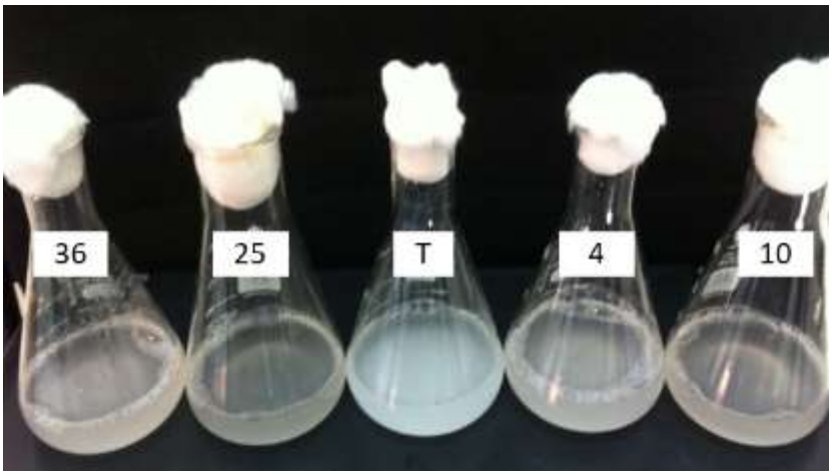

Figure 3. Phosphate solubilization on liquid medium manifested by a clarification of the medium's appearance compared to the control

Monitoring the pH of the Solubilization Medium:

During the incubation period of the solubilization medium, pH monitoring was conducted every 24 h. The results showed a significant decrease in pH for all isolate, compared to the control (Figure 5). The results showed that the pH of the medium decreased from pH 7 as early as 24 h after treatment, reaching stability around pH 4 by 72 h. These results of pH decrease indicate acidification of the medium, primarily attributed to the production of organic acids by the selected isolates.

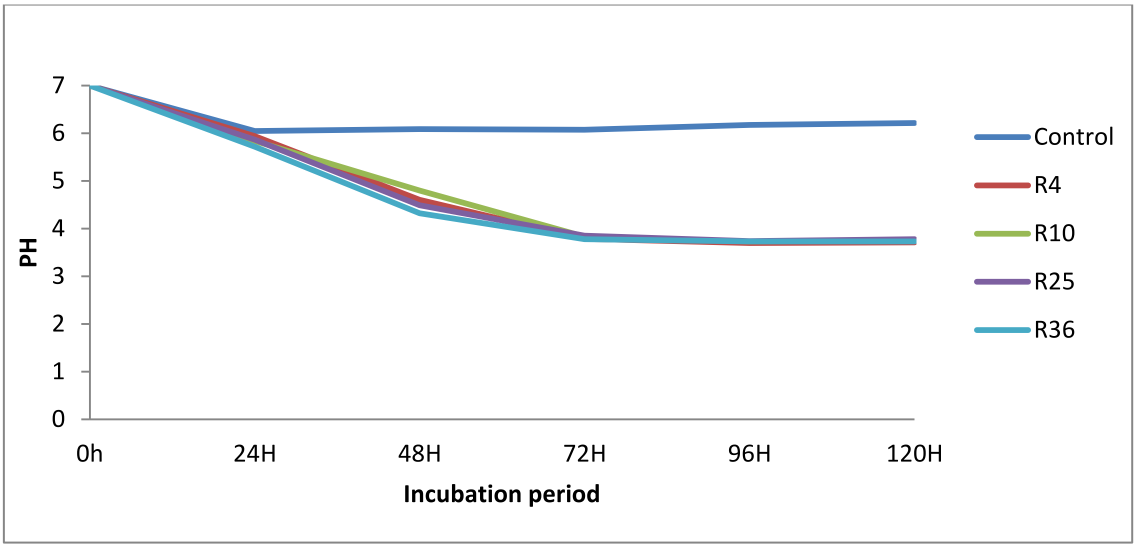

Figure 4. Monitoring the pH of the Solubilization Medium:

The results indicate that these four bacterial isolates formed a clear halos of phosphate solubilization on NBRIP medium, demonstrating their proficiency in phosphate solubilization. This characteristic is crucial for rhizospheric bacteria as it enhances phosphate absorption by plants, essential for their growth and development. Previous research highlighted the significant phosphate solubilization capabilities of *Pseudomonas* species (Joseph et al., 2005; Qessaoui et al., 2019). Many studies identified microbial genera such as *Pseudomonas*, Bacillus, *Rhizobium*, and *Enterobacter* among bacteria, and *Aspergillus* and *Penicillium* among fungi, as pivotal in phosphate solubilization (Xiao et al., 2011; Keditsu and Srivastava, 2014). The primary mechanism through which *Pseudomonas* solubilizes mineral phosphate involves the production of organic acids and acid phosphatase, crucial for the mineralization of organic phosphorus. Organic acid production induces acidification of the microbial cell and its surroundings, facilitating the release of phosphate from mineral phosphate through proton substitution for calcium (Goldstein, 1999). Qessaoui et al. (2019) demonstrated that isolates of *Pseudomonas* sp. (Q6B, Q14B, Q7B, Q1B, and Q13B) significantly enhanced seedling height, plant length, and collar diameter. These effects were attributed to their ability to solubilize phosphate, produce siderophores, ammonia, and indole-3-acetic acid, and colonize the roots of tomato plants. These findings underline the importance of selecting the most effective bacterial strains for agricultural applications, particularly in improving soil fertility and enhancing crop growth. Among these isolates, particularly isolate R36, with its healthy phosphate solubilization capacity, holds promise for future research aimed at developing effective and sustainable biofertilizers.

Conclusion

The study highlights the potential of rhizospheric *Pseudomonas* bacteria in enhancing phosphate solubilization. These strains could prove instrumental in improving soil fertility and agricultural productivity. The ability of these bacteria to convert insoluble phosphates into bioavailable forms suggests their practical application in sustainable agriculture, reducing the need for chemical fertilizers and promoting environmentally friendly farming practices.

Abstract

The chestnut has great economic importance in Portugal. Farmers and entrepreneurs of this crop have faced several problems that have led to a decrease in production due to the emergence of new pests and microbiological development during pre- and post-harvest stages. The main aim of this work was to investigate some chemical and biological parameters in different components of the chestnut infructescence – hedgehog, outer pellicle, integument+seed – at the harvest time in two varieties – Longal and Martaínha, to verify whether there are significant differences between the components and varieties after using an ecological extraction method. Three studies were carried out. In the first, the influence of the extraction method on the total reducing capacity, flavonoids, monomeric anthocyanins, hydrolyzable tannins, reducing power, and 2,2-diphenyl-1-picrylhydrazyl radical scavenging capacity (DPPH) was analyzed using two methods. The methanol:water (1:1, v/v) proved to be suitable. The second study aimed to replace the mixture of methanol:water with ethanol:water (1:1, v/v) (an environmentally friendly solvent) and to use ultrasound to shorten the extraction time. When analyzing the effects of the extraction method and the solvent mixture on the total reducing capacity, reducing power, and DPPH radical scavenging capacity of chestnut’s hedgehog, the ethanol:water (1:1, v/v) method with ultrasound was the most effective in most situations. When comparing the two varieties and fruit components (third study), Longal had the highest extraction yield. The outer pellicle was the component of the infructescence with the highest values in both varieties, followed by the hedgehog and the integument+seed.

Introduction

The European chestnut (Castanea sativa Mill.) is an imposing tree that can reach a height of up to 30 meters and a diameter of 2 meters to one meter above the ground throughout its life (Baltazar, 2015; Dias, 2020). This species belongs to the group of dicotyledonous angiosperms, is monoecious, and belongs to the family Fagaceae within the genus Castanea. The chestnut tree has great economic importance, as it provides valuable nuts for human and

animal feed. Its wood is highly appreciated in construction and carpentry, while the leaves and bark contain tannins that are beneficial in the treatment of bleeding and diarrhea, the infusion of the leaves is also used against fever and whooping cough. In addition, the tree provides excellent quality firewood as fuel (Baltazar, 2015; Paiva, 2007).
Studies by Braga (2014), Kalinová et al. (2014), Fuente-Maqueda et al. (2020) and Cerulli et al. (2021) demonstrate that the chestnut fruit is rich in phenolic compounds, which are associated with health benefits, thanks to their antioxidant properties and anti-inflammatory effects. Such compounds are fundamental not only for human nutrition, but also have considerable potential for applications in the food and beverage industry, contributing to the competitiveness of companies that process nuts. An example of the use of these phenolic compounds in the various components of the chestnut tree is their use as natural preservatives, due to their ability to inhibit microbial growth and increase the shelf life of food products. One of the traditional methods for extracting phenolic compounds is solvent extraction, which is widely used in the industry. This process combines a solvent with the use of heat to facilitate the mass transfer of the compounds. However, this method has disadvantages, such as the degradation of heat-sensitive compounds and high energy consumption. Therefore, it is crucial to employ more efficient extraction methods for phenolic compounds (Barba et al. 2016; Carvalho et al. 2018; Larue et al. 2021). Furthermore, phenolic compounds can vary in the different components of a plant product and between different varieties. Therefore, the main objective of this work was to investigate some chemical and biological parameters in different components of the chestnut infructescence, namely: hedgehog, outer pellicle, and integument+seed, at the harvest time in two chestnut varieties – Longal and Martaínha, to verify the existence of significant differences between the components and both varieties after using an ecological extraction method.

Material and Methods

The present work involved three studies. The first was related to the study of the extraction method to be applied in the future to the chestnut samples, namely: hedgehog, outer pellicle, and integument + seed, in order to quantify the total reducing capacity, flavonoids, monomeric anthocyanins, hydrolyzable tannins, reducing power, and 2,2-diphenyl-1-picrylhydrazyl radical scavenging capacity (DPPH), based on the works of Lameirão et al. (2020) and Fuente-Maqueda et al. (2020). The first work mentioned involves an aqueous extraction, while in the second methanol:water (1:1) was used. As the methanol:water (1:1) mixture proved to be adequate to determine the parameters proposed in the present work, the second study focused on the effect of replacing the mixture of methanol:water (1:1) with ethanol:water (1:1) because ethanol is a green solvent, just like water. It was also desirable to change the extraction method involving agitation for 24 hours at room temperature as used by Fuente-Maqueda et al. (2020) by ultrasound, in line with what was reported by Lameirão et al. (2020). These authors used ultrasound at 70 °C (50% amplitude) for 40 minutes. In the present work, the extraction was carried out without temperature control, since the equipment used does not have any thermostatic bath attached and because the operation of the ultrasounds causes heating of the sample, making it impossible to establish and maintain a constant temperature throughout the extraction. In the first and second studies, the following conditions were used: (A) Room temperature - Approximately 1.5 g of lyophilized sample was weighed into a 250 mL goblet, and 150 mL of water or methanol:water (1:1) or ethanol:water (1:1) was added. In both cases, the mixtures were left at room temperature for 24 h in agitation at 300 rpm; (B) Ultrasound - Approximately 1.5 g of lyophilized sample was weighed into a 250 mL goblet and 150 mL of water or methanol:water (1:1) or ethanol:water (1:1) solution was added. Ultrasound was applied for 5 minutes and 70% amplitude (Qsonica, Q500 Sonicator, 20 kHz). The total reducing capacity was determined by the Folin-Ciocalteu method described by Falcão et al. (2007), the reducing power and DPPH radical scavenging capacity by Delgado et al. (2010), the monomeric anthocyanins by Bchir et al. (2012) and Rajasekar et al. (2012), the tannins by Elfalleh et al. (2012), and the flavonoids by Viuda-Martos et al. (2011). In the third study, the best method was applied to the hedgehog, outer pellicle, and integument+seed of the Longal and Martaínha varieties at the harvest time for both varieties.

Results and Discussion

In this section, the results of the three studies carried out as part of this work are presented. In the first study, the use of water and methanol:water (1:1) was studied (Table 1). For these experiments, the matrix chosen for the extraction was the outer pellicle of the fruit.

Table 1. Parameters evaluated in the extracts prepared with methanol:water (1:1) (stirring and ultrasound) and water.

Extraction type	Extraction yield (%)	Total reducing capacity (mg Galic acid/g d.w.)	Flavonoids (mg Quercetin /g d.w.)	Anthocyanins (mg Cyanidin-3-glucoside /g d.w.)	Tannins (mg Tanic acid/g d.w.)	Reducing power[2]	DPPH (mg Ascorbic acid/ g d.w.)
MeOH:Water 24h	9.8 ± 0.6^{a}	54.7 ± 3.1^{a}	179 ± 15^{a}	0.008 ± 0.004^{b}	4.83 ± 0.08^{b}	0.135 ± 0.006^{a}	34.7 ± 2.4^{a}
MeOH:Water US	11.1 ± 0.9^{a}	55.9 ± 2.5^{a}	179 ± 21^{a}	0.020 ± 0.002^{a}	6.22 ± 0.14^{a}	0.130 ± 0.004^{a}	37.0 ± 4.0^{a}
H_2O US	5.6 ± 0.6^{b}	24.0 ± 2.2^{b}	81 ± 1^{b}	[1]ND	2.27 ± 0.27^{c}	0.094 ± 0.006^{b}	14.3 ± 2.0^{b}

[1]ND = Below the detection limit; [2]Absorbance at 700 nm of an extract solution with a concentration of 0.125 mg extract/mL Different lowercase letters per column indicate significant differences (*p<0.05*) between the different types of extraction.

The results obtained in the first study showed that in the extraction where the combination of the solvent methanol:water (1:1, v/v) was used, either with ultrasound or stirring for 24 hours, better results were obtained than with water, proving to be a more efficient solvent. When comparing the extraction methods, in most situations, no significant differences were found between the use of 24-hour stirring and ultrasound, except for anthocyanins and tannins. For both types of compounds, higher concentrations were obtained with the application of ultrasound. Considering these results and the fact that the ultrasound method is faster, it was decided to use methanol:water (1:1)+ultrasound in the following tests.
In the second study, it was decided to test the use of ethanol instead of methanol because it is an environmentally friendly solvent. Table 2 shows the results of the test comparing ethanol:water (1:1) with methanol:water (1:1). In this study, the hedgehog was used.

Table 2. Extraction yield and antioxidant activity of chestnut hedgehog when extracted with methanol:water and ethanol:water (1:1) under stirring for 24 hours or ultrasound (US).

Extraction type	Extraction yield (%)	Total reducing capacity (mg Galic acid /g d.w.)	Reducing power (mg Ascorbic acid / g d.w.)	DPPH (mg Ascorbic acid / g d.w.)
MeOH:Water 24h	14.7 ± 0.6^{b}	23.5 ± 2.0^{b}	60 ± 7^{c}	142 ± 4^{a}
EtOH:Water 24h	15.0 ± 0.8^{b}	39.7 ± 7.6^{a}	85 ± 4^{b}	94 ± 3^{b}
MeOH:Water US	14.5 ± 0.1^{b}	24.2 ± 4.4^{b}	71 ± 7^{c}	142 ± 5^{a}
EtOH: Water US	16.8 ± 0.3^{a}	36.6 ± 3.0^{a}	121 ± 13^{a}	106 ± 12^{b}

Note: Different lowercase letters per column indicate significant differences (*p<0.05*) between the different types of extraction.

Significant differences were found between the extraction methods. The ultrasound extraction showed the best results. In a study carried out by Vázquez et al. (2008) on the antioxidant activity and total phenolic compounds of chestnut and eucalyptus outer pellicle extracts, in which extraction solutions based on ethanol:water and methanol:water were used in different concentrations, the authors observed that when they used the solution of ethanol:water at 50:50 obtained an extraction yield of 8.28%, lower than that determined in the present work. This fact may be due to the application of different extraction methods since, in the aforementioned study, stirring was applied for 2 hours at the boiling temperature of the solvent. In general, in the present work, the ethanol:water (1:1) + ultrasound stood out in relation to the different parameters analyzed, except for the DPPH test, where the best results were obtained with methanol:water (1:1) + stirring or ultrasound. It was decided to carry out the subsequent extractions with ethanol:water (1:1) and ultrasound since ethanol is considered an environmentally friendly solvent that is more sustainable and has less environmental impact.

In the third study, the hedgehog, the outer pellicle, and the integument + seed of two chestnut varieties were analyzed. The results are presented in Table 3. The outer pellicle was the component of the infructescence with the highest values in both varieties, followed by the hedgehog and the integument+seed. The integument+seed of Longal variety presented higher total reducing capacity, reducing power, and DPPH radical scavenging capacity than Martaínha.

Table 3. Total reducing capacity, reducing power, and DPPH radical scavenging capacity of the different components of the chestnut infructescence when extracted with ethanol:water (1:1) for 5 minutes in ultrasound.

Parameters	**Part of infructescence**	**Longal**	**Martaínha**
Total reducing capacity (mg Galic acid /g d.w.)	Hedgehog	33.3±1.5^{b}	27.7±2.5^{b}
	Outer pellicle	75.1±4.0^{a}	91.1±11.8^{a}
	Integument+seed	15.1±6.7^{c}	4.9±0.7^{c}
Reducing power (mg Ascorbic acid / g d.w.)	Hedgehog	0.070±0.009^{b}	0.068±0.005^{b}
	Outer pellicle	0.160±0.013^{a}	0.178±0.006^{a}
	Integument+seed	0.059±0.047^{b}	0.025±0.002^{c}
DPPH (mg Ascorbic acid / g d.w.)	Hedgehog	0.092±0.010^{b}	0.094±0.011^{b}
	Outer pellicle	0.228±0.019^{a}	0.277±0.020^{a}
	Integument+seed	0.013±0.001^{c}	0.006±0.001^{c}

Note: Lowercase letters compare the samples to each other for a given variety. Different letters indicate significant differences ($p<0.05$).

In the study carried out by Vázquez et al. (2008), described previously, an average total reducing capacity of 45.6 mg gallic acid/g sample d.w. for the outer pellicle was obtained, lower than that determined in the present work. Again, the differences found between the two studies may be due to the extraction method. In another study carried out by Barreira et al. (2008) on the antioxidant activity of extracts from flowers, leaves, outer pellicle, integument, and chestnut seed, it was observed that the highest values of total reducing capacity expressed in mg of gallic acid/g extract were determined in the outer pellicle in relation to the integument and seed. The average values obtained for the total reducing capacity for the outer pellicle, integument, and seed were equal to 25.4, 103, and 0.73 mg of gallic acid/g sample d.w., considering the extraction yield. In the present work, the integument was found attached to the seed, explaining the higher values obtained. Fuente-Maqueda et al. (2020) obtained total reducing capacity values of 93.3, 56.0, and 1.8 mg gallic acid/g sample d.w. for the hedgehog, outer pellicle, and seed, respectively, slightly different from our values probably due to the different extraction methods applied.

Conclusions

In the first study, it was found that methanol:water (1:1) + ultrasound gave the best results when compared to the extraction with water + ultrasound and methanol:water (1:1) by stirring for 24 hours. In the second study, the extractions made with ethanol:water (1:1) with ultrasound provided good results. Regarding the components of chestnut, the outer pellicle was the component of the infructescence with the highest values in both varieties, followed by the hedgehog and the integument+seed. Some differences between varieties were also found.

Abstract

Weeds management are the main crop protection issue in rice cultivation, responsible by about 30% of production losses in the field. Rice cultivation provides stability revenues to rural populations, in swamp ecosystems, wetlands, and lowlands, even in soils with high salinity, where other crops are not economic viable. To reduce yield losses, rice farmers rely on chemical control which generated intense selection pressure for the evolution of herbicide-resistant weed populations. This study focused on rice farmers' perceptions and practices for weed management. The applied methodology was a questionnaire, carried out personally with 82 rice producers, in three Portuguese rice-growing regions, complemented by focus groups' meetings. The results reveal that *Echinochloa* spp. is the weed of greatest concern, followed by *Oryza sativa* var. *sylvatica*. Most growers are not, or average satisfied with the efficacy of pre-emergence herbicides for *Echinochloa* spp. control, and they are even less satisfied with the efficacy of post-emergence herbicides. Almost a quarter of producers (26.8%) changed previous year's herbicide application scheme, but only 12 producers (14.6%) changed any cultural practice related to plant protection in the last five years. The study results confirmed the low adoption of alternative physical and cultural measures, due technical, economic and climate constrains, namely the adoption of rotation (due to learning process and economic viability), and stale seedbed (available water restrictions and the delay on sowing time). To tackle the reduction herbicide resistance risk, it is essential to act at the level of the agriculture innovation system.

Keywords: *Weeds, rice, non-chemical control, European Ecological Pact.*

Introduction

Rice crop is one of the most important crops in the World and European Union, due the importance of rice in human nutrition but also because allows to obtain revenues from marginal lands for agriculture. This crop grows in swamp ecosystems, wetlands, lowlands, and very saline soils, generating revenues in rural areas where other crops could not thrive. It has environmental benefits, contributing to the diversity of fauna and flora, and playing a fundamental role in the integrated management of these particularly sensitive ecosystems.

The Portuguese rice area represents around 6% of the total rice area in Europe (EC, 2022), distributed over three regions: *Tejo* and *Sorraia* valleys (*Ribatejo* region), *Sado* river valley (*Alentejo* region) and *Mondego* valley (*Beira Litoral* region) (Clara, 2022; INE, 2023). The current average productivity (in the triennium 2020-2022) is 5.62 kg/ha, in 27,518 ha with a production of 155,573 tons. (INE, 2023). The degree of self-provisioning for rice was 60% in 2020/2022 (GPP, 2023), with a *per capita* consumption of 14.2 kg per year (2022/2021) (idem). The annual *per capita* consumption worldwide is 54 kg, while in the EU the figure is only 6 kg (EC, 2020a). The Portuguese rice consumption is the highest in Europe.

Weed resistance affects the main rice-producing countries of the European Union (UE) and is the key crop protection problem in rice, with losses close to 30% of production (Oliveira *et al*., 2021). The cost of herbicides is the main cost of the crop, 18% of the total, and weed management is the main concern of rice farmers in Portugal (idem).
The herbicide-resistant weed populations are evolving rapidly (Espig *et al*, 2022; Heap, 2024; Norsworthy *et al*., 2012), namely in rice crops (Karim, *et al*. 2004; Calha *et al*., 2023). The impact of pesticides on the environment constitutes a high risk, requiring urgent mitigation measures, in line with the goals established by Farm to Fork strategy (EC, 2020b; 2020c). However, the withdrawal of many herbicides and less diversity of modes of action increased the risk of herbicide resistance. To tackle these problems, it is necessary to find alternative ways to control weeds and better use of pesticides in rice crops (Karim *et al*., 2004; Paiman *et al*, 2020).
There are few studies on farmers' adoption of herbicide alternatives, despite numerous studies on sustainable pesticide use. In contrast to the many studies of herbicide resistance's biophysical aspects, its sociocultural dimensions have historically been overlooked until recently, resulting in few targeted practice change initiatives (Espig *et al*., 2022). To further the reduction use of pesticides, it is necessary to empirically focus on how the actors and processes that compose pesticide use are assembled, held in place, and work in different ways to open or close possibilities of pesticide use reduction (Argüelles and March 2023). Ferrero *et al*. (2021) analyzed the relationship between agronomic practices and weedy rice (*Oryza sativa sylvatica*), but not the producer’s willingness to adopt alternative methods of weed control. In this paper, we present the results of the research on rice farmers' perceptions and attitudes towards weeds and cultural practices related to spontaneous vegetation management, based on a survey complemented by a focus group meeting. Our questions are “Are rice producers willing to adopt alternative methods to herbicide use? What are the main constraints to those changes?”

Materials and Methods

The inquiry methodology by questionnaire was carried out in person, in the main three rice-producing regions (in 2018 and 2019), complemented by three focus group meetings (in 2019 and 2020). The data were analyzed by the IBM® SPSS® Statistics software version 25.0, using non-parametric methods for the analysis of the normative and ordinal variables. The chi-square test was applied to identify differences among the rice crop regions.
In complementarity, three meetings using focus group methodology were done in order to discuss the results and collect contributions, namely, to understand better the different perceptions and cultural practices applied for weed management in each region. It allowed going deeper in the alternative cultural practice’s issues, such as the possibilities, constraints, and particularities of the non-chemical alternatives to control rice weeds.
It was interviewed 82 rice growers distributed relatively equitably among the three rice-growing regions, after the rice cropping season, in the months of lower agricultural activity, from September to February. Technicians from producer associations and technicians from regional agricultural services carried out the survey.
The survey was structured in three sections: 1) Background of the cultural system; agricultural holding area; agricultural plot; ownership and cultivation system, crop rotation, and rice varieties. 2) Field operations: indication of the entire technical itinerary, from soil preparation for sowing to harvesting, with emphasis on main weeds, herbicide application in the last years, the farmer's perception of the most challenging weeds, and the efficacy of the herbicides. 3) Technology and organization: associations and technical advice, training, agri-environmental measures, and technology innovation.

The focus group meetings were held one year after the inquiries. One meeting in each rice-growing region, with around 20 people per group, involving the various stakeholders of the rice sector (producers, irrigation associations, researchers, technicians, producer organizations, companies input suppliers). The discussion focused on weed resistance to herbicides. The main questions were: the perception of weed resistance to herbicides in the region; which strategies were being implemented to tackle the weed resistance, and what their results were; which crops are best suited for crop rotation; how to implement stale seedbed.

Results and discussion

Most of the interviewees follow Integrated Crop Production and have been rice producers for more than 25 years. There are only two producers of organic rice. There are differences in the land tenure structure in the three regions. The mean rice areas cultivated are: 11.5 ha in *Mondego*; 16.7 ha in *Sado*; and 35.8 ha in *Sorraia* (in this region, there is a greater specialization in rice farming).

Main weeds and weeds resistance

The main weeds that most concern farmers were *Echinochloa* spp., followed by *Oryza sativa* var. *sylvatica, Alisma* spp., and *Heterantera* spp. It should be noted that emerging weeds such as *L. fascicularis* appear with greater importance in rice paddies in *Sorraia* region. In *Mondego* region, *O. sylvatica* is the biggest concern for farmers, after *Echinochloa* spp. *Cyperaceae* began to gain importance in the southern region of the *Sado* river valley.
Rice growers were also asked to rate the occurrence of new weeds in the last three years. More than a fifth of respondents mentioned the appearance of *L. fascicularis* in the last three years. One or two references were made to other weeds, such as *Heterantera*, *O. sylvatica*, *C(Cyperus?). difformis,* E. *phyllopogon* and *Leersia oryzoide* and *Leptochloa fusca* subsp. *fascicularis* that recently appeared in Portugal (Santos, 2022). Concerning the occurrence of new weeds, there are no significant differences among rice production regions.
When assessing awareness of herbicide resistance, around 90% of rice farmers stated that existing herbicides no longer control *Echinochloa* spp. as it controlled in the past, and they are most concerned with this weed.

The herbicides in weed-controlling

The study revealed that in a universe of 82 farmers, 71 used pre-emergent herbicides, of which 71 used oxadiazon and only four farmers used clomazone. Clomazone was only used in the *Sado* valley, associated with dry sowing in the line with buried seed. Most growers are 'Not satisfied' or 'Average satisfied' with the efficacy of pre-emergence herbicides for *Echinochloa* spp. control. There are no significant differences among the three rice-producing regions.
Post-emergence herbicides are farmers' main tool for weed control. Growers are even less satisfied with the efficacy of post-emergence herbicides in controlling *Echinochloa* spp. than with pre-emergent herbicides. More than half are "Not satisfied or dissatisfied" with post-emergent herbicides efficacy.

Production modes as control measures

Most farmers (90%) have been producing rice in monoculture for at least five years. Stubble and straw management significantly diverge among regions. In the *Mondego* valley there is a preference for burning (56%), while in the *Sado* valley almost only straw and stubble are incorporated without burning (96.2%).

In *Mondego* the incorporation of straw and stubble with a disc harrow on dry soil "lowering" operation, is an old practice that has fallen out of use since the employment of leveling the beds with laser technology. More than 96% of producers use this laser leveling. Tillage with a rotary ley allows for reducing the seed bank that develops after sowing. This technique is more used in *Mondego* valley than in the others two regions.
Regarding the irrigation and drainage structure, we verify that the inlet and outlet of water is independent for each bed. In 57% of the cases, the inputs and outputs of water are independent for each paddy field. In 42% of the cases where the water transits between beds, and a mix situation.
Considering a risk assessment, it is meaningful to associate the trends expressed by the rice growers surveyed within the field assessment, in which the following dissemination of resistance to penoxsulam in several *Echinochloa* spp. populations: 90% in *Mondego* 50% in *Sado* valley rice fields and 25% in *Tejo* and *Sorraia* valleys (Calha, 2016).
These results clarify the different use of penoxsulam in the three regions: larger use in *Mondego*, followed by the *Sado*, and finally the *Sorraia*. Once resistance builds up, resistant *Echinochloa* weeds are managed primarily by switching to herbicides with different mode of action (MoA) and, in some cases, by applying different agronomic practices (Harker et al, 2013).

Innovation in weeds management
Rice farmers were asked about changes to the usual herbicide application schedule, and whether they had changed any cultural practices related to plant protection in the last five years. Almost a quarter of producers (26.8%) changed previous year's herbicide application scheme. The main changes were in the herbicides used and date of application. Only 12 producers (14.6%) changed any cultural practice related to plant protection in the last five years, and of these, only one introduced crop rotation. Most of the cultural changes occurred in terms of sowing form and density. The results show a high dynamic in the change in the use of herbicides (26.8% of producers, from one year to the next), while changes in cultural practices are slow (14.6% over a period of five years). These results are more significant if we considering that 92.7% of producers receive technical support, and 90.2% are certified in integrated crop production.

Focus groups
The focus groups clarify some of the survey results. Weed resistance and herbicide efficacy decrease were mentioned in all regions, and *Echinochloa* spp. was identified in all regions as a top concern.
Regarding the strategies to be applied, the groups proposed different strategies, without consensus among the members of the focus groups. However, the need for better knowledge of herbicide use was highlighted. Crop rotation was considered by all focus groups as a means of weed control. However, at the same time, it was considered a difficult or impossible technique to apply, both from an economic and technical point of view, due to the characteristics of the soil in which rice is cultivated. The following were identified as possible crops for rotation: maize, sorghum, and peas. A stable seedbed is recognized as a good technical option for reducing problematic weeds such as *O. sylvatica* and *Echinochloa* spp., but it presents implementation difficulties due to the scarcity of water in some regions and the delay on sowing time that this technique implies in rice cultivation (Table 1).

Table 1. Summary of focus group

Questions	*Mondego* region	*Sado* region	*Sorraia* region
Q1. What is the perception regarding weed resistance in the region?	Increased level of resistance to herbicides. Emergence of new weeds	Water grass (*Echinochloa spp.)* are the most problematic. Doubts about whether we are dealing with herbicide resistance or lack of effectiveness in herbicide application.	Herbicide resistance for some weeds. Lack of efficacy is not always associated with herbicide resistance.
Q2. What strategies are being implemented in that direction, are there results?	Negative to dry soil preparation. Positive: rotation and other cultural practices; change in sowing date, rotation of herbicides and height of water blades after harvest. New solutions were not very feasible: cleaning of marrows, manual weeding and thermal weeding.	Several solutions were tested: dry seeding with buried seedlings, tillage, herbicide mix, and more effective water management. No agreement on the most effective solution. Consensus on the option of manual weeding, but with the problem of a lack of workforce.	Alternation of herbicides with different modes of action (most common) and localized application of herbicides. Crop practices such as tillage, change in soil preparation mode, improved irrigation management, dry sowing with buried seed, rapid soil covering.
Q3. Which crops are most adapted for a rotation, and what to consider in a three-year economic assessment?	Corn and pea. Positive: increases production and decreases the cost of the crop. However, there is the problem of uneven land and runoff from alternative crops.	Leguminous crops, especially chickpeas (low profitability and lack of organization). Difficulty in implementation: saline and heavy soils (hinders cropping alternatives); restrictions in terms of available water (the alternative is autumn/winter crops)	Corn and sorghum. Possibility of producing forage legumes or producing legumes for agro-industry. Implementation difficulties: saline soils and heavy soils (hinder cultural alternatives); problem of unevenness of the land; technical and economic difficulties for the implementation of alternative crops. Herbicide efficacy (with increased cost) preferred to the use of crop rotation.

Questions	*Mondego* region	*Sado* region	*Sorraia* region
Q4. False seeding, with or without flooding? How to be implemented?	Positive, but the three-week delay in sowing causes crop losses.	Water for irrigation is only available from late April or early May.	Late sowing problems (lack of early, productive varieties) and possibility of available water restrictions. The alternative is post-harvest tillage, taking advantage of the still favorable temperature.
Q5. What results would you like to see from this project?	Technical manual for crop practices. Mapping of weeds and herbicide resistance. Presentation of best practice cases in other countries, with an exchange of experiences.	Decision support tools for weed control. Raising public awareness about efforts in rice production and technological advances. Mediation between the project team and official entities to improve the search for solutions and their dissemination.	Technical solutions to improve the effectiveness of herbicides and the production of new herbicides; agricultural tools that allow for other forms of soil preparation and the improvement of the "tillage" technique. Dissemination of project results. Financial compensatory measures for the implementation of crop rotation and false sowing.

Conclusions

The survey results confirmed the low adoption of alternative physical and cultural measures, with the main reasons identified in focus groups, particularly for rotation and stale seedbed. These constraints are primarily due to climate and soil conditions: saline and heavy soils limit the cultivation of other crops, and the climatic conditions for sowing and harvesting make the stale seedbed option difficult. Crop rotation faces additional challenges, such as the learning curve for cultivating new crops, access to production factors, and knowledge of production practices. Furthermore, the viability of new crops and difficulties in commercialization, such as lack of commercial contacts, low market power, and low productivity, are significant barriers.

Weed control predominantly relies on chemical means, despite the high costs and dissatisfaction with herbicide efficacy. Rice farmers acknowledge the growing issue of herbicide resistance, exacerbated by incorrect application, poor choice of active substances, and timing errors. To adapt, farmers are adopting new products and mixing herbicides, with over a quarter of respondents changing their application schemes from the previous year, using nearly three different Modes of Action (MoA) over five years. On average, they apply fewer than two different herbicides *per* year, with almost all using ALS inhibitor herbicides.

Cultural practices are recognized for their importance in mitigating reduced herbicide efficacy.
The specificities of local ecosystems, farmers' knowledge gaps, and the complexity of learning new crops or techniques make non-chemical alternatives very risky. Despite the costs and herbicide resistance risks, farmers continue to rely on pesticides. Addressing this requires enhancing the innovation ecosystem by developing applicable scientific and technical knowledge, promoting social capital to build skills and relationships among economic agents, and implementing political measures to support sustainable practices. The problem of herbicide resistance is worsening, especially with the reduction in available active substances and Modes of Action. Adopting non-chemical weed control practices is crucial to reducing herbicide costs and meeting the European Green Deal's requirements for herbicide use reduction.
The application of these alternative control methods cannot be widespread but must be studied on a case basis, and require technical follow-up, adapted to the region and the plot. The procedure of learning new crops or practices makes non-chemical alternatives very risky for farmers. To reduce resistance risk and maintain the sustainability of the rice cropping system it is essential to act at the level of the innovation ecosystem: from the emergence of scientific and technical knowledge applicable to new solutions, to the evolution of social capital, promoting capacities and relationships between economic agents, and political measures supporting and stimulating innovation and implementation of greener and more sustainable practices.

Abstract

Building upon previous research in the domain of corn pest detection from some species of insects (Coleoptera Order) using Convolutional Neural Networks (CNNs), this study investigates the impact of a higher input resolution on the performance of the MobileNet-SSD neural network architecture. Our initial study focused on optimizing a deep-learning model for low-power mobile devices to detect various corn pests while preserving beneficial species. In order to further improve the detection capabilities of MobileNet-SSD, the present research explores the effect of a higher resolution of 512×512 pixels, as input for the MobileNet-SSD-v1 and v2-Lite models. These adjustments aimed to provide a more detailed input representation to facilitate enhanced detection performance. The evaluation metrics include average accuracy per class and mean average precision (mAP), as used in the previous study, to ensure consistency in performance assessment. Our findings indicate that training the networks on the augmented dataset at a higher resolution resulted in improved detection performance, with both models demonstrating enhanced mAP scores (MobileNet SSD v1: mAP = 0.912; MobileNet SSD v2 Lite: mAP = 0.919). Additionally, MobileNet SSD v2 Lite consistently outperformed MobileNet SSD v1 in terms of mAP across both training phases. This research contributes to a broader understanding of the relationship between input resolution and detection performance in CNNs, providing valuable insights on refining the approach to further enhance the precision and efficiency of modern pest detection systems in agricultural contexts.

Keywords: *Pest control, insects, Coleoptera, smart agriculture, neural network.*

Introduction

The demand for effective pest management solutions in agriculture is an important objective, alongside the need for sustainable and eco-friendly practices. Traditional methods relying heavily on chemical pesticides face environmental concerns and diminishing effectiveness over time. As a response, there has been a shift towards integrating artificial intelligence (AI) technologies into agricultural practices, offering innovative solutions for pest detection and management.

Previous research has demonstrated the potential of AI-driven techniques in various agricultural domains, including disease management in sunflower crops (Gulzar *et al.*, 2023), fruit classification in horticulture (Gulzar, 2023), and citrus fruit disease detection (Dhiman *et al.*, 2023). These studies showed the effectiveness of advanced algorithms, particularly neural networks, in addressing diverse agricultural challenges.

Insect pest detection and identification have been particularly emphasized in recent research, with studies employing a range of neural network models and methodologies. The most popular object detection algorithm was YOLO, followed by Faster R-CNN and VGG16 (Maican *et al.*, 2023). Noteworthy results in terms of mean average precision (mAP) are summarized in Table 1.

Table 1. Ranking of some insect identification neural networks by maximum mAP

Model	Dataset	Maximum mAP
YOLOv5m	Dataset from Maryland Biodiversity Project (Sava *et al.*, 2022)	99.2%
YOLOv5-X	7046 images, 23 pest classes (Ahmad *et al.*, 2022)	98.3% (mAP@0.5)
YOLOv7	4865 images of coccinellids, seven classes (Wang *et al.*, 2023)	Up to 97.31% (AP@0.50)
Faster R-CNN	36,000 images of harmful and non-harmful beetles (Butera *et al.*, 2022)	92.66%
YOLOv5	100,000 annotated images of small insects (Kranthi *et al.*, 2002)	92.4% (mAP@0.50)
Improved Faster R-CNN	AgriPest21 dataset: 21 pest classes, 25,000 images (Wang *et al.*, 2021)	78.7%
AgriPest-YOLO	Pest24 dataset: 25,000 images of small pests (Zhang *et al.*, 2022)	71.3% (mAP@0.50)

However, most existing research faces challenges when applied to low-power agricultural mobile systems, which require lightweight neural networks both to conserve battery life and to accommodate their limited processing capabilities. In this context, MobileNet networks have received limited attention despite their potential advantages in resource-constrained environments.

In our previous research (Maican *et al.*, 2023), we focused on developing optimized MobileNet SSD networks, for crop pest detection. Utilizing a two-step transfer learning approach, we aimed to enhance the accuracy of these networks, particularly MobileNet-SSD-v1 and MobileNet-SSD-v2-Lite. Despite using a reduced training set (2648 images), both models demonstrated similar and good overall accuracies (MobileNet-SSD-v2-Lite: mAP = 0.8923; MobileNet-SSD-v1: mAP = 0.908), highlighting their potential for real-time pest control.

Building upon these findings, the main objective of our current study is to investigate the impact of input image resolution on the performance of MobileNet-SSD networks for crop pest detection. Specifically by increasing the input resolution from 300 to 512 pixels, we aim to assess whether higher-resolution images yield improved accuracy in pest identification. This adjustment aimed to provide a more detailed input representation to facilitate enhanced detection performance.

Materials and methods

In this study, we modified the MobileNet SSD v1 and MobileNet SSD v2 Lite networks to process images with a resolution of 512×512 pixels. This adaptation aimed to enhance the networks' ability to detect and classify objects with finer details, ultimately improving their overall performance. The training process was conducted on the Nvidia Jetson AGX Orin platform using PyTorch 2.0.0 for JetPack 5.1.1. Additionally, we utilized Nvidia TensorRT for real-time inference optimization on Nvidia GPUs.

The training dataset consisted of 2648 images after augmentation, sourced from the iNaturalist web portal (iNaturalist, 2023). These images represented four beetle species know as pests that cause substantial damage to crops such as corn, wheat, sunflower, and beans (*Anoxia villosa*, *Diabrotica virgifera virgifera*, *Opatrum sabulosum*, and *Zabrus tenebrioides*). Additionally, the dataset includes images of the beneficial *Coccinella* sp., an

aphid predator in agricultural ecosystems. This inclusion aimed to evaluate the network's ability to distinguish between pest species and beneficial organisms.
The training process involved both a common transfer learning procedure, as well as a novel two-step transfer learning procedure, which consisted of the following steps:

- Initial Transfer Learning: in the first step, we performed transfer learning using the Open Images dataset to recalibrate the pre-trained MobileNet-SSD models for insect detection task. This involved retraining the models on an Open Images subset of 2605 images, containing only two classes: Beetle and Ladybug.
- Refinement Transfer Learning: in the second step, we further refined the pre-trained models using our custom dataset, organized according to the Pascal VOC format. This dataset included images of the five insect species mentioned earlier, allowing the models to learn specific features relevant to our pest detection task.

The training and evaluation procedures were conducted using two PyTorch scripts: 'train_ssd.py' and 'eval_ssd.py', respectively. These scripts were used for model training, validation, and performance evaluation, including metrics such as mean average precision (mAP). Further optimization for real-time inference was achieved using Nvidia TensorRT and detectNet – an object detection framework that performs optimized real-time inferencing on Nvidia Jetson GPUs. Detailed information on the training and evaluation procedures can be found in our previously published work (Maican *et al.*, 2023).
To summarize, in order to ensure consistency in performance assessment between the results obtained by increasing the image resolution and those from our previous research, experiments were conducted under identical conditions:

- The same two MobileNet-SSD models (MobileNet-SSD-v1 and MobileNet-SSD-v2-Lite) were trained but modified to process images with resolutions of 512×512 pixels;
- Both models were trained on the same dataset, with the same images in the training, validation, and test sets;
- Identical values were employed for hyperparameters such as batch size, number of workers, and epochs;
- The same evaluation metrics were employed (average accuracy per class, and mAP@.50).

Results and discussion

In our previous work, we demonstrated that training the MobileNet-SSD-v1 and MobileNet-SSD-v2-Lite networks on the unaugmented dataset yielded inferior results compared to training on the augmented dataset. Therefore, in this research, all training was conducted on the augmented dataset. For experimentation, we downloaded pre-trained versions of the two neural networks: MobileNet-SSD-v1 pre-trained on the PASCAL-VOC dataset, and MobileNet-SSD-v2-Lite pre-trained on the COCO dataset. We conducted the following experiments (Figure 1):

3. Single transfer learning training:
    3.1. Training the downloaded MobileNet-SSD-v1 and MobileNet-SSD-v2-Lite directly on the augmented dataset (5 classes, 2648 images, input resolution: 512×512 pixels);
    3.2. Comparing the results from step 1.1 with the results obtained through the same procedure in the previous research, but with an input resolution of 300×300 pixels;
4. Two successive transfer learning trainings, as described in the Materials and Methods section (Two-step Transfer Learning):
    4.1. Training the downloaded MobileNet-SSD-v1 and MobileNet-SSD-v2-Lite on the Open Images subset of 2605 images (2 classes: Beetle and Ladybug, input resolution: 512×512 pixels);

4.2. Training the MobileNet-SSD-v1 and SSD-v2-Lite networks pretrained at 2.1. on the augmented dataset (5 classes, 2648 images, input resolution: 512×512 pixels);
4.3. Comparing the results from 2.2. with the results obtained through the same procedure in the previous research, where the input resolution was 300×300 pixels.

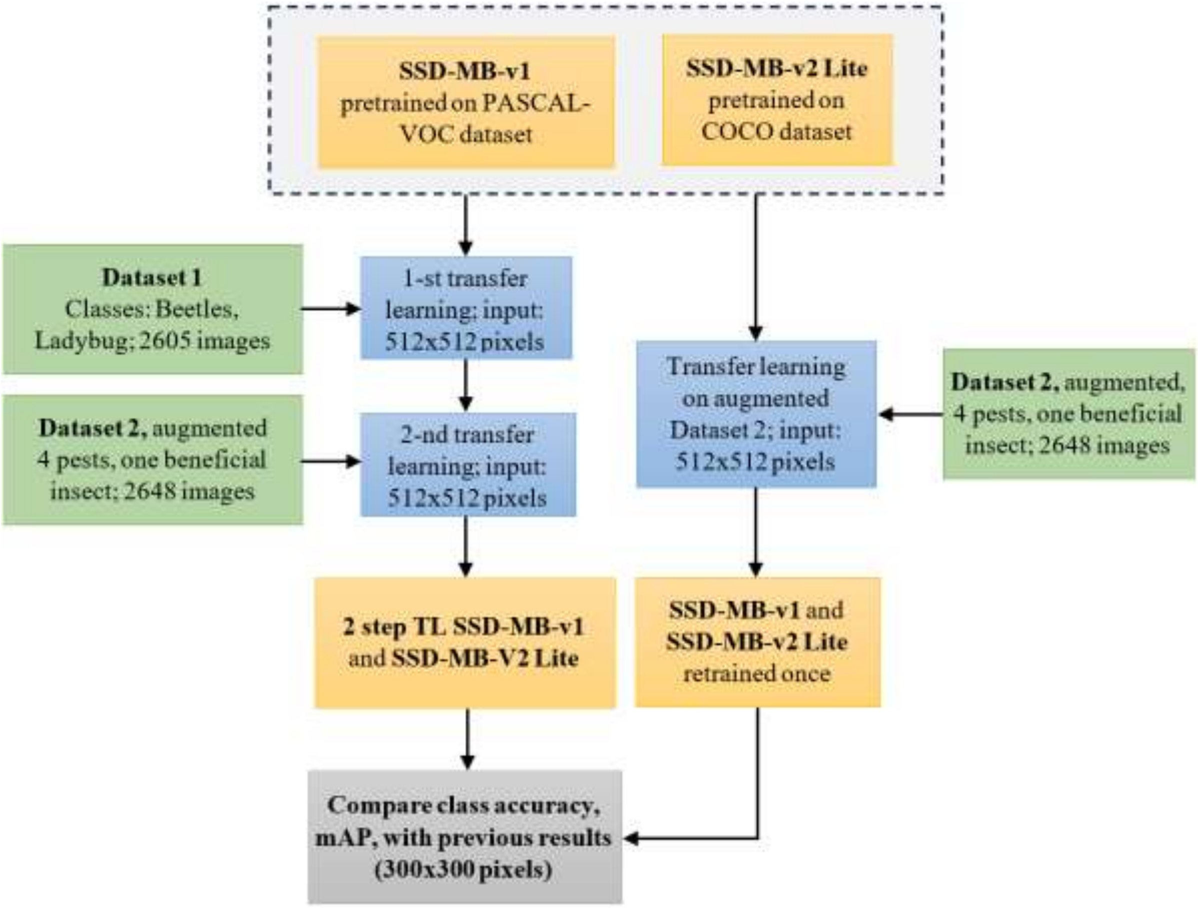

Figure 1. Schematic representation of the training and performance evaluation procedures; 2 step TL: two-step transfer learning; color scheme: orange - neural network models; blue - training procedures; green - datasets; grey - evaluation (adapted from Maican *et al.*, 2023)

To compare the results obtained from the experiments conducted in the current work, using a resolution of 512×512 pixels, with those from the previous work, where a resolution of 300×300 pixels was employed, we analysed the mean average precision (mAP), and the accuracy per class, for both MobileNet SSD v1 and MobileNet SSD v2 Lite.
The mAP metric provides an overall measure of the performance of the object detection models across all classes, capturing their ability to detect objects accurately and localize them within the image.
Conversely, the accuracy per class is a measure of the performance of the object detection neural networks for each individual class, showing their ability to differentiate between various pest species. This allows for a nuanced evaluation of their capabilities across different categories.
In the case of the Single Transfer Learning training at the resolution of 512×512 pixels, both MobileNet SSD v1 and MobileNet SSD v2 Lite achieved higher mAP values compared to the previous work at 300×300 pixels (Table 2). Specifically, for MobileNet SSD v1, the mAP increased from 0.887 in the previous work to 0.912 in the current work. Similarly, for

MobileNet SSD v2 Lite, the mAP increased from 0.884 to 0.891. This indicates that training the networks on the augmented dataset at a higher resolution improved detection performance.

Table 2. Average accuracy per class and mAP for single transfer learning training

Resolution: 512 × 512 (current work)				**Resolution 300 × 300 (previous work)**			
Mobilenet SSD v1		**Mobilenet SSD v2 Lite**		**Mobilenet SSD v1**		**Mobilenet SSD v2 Lite**	
Anoxia	0.998	Anoxia	0.977	Anoxia	0.987	Anoxia	0.991
Diabrotica	0.768	Diabrotica	0.766	Diabrotica	0.726	Diabrotica	0.727
Ladybug	0.977	Ladybug	0.909	Ladybug	0.874	Ladybug	0.891
Opatrum	0.909	Opatrum	0.909	Opatrum	0.924	Opatrum	0.909
Zabrus	0.909	Zabrus	0.895	Zabrus	0.947	Zabrus	0.903
mAP	0.912	mAP	0.891	mAP	0.887	mAP	0.884

Examining the results from the Two-step Transfer Learning training pipeline, at the resolution of 512×512 pixels, both networks showed better performance compared to the previous work (Table 3). The mAP values increased from 0.908 to 0.915 for MobileNet SSD v1 and from 0.892 to 0.919 for MobileNet SSD v2 Lite. This further confirms the advantage of using the augmented dataset at a higher resolution for training.

Table 3. Average accuracy per class and mAP for two-step transfer learning training

Resolution: 512 × 512 (current work)				**Resolution 300 × 300 (previous work)**			
Mobilenet SSD v1		**Mobilenet SSD v2 Lite**		**Mobilenet SSD v1**		**Mobilenet SSD v2 Lite**	
Anoxia	0.989	Anoxia	0.986	Anoxia	0.907	Anoxia	0.985
Diabrotica	0.787	Diabrotica	0.795	Diabrotica	0.777	Diabrotica	0.807
Ladybug	0.988	Ladybug	0.998	Ladybug	0.944	Ladybug	0.894
Opatrum	0.909	Opatrum	0.906	Opatrum	0.906	Opatrum	0.951
Zabrus	0.902	Zabrus	0.907	Zabrus	0.903	Zabrus	0.905
mAP	0.915	mAP	0.919	mAP	0.908	mAP	0.892

Comparing the performance of the two networks at the resolution of 512×512 pixels, one can notice that MobileNet SSD v2 Lite consistently outperformed MobileNet SSD v1 in terms of mAP. This suggests that MobileNet SSD v2 Lite is more effective in handling object detection tasks at the higher resolution. The accuracy per class analysis reveals that while higher input resolutions lead to improved detection performance in most cases, there are specific instances where lower resolutions yield better results. For example, in Table 2, using MobileNet SSD v1, higher accuracies at the 300×300 pixel resolution were observed for the classes *Zabrus* (0.947 at 300×300 pixels vs. 0.909 at 512×512 pixels) and *Opatrum* (0.924 at 300×300 pixels vs. 0.909 at 512×512 pixels). Similarly, for MobileNet SSD v2 Lite, the classes *Zabrus* (0.903 at 300×300 pixels vs. 0.895 at 512×512 pixels) and *Anoxia* (0.991 at 300×300 pixels vs. 0.977 at 512×512 pixels) also showed higher accuracies at the lower resolution.

In Table 3, the trend persists. For MobileNet SSD v1, the class *Opatrum* achieves higher accuracy at 300×300 pixels (0.906 at 300×300 pixels vs. 0.909 at 512×512 pixels), and *Zabrus* (0.903 at 300×300 pixels vs. 0.902 at 512×512 pixels). For MobileNet SSD v2 Lite, the classes *Diabrotica* (0.807 at 300×300 pixels vs. 0.795 at 512×512 pixels) and *Opatrum* (0.951 at 300×300 pixels vs. 0.906 at 512×512 pixels) also exhibit slightly better performance at the lower resolution.

These variations suggest that while higher resolutions are generally advantageous, the optimal resolution can vary depending on the specific class. This nuanced behavior highlights the complexity of object detection tasks, particularly in agricultural environments, and the importance of selecting the appropriate resolution for each specific use case.

Conclusions

This study investigated the impact of input resolution on the performance of two MobileNet-SSD neural network architectures for crop pest detection, focusing on the Coleoptera order. By increasing the input resolution from 300×300 to 512×512 pixels, we aimed to assess whether higher-resolution images would yield improved accuracy in pest identification. Our findings suggest several key conclusions:

5. Both MobileNet SSD v1 and MobileNet SSD v2 Lite demonstrated enhanced mAP scores when trained on datasets with a resolution of 512×512 pixels compared to 300×300 pixels. This improvement indicates that higher-resolution images provide more detailed input representations, facilitating better detection performance.
6. The use of a two-step transfer learning approach resulted in improved detection performance for both MobileNet SSD v1 and SSD v2 Lite at the higher resolution.
7. Most of the time, MobileNet SSD v2 Lite slightly outperformed MobileNet SSD v1 in terms of mAP across both training phases at the resolution of 512×512 pixels.
8. The findings of this study have practical implications for pest control in agriculture. By using higher-resolution images on neural networks for limited-power devices such as MobileNet SSD, farmers and agricultural professionals can benefit from more accurate and efficient pest detection systems, leading to improved crop management practices and reduced environmental impact.

Overall, this research contributes to a deeper understanding of the relationship between input resolution and detection performance in convolutional neural networks, offering valuable insights for optimizing pest detection systems in agricultural contexts. Future studies may explore additional factors such as dataset size, augmentation techniques, and model architecture modifications to further enhance the precision and efficiency of crop pest detection systems.

Abstract

Romania's agricultural sector serves as a vital pillar of the nation's economy, ensuring food security and economic stability for its population. This study investigates the complex array of issues surrounding energy utilization in Romanian agriculture, with a specific focus on the significant role played by mechanical engineering in addressing these challenges. Traditional farming methods, such as irrigation, plowing, and harvesting, often rely on outdated machinery and inefficient practices, resulting in excessive energy waste. By leveraging advanced technologies like smart sensors, automation, and data analytics, mechanical engineering solutions can optimize crop production, minimize energy usage, and mitigate environmental harm. However, the adoption of these innovations encounters formidable obstacles within the Romanian context, including financial constraints and limited access to modern equipment and technology.The integration of energy-efficient practices through mechanical engineering interventions is pivotal for promoting sustainable and eco-friendly farming techniques in Romania. These innovations have the potential to significantly reduce energy consumption, resulting in cost savings for farmers and a reduction in greenhouse gas emissions. Nonetheless, the widespread implementation of such advancements faces resistance due to initial financial burdens and deficiencies in infrastructure and knowledge.This paper aims to delve into the challenges associated with energy consumption and efficiency in Romanian agriculture, highlighting the vital contributions of mechanical engineering in addressing these issues. By raising awareness about the inefficiencies inherent in conventional farming practices and their associated costs and environmental repercussions, the study seeks to advocate for the adoption of sustainable and energy-efficient methodologies in Romanian agriculture.

Keywords: *agriculture, energy efficiency, electric tractors.*

Introduction

The agricultural industry plays a crucial role in ensuring the food supply for humanity. To perform a wide array of activities within the agricultural and food production chain, spanning from fundamental tasks like soil cultivation, planting, pest control, harvesting, irrigation, and drying, to intermediate processes like storage and packaging, as well as more advanced functions such as sourcing essential supplies and constructing farm infrastructure, a dependable energy source is essential (Becerril et al., 2016; Gorjian et al., 2021). In order to conduct operations in the field and facilitate large-scale production, the utilization of agricultural machinery becomes imperative. This necessitates the consumption of resources like fossil fuels and the procurement of various materials. While the mechanization of agriculture has undoubtedly improved profitability, it has also led to increased energy requirements, heightened water usage, and the elevation of greenhouse gas emissions, posing significant sustainability challenges (Balafoutis et al., 2017).

Agricultural equipment, such as tractors, combines, wagons, loaders, pickups, and trucks, holds a vital role within the agricultural sector, as they are utilized for a wide range of farm activities across small to large-scale farms worldwide (Malik et al., 2020). Enhancing agricultural processes through optimization, automation, mechanization, and efficient resource management has the potential to promote sustainability in the agricultural sector, leading to increased production and income. Nonetheless, this approach is accompanied by elevated energy requirements for agricultural operations. Moreover, to meet the growing global food demand, the expansion of agricultural land and the workforce are essential. Within this framework, precision agriculture (PA) emerges as a more beneficial solution, offering food security with reduced labor demands, enhanced environmental stewardship, and decreased energy consumption (Piechocki et al., 2018, Saiful et al 2020).

Material and methods

PV technology in agriculture. Photovoltaic (PV) technology in agriculture refers to the use of solar panels or solar cells to capture sunlight and convert it into electricity for various applications in farming and agriculture. This technology offers several benefits, including sustainability, cost savings, and increased energy independence. Agrivoltaics, or the concept of agrophotovoltaics (APV), involves the concurrent utilization of agricultural fields for both farming and photovoltaic power generation. This innovative approach addresses the issues of limited available land while expanding photovoltaic capacity and preserving valuable arable land for a wide range of crops (Dupraz C., et. al., 2011).

Electric vehicle technologies. Electric vehicles (EVs) typically refer to automobiles that employ one or more electric motors for propulsion. These EVs are further categorized into two main types: Battery Electric Vehicles (BEV) and Hybrid Electric Vehicles (HEV), as depicted in Figure 1.

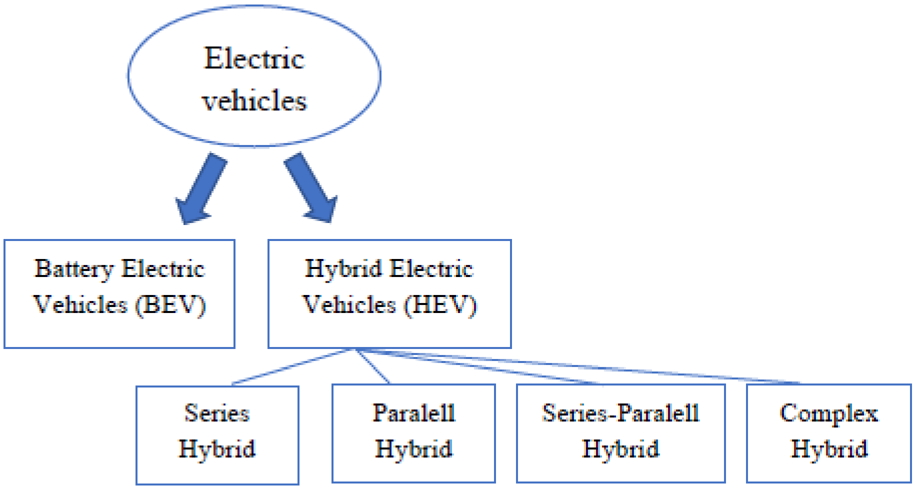

Figure 1. Electric Vehicles classification

While the agricultural and forestry sectors have historically been major contributors to global emissions due to their reliance on diesel-powered machinery, there is a notable shift towards achieving environmental sustainability in these industries. The adoption of electric vehicles (EVs) for agricultural purposes is now a pivotal step in ensuring sustainable food production and reducing greenhouse gas emissions (Magalhaes et al., 2017). Multiple agricultural researches indicates that designing and developing an effective tillage system can result in achieving a better desired soil behavior while using less draft force and energy. It is widely recognized that the oscillation of tillage equipment can effectively lower the draft and drawbar power needs, offering a potential solution to this issue (Shagoli et al 2010). In the context of the transition to a low-carbon economy, the production and use of energy from renewable sources is one of the ways to reduce GHG emissions. Romania has a wide range of renewable energy resources that can be used in the actions proposed in the rural development projects. There is also a wide range of potential renewable energy production resources from agriculture (crop residues resulting from agricultural harvesting or animal waste). These resources, together with other renewable resources (solar, wind, geothermal, etc.) can be used to obtain renewable energy to be used in the production process of farms or processing units, thus helping to reduce energy costs (electricity and heat) and contributing to efforts for developing a low-carbon economy (Romania: new financing for renewables in agriculture, 2021). Romanian agricultural operations face limited digital integration primarily because of the substantial expenses associated with digital infrastructure and the scarcity of financial resources. Nevertheless, Romanian farmers exhibit a readiness and awareness to enhance farm management by embracing digital technologies (Rodino et al., 2023). In Romania, reduced soil tillage methods commonly employ equipment like the chisel plow, which minimizes soil disturbance while promoting aeration and water infiltration. Strip-till machines, another popular choice, till only narrow strips where seeds will be planted, preserving soil structure and reducing erosion. Disk harrows, used for shallow tillage, effectively manage crop residues and prepare seedbeds with minimal soil turnover. No-till drills directly plant seeds into the residue-covered soil, maintaining soil health and moisture. These machines collectively contribute to sustainable farming practices, enhancing soil conservation and crop yields.

Results and discussions

Romania's strength regarding renewable energy is the wide range of available renewable energy resources and weakness the low level of production and use of renewable energy resources in the agricultural and forestry sector. Opportunities in the programme area are connected to widespread access to renewable energy technologies, while increase in energy prices is seen as a threat to the area. The initial expense for any electric vehicle, including electric tractors (Figure 2), is typically two to three times greater than that of a similarly capable internal combustion engine (IC engine) vehicle. The cost of the battery constitutes a significant portion, ranging from 30% to 50% of the total vehicle cost.

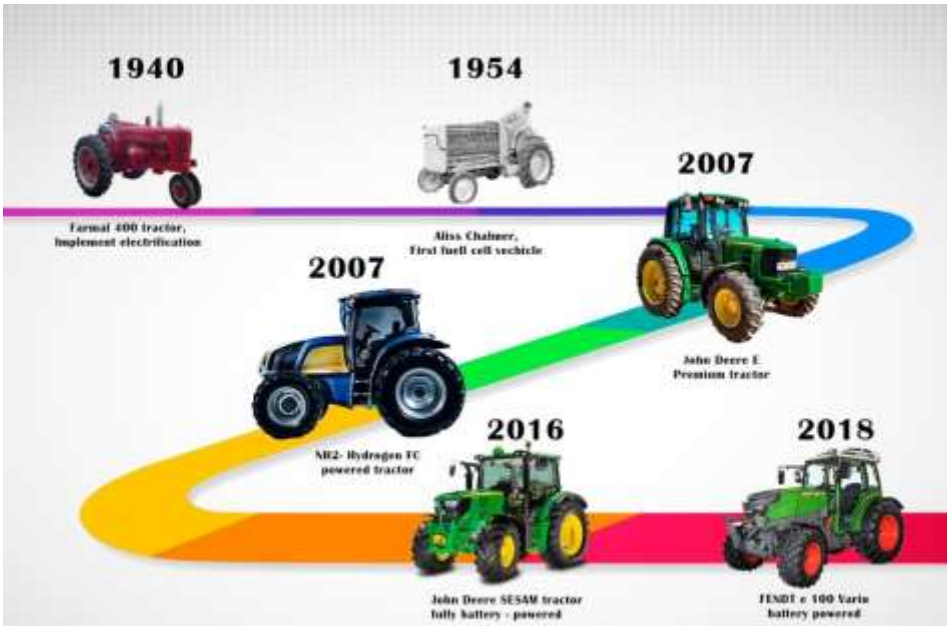

Figure 2. Historical development of hybrid tractors, adapted from (Ghobadpour et al., 2019).

Romania possesses the requisite resources for implementing the technology of cultivating straw cereal crops using a reduced tillage system, thanks to the research conducted by INMA Bucharest. This research has resulted in the development of specialized equipment (as depicted in Figure 3) capable of simultaneously performing tillage and sowing of straw cereal crops, even on partially prepared or unprepared fields. This innovative approach significantly mitigates issues related to soil compaction, energy usage, and labor costs (Marin et al., 2011).

Figure 3. Technical equipment endowed with working parts for preparing the soil and sowing straw cereals

Table 1 offers an insightful comparison of electric tractors gaining popularity in Romania, showcasing models from Fendt, John Deere, Farmtrac, Solectrac, and Rigitrac. Each tractor is evaluated based on its battery capacity, power output, operating time, charging time, and key features, providing a clear understanding of their performance and suitability for different farming needs. For example, the Fendt e100 Vario, with a 100 kWh battery and 67 hp, operates for up to 5 hours and charges quickly in 5 hours. It's noted for its versatility and zero emissions, making it ideal for diverse farm tasks. The John Deere SESAM, featuring a robust 130 kWh battery and 400 hp, offers up to 4 hours of operation and a rapid 3-hour fast charge, emphasizing advanced technology for sustainable energy use.The Farmtrac FT25G is compact and affordable, with a 21 kWh battery and 25 hp, providing up to 6 hours of operation, suitable for small-scale farms. Solectrac's eUtility model, equipped with a 40 kWh battery and 70 hp, ensures up to 8 hours of efficient and eco-friendly performance, ideal for medium-sized farms. The Rigitrac SKE 50, with an 80 kWh battery and 50 hp, offers up to 6 hours of robust operation, handling various terrains effectively. This detailed comparison underscores the growing adoption of electric tractors in Romania, highlighting their environmental benefits and potential to enhance sustainable farming practices.

Table 1. Comparison of Leading Electric Tractors in Romania

Brand & Model	Battery Capacity	Power Output	Operating Time	Charging Time	Key Features
Fendt e100 Vario	100 kWh	67 hp	Up to 5 hours	5 hours (fast charge)	Versatile, zero emissions, suitable for various farm tasks
John Deere SESAM	130 kWh	400 hp	Up to 4 hours	3 hours (fast charge)	High power, sustainable energy supply, advanced tech
Farmtrac FT25G	21 kWh	25 hp	Up to 6 hours	6 hours	Compact, affordable, practical for small-scale farms
Solectrac eUtility	40 kWh	70 hp	Up to 8 hours	4-6 hours	Eco-friendly, efficient, good for medium-sized operations
Rigitrac SKE 50	80 kWh	50 hp	Up to 6 hours	6 hours	Robust design, all-electric, suitable for various terrains

Oscillating mode tools have several advantages over non oscillating one. Oscillating tools requires less draft as compared to non-oscillating one. Therefore, oscillatory tillage tool can resolve the problems related to tillage applications.

Figure 4. Elastic supports for the working bodies of cultivators

Many studies have been conducted regarding the influence of the angle of attack of vibratory working tools (Figure 4), with the main objectives of the research being be to find the most efficient oscillation angle for draft reduction and low power requirement. At the end of January 2021, the National Rural Development Programme of Romania was approved. The SWOT analysis carried out to elaborate the document revealed the current situation of renewable energy consumption in agriculture, noting that the production and use of energy from renewable sources in agriculture (RES) are low. Only 2.5% of the total production in Romania came from agriculture compared to 9.8% in the EU27.

Through measure 4.1 the type of support is in the form of grants with reimbursement of eligible costs actually incurred and payed in advance. Eligible beneficiaries may be farmers (except for unauthorized individuals), cooperatives (agricultural cooperatives and agricultural cooperative societies), and producer groups (set up on the basis of the national legislation in force, serving the interests of the members; and have eligible costs for investments in installations whose main purpose is the production of electricity). Measure 4.2 "Support for investments in the processing / marketing of agricultural products" - grants will be awarded for eligible activities such as the production and use of energy from renewable sources (solar, wind, geothermal), by heat pumps, exclusively for own consumption and also grants for investments to improve energy efficiency. The launch of financing measures is eagerly awaited - there is major interest from rural communities to submit and implement projects that generate energy produced sustainably, thus succeeding to reduce greenhouse gases generated by agricultural activities (Romania: new financing for renewables in agriculture, 2021).

Conclusions

The introduction of energy-efficient machinery and electric vehicles in Romanian agriculture is becoming increasingly popular due to their ability to lower operational expenses and mitigate environmental impact. These vehicles provide a greener alternative to conventional fossil fuel-powered equipment. Despite this, obstacles such as significant initial investment and insufficient charging infrastructure must be overcome to achieve broader adoption. Incorporating electric vehicles into Romanian agriculture offers potential for greater efficiency and reduced emissions, supporting the country's environmental sustainability goals. Ongoing research and investment are essential to fully realize the benefits of electric vehicles in Romania's agricultural industry.

PNEUMATIC CONVEYING SYSTEMS IN THE AGRI-FOOD INDUSTRY – STATE OF THE ART

Raluca-Adriana ZOTA*, Sorin-Ștefan BIRIȘ, Neluș-Evelin GHEORGHIȚĂ

Faculty of Biotechnical Systems Engineering, National University of Science and Technology POLITEHNICA Bucharest, Romania
*Corresponding author: raluca_zota@yahoo.com

Abstract

Pneumatic conveying systems for agri-food materials have become a crucial part of controlling the flow of raw materials along with finished goods in an era defined by the fast pace of technical development and higher productivity demand within the agri-food industry. The agri-food sector must contend with several obstacles, such as strict regulations governing food safety, elevated product quality standards, and high operational efficiency requirements. The selection of pneumatic conveying systems, whether low, medium, or high pressure, is subject to various criteria, including the distance to be transported, the necessary throughput rates, the properties of the material, and budget constraints. Pneumatic conveying systems offer several benefits to the agri-food industry, such as effective handling, space optimization, cost savings on material shipping and storing, and the supply of an inert transport environment that prevents contamination or deterioration of agri-food products. This paper presents a multi-point perspective overview of today’s status of pneumatic conveying systems research and development, aspects such material handling efficiency, pressure control and monitoring, integration with Industry 4.0 technologies, environmental sustainability, and safety features. Taking all into account, the state of the art in pneumatic conveying systems is a result of a blend between industry-specific adaptation, technological innovation, and an increasing focus on efficiency and sustainability.

Keywords: *pneumatic systems, material handling, conveyors, agri-food.*

Introduction

Conventional conveyors are predisposed to dust and foreign matter entering the systems, generating material quality degradation and consequent losses from material that is no longer appropriate to be used. Pneumatic conveyors are progressively replacing traditional ones. One of the reasons for this migration is product contamination, still a key worry for end-users.

Pneumatic conveying, an essential component in a wide range of sectors, from food processing to pharmaceuticals, mining to chemical engineering, has withstood the test of time due to its effectiveness in transferring bulk materials over long distances. The handling of granular materials, ranging from micrometers to millimeters in size, poses significant challenges in the packaging industry. The flowability of these materials is crucial for the efficient operation of bulk solids handling equipment. Apart from cohesive effects, the flow regimes are primarily influenced by particle collisions and friction. Flowability is also affected by particle characteristics such as size, shape, density, and surface properties, as well as environmental conditions like humidity and temperature. However, the impact of complex grain-scale interactions on bulk behavior is not yet fully understood (Jones, 2021).

The main market participants are investing in the introduction of new technologies. Industry forecasts suggest that the global market for conveying systems is expected to see significant growth within the next three to five years (Klinzing, 2018).

Recent advancements in pneumatic conveying technology hold substantial potential to revolutionize material transport across various sectors by offering more energy-efficient and environmentally friendly solutions. These improvements could significantly lower costs, enhance productivity, and reduce environmental impacts, benefiting industries like pharmaceuticals, food, cement, minerals, and power (Abe, 2023).
This paper provides a comprehensive overview of current research and development in pneumatic conveying systems, focusing on aspects such as material handling efficiency, pressure control and monitoring, integration with Industry 4.0 technologies, environmental sustainability, and safety features. It suggests that the state-of-the-art ~~p~~pneumatic conveying systems emerge from a combination of industry-specific adaptations, technological advances, and a growing emphasis on efficiency and sustainability.

Material and methods

The forms of pneumatic conveying are the dilute phase and the dense phase. Each type moves materials using air pressure and an enclosed line or tube. The difference between them is their method of creating air pressure and how the material travels through the system.
There are two methods for moving materials using dilute, suspension, or lean phase pneumatic conveying: positive and negative. In a positive or blowing phase system, a fan or blower generates pressure in the line to suspend the material. At the end of the line, a separator or filter removes the material (Javaid, 2023).

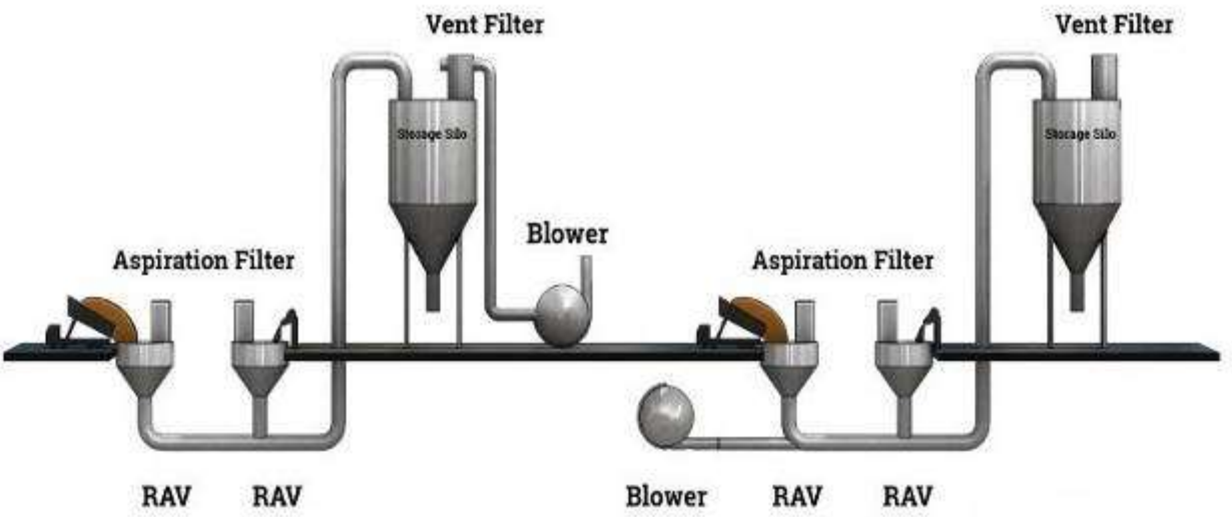

Fig.1 Dilute phase pneumatic conveyor (Javaid, 2023)

Dense-phase pneumatic conveying uses a small amount of air to move a large amount of material in slugs, much like extruding. A dense phase system pushes a denser concentration of bulk solids at low velocities, as can be seen in Figure 3 below.

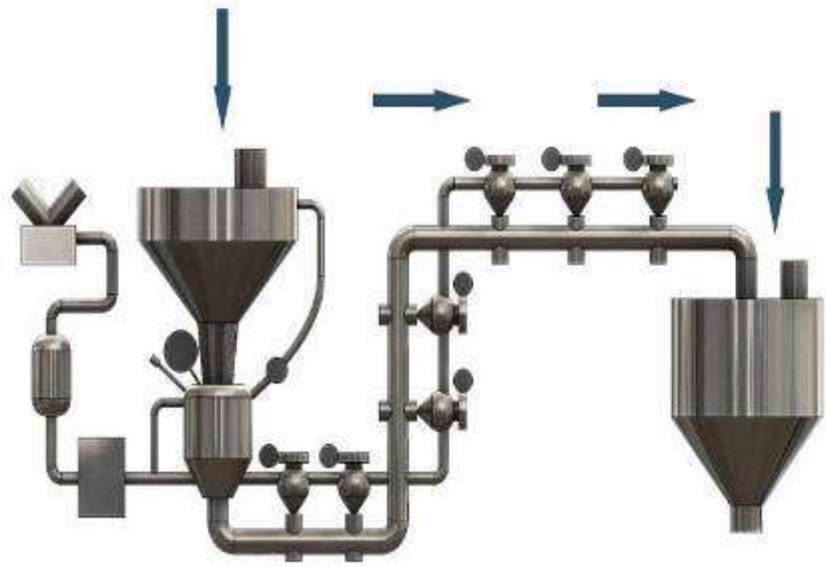

Fig.2 Dense phase pneumatic conveyor (Javaid,2023)

The dilute phase moves materials at high velocities under pressure and has some breakage during transport. The dense phase is used for fragile materials since it operates at low pressure. The dilute phase has a high air-to-product ratio, while the dense phase has a low ratio. Figure 3 below shows the difference between the dilute phase on the left and the dense phase on the right (Javaid, 2023).

Fig.3. Dilute and dense phase pneumatic conveying (Javaid, 2023)

Results and discussion

With the advent of Industry 4.0 and the increasing integration of industrial IoT technologies, cloud systems, and advanced analytics, the field of traditional pneumatic conveying is set for significant changes. At the heart of this evolution is the concept of 'digital twinning'. Digital twinning goes beyond a mere technological trend; it represents a transformative method that unites the physical and digital realms. Essentially, it involves creating a dynamic, virtual representation of a physical system or entity. This digital twin, continuously updated with real-time data from sensors and other sources, reflects the condition and performance of its physical counterpart (Salihler, 2023).
This advanced technology enhances operational efficiency, reduces power consumption and component wear, and offers real-time, comprehensive insights into the conveying system. Its predictive capabilities allow for proactive measures against potential blockages, ensuring smoother operations. Furthermore, digital twins enable better planning and optimization of

the process, contributing to improved workflow coordination and overall operations management (Premarathna, 2023).

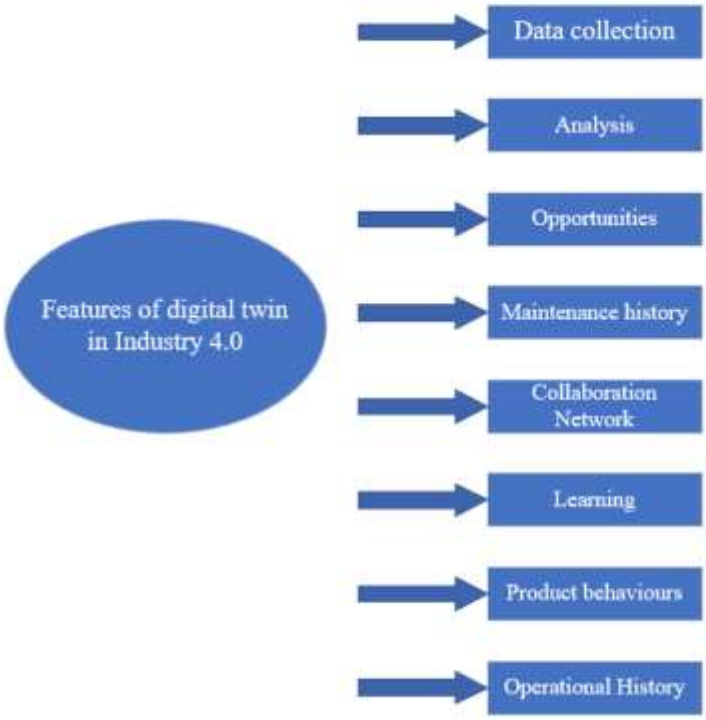

Fig.4. Features of Digital Twin in Industry 4.0 (Javaid,2023)

A fundamental framework for digital twin implementation is demonstrated in Figure 5, illustrating the division between the physical space, the digital space, and an optional web space that facilitates remote monitoring and control via 3D graphical representation (Premarathna, 2023).

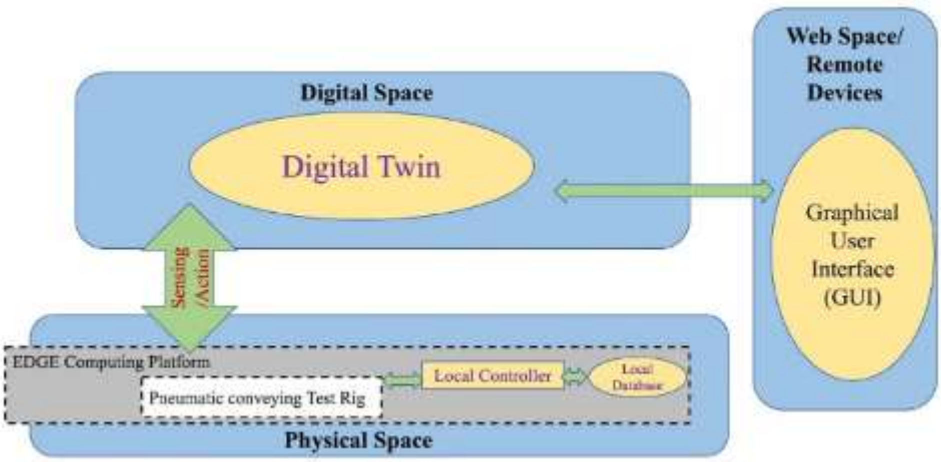

Fig. 5 Fundamental Framework for a Digital Twin (Premarathna, 2023)

One of the most advanced pneumatic conveyors is the Gericke Pulse-Flow PTA Dense Phase presented in Figure 6, which utilizes pulse-flow technology to achieve efficient dense phase conveying. It minimizes air consumption while ensuring gentle handling of materials, making it suitable for fragile products (Gericke, 2023).

Fig.6. Gericke Pulse-Flow PTA Dense Phase conveyor (Gericke, 2023)

One of its main advantages is that has enhanced material flow control, reduced energy consumption, and minimized wear on system components. Gericke says the system can be Custom-engineered for each application, matching the product design to the desired throughput rates, conveying distances, and other requirements in either batch or continuous operation (Plastics technology, 2019).

Aerocon has conducted research and tests on VAC-U-MAX Aero-Mechanical Conveyors which enable the user to move certain products at critical speeds, approaching the equivalents of dense or dilute phases in the system. High speed, lean (or dilute) phase conveying fluidizes the material and handles particles more gently than pneumatic conveying. The dynamics of fluidization within the cable-disc configuration, around the corners, causes minimal impact between particles and against the housing. The result is less particle degradation, less conveyor wear, than with dilute pneumatic conveying (Anonymous, 2024).

Fig.7. VAC-U-MAX Aero-Mechanical Conveyor (Anonymous, 2024)

The E-Finity system presented in Figure 8 is a patented continuous dense phase system from the Schenck Process, which provides gentle and energy-efficient conveying of granular and pelleted products. Traditional continuous dense phase systems use blowers and rotary valves, which can cause unstable air leakage due to the increased pressure in the pipeline. To overcome this problem, E-Finity uses precise pressure monitoring to control the valve and manage the airflow, automatically compensating for any leakage or changes in temperature. With the E-Finity conveying system, Schenck Process can carry out comparative monitoring of conveying air, pressure, feed rate, leakage, and power consumption.

Fig.8 Advances in pneumatic conveying technology showcased at UK Test & Innovation Centre

The news is that Schenck Process FPM is becoming Coperion - Effective August 1, 2024, the company will officially transition its name under Coperion. Coperion designed the High-pressure ZVH rotary valve presented in Figure 9, used for continuous gentle conveying of coarse granular or pellet size, friable or Temperature-sensitive materials such as plastic pellets, coffee beans, grains, etc.
A Dense-phase rotary valve system is ideal for achieving high conveying capacities, even at long distances. These parameters are possible due to the rotary valve’s ability to withstand 3.5 bar(g) while minimizing leakage and through use of the Coperion LMR-X air control unit.

Fig.9 High Pressure Rotary Valve

Another research for the food and beverage sector was conducted by Bürkert, designing FLOWave, a sensor that is easy to integrate into an existing installation and its control infrastructure. The ability to offer improved control systems that reduce waste, save time, and maintain rigorous hygiene standards are distinct advantages for the industry. Figure 10 shows the sensor installed on a food sector pneumatic conveyor (Bürkert, 2020).

Fig.10 FLOWave sensor mounted on the pneumatic conveyor (Bürkert, 2020)

Conclusions

In the agri-food sector, pneumatic conveying systems are essential for effective and controlled movement of products. Proper handling, space efficiency, cost savings, and contamination protection are just a few advantages they provide. Technological advancements, particularly digital twins, enhance operational efficiency, provide real-time insights, and improve planning and monitoring.

Innovative solutions for material flow control and hygiene standards are demonstrated by case studies such as the Bürkert FLOWave sensor and the Gericke Pulse-Flow PTA Dense Phase conveyor. The emphasis on energy conservation and environmental friendliness is growing, lowering costs, and reducing environmental impacts. Numerous industries, including pharmaceuticals, food, cement, minerals, and power, benefit from these improvements. Integration of digital twinning and IoT technologies is set to transform pneumatic conveying systems, emphasizing efficiency and sustainability.

Abstract

In March 2021, unusual plant stunting, collar and root rot of lettuce during rosette stage were observed in two commercial fields in Serbia. Initial above-ground symptoms were yellowing and wilting of leaves, while below-ground symptoms were collar and root rot. Eventually, whole plants wilted, collapsed and died. In total, twenty *Plectosphaerella* spp. isolates obtained from 35 symptomatic lettuce plants were identified on the basis of morphology and evaluated for their pathogenicity. To confirm the species identity, internal transcribed spacer (ITS) region and the D1/D2 region, of a selected representative isolate 13-3-c, were amplified and sequenced by using primer pairs ITS1/ITS4 and N1/N2, respectively. Sequence analysis of both regions revealed 100% nucleotide identity with *Plectosphaerella cucumerina* isolates from different countries deposited in the NCBI GenBank. Neighbour-joining analysis was conducted based on combined ITS and D1/D2 regions, and the tree was constructed with the substitution models. Combined phylogeny confirmed that the sequences shared a common clade with *P. cucumerina*. To our knowledge, this is the first molecular identification of *P. cucumerina* on lettuce or any other crops in Serbia and Balkan region. *P. cucumerina* has already been known as a pathogen of lettuce and other hosts grown in many countries worldwide, as well as in some European countries. This emerging pathogen may cause significant economic losses in lettuce production in Serbia and in the other Balkan countries. Our results may help to develop efficient monitoring and detection of *P. cucumerina* and effectively manage the spread of the disease.

Keywords: *Lactuca sativa, soilborne pathogen, detection.*

Introduction

Leafy vegetables, especially lettuce (*Lactuca sativa* L.), are economically important crops with a relevant role in the diet all over the world, and are grown worldwide under intensive cultivation systems (Das and Bhattacharjee, 2020). Fungal pathogens are major threat for producers and can cause significant losses under favourable conditions. Recently, a new fungal disease of lettuce caused by *Plectosphaerella cucumerina* in Serbia and the Balkan area was detected (Mihajlović et al., 2024). *Plectosphaerella* species are causal agents of root and collar rot, vascular and leaf symptoms in different hosts (Raimondo and Carlucci, 2018). This filamentous ascomycete is cosmopolitan in distribution, and acts as both and airborne pathogen being able to infect aboveground and belowground plant parts (Palm et al., 1995; Carlucci et al., 2012; Gao et al., 2016). *P. cucumerina* causes brown-black lesions, which, on older leaves, are surrounded by a yellow halo, causing the progressive defoliation of the plants and, on rare occasions, plant death. Its ability to survive as a saprotroph in soil, its polyphagous nature and the ability to contaminate seeds, make its management difficult (Domsch and Gams, 1972). *P. cucumerina* has already been known as a pathogen of lettuce and other hosts grown in many countries worldwide, as well as in some European countries such as Belgium, England, Italy, Netherland and Switzerland (Zhang et al., 2019). In Serbia, it was discovered recently (Mihajlović et al., 2024). However, there is no any additional information about the pathogen features, or the damage it causes in lettuce plants. Therefore, the objectives of this study were: 1) to estimate the disease incidence in inspected fields and 2) to characterize the causal agent of collar and root rot of lettuce caused by *P. cucumerina* using morphological and molecular methods.

Materials and methods

In March 2021, unusual plant stunting, collar and root rot of lettuce during rosette stage were observed in two commercial fields in Banat region of Serbia. To identify the causal agent, a total of 35 symptomatic plants were collected from the fields. Diseased tissue from the collar of all collected plants were cut into small pieces, surface sterilized with 70% ethanol for 1 min, rinsed three times in sterile distilled water and plated on potato dextrose agar (PDA) for 10 days at 25°C. From the developed colonies mono-hyphal-tip isolates were derived and used for pathogenicity tests. Cultural characteristics and morphological features of the isolates were determined on PDA (Palm et al., 1995; Carlucci et al., 2012). To confirm the species identity, internal transcribed spacer (ITS) region and the D1/D2 region, of a selected representative isolate 13-3-c were amplified and sequenced by using primer pairs ITS1/ITS4 (White et al., 1990) and N1/N2 (O’Donnell and Gray, 1995), respectively. Neighbour-Joining method phylogenetic tree was constructed from ITS and D1/D2 regions of ribosomal RNA gene sequences of 17 selected *Plectosphaerella* sp. isolates. The phylogram was generated with MEGA 11 using the p-distance model. Bootstrap analysis was performed with 1,000 replicates. In pathogenicity assay 10 isolates were tested. Five 30-day-old lettuce plants (cv. Majska kraljica) per isolate were root-dipped in the conidial suspensions (1×10^5 conidia/ml) prepared from 10-day-old colonies grown on PDA, transplanted into 1 L pots containing sterile substrate (Floragard, Germany) and maintained in a greenhouse at 25-28°C under a 12-h photoperiod (Cai et al., 2021). Five plants treated with sterile distilled water were used as controls. Inoculated plants were inspected daily for the occurrence of symptoms. After the appearance of disease symptoms, the pathogen was re-isolated on PDA. Then, the morphological features of the re-isolated fungi were compared and matched with the original ones used for inoculation.

Results and discussion

Unusual symptoms on lettuce plants were noticed in two commercially cultivated fields in the Banat region of Serbia, (44°58'N, 20°32'E; 44°45'N, 20°43'E) during March 2021. Disease incidence in the fields (≈ 0.9 ha each) was approximately 15 and 20%. Initial aboveground symptoms were yellowing and wilting of leaves, while belowground symptoms were progressive collar and root rot.

Figure 1. Symptoms of collar root rot on lettuce plant collected from the field

Eventually, whole plants wilted, collapsed and died (Figure 1). Isolation resulted in 20 morphologically uniform monoconidial isolates, derived from 35 diseased lettuce plants. The isolates formed white to creamy colonies, gradually becoming salmon pink in colour, slimy, or moist in appearance, with a sparse aerial mycelium after 10 days on PDA at 25°C. Numerous hyphal coils with conidiophores and conidia were formed. Conidia were hyaline, smooth-surfaced, ellipsoid to ovoid, septate or aseptate, 4.5-10.07×1.2-3.7 μm in size (n=100). Chlamydospores were absent (Figure 2). Morphological characteristics of the isolates were similar to the description of *Plectosphaerella cucumerina* (Lindf.) (anamorph: *Plectosporium tabacinum*) (Palm et al., 1995; Carlucci et al., 2012).

Figure 2. Left: Culture characteristics of a Plectosphaerella cucumerina isolate 13-3-c, grown on potato dextrose agar for 10 days. Right: Conidia of a Plectosphaerella cucumerina isolate 13-3-c (X40)

The ITS sequence analysis revealed 100% nucleotide identity between representative isolate 13-3-c isolate (OR880564) and *P. cucumerina* isolates from different countries deposited in the NCBI GenBank, including isolate MH860704 (Vu et al., 2019), while the D1/D2 region showed 100% nucleotide identity between the 13-3-c isolate (OR880567) and *P. cucumerina* isolate KY662256 (Su et al., 2017). Sequence was deposited in GenBank (ITS - OR880564 and D1/D2 - OR880567). Combined phylogeny confirmed that the sequences shared a common clade with *P. cucumerina* (Figure 3).

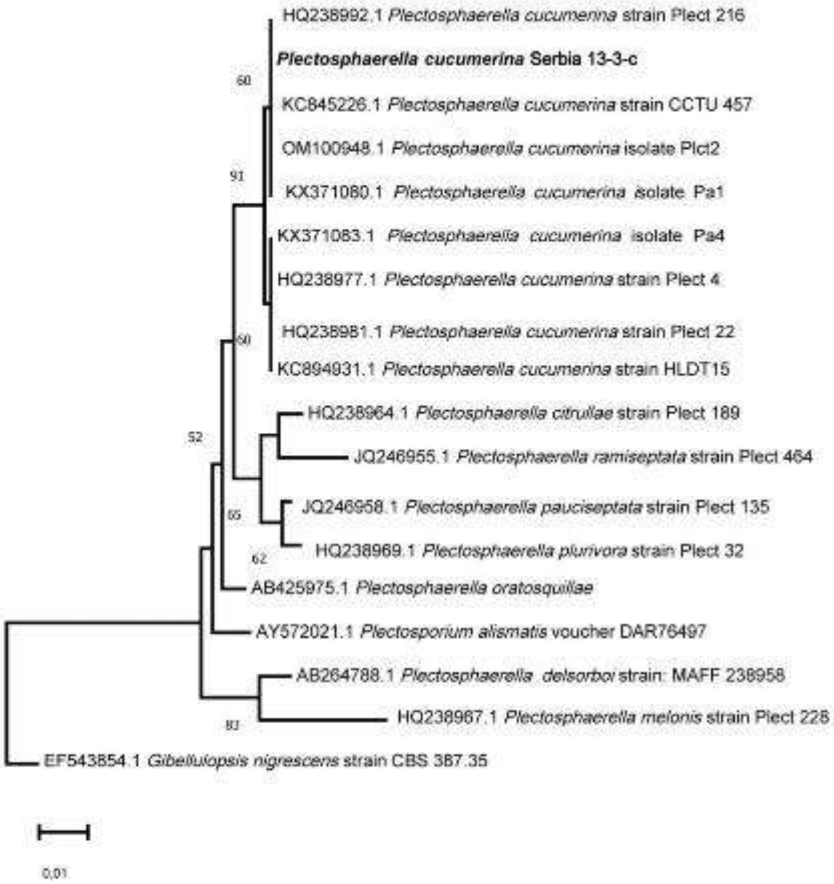

Figure 3. Neighbour-Joining method phylogenetic tree inferred from ITS and D1/D2 regions, region of ribosomal RNA gene sequences of 17 selected *Plectosphaerella* sp. isolates. The phylogram was generated with MEGA 11 using the p-distance model. Bootstrap analysis was performed with 1,000 replicates, and bootstrap values (>50%) are shown next to the branches. There were a total of 377 positions in the final dataset. *Gibellulopsis nigrescens* isolate CBS 387.35 is included as an outgroup. *Plectosphaerella cucumerina* isolate obtained in this study from Serbia is indicated in bold.

The results of the pathogenicity test revealed that *P. cucumerina* is the causal agent of lettuce collar and root rot. Four weeks after inoculation, stunting, chlorosis and wilting of plants were observed, while collars and roots of inoculated plants exhibited typical decaying symptoms. No symptoms were observed on the control plants. The pathogen was re-isolated from symptomatic tissue as previously described, while isolation from control plants was unsuccessful. Koch's postulates were completed by confirming the identity of re-isolates based on morphological features.

P. cucumerina has been detected on numerous crops including tomato, fennel, soybean, muskmelon, potato, pepper, and other important commercial crops (Abad et al., 2000; Cai et al., 2021). In addition, it has already been known as a pathogen of lettuce and other hosts grown in many countries worldwide, including some European countries such as Belgium, England, Italy, Netherland and Switzerland (Zhang et al., 2019). In Serbia, it was discovered recently, but there is no information on the damage and distribution of diseases caused by *Plectosphaerella* species. Additionally, *P. cucumerina* on lettuce or any other crops is still not reported in other Balkan countries. In recent years, *P. cucumerina* has become more visible worldwide as a new or emerging pathogen on plants (Abad et al., 2000; Cai et al., 2021). The wide distribution and broad host range of *P. cucumerina* can present it as a severe threat to Balkan lettuce production region.

Conclusion

More research is needed to better understand biology of *P. cucumerina*, and minimize the spread of the pathogen to the other lettuce-producing areas. This emerging pathogen may cause significant economic losses in lettuce production in Serbia and in the other Balkan countries. Due to the economic importance of lettuce, the management of the disease should be considered in further studies.

Abstract

Suckers can have adverse effects in fruit orchards for various reasons. In addition to their competition with the plant, they also provide hiding places for insect pests, promote favorable environmental conditions for disease development, serve as entry points for plant diseases, and interfere with in-row weed management. The efficacy of a herbicide based on pyraflufen-ethyl (26,5 g a.s./l) in the control of suckers was studied in raspberry, apple and plum orchards across four field sites in Serbia (Kušići, Zminjak, Padinska Skela and Morović). The trials were set up following the standardized EPPO protocol, and herbicide application was done in spring, when the longest suckers were 10-15 cm long. In the split application treatments, the second treatment was done when the new suckers had reached a length of 10-15 cm. The efficacy of the tested product was assessed in comparison to the untreated control. Pyraflufen-ethyl was shown to be highly effective in controlling the number of suckers (>90%), both in single and split application in all three orchards. The highest level of efficacy in raspberry and plum orchards was observed in the split application treatment, when the tested product was applied at a dosage of 0,8 l/ha + 0,8 l/ha. When applied in combination with the adjuvant Alteox T prima, the highest efficacy levels were also observed in the split application treatments. In contrast, the efficacy of the inhibition of subsequent regrowth was comparatively lower, with efficacy percentages between 69 and 84% in raspberry, 50 and 64% in plum and between 51 and 65% in apple orchards.

Key words:*, herbicide efficacy, sucker control, pyraflufen-ethyl, orchards.*

Introduction

Plant suckers represent natural, but unwanted, vegetative growth of many deciduous fruit trees (Smith and Gutierrez, 2014). Suckers can occur either in the form of basal shoots, growing at the base of a tree (Lippi et al. 2023), or as crown suckers, when buds located at the point of branch curvature produce suckers, as a result of apical dominance (Meyer et al., 2016). In raspberry plantations, suckers develop from root buds, occupying the inter-row and must be removed to avoid competition with the crop (Graham et al., 2007).
In general, plant suckers have many potentially adverse effects in fruit plantations. In addition to their competition with the plant for light, water, and nutrients, potentially resulting in yield losses (Graham et al., 2007; Pacchiarelli et al., 2022), they also provide hiding places for insect pests (e.g. wooly apple aphid; Johnson et al., 2020), promote favorable environmental conditions for disease development and/or serve as entry points for plant diseases (e.g. fire blight in apples; Aćimović et al. 2023), and disrupt weed management within rows (Johnson et al., 2020).

Chemical control of plant suckers usually requires several treatments during the growing season, due to their constant regrowth. These treatments must be performed when the suckers

are herbaceous and reach a height of 15–20 cm. Alternatively, their management can also be conducted using physical techniques later in the season, when they have lignified (Pacchiarelli et al., 2022). However, manual removal of suckers is very expensive, and consequently only possible in cases when their presence is limited (Smith and Gutierrez, 2014). Chemical control of plant suckers can be performed using herbicides, plant growth regulators, or desiccants (Johnson et al. 2020). In conventional agriculture, the application of herbicides remains the most widely used control method for the management of plant suckers (Smith and Gutierrez, 2014), as it offers two main advantages - quick implementation and lower cost, when compared with other management techniques (Serdar and Akyuz, 2017).
Pyraflufen-ethyl is a fast-acting and effective contact herbicide, primarily used for POST-EM control of broadleaf weeds. It is also used to control suckers in fruit trees (Johnson et al., 2020). The efficacy of a herbicide based on pyraflufen-ethyl (26,5 g a.i./l) in controlling suckers was studied in raspberry, apple and plum orchards in Serbia.

Materials and methods

The efficacy of a herbicide based on pyraflufen-ethyl (26,5 g a.i./l; commercial product Kabuki 2.5 EC) in controlling suckers was studied in raspberry, apple and plum orchards at four locations in Serbia: Kušići (+43.493026, +20.075460), Zminjak (+44.745574, +19.463703), Padinska Skela (+44.957823, +20.433335) and Morović (+45.013222, +19.253138). The trials were set up following the standardized EPPO protocols: PP1/304(1) for apple and plum orchards (EPPO, 2017) and PP1/154(3) for raspberry plantations (EPPO, 2009).
In apple and plum orchards each plot contained three trees (EPPO, 2017), while in the case of raspberry plantations the plot size was 10 m long, and comprised two raspberry rows (EPPO, 2009). Herbicide application was done in spring, when the longest suckers were 10-15 cm long. In the split application treatments, the second treatment was done when the new suckers had reached a length of 10-15 cm.
In apple and plum orchards, the number of suckers and their length per tree were recorded prior to application (EPPO, 2017). On the other hand, in raspberry plantations, prior to the application, the number and mean height of suckers were recorded in several fixed squares in each experimental plot (EPPO, 2009). The assessments included counting the total number of newly regrown suckers per plot and the degree of regrowth of partly injured suckers (in cm). The assessments were done 7 and 14 days after application. In the split application treatments, assessments were done after the second application. In all assessments, the efficacy of the tested product was assessed in comparison to the untreated control.

Results and Discussion

Field trials conducted at all four locations have shown that pyraflufen-ethyl is highly efficient in controlling the number of suckers (>90%), both in single and split application in all three types of fruit orchards (Figures 1-3). Our results are in line with previous findings of Querzola et al. (2010) who have also shown pyraflufen-ethyl to be highly efficient in the control of suckers in pome and stone fruit orchards, both regarding its speed of action and its persistence. Similarly, Allegri and Manucci (2012) have documented high efficacy of sucker control in apricot and plum orchards, higher than that of the previously used gluphosinate ammonium. Lower efficacy of chemical sucker control in hazelnut orchards when using other herbicides, such as 2,4-D, glufosinate and paraquat was also documented by De Souza and Moretti (2020).

An overview of the documented levels of efficacy in different fruit orchards, both regards its efficacy in controlling the number of suckers and the average length of suckers is given in Figures 1-6.
The highest level of efficacy in raspberry plantations (location Zminjak; Figure 1) and plum orchards (location Zminjak; Figure 2) was observed in the split application treatment, when the tested product was applied at a dosage of 0,8 l/ha + 0,8 l/ha. The addition of the adjuvant did not drastically increase the efficacy of the tested product (approx. 2% higher efficacy in some locations) (Figures 1-3). Johnson et al. (2020) state that suckers in cherry orchards are more susceptible to pyraflufen-ethyl compared to those in apple orchards. Nevertheless, our results show high efficacy of in controlling the number of suckers in apple orchards in both locations and all four treatments (≥89%; Figure 3).

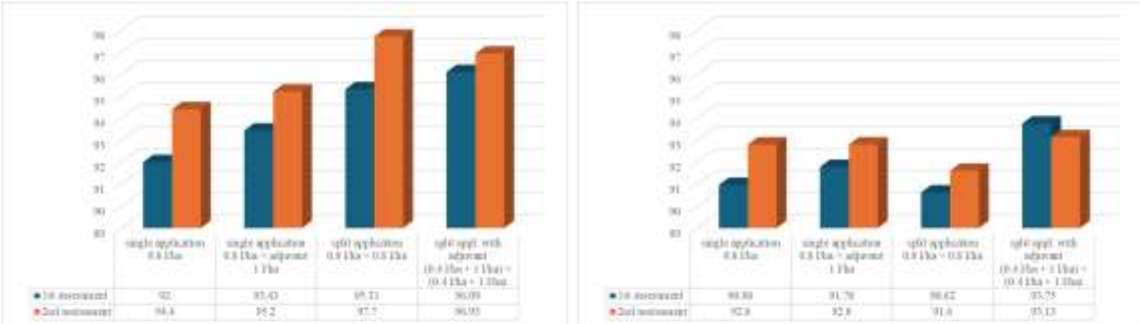

Figure 1. Efficacy of pyraflufen-ethyl in controlling the number of suckers in raspberry plantations in Serbia (a –location Zminjak; b –location Kušići).

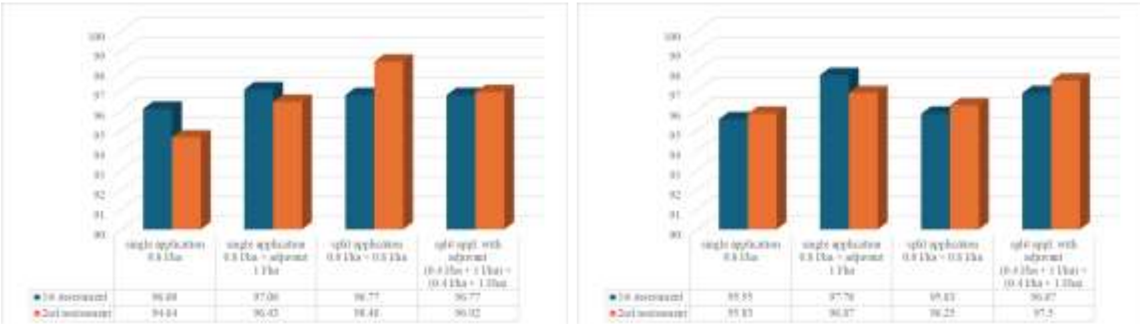

Figure 2. Efficacy of pyraflufen-ethyl in controlling the number of suckers in plum orchards in Serbia (a –Zminjak; b –location Padinska Skela).

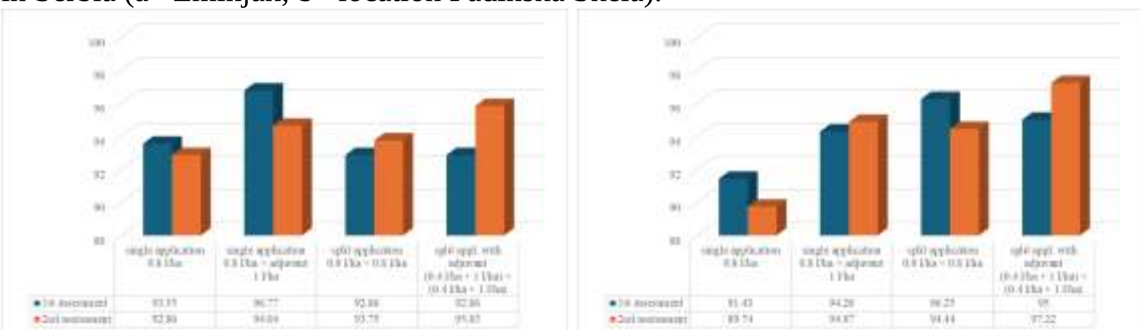

Figure 3. Efficacy of pyraflufen-ethyl in controlling the number of suckers in apple orchards in Serbia (a –location Morović; b –location Padinska Skela).

Meanwhile, the efficacy of the tested product in inhibiting subsequent regrowth (Figures 4-6) was comparatively lower, with the percentage of efficacy (observed in the second assessment) ranging between 69 and 84% in raspberry, 50 and 64% in plum and between 51 and 65% in apple orchards. It was slightly higher in split-application treatments, with the addition of the adjuvant Aleox T prima.

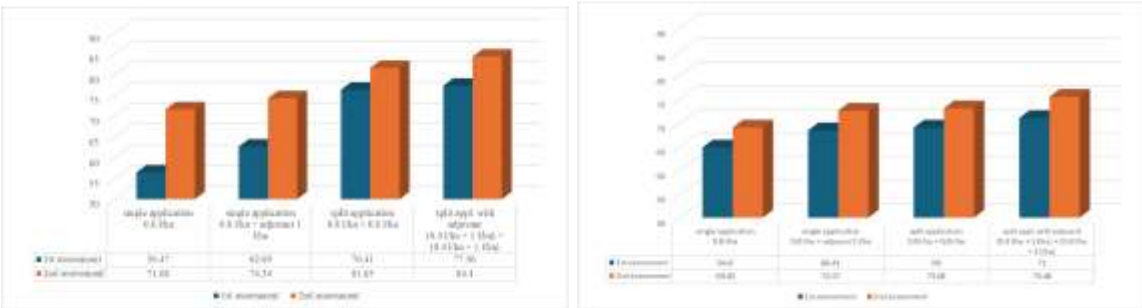

Figure 4. Efficacy of pyraflufen-ethyl in controlling the average length of suckers in raspberry plantations in Serbia (a –location Zminjak; b –location Kušići).

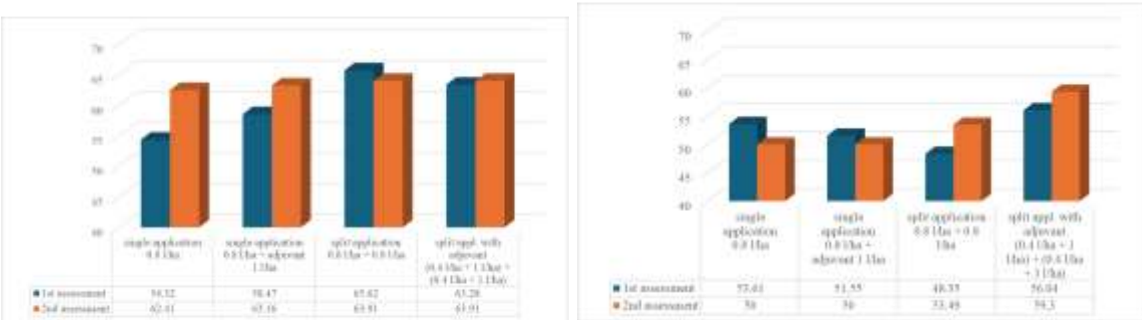

Figure 5. Efficacy of pyraflufen-ethyl in controlling the average length of suckers in plum orchards in Serbia (a – location Zminjak; b –location Padinska Skela).

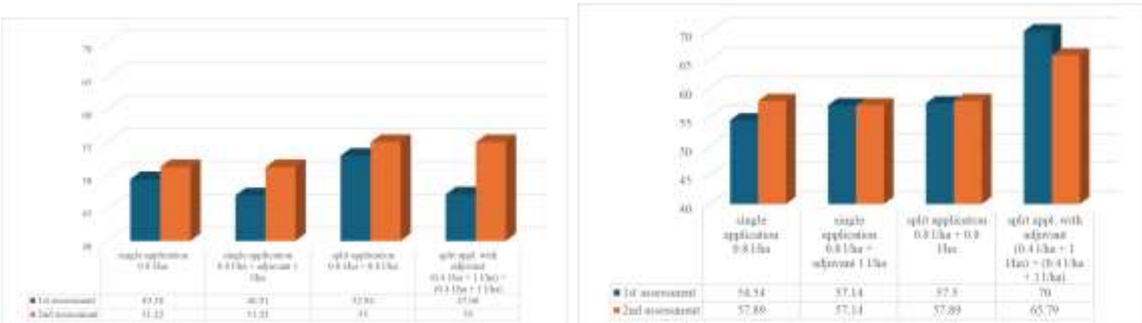

Figure 6. Efficacy of pyraflufen-ethyl in controlling the average length of suckers in apple orchards in Serbia (a –location Morović; b –location Padinska Skela).

Conclusion

In conclusion, it can be said that herbicides based on a.i. pyraflufen-ethyl are highly efficient in controlling plant suckers in raspberry, apple and plum orchards. When considering their effectiveness in controlling the number of suckers, split application treatments show the highest level of efficacy. In contrast, the efficacy of the tested product in inhibiting subsequent regrowth of new suckers is slightly lower, showing highest levels in the split application treatments with the addition of the adjuvant.

Abstract

Apple production has become highly demanding and requires great commitment. During the year, a large number of plant protection products (PPPs) for different harmful species, have been applied. The green apple aphid *Aphis pomi* (Hemiptera: Aphididae) represents one of the most economically important apple pests. It feed in dense colonies onon undersides of leaves and young shoots. If adequate control measures for this pest are not implemented, it could cause great damage, especially for young apple plants. In 2023, the trials were carried out according to the standard EPPO methods to establish the level of apple protection in the control of *A. pomi*. Two products based on lambda-cyhalothrin, with different amounts of active ingredients (50 g a.i./L, CS) and (100 g a.i./L, CS), were applied. In apple orchards variety Idared, Red Delicious and Granny Smith, at localities Kać, Mala Remeta, Rumenka and Budisava (Serbia), the PPPs were foliar applied by backpack sprayer at an amount/concentration of 0.2 L/ha and 0.01%, respectively. The experiment was set up in four replications in randomized block design. By visual examination, when the apple was in the BBCH 75 stage, the presence of *A. pomi* adults was registered. The obtained results were analyzed using one-way ANOVA and LSD test, while the efficacy was calculated according to Henderson-Tilton. Three days after the application the efficacy was between 82.3% and 99.4%, while after seven days it was 79.5-95.6%, depending on the applied product and locality. Fourteen days after the treatment efficacy was high and it ranged from 81.9 to 97.5%. In all assessments, the number of green apple aphid in the variants with insecticide was significantly lower comparing to the control. The populations of *A. pomi* in the mentioned localities showed a satisfactory sensitivity to lambda-cyhalothrin, which allows the use of this insecticide according to the recommendations of the anti-resistance strategy.

Key words: *Aphis pomi***,** *apple, lambda-cyhalotrin, efficacy.*

Introduction

Nowadays, the apple is among the most widespread types of fruit worldwide. Agroecological conditions in Serbia are suitable for its cultivation, yet they also favor the development of numerous harmful insect species, as well as disease-causing agents. In addition to aphids (Aphididae) and mites (*Tetranychus urticae*, *Panonychus ulmi*), economically significant pests in apple orchards are the codling moth (*Cydia pomonella*), fall webworm (*Hypanthria cunea*), apple blossom weevil (*Anthonomus pomorum*) and apple ermine moth (*Hyponomeuta malinellus*). *Aphis pomi*, known as the green apple aphid, is European in orgin, and widespread in Asia, North Africa, and North America. Consequently, its presence is also significant in Serbia. Throughout its development, it remains on a single host, which can be an apple, pear, quince, or whitebeam. The aphid damages leaves and green shoot tips by sucking juices from them. As a result, leaves may curl or dry under heavy infestation, while the shoots exhibit delayed growth and deform. This is more significant in nurseries and newly planted seedlings. On older trees and shrubs, the occurrence can remain below the damage threshold for many years, due to the action of natural enemies (Kereši et al., 2019). This paper aims to evaluate the efficacy of the insecticide lambda-cyhalothrin since it has been used for many years, in controlling the green apple aphid in apple orchards at four locations in the territory of Vojvodina.

Material and Methods

The control of the green apple aphid was carried out in apple orchards, with the Idared, Red Delicious, and Granny Smith varieties, located in Kać, Mala Remeta, Rumenka, and Budisava in Serbia. The experiments were set up according to standard OEPP methods: OEPP/EPPO, PP1/152 (4) (2012) for experiment design and data analysis; OEPP/EPPO, PP 1/258 (2) (2022) for the efficacy of insecticides in controlling *A. pomi* and OEPP/EPPO PP 1/135 (4) (2014) for phytotoxicity. The experiment was designed using a randomized block system with four repetitions, with each basic plot consisting of four trees. The treatment was applied foliar, using a backpack sprayer with 1000 liters of water per hectare. At the time of treatment (June 26 and 27, 2023), the apple was in the BBCH 75 phenophase. Visual assessments of the orchards registered the presence of the green apple aphid. Four assessments were made: right before treatment, and then three, seven, and 14 days after treatment. The efficacy of the products was assessed by counting the number of live aphids on 10 marked apple shoots per repetition. Insecticides based on lambda-cyhalothrin were applied in the recommended quantity/concentration of 0.2 l/ha and 0.01%. The efficacy was determined using the Henderson Tilton method (Wentzel, 1963), as well as the least significant difference (ANOVA).

Results and Discussion

Results on the control of *A. pomi* in M. Remeta, Kać, Rumenka, and Budisava are shown in Tables 1-4. The initial number of *A. pomi* before the application of insecticides ranged from 39.0 to 356.2, varying across the locations.

Table 1. Average number of green apple aphids (*A. pomi*) before treatment

Insecticide	Mala Remeta	Kać	Rumenka	Budisava

At all localities, the number of aphids three days after the application of lambda-cyhalothrin (50 g a.i./l CS and 100 g a.i./l CS) was significantly lower compared to the control. The efficacy of the insecticide ranged from 74.7 to 99.4%, depending on the product and localities (Table 2). Additionally, seventh day after pesticide application, the number of aphids was noticeably reduced compared to the control. The efficacy of the insecticides ranged from 72.1 to 95.6% compared to the control (Table 3). 14 days after the application, the efficacy varied between 77.9 and 97.5%, depending on the applied products and the examined localities (Table 4).

Over the years, resistance to insecticides has become a growing concern in aphid control. The decreased susceptibility of aphids to insecticides belonging to the organophosphate and carbamate groups has been determined with a lesser extent of resistance observed in pyrethroids. Among the spectrum of aphid resistance mechanisms, the most commonly detected ones include increased capacity for insecticide deactivation due to excessive production of esterase enzymes, and changes in sensitivity of the target site of action (Elezović et al., 2006). Our professional community often presents data regarding the insufficient efficacy of applied insecticides, particularly those belonging to the organophosphate and pyrethroid groups, in managing plant aphids. However, there is no official data concerning plant aphids that have developed resistance to insecticides or any organized monitoring of this undesirable phenomenon. Some researchers have found that lambda-cyhalothrin can be recommended for effective control of insects from the order Hemiptera: Aphididae in apple orchards and other crops (Seni and Naik, 2017; Saabome, 2013; Pezzini and Koch, 2015). Moreover, products based on lambda-cyhalothrin (0.03%) have exhibited high efficacy (81-90%) in controlling aphids 24 hours after treatment (Ganchev and Atanasova, 2018).

Conclusions

Based on the conducted experiments and the results obtained regarding the efficacy of products based on lambda-cyhalothrin 50 g a.i./L CS and 100 g a.i./L CS in controlling A. pomi in apple orchards located in Mala Remeta, Kać, Budisava and Rumenka, the following conclusions can be drawn:

• At all examined localities, the number of A. pomi, three, seven, and 14 days after treatment, significantly decreased compared to the control. The efficacy of the insecticides ranged from 72.1 to 99.4%, depending on the applied products and the localities.

• Based on the achieved results, it can be concluded that the A. pomi populations at the mentioned localities have shown satisfactory sensitivity to lambda-cyhalothrin, which allows the continued use of this insecticide while following all recommendations of the anti-resistance strategy.

Abstract

The paper provides an overview of various aspects of paraquat and other desiccants and bleaching herbicides, from various chemical groups, which have in common the drying and bleaching of leaf mass. In weed plants, they can act as total or selective herbicides, and applied in the mature stages of the crop, by drying the leaf mass, they promote the maturation of some important crops (sunflower, soybeans, potatoes). More or less, all these various herbicides are highly or significantly toxic, which greatly complicates their application. In the EU, there was an initiative to ban some of them (eg Paraquat). However, we are of the opinion that despite their significant toxicity, they should be considered as an alternative to some other herbicides.

Key words: *dessicant herbicides, bipyridyl herbicides, paraquat, weeds, crop plants, toxicity.*

Introduction

Weeds have always been encountered by humans since the beginning of the development of agriculture, simply because the selection of cultivated plants is most often carried out by cross-breeding. (Quarrie, 1997), which has a positive effect on quantitative properties, such as on crop yield (economically the most important property of cultivated plants), but significantly reduces the competitive ability of cultivated plants, i.e. native species that grow around them (which by definition are weeds). Man has always solved that problem manually, by weeding and other ways of physically removing weeds, so that the rapid development of plant physiology and organic chemistry in the first half of the 20th century created the preconditions for a completely different way of solving that important problem. Namely, that knowledge led to the fact that in the years before the WW2, weeds could be selectively removed chemically, without major negative consequences of those compounds on the health and yield of cultivated plants. After the WW2, these promising findings led to systematic research into the synthesis of various organic compounds and their testing in terms of weed removal efficiency and selectivity, i.e. the absence of significant negative effects of those phytotoxic compounds on crop plants (Ashton and Crafts, 1981; Corbet et al., 1984; Percival and Baker, 1991). Such an approach soon proved to be promising because, while routine application of herbicides (as these phytotoxic compounds are called) leads to a reduction in crop yield due to weed competition of 8-15%, without chemical weed removal with herbicides, this loss of total yield can and 50% of the potential total crop yield (Percival and Baker, 1991). The introduction into practice of a new agrotechnical measure, chemical crop protection, in addition to its benefits, also led to new unknowns and problems, f.e. the resistance of weeds to previously phytotoxic doses of herbicides. This becomes a serious problem, because investments in the development of new, phytotoxic formulations and herbicidal compounds are very expensive and demanding, and the profit can be small, because the question arises of the economic expediency of using these means, if there is a rapid development of weed resistance to some classes of herbicides (Percival and Baker, 1991; Travlos et al., 2020). This then entailed the need for a more careful study of the effects of herbicides, both on plants and on other living nature and ecosystems, due to health and ecological problems.

Effects of a Paraquat and other dessicants on weeds

Paraquat and its related diquat, as bipyridyl molecules (Averina et al., 1991), lead to desiccation of weeds and partially controlled desiccation of crop leaf mass (for faster ripening), inhibiting electron transport in PS_1 (Ashton and Crafts, 1981; Corbet et al., 1984), whereby those electrons, instead of the usual photosynthetic acceptors (Figure 1), transferred to oxygen and through the so-called Mehler's reactions or water-water cycle (Kleczkowski, 1993; Janjić et al., 1994; Asada, 2000) they produce reactive oxygen species, disrupting cellular metabolism, which leads to drying and death of plant foliage.

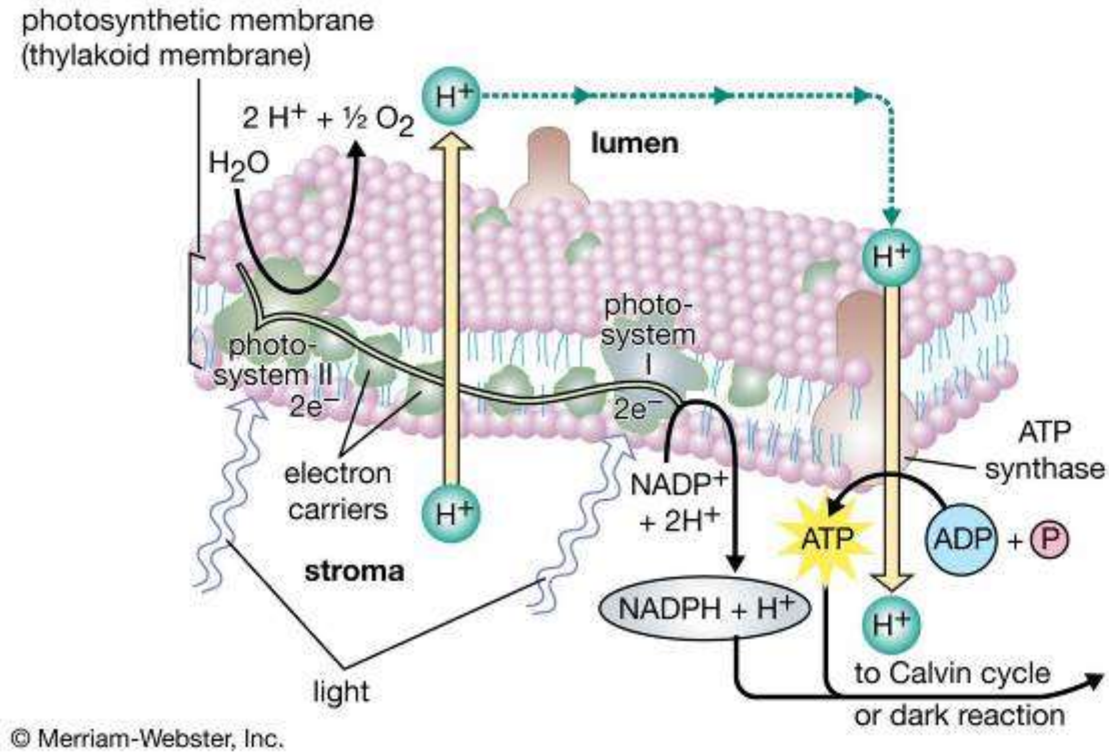

Figure 1. Transport of electrons in light phase of photosynthesis.

In addition to the well-known bipyridyl herbicides with desiccation properties, and due to the development of resistance to bipyridyls (Amsellem et al., 1993; Streller et al., 1994; Weaver et al., 2004; Qin et al., 2004; Yu et al., 2004; Asaduzzaman et al., 2022; Farago et al., 2022), naturally occurring or due to genetic modification, mainly due to the increased content of antioxidant small compounds (e.g. polyamines) or antioxidant enzymes (which inactivate reactive oxygen species, thereby preventing phytotoxic processes associated with bipyridyls), a new type of desiccant that induces the Mehler reaction (s.c. water-water cycle) has recently been developed (Gerwiuck et al., 1997). In addition to bipyridyl's, as PS_1 inhibitors, which induce Mehler's reaction, there is another type of desiccant herbicidess, which at the same time lead to leaf bleaching (indicates an increased production of reactive oxygen species), whose mechanism of action is mainly based on the inhibition of one of the pathways in the biosynthesis of chlorophyll or carotenoids (Sandman et al., 1990; Sherman et al., 1991; Jacobs et al., 1991; Averina et al., 1991). These are diethyl ether, pyridazinone and furanone types herbicides, as well as amitrole (Ashton and Crafts, 1981; Corbet et al., 1984; Percival and Baker, 1991). Such an approach, due to the appearance of weeds resistant to bipyridyl, influenced to the emergence of new desiccant herbicides (Ison et al., 2022), such as Voraxor®!? However, it should be mentioned that paraquat, although generally understood as a contact herbicide, has been observed to be taken up and transported through plants by the same pathways as polyamines. (Fujita and Shinozaki, 2021), which indicates possible new types of weed resistance to this and other desiccant herbicides (Thies et al., 1996; Farago et al., 2022; Lyu et al., 2022). In addition to other treatment practicies, the effect of paraquat, as well as other desiccants, can be enhanced by encapsulation processes (e.g. with chitosan), which prolongs the otherwise short-term contact effect of this herbicide (Kurniadie et al., 2022).

Effects of a Paraquat and other dessicants on crops

Although the application of herbicides is directed primarily against the harmful effects of weeds on crops, their influence on growth and development, as well as the quality and quantity of yields, it is also important to study the effects of herbicides on cultivated plants. That is why it is important to study the effect of desiccant herbicides, either because they belong to the group of total herbicides (bipyridyls, amitrol), or because of their persistence, both in the products of cultivated plants and food, and in the soil where the mentioned herbicides are applied. All in all, it is necessary to distinguish the phytotoxic from the health aspects of the application of herbicide-desiccants when they are used in cultivated plants. And the mode of action of desiccant herbicides on cultivated plants is very diverse. Bipyridyl herbicides (paraquat, diquat and some related compounds) haver many different effects on crop plants. In addition to inducing the production of reactive oxygen species (Asada, 2000), which disrupt cellular metabolism and lead to the decline of crop leaf mass (which is useful in the case of ripening of some crops, such as sunflower, soybean, potato), this group of herbicides leads to pheophytinization, which is another factor in the inhibition of photosynthesis and other metabolic processes (Averina et al., 1991).

This effect was studied in a series of papers by Nikolić and colleagues and it was found that, in addition to the confirmation of pheophytinization of chlorophyll under the effect of diquat (Nikolić and Janjić, 1995; Nikolić et al., 1996a, 1996b; Nikolić, 1997; Pavlović et al., 2014), importante changes in the photosynthetic membrane proteins (Milivojević and Nikolić, 1995, 1996, 1998, 1999; Milivojević et al. 1997) under the effect of diquat, among other things mediated by far-red light (Milivojević and Nikolić, 1998; Table 1 and 2), which is primarily adopted through PS_1, the main site of action of bipyridyl herbicides (Ashton and Crafts, 1981).

As indicated in the previous chapter, plant resistance to bipyridyl herbicides is possible either through enzymatic antioxidant systems or through small molecules with antioxidant properties. This topic was investigated in detail on cultivated plants, and it was found that resistance to bipyridyl herbicides in cultivated plants is increased by the action of small molecules (Hart et al., 1992, 1993; Zer et al., 1994; Gosset et al., 1996; Donahue et al., 1997; Fujita and Shinozaki, 2021), which probably exert complexation of ions of transitional metal elements (Fe, Cu, Zn, etc.), as well-known promoters of the Mehler reaction (Chang and Kao, 1997).

In addition to the effect on transition metals as mediators of the Mehler reaction, increased resistance to bipyridyl herbicides in cultivated plants is also possible through antioxidant enzyme systems (Peleg et al., 1992; Aono et al., 1995; Kuk et al., 2006; Wang et al., 2021). Since the induction of the production of reactive oxygen species on a small scale has a favorable effect on plant metabolism, it was considered, as in the case of some other types of herbicides (Ashton and Crafts, 1981), to treat crop plants with bipyridyls in small doses maybe induced the effect of the so-called. hormesis, i.e. increasing plant metabolism (which would theoretically have a favorable effect on crop yield), but such attempts did not give sufficiently promising results (Ferrari et al., 2021), although equivalent trials have given favorable results in the model plant *Arabidopsis thaliana* (Farago et al., 2022). In case of effect of some other types of desiccant herbicides, which at the same time lead to leaf bleaching (which indicates an increased production of reactive oxygen species, with mechanism of action based on the inhibition of one of the pathways in the biosynthesis of chlorophyll or carotenoids), we observe the binding of these herbicides to enzymes such as phytoene desaturase and protoporphyrinogen oxidase (Sato et al., 1991; Lee et al., 1993; Dalla Vekia et al., 2001; Di Baccio et al., 2001), which leads to their inhibition, and thus to increased production of reactive oxygen species. But a physiological difference was found in the degree of binding of those herbicides to the mentioned enzymes, which can be the basis for the possible resistance of cultivated plants to their effect (Sherman et al., 1991).

Effects of a Paraquat and other dessicants on health of human and animals

Paraquat, partly diquat, as well as other desiccants are poisonous substances. Paraquat is one of the most poisonous and according to the nomenclature applied in Serbia, it belongs to the most poisonous, the 1st group of poisons. This is partly due to the fact that paraquat induces the production of reactive oxygen species, which disrupt metabolism (Brown and Sejther, 1990) and damage human and animal cells, as well as plant cells, partly due to the high volatility of paraquat, which can damage the eyes, while diquat penetrates the skin. So that bipyridyl compounds easily penetrate into the body of humans and animals, even without inhalation or via food or liquid. Herbicides-desiccants from other chemical groups mostly cause poisoning by ingestion via contaminated food or liquid or when they are inadequately applied in the field, but unlike bipyridyl, which are highly toxic, but have a short-term effect due to rapid inactivation, desiccants from other chemical groups are persistent, so their prolonged action in the environment can lead to their accumulation and prolonged toxicity in human and animal organisms. Detoxification and relief of bipyridyl poisoning symptoms are performed in different ways, either by removing or inactivating transition metal ions (Krall et al. 1991; Sato, 1991), as cofactors with bipyridyl in the production of reactive oxygen species, or by using natural ones (Palipoch et al., 2022; Chen et al., 2023) or synthetic (Li et al., 2021) drugs. The consequences of intoxication with bipyridyl herbicides are very serious (damage to the eyes, lungs, liver, kidneys), but also lead to longer-term symptoms, such as causing Alzheimer's disease (Marshall and Prior, 2022). That is why, at the first instance of the Court of the European Union, Sweden, with the support of Denmark, Finland and Austria, and against the European Commission launched an initiative to cancel the license for the use of paraquat as a plant protection agent, due to health risks (Anonymus, 2007). At that decision-making level in EU, the court of EU gave support to that initiative.

Other aspects relating to a Paraquat and other dessicants

Because of these health risks, very sophisticated analytical techniques have been developed for the detection of bipyridyl herbicide residues in various human, animal, and plant tissues (Hao et al., 2013; Tsao et al., 2016; Guo et al., 2023). In addition, various techniques are being considered for the fastest possible inactivation of these highly toxic substances, should soil or water be polluted by them (Inthama et al., 2021; Hammami et al., 2022)

Conclusions and future perspectives about Paraquat and other dessicants

Bipyridyl herbicides, as well as other desiccants, showed high efficiency, either for the complete removal of weed vegetation (total herbicides: paraquat, diquat, amitrole), or for its selective removal (e.g. diethyl ether, pyridazinone and furanone types herbicides), however their high toxicity (paraquat) or persistence in the environment more and more raise the issue of restrictions and even bans on their use. But certainly, despite these restrictions, their high efficiency in removing weeds cannot be ignored. So developed countries, similar to in the case of some organochlorine insecticides (e.g. DDT), which are known to have high persistence and a proven harmful effect on the environment, they still have their stocks, simply because in palliative situations it is absolutely necessary to have such substances as the possibility of choosing a solution suddenly We are of the opinion that, taking into account all the limitations in the application of these types of pesticides, our country must also develop a strategy for responding to possible palliative situations, even with these highly toxic herbicides.

Abstract

Plants can communicate with each other and with the surrounding environment through volatile organic compounds (VOCs). VOCs will give plants a signal to communicate about different stressors and dangers to survival and well-being. When a plant is under stress or when it communicates with other plants or the soil, it releases VOCs. Sometimes, to protect themselves from herbivores and other predators, plants will release a VOC signal. Soil microorganisms and plant roots are the main sources of soil volatile organic compounds emissions. We have kept an observation on these VOCs which were released into the soil during the experiment. We have selected two distinct genotypes of basil-*Ocimum basilicum purpurescens* and *Ocimum basilicum* L.-were planted for observation. Headspace gas-mass chromatography (GCMS) was utilized to detect VOCs. GCMS headspace analysis was performed on the native samples. Examining both genotype types indicated the presence of monoterpenes (alpha-Pinene and (+)-3-Carene), which primarily reflect abiotic stress. Plant-to-plant communication was facilitated by the monoterpene cymene, which was detected. Alcohol was also shown to be among the other category of chemicals. While nonanal and decanal signals are indicative of insect pheromones, octanal signals *(Ocimum basilicum purpurescens* and *Ocimum basilicum* L), which is implication of inhibition for plant growth. Additionally, hexanal and benzaldehyde were also detected as indicators of damage, which can trigger defense responses in plants. The collected data show that volatile organic components should be closely monitored as signal substances and future observation will include other genotypic types. Whereas prompt identification of signal volatile organic compounds in soil and plants may improve plant's protection and yield.

Key words: *plant communication, volatile organic compound, terpenes, chromatography.*

Introduction

In the plants, there are numerous defense reactions and mechanisms that will enable survival in unfavorable conditions. For centuries, plants have adapted to natural climate and established a relationship with the environment in which they are established. In principle, a stressful situation causes a series of physiological changes in the plant that neutralize and preserve the basic vital functions in the organism. However, plants cannot move and change the site environment from which they show a negative response and less stable reaction. As they suffer pressures reflected through negative response and low yield quantity and quality. It is difficult to find an adequate explanation and interpret the signals that the plant release in response.

Therefore, detecting the answers that the plant sends, plant language and understanding plants could be the solution for real time decisions. Recent studies suggest that plants sense and respond to many changes in their environment, both above as plant–plant interactions aboveground and below ground, as root–root interactions.

The agronomic potential of identification and detection of VOCs as signal which can be a natural and environmentally friendly for protecting plants from various stresses and increase crop yield is invaluable. VOCs can ensure prevention of many diseases, as well as providing protection from environmental stresses when detected at the right moments. VOCs also, stimulate plant defense mechanisms for enhanced resistance/tolerance to the increasing stress, reduce reactive oxygen species (ROS), possess potent antimicrobial and allelopathic effects, and that may be important in regulating plant growth, development, and senescence through interactions with plant hormones.
Plants produce an amazing variety of metabolites, a few of these are involved in "primary" metabolic pathways, as well as secondary metabolites. These secondary metabolites are the result of different plants' responses, through the course of evolution, to specific needs. Among such metabolites, VOCs may play a dominant role (Pichersky et al., 2000). Volatile organic compounds are important mediators of mutualistic interactions between plants and their physical and biological surroundings. These volatiles rapidly indicate competition or potential threat before these can take place, and they regulate and coordinate adaptation responses in neighbouring plants, fine-tuning them to match the exact stress encountered (Ninković et al., 2020). Being released by almost any kind of tissues and type of vegetation as green leaf volatiles, nitrogen-containing compounds and aromatic compounds, plants VOCs can be emitted constitutively or in response to a variety of stimulus. They are involved in a wide class of ecological functions, as a consequence of the interactions of plants with biotic and abiotic factors (Spinelli et al., 2011). Several trials have shown the capacity of various VOCs produced by leaves to inhibit germination and growth of plant pathogens, yet the mechanisms of action remain unknown. Plants use VOCs to indicate a variety of responses, such as: indirect plant defense against insects (Mumm et al., 2017); plant-pathogen interactions (Anjali et al., 2023), pollinator’s attraction (Dudareva and Pichersky, 2000); plant-to-plant communication (Baldwin et al., 2016; Heil and Karban, 2010), thermo-tolerance and environmental stress adaptation (Holopainen and Gershenzon, 2010); defence from predators (War et al., Vivaldo et al., 2017). The types of interactions that occur between host plants and pathogens involve varied and complex mechanisms, whereas the first is recognition. There may be molecules produced in both host and parasite that can interact. Second, there must be metabolic changes in the host or pathogen or both that are triggered by the initial interaction step. Genetic mutations in either host or pathogen can change the specificity of such molecular interactions or their ability to trigger metabolic change (National Research Council US Committee on Biosciences, 1985).
The aim of this work was detecting volatile organic compounds (VOCs), as signals, in soil where two different genotypes of basil, *Ocimum basilicum purpurescens and Ocimum basilicum L*, were grown for observation.

Material and methods

For analysis was used a GC 8890 GC equipped with a split/splitless inlet. The Pal Sistem, PAL PSI 85, sampler was used to extract and transfer the VOCs in the sample to the GC. The sample was then analyzed using a 5977B GC/MSD configured with an inert extraction ion source. Agilent MassHunter Acquisition software version 10.0 was used for analytical data collection.
In this study 3g of soil was used for analysis and transferred in vials. In each vial, added water to total volume of 5ml. Non target analysis included scan mode of analysis which lasted 30 min.
The scanning mass was in the range of 50 to 500 AMI.

Results and Discussion

Several types of analytes, including terpenes, aldehydes, alcohols, and others, were identified in our investigation employing headspace technique in a soil sample. Table 1. Table 1 displays the results.

Table 1. List of detected VOCs in soil

Aldehydes	Terpenes	Alcohols/Phenols	Other	Kethon
Hexanal	(+)-3-Carene-	Phenol	Cyclotrisiloxane, hexamethyl	5-Hepten-2-one, 6-methyl-
Butanal, 3-methyl-	alpha-Pinene-	-	m-Menthane	
Benzaldehyde	Camphene	-	Cyclotetrasiloxane, octamethyl-	
Octanal	Cymene			
Nonanal	Eucalyptol			
Decanal				

As expected, the aldehydes and terpenes were the dominant group of analytes, and they are the main group of compounds relevant to soil and plant communication. Terpenoids are naturally occurring chemicals and are commonly found in the whole living world. Investigations have shown that all organisms can and often do emit VOCs. In this study we will focus on emission of VOCs in the soil. It is well known that plant VOCs mediate plant interactions with the surrounding environment (Erb and Kliebensteinb, 2020). Emission of VOCs by plants is ubiquitous and can take place from their above-ground (Mofikoya et al., 2019) and below-ground parts (Massalha et al., 2017). Many other VOCs are instead induced by abiotic (Loreto et al., 2006; Loreto and Schnitzler 2010) or biotic stresses (Dicke and Loreto, 2010). In this study, we identified terpenes (+)-3-Carene-, alpha-Pinene-, Camphene, Cymene, and Eucalyptol) that are directly communicators of abiotic stresses.

On other hand we detected aldehydes which mainly inhibit mycelial growth as is case with Butanal, 3-methyl. Benzaldehyde plays important roles in chemical communications serving as a sex, aggregation and alarm pheromone as well as a defense compound in some insects and non-insect arthropods, and as a pollinator attractant, flavor volatile and antifungal compound in plants (Huang et al., 2022). Benzaldehyde also contributes to the green and fresh odor (Qian et al., 2019). Some of aldehydes as nonanal, decanal represent volatile signaling compounds and insect pheromone (Conchou et al. 2019). One more interesting VOC is phenol, who is emitted mainly for protection against stress (Naikoo et al.2019). Compounded as Cyclotrisiloxane, hexamethyl; m-Menthane and Cyclotetrasiloxane, octamethyl- usually formed as a product of hydrogenation or hydrogenolysis of various terpenoids (Madji et al., 2019).

Conclusions

Terpenoids are natural chemicals that are found everywhere in the living world. Research has shown that all living things release volatile organic compounds (VOCs). In our study, we looked at VOC release in soil, which is very important for how plants interact with their environment (Erb and Kliebenstein, 2020). Plants can release VOCs from both their parts above the ground and below the ground. Many VOCs are also caused by non-living (abiotic) or living (biotic) stresses

In our research, we discovered terpenes such as (+)-3-Carene, alpha-Pinene, Camphene, Cymene, and Eucalyptol, which clearly demonstrate the impact of non-living stress factors. We also identified aldehydes like 3-methyl Butanal, which primarily inhibit the growth of fungal strands. Benzaldehyde plays a crucial role in chemical communication, serving as a signal for mating, gathering, and warning, as well as providing a protective scent. Future research should focus on detailed quantifications of volatile compounds to produce sensors for their fast and accurate detection in real-time.

Abstract

This study investigates the impact of Trichoderma spp. on the protein structure of tomato (Solanum lycopersicum L.) seeds using FTIR spectroscopy. Tomato seed dormancy, which often leads to germination failure, poses a significant challenge for production. Trichoderma, a beneficial fungus, enhances plant growth, stress resistance, and seed quality. By applying T. harzianum and T. brevicompactum to tomato seeds, we monitored changes in protein content and structure through the Amide I (1600-1700 cm^{-1}) and Amide II (1510-1575 cm^{-1}) regions of the FTIR spectra. Mathematical decomposition of these bands allowed us to differentiate between ordered and disordered protein structures, as well as various secondary structures such as α-helices, β-pleated sheets, and β turns. Our analysis revealed that Trichoderma treatments increased the proportions of α-helices and β-pleated sheets while reducing β turns. Additionally, the treatments led to higher proportions of disordered structures in the proteins. This study demonstrates the efficacy of mathematical decomposition in interpreting spectroscopic results and highlights the potential of Trichoderma spp. to improve tomato seed quality and performance.

Keywords: *mathematical deconvolution, FTIR, proteins structure, tomato seed.*

Introduction

Tomato (*Solanum lycopersicum L.*) is one of the most economically important vegetables worldwide. Due to its short development cycle, diverse secondary metabolites, and small genome size that is suitable for genetic manipulation and transformation, the tomato is frequently used as a model organism. However, seed dormancy often results in germination failure, posing a significant challenge for production.

Trichoderma spp. are cosmopolitan filamentous fungi that inhabit soil and the rhizosphere [1]. They are mostly opportunistic, avirulent plant symbionts, characterized by rapid multiplication and efficient substrate colonization [2]. They have several beneficial effects on plants, which are manifested in the stimulation of plant growth and tolerance to abiotic and biotic stress factors [3]. In addition to the acquisition of resistance to abiotic stress and the control of plant pathogens, the stimulation of plant growth is also associated with various mechanisms. These include increased uptake of nutrients, influence on metabolic processes, photosynthesis, and synthesis of phytohormones. This trait is specific to selected strains and cannot be applied to the entire species. Over the past decade, *Trichoderma spp.* has been recognized as an effective seed germination enhancer. Consequently, seed treatments with *Trichoderma* can improve seed quality and plant performance both in the short and long term.

However, the early interactions between seeds and *Trichoderma spp*. remain poorly understood.
Using the Amid I (1600-1700 cm^{-1}) and Amid II (1510-1575 cm^{-1}) regions in FTIR spectra, researchers can monitor changes in the protein content and structure of tomatoes treated with *Trichoderma*. Mathematical decomposition of these bands allows the differentiation between ordered and disordered protein structures, providing detailed information on how fungal treatments affect the protein structures in tomatoes. The use of mathematical models can significantly support and assist in the monitoring of various biological experiments.

Material and Methods

Fungal strain and growth condition

The strains utilized in this study, T. harzianum (T4) and T. brevicompactum (T9), were sourced from the A horizon (5–30 cm) of agricultural soil and deposited at the Faculty of Ecological Agriculture, Educons University, Serbia, and the Department of Microbiology, University of Szeged, Hungary. Initially, pure cultures of the two Trichoderma isolates were revived from a 20% glycerol solution stored at −20 °C and propagated in potato dextrose broth (PDB) medium at 25 °C in darkness. After four days, the Trichoderma isolates were transferred from the PDB medium to the center of 9 cm diameter Petri dishes containing Murashige and Skoog medium (MS). Additionally, 30 seeds were evenly distributed around the periphery of each Petri dish for each treatment condition.

Plant material and growth conditions

Two medium-late tomato cultivars, Gruzanski zlatni (GZ) and Narvik (N) were investigated. The seeds of these tomato varieties were obtained from the Institute for Vegetable Crops, Smederevska Palanka, Serbia. At the same time, germination and plant material collection were conducted at Educons University, Sremska Kamenica, Serbia.
Tomato seeds were sterilized in a 2% NaClO solution for 20 minutes and then washed with distilled water. The seeds were germinated in a Petri dish (Ø 15 cm) on 0.5x MS medium for 48 hours in the dark at 25 °C. Tomato seeds of GZ and N were co-cultured with two Trichoderma species. The impact of Trichoderma spp. on the germination process of the two tomato cultivars was investigated over 48 hours before direct physical contact between the Trichoderma and the tomato seeds was established.

Fourier-transform infrared spectroscopy (FTIR) measurements

The influence of Trichoderma spp. on the germination process of tomato seeds was conducted using an FTIR spectrophotometer (IRAffinity-1, Shimadzu, Japan). Radicles of tomato cultivars GZ and N grown under control conditions as well as in co-culture with, two most perspective strains, T. harzianum and T. brevicompactum were collected from MS media. Radicles (length ~ 4 mm) were dried for five days at 60°C, after which they were homogenized. From each treatment, 250 mg of dry material was collected. Sample analysis was conducted utilizing the KBr tablet technique [4] (1 mg of sample in 200 mg of KBr) encompassing a wavelength range of 4000-600 cm^{-1}, 100 scans per spectrum and a resolution of 4 cm^{-1}.

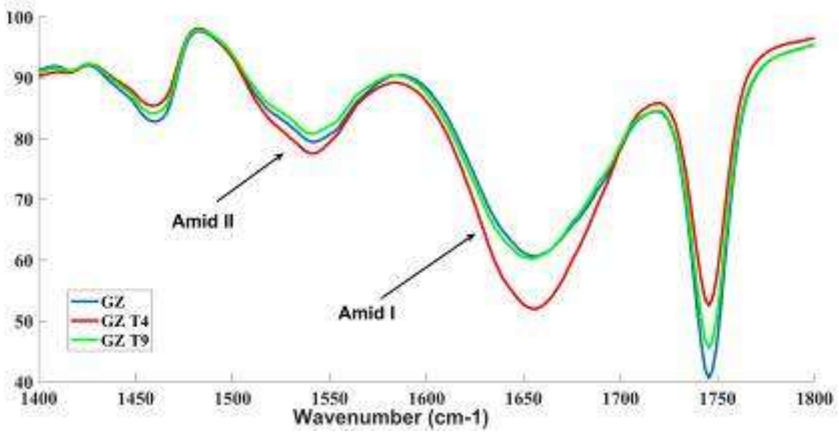
Mathematical deconvolution

All non-linear fittings were made using the Nelder–Mead simplex algorithm, performed in Matlab 6.5 [5]. The corresponding FTIR region was deconvoluted into four components for Amid II and three components for Amid I using the Gaussian model to obtain the optimal position and area for each component. To check their origin, the positions of all components were plotted as a function of the excitation wavelength. All spectra were normalized. The spectral components' areas obtained by deconvolution of normalized FTIR region for Amid I and Amid II region were determined.

Results and Discussion

The detection of differences in the structural organization or conformation of proteins in the radicles of tomato seeds was performed based on the parts of the spectrum where the deconvolution of the protein bands normalized to the unit area was performed. Obtain FTIR spectra for Gruzanski zlati (GZ) and Narvic (N) radicule are presented on Figure 1. An example of deconvolution, for the variety GZ, is given in Figure 2. Analysis was performed using a Gaussian deconvolution model, four-component for the Amide I band and three-component for the Amide II band using Matlab 6.5 (R2010a) software. The maxima positions of the components obtained by deconvolution of the Amide I band are assigned to the α-helix, β-pleated sheet, and turns, while the proportions of the ordered and unordered structure in proteins are obtained by deconvolution of the Amide II band [6-8]. The share of α helixes, β pleated sheets and turns in the protein structure was determined as the percentage share of the area of the components obtained by deconvolution and which correspond to these structures in the area of the entire Amide I band. The share of ordered and disordered structures in proteins was determined as the percentage share of the area of the corresponding components in the area of the Amide II band, with the band area taken as 100%.

Through deconvolution analysis of the Amid I protein band, which provides in-sights into the composition of various secondary structures within proteins, it was ascertained that in the presence of *T. harzianum* T4 and *T. brevicompactum* T9 treatments, there is a reduction in the proportion of twists and a simultaneously increase in the fractions of α-helixes and β pleated sheet. Notably, this effect is more pronounced in the GZ T4 sample compared to the GZ T9 (Figure 2A). The Amide II band is not so indicative of the share of types of secondary structure in the protein, but based on its deconvolution, the ratio of disordered and ordered structure, which includes all types of secondary structure, in plant proteins was estimated (Figure 2). The result shows that *T. harzianum* and *T. brevicompactum* do not change the ratio of ordered and disordered structure of proteins in seed radicle.



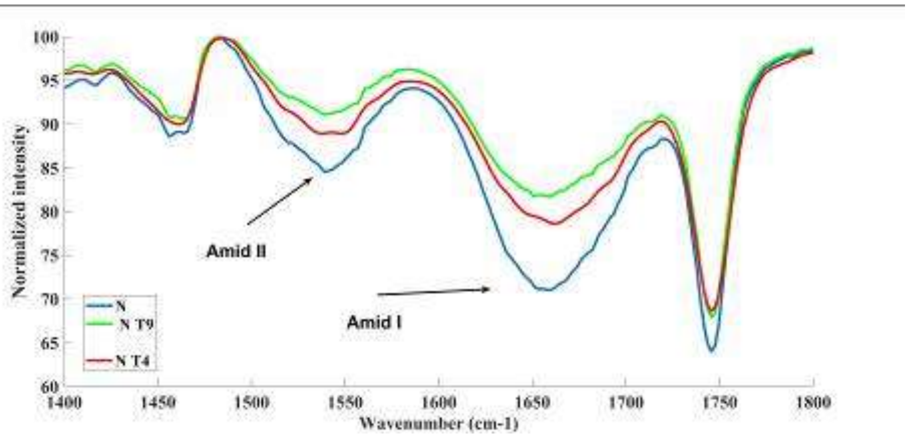


Figure 1 FTIR spectra of homogenized Gruzanski zlatni (A) and Narvik (B) radicles under different treatments: control (GZ, N), seeds treated with T. harzianum (GZ T4, N T4), seeds treated with T. brevicompactum (GZ T9,N T9)

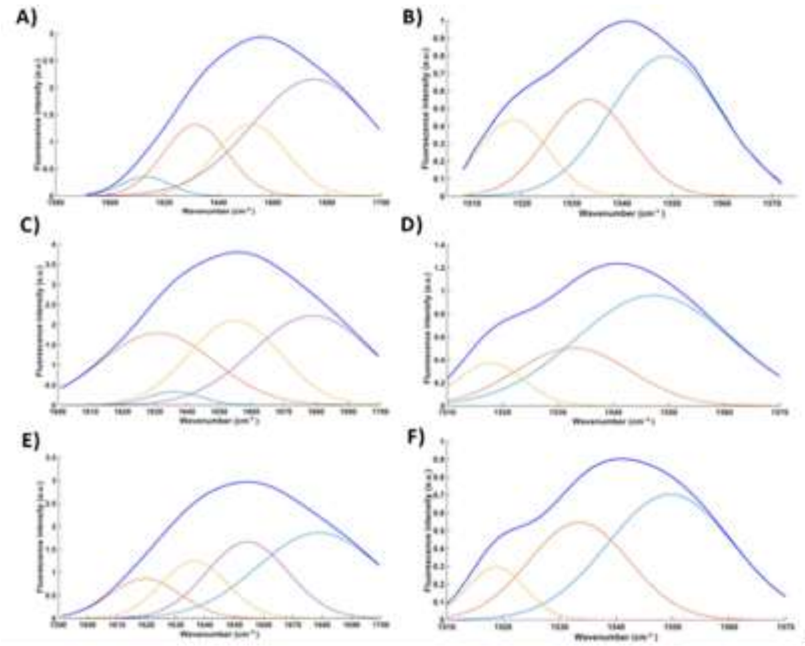

Figure 2. Examples of deconvolution of the Amide I band (A, C and E) and Amide II band (B, D and F) of the FTIR spectrum for tomato radicles: GZ control (A, B), GZ in co-culture with T. harzianum (C, D), GZ in co-culture with T. brevicompactum (E, F)

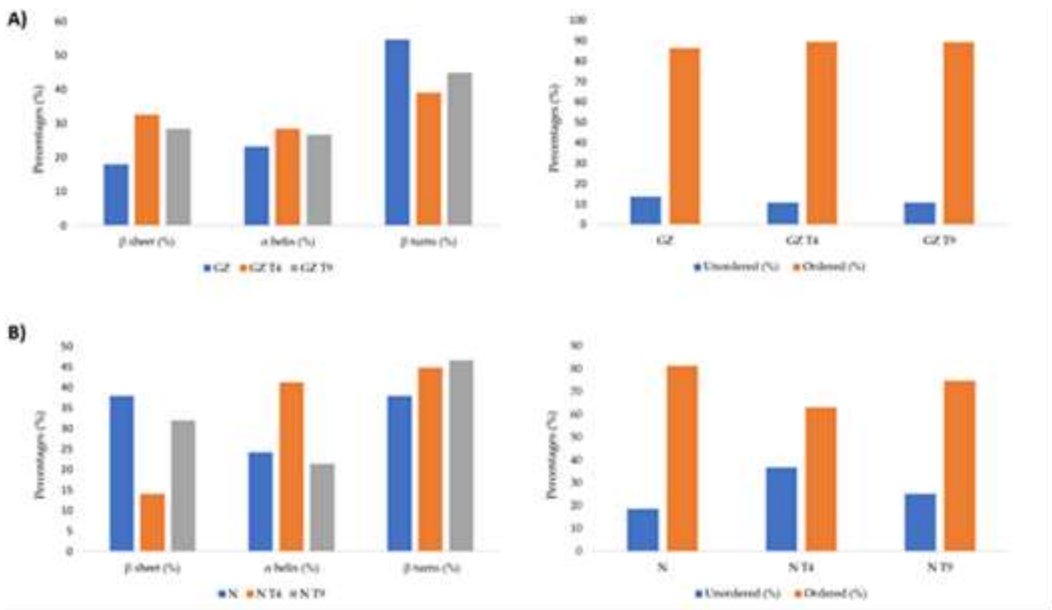

Figure 3. The proportional distribution of three distinct secondary structure types within seed radicles of GZ (A) and N (B), as determined through deconvolution of the FTIR band associated with Amide I (1600-1700 cm-1) (left column); The proportional distribution of ordered and disordered structure within seed radicles, as determined through deconvolution of the FTIR band associated with Amide II (1500-1580 cm-1) (right column).

Upon a comparative analysis of the spectra of GZ and N, distinct alterations in the protein structure are evident. Decomposition of the Amide I band (1600-1700 cm^{-1}) in N showed that both treatments resulted in an increased proportion of β turns compared to the control (Figure 3B). In the sample N T4, there is an observed increase in the proportion of α-helices, accompanied by a simultaneous reduction in β-pleated sheets, when compared to the control. Conversely, in the sample N T9, there is no significant alteration in the representation of these structural elements compared to the control group. Based on the Amide II band (1510-1575 cm^{-1}), the ratio of ordered to disordered structures was estimated. Compared to the control, the samples N T4 and N T9 have higher proportions of disordered structures in proteins compared to the ordered ones, which is more pronounced in the sample T4 (Figure 3).

Conclusion

Analysis using FTIR spectra, particularly the Amide I and Amide II bands, reveals that Trichoderma treatments lead to changes in protein secondary structures. Specifically, *T. harzianum* and *T. brevicompactum* treatments increase the proportions of α-helices and β-pleated sheets while reducing β turns. Although these treatments do not significantly alter the ratio of ordered to disordered protein structures in seed radicles, they do increase the proportion of disordered structures in other protein regions. These findings underscore the potential of *Trichoderma* spp. as an effective agents in improving tomato seed quality and plant performance.

Abstract

Drosophila suzukii is a globally invasive pest that mostly targets soft-skinned fruits by laying eggs in ripening fruit, which leads to tissue damage by larval feeding on pulp. This pest is particularly damaging due to its unique ability, to attack healthy, ripening fruit with serrated ovipositor. Current control methods heavily rely on application of synthetic insecticides. Due to risk of pesticide residues in fruit, there is a growing effort for finding alternative, environmentally sustainable, control strategies. This study aimed to assess the insecticidal impacts of *Pinus sibirica* (Siberian pine) essential oil on *D. suzukii* adults in contact toxicity in three concentrations (1, 5 and 10%). The mortality, differentiated by sex, was observed after a 24-hour exposure period. Experimental units were equipped with moist tissue and a medium for water and feed supply, while medium also served for monitoring females' egg-laying ability under stressful environment. For better understanding of its potential mode of action, the chemical composition of *P. sibirica* essential oil was analyzed using Gas chromatography coupled with mass spectrometry (GC-MS). In this study, Siberian pine essential oil resulted in 35% mortality at 1% concentration, while concentrations of 5% and 10% caused 100% mortality of *D. suzukii* adults. Females exhibited higher resistance to treatments compared to males. At a concentration of 1%, the number of emerged adults was lower compared to the control treatments. Considering all above stated, essential oils offer a promising alternative management tool to chemical insecticides in various agriculture systems.

Keywords: *bioinsecticide, ecofriendly, D. suzukii, essential oil.*

Introduction

Drosophila suzukii (Matsumura, 1931) or spotted wing drosophila (SWD) is an invasive, highly adaptable pest that infests soft-skinned fruits, targeting a wide variety of stone and berry crops (raspberries, blueberries, strawberries, blackberries, cherries, and grapes). It can also infest wild plants across diverse genera. Females have unique serrated ovipositor, which allows them to penetrate the skin of undamaged and ripening fruits to deposit eggs (Walsh, 2011; Lee et al., 2011). Symptoms of *D. suzukii* infestation include the appearance of soft spots, structural collapse of berries, wrinkling, color changes, increased sugar level, and skin softening. Damage results from both egg-laying and larval feeding on the fruit pulp, leading to premature decay and fruit collapse before harvest. Infested fruits are more susceptible to secondary infections by other pests and pathogens such as bacteria, fungi, and yeasts, which accelerates decay of the infested fruit (Tait et al., 2018; Kirschbaum et al., 2020). This pest can produce up to 13 generations annually, facilitating its rapid and uncontrolled spread (Walsh et al., 2011; Kirschbaum et al., 2020). The spotted wing drosophila has a broad

distribution in moderate climate regions (Rota-Stabelli et al., 2013). The first record of *D. suzukii* flies in Serbia occurred in 2014, at several localities (Toševski et al., 2014).
Current control measures for *D. suzukii* mostly depends on synthetic insecticides. Given the pest's rapid and frequent reproduction cycles during the growing season, multiple applications of these insecticides are required to prevent significant fruit loss (Van Timmeren and Isaacs, 2013). However, this frequent use promotes resistance development within *D. suzukii* populations and leaves chemical residues on fruits. Consequently, there is an urgent need for alternative management strategies that are compatible with both integrated and organic crop production. Current research focuses on natural product-based methods, particularly essential oils-based botanical insecticides (Bošković et al., 2023). Natural pesticides are considered as alternatives to synthetic ones, with the goal of reducing reliance on artificial chemicals and promoting more sustainable and environmentally friendly pest control methods. Botanical insecticides are natural compounds derived from plants or plant components. Essential oils are biodegradable, environmentally safer, and have minimal impact on beneficial organisms, leaving little to no residues on fruits. With diverse modes of action compared to synthetic insecticides, essential oils help prevent the development of resistant insect populations (Isman, 2020; Vuković and Šunjka, 2021). These compounds, which consist of a complex mixture of volatile chemicals, can function as fumigants, contact insecticides, and influence pest behavior by deterring oviposition, repelling, or even attracting pests (Dam et al., 2019). By implementing biological control strategies, such as introducing natural predators or parasitoids, using microbial agents, or applying botanical bioinsecticides, a sustainable and eco-friendly approach can be taken to manage *D. suzukii* populations and minimize crop damage (Poveda et al., 2020).
The objective of this study was to assess the insecticidal and behavioral impacts of *Pinus sibirica* Du Tour essential oil on adults of *D. suzukii* through contact toxicity bioassay in three different concentrations (1, 5 and 10%). Effects of essential oils were evaluated on male and female adult flies. The emergence of adults from treated berries was also monitored and sex of newly emerged flies was also recorded.

Material and methods

Rearing of *D. suzukii* colony: The experimental part was conducted in the Insectarium facility of CIHEAM Bari, Italy. Adults in the Insectarium of CIHEAM has been maintained in a climatic chamber in Plexiglas cages under controlled conditions (22 °C ± 1 °C; 62% ± 4%, 12:12 h light:dark) with artificial diet (Schlesener et al., 2017). The genetic diversity of the colony was enhanced annually by introducing wild-caught flies from infested fruits, in order to avoid inbreeding. For the bioassay, adult flies aged 4 to 7 days were used and organic healthy blueberry purchased from the supermarket were selected as experimental fruits due to their year-round availability.
Essential oil solution: The essential oil tested in the multiple-choice test was anise oil (*P. sibirica*), obtained from Nature in Bottle, New York, SAD (Avena Lab – Farmadria ©). The essential oil was diluted in pure acetone at concentrations of 1%, 5%, and 10%, with water (marked as Control 1) and acetone (marked as Control 2) serving as control treatments.
GC–MS Analysis of the essential oil composition: For the characterization of *P. sibirica* essential oil chemical composition, gas chromatography with mass spectrometry (GC–MS Shimadzu QP2010) was used under conditions: fused silica HP-5 column; carrier gas He (1.0 mL/min); temperature programmed from 55 °C to 240 ° C with a temperature increase of 3 ° C/min; injection port temperature 250 ° C; and detector temperature 280 ° C. The constituents were identified by comparing their retention indices and MS spectra with those in the

databases available in the licensed MassFinder 4 software (EssentialOil 4a and Adams2205 databases). Prior to GC-MS analysis, the essential oil sample was dissolved in n-hexane.
Contact toxicity bioassay: In the experiment transparent polystyrene containers with a volume of 50 mL were used as the experimental units. Essential oil solutions were applied to the bottoms and sides of the containers with a spray finger. A fine mesh cover was placed over an opening to prevent saturation with essential oil volatiles and escape of flies. Paper discs were placed at the container bottoms, and the sprayed surface was allowed to dry before introducing ten *D. suzukii* flies (5 males and 5 females) into each test container. Each concentration (1%, 5%, and 10%) of the essential oil was tested in four replicates, along with control treatments. Control containers were treated with water and acetone, then allowed to dry completely. The test containers were maintained under controlled conditions (22°C ± 2°C, 62% ± 4% RH, 12-hour light:dark cycle) in a climate chamber. Flies mortality, taking into account the sex of the dead flies, was recorded after a 24-hour exposure period (Bošković et al., 2023). Each container contained a small wet tissue and an amount of medium to provide water and food for the adult insects, as well as to observe the females' egg-laying behavior in a stressful environment, when exposed to essential oil treatment. The counting of newly hatched flies began ten days into the experiment and continued until three consecutive days without any new emergence observed. The sex of the newly emerged flies was also documented.
Statistical analysis of the data was conducted using the statistical software "Statistica" version 14.0.0.15 (Tibco Software Inc., Palo Alto, CA, USA, 2021) for one-way ANOVA. Duncan's multiple range test was employed to compare treatment differences, while the chi-square test was utilized to assess the statistical significance of male and female emergence.

Results and discussion

In this study, *P. sibirica* essential oil caused 35% mortality in a contact test at a concentration of 1%, while at concentrations of 5% and 10%, mortality was 100% (Table 1). Statistically significant differences ($p<0.05$) in mortality was observed for all three oil concentrations compared to both controls. Using Duncan's multiple range test, statistically significant differences were determined between the 1% and 5% concentrations and between the 1% and 10% concentrations. The number of dead males at the 1% concentration was 11, while the number of dead females was 3, indicating that females exhibited greater resistance to the treatment compared to males, which can be possible attributed to the different immune molecular responses.

Table 1. Mortality of adult flies in the contact bioassay

Concentration	Mortality ± SD (%)	F	M
Control 1	0^{a}	0	0
Control 2	0^{a}	0	0
1%	35^{b} ± 0,57	3	11
5%	100^{c}	20	20
10%	100^{c}	20	20

Pinus sibirica, has been poorly studied in the form of essential oil in biological tests for evaluating insecticidal effects, but its relative, *P. sylvestris* L., has been more extensively tested in biological assays using essential oils. The chemical composition of *P. sibirica* essential oil is very complex and largely depends on the plant part from which it is isolated (bark, trunk, needles) (Rogachev and Salakhutdinov, 2015). The most abundant compounds in the *P. sibirica* essential oil used in our study are *cis*-thujopsene, β-himachalene, and α-cedrol. The compound α-cedrol is also found in the essential oil of *Mosla soochowensis* Matsuda, which has been shown to exhibit fumigant and contact effects on two species of stored product pests, *Sitophilus zeamais* (Motschulsky, 1885) and *Tribolium castaneum* (Herbst, 1797) (Chen et al., 2017). In this research, Siberian pine essential oil demonstrated insecticidal contact effect at higher concentrations (5% and 10%) on the *D. suzukii* adults. The mechanism of action of botanical insecticides derived from essential oils is intricate and varies for each compound, often involving a synergistic interaction of multiple compounds at once. The specific components of essential oils play a vital role in determining their effectiveness against insects. Further research on the safety of botanical insecticides for non-target organisms is essential to ensure the practical application of plant essential oils, particularly in organic agriculture. Comprehensive studies are needed to assess the potential impact of these insecticides on beneficial insects, wildlife, and the environment as a whole. Understanding the broader implications of using botanical insecticides will help in developing sustainable and environmentally friendly pest management strategies in organic farming practices.

Conclusion

Siberian pine in this study has demonstrated significant efficacy against *D. suzukii* in laboratory experiments, that represent the first data on its effect on this pest. Essential oils, such as those from *P. sibirica*, offer several advantages as protective agents in agriculture. They are biodegradable, environmentally friendly, and exhibit multiple modes of action, which reduce the likelihood of pests developing resistance. Additionally, essential oils have minimal impact on beneficial organisms and leave little to no harmful residues on crops. Future research should focus on field trials to confirm the laboratory findings, investigate optimal application methods, and assess the long-term sustainability and economic feasibility of using essential oils in integrated pest management strategies. Given their chemical composition and insecticidal properties, *P. sibirica* essential oils has the potential to be a leading choice for biological control against *D. suzukii*.

Abstract

The causal agent of grey mold, *Botrytis cinerea*, attacks a wide range of crop species worldwide and leads to great economic losses. In fruits and vegetables, it causes pre- and post-harvest decay, reducing the quality and market value of the product. Controlling *B. cinerea* is challenging, due to its diverse modes of attack, numerous host plants, and ability to survive in various forms, including mycelia, conidia, and sclerotia for long periods. The current management strategy includes spraying fungicides during the flowering and fruiting stages. Intensive pesticide use leads to the development of resistance in target organisms, which makes it difficult to control. With the negative impact that conventional pesticides have on human health and the environment, it is necessary to implement alternative and eco-friendly methods against this pathogen. Essential oils are widely recognized for their antifungal effects, garnering significant interest among researchers nowadays. This study aimed to compare the inhibitory effects of star anise (*Illicium verum* L.), laurel (*Laurus nobilis* L.), and parsley (*Petroselinum sativum* Hoffm) essential oils on *B. cinerea in vitro*. Mycelial growth inhibition was assessed using a fumigation bioassay, with three replicates per essential oil. Star anise essential oil showed the highest efficacy, resulting in complete inhibition (100%) of *B. cinerea* mycelial growth. The efficacy of laurel and parsley essential oils decreased over seven days. The study showed that star anise essential oil has the potential to act as a biocontrol agent against *B. cinerea*.

Keywords: *Botrytis cinerea, essential oils, fumigation bioassay, eco-friendly, biocontrol.*

Introduction

Phytopathogenic fungi represent one of the major challenges in plant production. They lead to reduced crop yields and quality, resulting in significant losses in agricultural production. Synthetic fungicides are the main method for controlling fungal diseases. However, their irregular and excessive use increases concerns about residues in the environment, negative impact on human and animal health and developing resistance to pesticides prompting a search for alternatives. Essential oils are attracting growing interest due to their relative safety to nature and humans, worldwide production, and demonstrated antimicrobial and antifungal properties (Mohammadi et al., 2013). They are volatile liquids obtained from various parts of aromatic plants. These secondary metabolites protect plants from pests and diseases (Hanif et al., 2019). Essential oils often have a complex chemical composition, consisting of mono- and sesquiterpenes, aldehydes, ketones and phenols (Isman et al., 2011). They exhibit antifungal properties by inducing critical physiological and metabolic disruptions, leading to decreased mycelial growth and spore germination (Fincheira et al., 2023). They are lipophilic which leads to their rapid diffusion through the fungal cell wall and cytoplasmic membrane (Andrade-Ochoa et al., 2021). Affecting the leakage of ions such as K^+, Ca^{2+}, and Mg^{2+}, essential oils disrupt the integrity of the cell plasma membrane (Fincheira et al., 2023). Furthermore, they can interact with mitochondria, influencing membrane potential, proton pumps, and ATP synthase, thereby disturbing cellular pH and the electrochemical gradient across the plasma membrane (Maurya et al., 2021). However, research on essential oils for controlling phytopathogenic fungi primarily focuses on their ability to inhibit growth, with the mechanisms of action remaining unclear (Fincheira et al., 2023). *Botrytis cinerea* (teleomorph: *Botryotinia fuckeliana*) is a fungus from the class *Ascomycota* that causes gray mold disease in many plant species. It is found worldwide and can infect nearly every plant and plant part. This highly destructive pathogen can live both pathogenically and saprophytically, and can adapt to various environmental conditions, which significantly complicate its control in agriculture (Cheung et al., 2020; Rosslenbroich et al., 2000). It can remain in the latent phase and occur in the fruits in storage, where the infection can rapidly spread to adjacent fruits, leading to a subsequent rise in product loss (Álvarez-García et al., 2023). In the Republic of Serbia, fungicides based on 13 active ingredients are currently registered for controlling *B. cinerea* in various plant species. These active substances include boscalid, cyprodinil, dimoxystrobin, fludioxonil, fluopyram, fenhexamid, isofetamid, penthiopyrad, prothioconazole, pyraclostrobin, pyrimethanil, tebuconazole and trifloxystrobin, with specific usage varying depending on the plant species. Additionally, biopesticides based on *Bacillus subtilis*, *Bacillus amiloliquefaciens*, *Pythium oligandrum*, eugenol, geraniol, tea tree oil, thymol and sodium hydrogen carbonate are also registered (Group of authors, 2022). A challenging aspect in controlling *B. cinerea* is the lack of fungicides with short pre-harvest intervals, as well as the development of resistance to existing fungicides. *B. cinerea* is categorized among high-risk pathogens prone to developing resistance to conventional fungicides (Rosslenbroich et al., 2000). It has been extensively researched regarding the antifungal properties of vapor-phase essential oils, both in *in vitro* and *in vivo* (Fincheira et al., 2023). This research focused on assessing and comparing the effectiveness of essential oils from star anise (*Illicium verum* L.), laurel (*Laurus nobilis* L.), and parsley (*Petroselinum sativum* Hoffm) in inhibiting the growth of *B. cinerea* in a controlled laboratory conditions.

Materials and Methods

The experiment was carried out in 2024 in laboratory conditions. Three commercially available essential oils were tested to determine their vapor-phase antifungal activity against *B. cinerea*: star anise (*Illicium verum* L.), laurel (*Laurus nobilis* L.) and parsley (*Petroselinum sativum* Hoffm). *B. cinerea*, which is part of the permanent collection of microbiological cultures at the Laboratory for Biological Research and Pesticides, Faculty of Agriculture, University of Novi Sad in Serbia, was inoculated on potato dextrose agar (PDA) and kept at 23 °C for seven days. Mycelial growth inhibition was tested using a fumigation bioassay, with three replicates per essential oil. In each Petri dish, a mycelium slice of *B. cinerea* (5 mm) was placed onto the prepared PDA medium. Fifteen microliters of each essential oil were added to the inverted lid of the Petri dish, and then it was covered with the bottom part containing the mycelium. A sterile distilled water is placed on the lid of the control variant. The Petri dishes were sealed with parafilm and incubated in a thermostat at 23 °C for seven days (Figure 1).

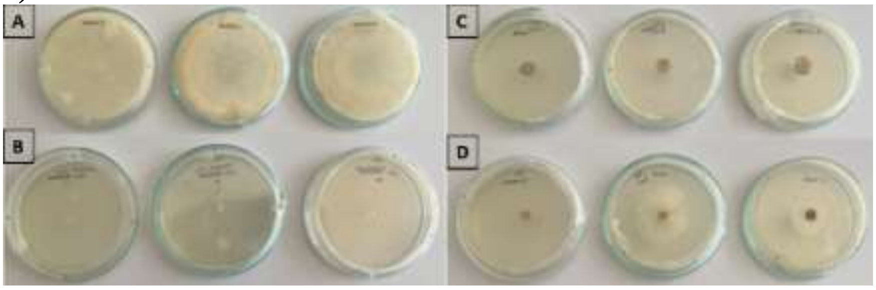

Figure 1. Petri dishes after seven days: A – control, B – star anise, C – parsley, D – laurel

Results and Discussion

The fungal growth was assessed daily for one week, measuring from the edge of the agar inoculum plugs. The mean value of *B. cinerea* mycelial growth of each treatment is given in Table 1.

Table 1. The mycelial growth of B. cinerea

Treatment	Mycelial growth (mm)						
	1st d	2nd d	3rd d	4th d	5th d	6th d	7th d
Control	11 ±2.94	35.67 ±0.47	55 ±1.63	79 ±1.41	82.33 ±2.05	82.67 ±2.05	85±0
EO of *I. verum*	0	0	0	0	0	0	0
EO of *L. nobilis*	0	0	0.67 ±0.94	3.67 ±2.36	7.33 ±3.30	15.67 ±8.99	18.67 ±8.96
EO of *P. sativum*	0	0	1.67 ±0.47	5.67 ±0.94	8.67 ±1.70	9±1.41	10.33 ±0.94

Using the data from Table 1, the daily efficacy of each essential oil was calculated by applying the following formula:

$$E, \% = \frac{\text{mean colony diameter of control sets} - \text{mean colony diameter of treatment sets}}{\text{mean colony diameter of control sets}} \times 100.$$

The efficacy of each essential oil is presented in Figure 2.

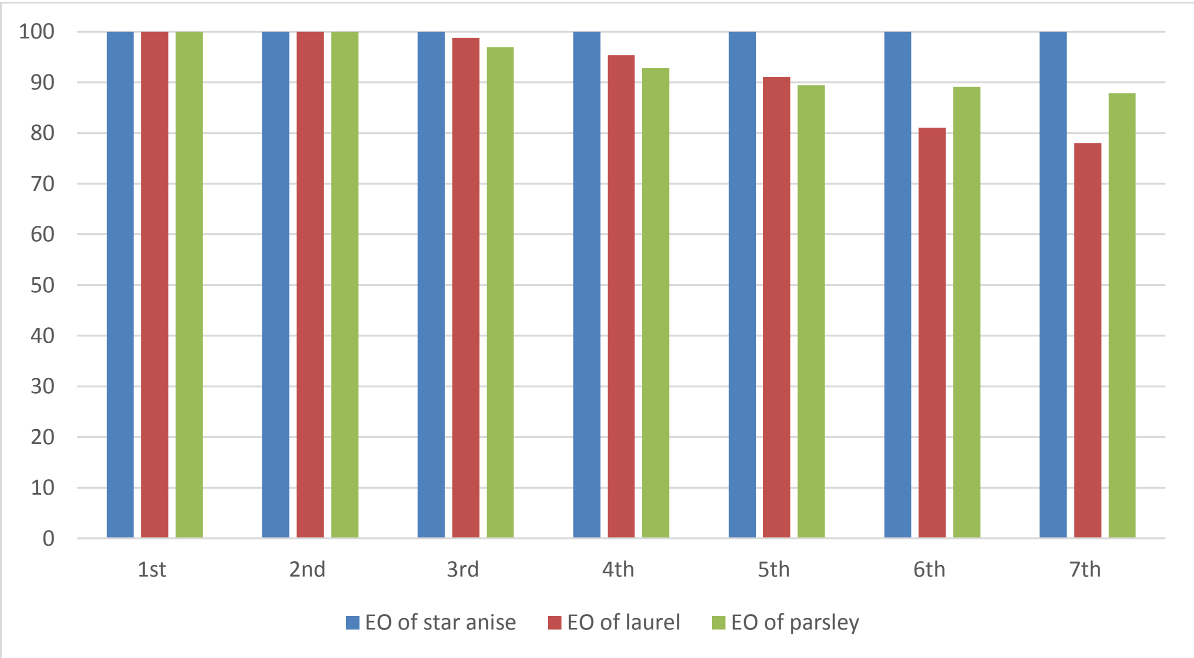

Figure 2. Efficacy (%) of essential oils against *B. cinerea* by days

This study indicates that analyzed essential oils have an inhibitory effect on the mycelial growth of *B. cinerea*. Among three tested essential oils, *I. verum* showed strong antifungal activity (100%) which was maintained throughout the seven days. The efficacy of laurel and parsley essential oils was 100% in the first two days, afterward gradually decreasing over

time. Parsley demonstrated better efficacy at the end of the seventh day (87.85%). The decrease in efficacy could be due to the fast volatility of parsley and laurel essential oils.
Several studies have tested the antifungal effect of star anise essential oil and obtained similar results. Lee et al. (2007) showed that this essential oil inhibits the mycelial growth of *B. cinerea* by about 90%. Huang et al. (2010) conducted experiments to evaluate the antifungal activity of star anise essential oil against several plant pathogenic fungi such as *Alternaria solani*, *Bipolaris maydis*, *Fusarium graminearum*, *Fusarium oxysporum* f. sp. *cucumerinum*, *Fusarium oxysporum* f. sp. *lycopersici*, *Pythium aphanidermatum*, *Rhizoctonia solani* etc. Their findings indicated a potent inhibitory effect against all tested fungi, suggesting that the presence of trans-anethole in the oil contributed significantly to its observed antifungal properties. Using gas chromatography-mass spectrometry, Lee et al. (2007) determined that *trans*-anethole is the main antifungal constituent of *I. verum* essential oil.
The fungicidal activity of the essential oil of *L. nobilis* was analyzed by De Corato et al. (2010). The authors investigated the inhibition of *B. cinerea*, *Monillinia laxa* and *Penicillium digitatum* mycelial growth depending on the applied concentration (200, 400, 600, 800 and 1000 µg/mL). *M. laxa* was completely inhibited by the oil at the lowest concentration, while *B. cinerea* was fully inhibited at the concentration of 1000 µg/mL. *P. digitatum*, was only partially inhibited across all concentration levels. Additionally, the authors examined the composition of the essential oil by gas chromatography analysis. Laurel essential oil was found to have a high content (over 10%) of 1.8-cineole, linalool, terpineol acetate, and methyl eugenol, and a low content (under 10%) of linalyl acetate, eugenol, sabinene, b-pinene, and a-terpineol.
Pineda et al. (2018) examined the effect of the essential oil of parsley against Collectotrichum acutatum, by the poisoned agar method. Results showed that essential oil significantly inhibits the radial growth of C. acutatum at concentrations higher than 100 µg/mL. Analysis by gas chromatography with mass spectroscopy (GC-MS) showed that the major components are phenylpropanoids myristicin (18.7%), parsley-apiole (27.6%) and 1,3,8-p-menthatriene (11.2%).

Conclusion

Nowadays, the focus in controlling postharvest diseases is towards more sustainable strategies. This can involve the use of various biological agents for plant protection, among which are essential oils. This study concludes that the essential oil of star anise exhibits significant antifungal properties and has the potential to be utilized as a natural fungicide to manage disease caused by *B. cinerea*. Due to the instability of essential oils in the environment, it is necessary to work to improve their persistence.

Abstract

Raspberry is a perennial deciduous plant, bushy or semi-shrubby, with annual and long biennial shoots, which belongs to the rose family. For many years, raspberries have been among the most economically important types of fruit in the Republic of Serbia. So far, there have been no systematic researches on raspberry mycopopulation in Serbia. In this paper, we present the results of preliminary research on raspberry mycopopulation originating from Serbia. A total of 28 randomly collected samples from three locations in Serbia were analyzed. Root and stem were analyzed. Plant fragments were carefully washed under running water. The samples thus prepared were disinfected with 1% sodium hypochlorite (NaOCl) for 1 minute and washed three times in sterile distilled water. They were then dried on sterile filter paper and placed on potato dextrose agar (KDA). In each Petri dish, five fragments taken per sample were placed in five repetitions, and incubated in a thermostat at 24°C. The examination was performed every three days, and on most samples mycelia developed around the plant fragment by the 14th day. Microscopic examination was performed using an Olympus CX31 microscope. The frequency of isolation was calculated in % according to the formula: number of colonized parts with fungi/total number of analyzed plant parts x 100. A total of 700 plant fragments were examined, from which six genera of fungi were isolated: *Didymella, Fusarium, Rhizoctonia, Verticillium, Alternaria* and *Epicoccum.*

Key words: *Frequency of isolation, mycopopulation, raspberry*

Introduction

Raspberry is a perennial deciduous plant, with bushy or semi-shrub growth, with annual and long biennial shoots, which belongs to the Rosaceae family. For many years, raspberries have been among the most economically important fruit species in the Republic of Serbia (Leposavić, 2023). The world production of raspberries in 2019 was 684,000 tons (Petrović *et al*., 2020; Leposavić, 2023). On the European continent, Russia, Poland, Serbia and Spain are the biggest producers. However, the largest commodity production is realized in Serbia, because more than 95% of processed and fresh raspberry fruits are placed on the world market.

The most common causes of raspberry diseases are phytopathogenic fungi, bacteria and viruses. Due to the characteristic habitus of plants and intense vegetative growth, microclimatic conditions are created in raspberry plantations that favor the development of pathogens and the emergence of infections. Phytopathogenic fungi represent a very numerous and economically harmful group of pathogens on raspberries. The most economically important fungal diseases on raspberry are: *Didymella applanata* (Niessl.) Sacc. – spur blight; *Elsinoe veneta* (Burkh.) Jenkins – anthracnose (cane spot); *Phragmidium rubi-idaei* de Candolle P. Karsten – raspberry rust; *Paraconiothyrium fuckelii* (Saccardo) Verkley &

Gruyter – raspberry blight; *Phytophthora rubi* Man in’t Veld – raspberry root rot; *Podosphaera macularis* (Wallroth) Braun & Takamatsu – powdery mildew; *Verticillium dahliae* Klebahn and *Verticillium albo-atrum* Reinke & Berthold – verticillium wilt; *Botrytis cinerea* Pers. Fr. (teleomorph *Botryotinia fuckeliana* (de Bary) Whetzel) – raspberry gray mold (Hai and Sutton, 1997; Munro *et al.,* 1988; Williamson, 2003; Williamson *et al.,* 2007; Mirković *et al.,* 2015). Among the bacterial disease-causing agents of raspberry, the most important are: *Agrobacterium tumefaciens* (Smith & Townsend) Conn – crown gall disease, *Pseudomonas syringae* pv. *syringae* van Hall. – pseudomonas blight disease and *Erwinia amylovora* (Burrill) Winslow, Broadhurst, Buchanan, Krumwiede, Rogers & Smith – fire blight (Braun and Hildebrand, 2006; Ivanović *et al.,* 2012). More than 30 viruses that can infect raspberries have been described in the world literature. Viral diseases occur everywhere where raspberries are grown. Economically the most important some viruses of raspberries are: black raspberry necrosis virus, BRNV; Raspberry leaf mottle virus, RLMV; Rubus yellow net virus, RYNV; raspberry bushy dwarf virus, RBDV; raspberry leaf blotch virus, RLBV and others (Jevremović and Paunović, 2011; Jevremović *et al*., 2016; Jevremović *et al*., 2019).

Considering the great importance of raspberry as a fruit species, especially for less developed hilly and mountainous areas in Serbia, the aim of this work was the isolation and morphological determination of mycopopulation on raspberry in order to better understand the problems in raspberry production (extinction of plants and reduction of yield) as a consequence of the presence of phytopathogenic fungi. Despite the intensive effort to find alternative solutions for controlling phytopathogenic fungi on raspberry, chemical protection is the dominant method. However, the application of chemical measures is difficult. The biggest problem is the timing of fungicide application, because flowering and raspberry harvest often overlap, and the presence of pesticide residues in fruits can be a problem. Also, the significant problem is the fact that a small number of fungicides are registered for the control of phytopathogenic fungi on raspberries.

Materials and methods

The samples were collected from 2019 to 2022 in the period June - August. A total of 28 samples from three localities in Serbia were analyzed (Čačak 8, Ivanjica 10, and Arilje 10). The experiment was conducted in the phytopathological laboratory of the Faculty of Agriculture in Kruševac, University of Niš. The plant parts were carefully washed under running water. After washing, parts of the stem and roots were cut into pieces measuring 0.5–1 cm. The samples thus prepared were disinfected with 96% ethanol for 30 seconds, 1% sodium hypochlorite (NaOCl) for 1 min and washed three times in sterile distilled water. They were then dried on sterile filter paper and placed on potato dextrose agar (PDA) with streptomycin. In each Petri dish, 5 plant parts were placed, in five repetitions. They were kept in a thermostat at 24°C and a light regime of 12 hours day/12 hours night. Examination was performed every 3 days, and on most samples, mycelia developed up to two weeks. The developed mycelia were screened on a new PDA substrate and, after the initial growth, the top part of the mycelium was screened again on PDA. Microscopic examination was performed using an Olympus CX31 microscope. Morphological identification of fungi was performed using standard keys (Dhingra and Sinclair, 1995). The frequency of isolation in % was calculated according to the formula (Vrandečić *et al*., 2011):

$$(\%)\ \text{Isolation frequency} = \frac{\text{Number of segments containing the fungal species}}{\text{Total number of segments used in the isolation}} \times 100$$

Results and discussion

A total of 700 plant parts were examined, from which 6 genera of fungi were isolated: *Didymella, Fusarium, Rhizoctonia, Verticillium, Alternaria* and *Epicoccum* (Table 1). Macroscopic symptoms of infection were clearly visible on the plants from which the fungi were isolated. On all plants from which the fungi were isolated, clearly expressed symptoms on the stems in the form of necrotic spots and lesions were observed. From those plants *Alternaria* fungi were isolated. In plants where purple-brown necrosis was observed on the stems, in the lower third of the stem, the fungi from the genus *Didymella* were isolated. Fungi from the genera *Fusarium* and *Rhizoctonia* were isolated from the plants with symptoms in the form of light to dark brown necrosis on the root system. Discoloration of the conducting tissue was also observed in some plants on the root system, and fungi from the genus *Verticillium* were isolated from those plants.

Table 1. Frequency of fungal isolation on raspberry

Location	Number of samples Plant part	Fungi species	(%) Isolation frequency
Čačak 1	25	*Alternaria* sp., *Fusarium* sp., *Didymella* sp., *Verticillium* sp.	15, 10, 25, 10

D. applanata is widespread in all raspberry growing regions in Europe, America, Africa, Asia and Australia (Mirković, 2018). In the Fraser Valley, British Columbia in the 1930s, several phytopathogenic fungi were isolated from infected raspberry plants: *Leptosphaeria coniothyrium* (*Coniothyrium fuckelii*), *Ilyonectria destructans* (*Cylindrocarpon radicicola*), *Fusarium* spp., *Cylindrocladium* spp., *Pythium* spp., *R. solani*, *Rhizoctonia* spp. After artificial inoculations of healthy raspberry plants, obtained with fungal isolates, it was determined that all isolated species can cause necrosis on the roots of healthy plants (Berkeley, 1936). Raspberries are the third most popular berry in the United States and a growing specialty crop for both the wholesale industry. Postharvest susceptibility to gray mold (*B. cinerea*) drastically reduces the shelf life of this delicate fruit (Hai and Sutton, 1997; Williamson, 2003; Williamson *et al.*, 2007; Harshman *et al*., 2014). *D. applanata* causes spur blight of raspberry was isolated from canes of diseased raspberries in a plantation in Novosibirsk, Russia (Shternshis *et al.,* 2006). *Alternaria tenuissima* has been reported on raspberries in China, in 2014 and 2015, as a leaf spot disease was observed on cultivated raspberry. The disease incidence averaged approximately 75%. Some small, circular, light brown spots appeared on the leaves in the early stage of disease development. The spots gradually enlarged and became round or irregular, dark brown, and developed concentric rings with dark brown margins normally surrounded by light yellow halos measuring 0.5 to 4.0 mm. Finally, the necrotic spots often coalesced to large blights of 11.0 to 15.0 mm. Severely infected leaves aged early and some fell off (Cong *et al.,* 2016). Raspberry cane disease is caused by various phytopathogenic fungi, including *Fusarium avenaceum* (Fusarium wilt), *D. applanata* (spur blight), *L. coniothyrium* (cane blight) and *B. cinerea* (cane *Botrytis*) with *F. avenaceum* being the major cause of cane diseases in Northern

Germany (Girichev *et al.,* 2018). Soilborne pathogens are a major concern to red raspberry and strawberry producers throughout the Pacific Northwest. Red stele, caused by *Phytophthora fragariae* var. *fragariae*, and raspberry root rot, caused by *P. fragariae* var. *rubi*, can cause serious economic losses in cool, wet production areas (Pinkerton *et al*., 2002). Soilborne fungal pathogens (such as *Phytophthora* spp., *Verticillium* spp., *Rhizoctonia* spp., *Pythium* spp. and *Fusarium* spp.), lesion nematode (*Pratylenchus penetrans*) and weeds are common pests of Mexican strawberry and raspberry nurseries. Phytophthora root rot caused by *P. fragariae* var. *rubi* is the most serious root disease of red raspberries in many growing regions Mexico. Raspberry roots are also very sensitive to excessive moisture and lack of oxygen in the soil for extended periods of time. These conditions cause decay and root death. Best roots are produced in non-infested soils with good drainage (Lopez-Aranda *et al.,* 2016).

Conclusion

Growing raspberries is a very important and economically significant activity in Serbia. One of the most important factors that limits the profitability of raspberry cultivation are phytopathogenic fungi, the cause of economically important diseases. In rainy and humid conditions, diseases develop more intensively, and yields in the following year may be significantly reduced. The use of pesticides, i.e., fungicides, is the dominant method for phytopathogenic fungi control in raspberries. The reason why raspberry protection is based on the use of fungicides is the lack of raspberry varieties that show tolerance to economically significant disease agents. Such as *Didymella, Rhizoctonia, Verticillium, Phytophthora* and *Botrytis*. However, the implementation of these measures is difficult. The biggest problem is the limited time of pesticide application because the flowering and harvesting of raspberries can take a very long time, over 60 days. As a problem in the chemical protection of raspberries, a fairly poor range of fungicides is cited as a result of chemical companies' lack of interest in registering new active substances and formulations because the market is small and the registration of preparations is expensive. However, the application of chemical agents to protect raspberries from pathogenic fungi is the only measure that is necessary for profitable production. Without the application of all other available measures, primarily agrotechnical and mechanical, their full effect will be absent.

Abstract

Alfalfa (*Medicago sativa* L.) occurs in nature as a cultivated and wild species. As one of the oldest and most important perennial forage crops, alfalfa has the potential to produce large amounts of high-quality forage. This paper presents the preliminary results of the population study of phytopathogenic fungi on alfalfa. A total of 625 samples of alfalfa plants were collected between 2002 and 2019 in Serbia from 17 locations. Standard phytopathological isolation was performed from the transition of healthy to diseased tissue on potato dextrose agar (PDA) with streptomycin. After incubation at 22°C and a light regime of 12 hours day/12 hours night, the obtained cultures were examined microscopically and the morphological identification of fungi to the genus level was carried out using standard keys. Checking the pathogenicity of the obtained isolates was done through artificial inoculation with damage to plant parts. Inoculation was performed with 7-day-old fungi isolates, and the inoculated plants were stored at a temperature of 20 to 25°C. Based on the morphological and pathogenic characteristics of the obtained isolates, it was determined that alfalfa pathogens were dominant in Serbia *Colletotrichum*, *Fusarium, Verticillium, Rhizoctonia, Sclerotinia* and *Phoma*. As the causative agents of alfalfa diseases are not sufficiently studied in Serbia, the conducted research represents a significant contribution to defining the role of phytopathogenic fungi in the symptoms they cause on alfalfa, all with the aim of contributing to finding adequate measures for their successful suppression.

Key words: *alfalfa, phytopathogenic fungi.*

Introduction

The genus *Medicago* has more than 60 species, of which about 70% are annuals. Among the field plants for feeding cattle, alfalfa has the most important place, so many call it the "queen of fodder plants". After destroying the areas under alfalfa, large amounts of nitrogen and organic matter remain in the soil, the decomposition and mineralization of which improve the physical, chemical, and microbiological properties of the soil (Đukić *et al*., 2009).
At least 62 parasitic fungi that cause alfalfa diseases have been described in the world, of which only 19 types of disease-causing fungi have been described in our country. According to the part of the plant that primarily endangers, parasites on alfalfa are classified as those that inhabit the above-ground parts of alfalfa with the manifestation of symptoms on the leaves and stems, and parasites that inhabit the ground part of the tree, the crown, and the root (Balaž and Popović, 2005; Vasić, 2013). The most widespread and harmful parasitic fungi that threaten alfalfa are: *Colletotrichum trifolii*, *C. destructivum*, *C. truncatum* and *C. dematium* – causes of anthracnose; *Pseudopeziza medicaginis* and *Stemphylium botryosum* – causes of alfalfa leaf spotting; *Peronospora trifoliorum* – the causative agent of alfalfa blight, *Uromyces striatus* – the causative agent of alfalfa rust, *Cercospora medicaginis* – the cause of leaf

spotting; *Leptotrochila medicaginis* – the cause of yellowing of alfalfa leaves; *Fusarium oxysporum* f. sp. *medicaginis*, *Verticillium albo-atrum* and *V. dahliae* – causes of wilting of alfalfa; *Rhizoctonia solani*, *Sclerotinia trifoliorum* and *S. rolfsii* – causative agents of root and ground rot (Mackie *et al*., 2003; Ivanović, 2005; Krnjaja *et al*., 2005a; Vasić, 2007; Vasić *et al*., 2010; Vasić *et al.,* 2011a, 2011b; Vasić, 2013). In addition to the aforementioned pathogenic fungi, alfalfa root and crown rot is caused by *Phytophthora megasperma*, *Phoma medicaginis* – the cause of the blackness of the tree and leaf spotting of alfalfa, as well as species from the genus *Pythium* – the cause of seedling blight and rotting of alfalfa seeds. The most commonly isolated *Fusarium* species that cause root rot and root neck are *F. oxysporum*, *F. solani* – the causes of fusarium wilt of alfalfa (Stuteville and Erwin, 1990; Krnjaja *et al*., 2005a; Krnjaja, 2005b). In addition to fungi, bacteria also cause significant damage to alfalfa production, including *Pseudomonas syringae* pv. *syringae* – the cause of bacterial stem spotting; *Pseudomonas marginalis* pv. *alfalfae* – the cause of bacterial root rot; *Clavibacter michiganensis* susp. *insidiosum* – the cause of bacterial wilt; *Xanthomonas campestris* pv. *alfalfae* – the cause of bacterial leaf spot and others (Stuteville and Erwi1990; Arsenijević, 1997; Balaž and Popović, 2005). Numerous phytopathogenic viruses that cause diseases have been described on alfalfa, such as Alfalfa mosaic virus, AMV; Cucumber mosaic virus, CMV; Clover yellow mosaic virus, CYMV and others (Stuteville and Erwin, 1990; Šutić, 1995; Jasnić, 2005). Damages resulting from the presence and development of pathogenic agents are expressed through a reduction in the quantity and quality of green mass from 10 to even 70% depending on the alfalfa variety, pathogen type, climatic and edaphic conditions. Reduction of the assimilation surface, falling of leaves, immaturity of seeds, the presence of harmful pathogen metabolites are also consequences of the presence of pathogens on alfalfa leaves. Diseases of the crown and roots cause a weakening of the plant's vitality, an increase in sensitivity to frost, premature decay, an increase in weediness, and thus a decrease in hay quality (Vasić, 2013). During a longer period of monitoring (2002-2019), it was determined that in some locations in Serbia there were large losses in alfalfa fields, with typical symptoms of root rot, necrosis, chlorosis and wilting of alfalfa plants. The phytopathogenic fungi affecting alfalfa have not been extensively studied in Serbia. Therefore, a research initiative was undertaken to identify and characterize the fungal species responsible for alfalfa diseases. The objective of this study is to contribute to the development of effective management strategies for the successful control of these fungal pathogens.

Materials and Methods

The isolates analyzed in this study were obtained from diseased alfalfa plants collected over the period from 2002 to 2019. The collection of samples was carried out in the main production areas of alfalfa in the territory of the Republic of Serbia, including a total of 17 localities: Čurug, Ašanja (Southern Bačka District), Srpska Crnja, Farkaždin (Southern Banat District), Trnavci (Nišava District), Vraneši (Raška District), Banatsko Karađorđevo, Aleksandrovo (Middle Banat District), Banovci (Srem District), Markovac (Danube District), Selo Varvarin, Kobilje, Globoder, Bela Voda (Rasina District), Kloka (Šumadija District), Davidovac (Pčinj District) and Dobrichevo (Pomeranian District). During field sample collection, plants exhibiting symptoms of chlorosis, necrosis, rot, and withered tops were selected. In total, 625 samples were collected for analysis. The pathogen was isolated from the stem and roots of alfalfa. After bringing the samples to the laboratory, the samples were first washed with running water, and after washing, parts of the stem and roots were cut into pieces measuring 0.5-1 cm. The samples thus prepared were disinfected with 96% ethanol for 10 seconds, 1% sodium hypochlorite (NaOCl) for 1 min. and washed three times in sterile distilled water. They were then dried on sterile filter paper and placed on potato dextrose agar

(PDA) with streptomycin. In each Petri dish, five plant parts were placed, in two repetitions. They were kept in a thermostat at 22°C and a light regime of 12 hours day/12 hours night. The developed mycelia were transplanted onto a new PDA medium (Dhingra and Sinclair, 1995). A microscopic examination was performed using an Olympus CX31 microscope. Morphological identification of fungi to genus was performed using standard keys.
In order to determine the pathogenic properties of selected isolates obtained from infected alfalfa plants, a pathogenicity test was performed by inoculating injured alfalfa plants (Vasić, 2007). Before inoculation, all plants were wounded at the base of the stem with a sterile spear needle. In this way, the injured plants were inoculated by placing small fragments of the colony of studied isolates in the wounds. Inoculation was performed with isolates of the obtained mushrooms, 7 days old, grown on PDA medium. Plants inoculated in this way were stored at a temperature of 20-25°C. The experiment was set up in two replicates with five plants per isolate. Alfalfa plants that were injured in the same way served as a control, after which they were inoculated with small fragments of the substrate without mycelia.

Results and discussion

After checking the alfalfa crop, several alfalfa fields showed signs of wilting. Plants with symptoms were collected from 17 locations in Serbia. All the plants from which the fungi was isolated clearly showed symptoms in the form of necrotic spots and lesions on the stem. Fungi of the genus *Fusarium* were isolated from these plants. Similarly, necrosis with white aerial mycelium in the lower third of the stem was observed in some plants, and fungi of the genus *Sclerotinia* were isolated from these plants. On some plants, black fruiting bodies-pycnidia belonging to the genus *Phoma* were observed on the stem. When fungi of the genus *Colletotrichum* are isolated from alfalfa, the tips of the stems are usually bent down. Fungi are also distinguished based on morphological and pathogenic characteristics, in addition to the symptoms of plants present in the field, the causative agents of alfalfa diseases were determined (Table 1).

Table 1. Morphological and pathogenic characteristics of the obtained isolates on alfalfa plants

Types of fungi	**Morphological characteristics**	**Pathogenic characteristics**
Fusarium spp.	52.09–84.35 x 0.86–9.25µm	On the roots, the alfalfa plant test causes typical symptoms of root system rot
Rhizoctonia spp.	12.87–85.8 x 3.6–8.56 µm	Causes root neck rot on alfalfa test plants
Sclerotinia spp.	6–9 x 10–20 µm	On the test plants, it causes rot from the roots towards the root neck and stem
Phoma spp.	5.45–7.14 x 2.98–4.18 µm	Black fruiting bodies develop on the test plants
Verticillum spp.	6–12 x 2.5–3 µm	The pathogen on the test plants causes symptoms in the form of discoloration of the vascular tissue of the roots
Colletotrichum destructivum *C. trifolii* *C. linicola*	10–25 x 2.5–7.4 µm 12.5–17.5x 5.75 µm 12.5–25x 2.5–7.5 µm	On the test plants, lesions were observed in the ground part of the tree, most often on the lower third, light to dark brown in color, irregular in shape, with dark brown edges

The roots of the plants showed symptoms in the form of light brown necrosis, and fungi of the genera *Fusarium* and *Rhizoctonia* were isolated from these plants. Discoloration of the conducting tissue has also been observed in some root system plants and fungi belonging to the genus *Verticillium* have been isolated from these plants.
